Methods: Chemotherapy at home obeys to strict rules. The first chemotherapy cycle (C1) and the first injection (D1) of subsequent cycles were administered at the outpatient care unit. The following injections were administered at the patient’s home and carried out by HaH, according to a predefined procedures (Fig 1) to comply with safety rules essential to the protection of the professional, the patient, the entourage and the environment. Subcutaneous AZA injections were administered to 101 pts and the medico-economic interest of such care with the median duration of HaH management lasting from less than 1 day to more than 3.4 years with a mean of 6.3 months. During the period of HaH administration of AZA, 101 pts (60%) had to return to a referral hospital for a non programmed rehospitalization: 90% of the time the patient needed a transfusion, 4% because of infection and 6% for other reasons.

Aims: Our work aimed to demonstrate that HaH administration of AZA is feasible and well preferred by patients compared to hospital administration.

Methods: Chemotherapy at home obeys to strict rules. The first chemotherapy cycle (C1) and the first injection (D1) of subsequent cycles were administered at the outpatient care unit. The following injections were administered at the patient’s home and carried out by HaH, according to a predefined procedures (Fig 1) to comply with safety rules essential to the protection of the professional, the patient, the entourage and the environment. Subcutaneous AZA injections were administered to 101 pts and the medico-economic interest of such care with the median duration of HaH management lasting from less than 1 day to more than 3.4 years with a mean of 6.3 months. During the period of HaH administration of AZA, 101 pts (60%) had to return to a referral hospital for a non programmed rehospitalization: 90% of the time the patient needed a transfusion, 4% because of infection and 6% for other reasons.

Results: From 2009 to 2015, a total of 6369 subcutaneous injections of AZA were administered at home for 169 pts with AML/MDS received AZA therapy. Among all pts, 110 were men and 59 females with a median age of 75 years (range 41-92) there are 88 (52%) MDS patients and 81 pts (48%) with AML. Patients received a median number of 5 cycles (1-41) and 26 injections of AZA (1-244) at home. The total duration of HaH management lasted from less than 1 day to more than 3.4 years with a mean of 6.3 months. During the period of HaH administration of AZA, 101 pts (60%) had to return to a referral hospital for a non programmed rehospitalization: 90% of the time the patient needed a transfusion, 4% because of infection and 6% for other reasons.

Figure 1.

Summary/Conclusions: Administration of oral analgesia and anxiolysis is a safe and feasible option to be used in outpatient setting: sedo-analgesia is very effective in reducing pain during the biopsy and diminishes the anticipatory anxiety related to a painful procedure. Patients should have the possibility to choose between local anaesthesia alone or sedo-analgesia plus local anaesthesia.

E1459 USE OF COMBINED ORAL FENTANYL CITRATE (ACTIQ®) AND MIDAZOLAM AS PREMEDICATION FOR BONE MARROW BIOPSY IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES: A RANDOMIZED CONTROLLED PATIENT BLINDED CLINICAL TRIAL
C. Cerchione1,*, M. Picardi1, N. Pugliese1, R. Della Pepa1, A. Gravetti1, A. Casoria1, L. Catalano1, D. Nappi1, G. Ciancia2, G. Pettinato2, F. Pane1, V. Martinez1
1Hematology, Ematologia e trapianto/aufederico ii, 2Anatomy Patologica, AOU Federico II, Napoli, Italy

Background: Bone marrow aspiration and biopsy (BMAB) is a painful procedure that requires local infiltration anaesthesia (LIA) with lidocaine is unable to relieve the pain during the most uncomfortable phases, or the anticipatory anxiety related to pain recelling thereafter. As there are no formal guidelines for adding a sedoanalgesic premedication before beginning the BMAB, many combinations have been adopted by several authors.

Aims: The aim was to minimize the frequency of hospital visits that these treatments require. This organization includes the three previously mentioned hospitals, four HaH structures, and three central pharmacies with an integrated preparation unit for cancer treatments. From 2009 to 2015, a total of 11,367 infusions were administered at home for 464 pts. In 2016, we demonstrated the feasibility of ESCADHEM and the medico-economic interest of such care with the median duration of HaH management lasting from less than 1 day to more than 3.4 years with a mean of 6.3 months. During the period of HaH administration of AZA, 101 pts (60%) had to return to a referral hospital for a non programmed rehospitalization: 90% of the time the patient needed a transfusion, 4% because of infection and 6% for other reasons.

Methods: Patients were randomly assigned into two arms for receiving either sedoanalgesic placebo plus LIA (standard group, 48.6%) or oral fentanyl citrate 200 mcg plus oral midazolam 5mg in addition to LIA (combo-group, 51.4%) during BMAB. Pre-procedural anxiety and procedural pain were assessed according to the Numered Rating Scale (NRS: 0-10), dividing the time of the procedure into five intervals (T0, T1, T2a, T2b, and T3) and evaluating discomfort grade during each moment of procedure in both groups. Cognitive function was measured before and 30 minutes after the procedure. Possible side effects were recorded, as well as the adequacy of tissues samples harvested. A telephone interview was performed 24 hours later: A total number of one-hundred-sixteen (n=116, Table 1) were enrolled in the study. Nine (n=9) patients did not meet inclusion criteria and were excluded. Fifty-two (n=52) patients were randomized and assigned to standard group and fifty-five (n=55) to combo group.

Results: At T2b (corresponding to the biopsy time and time after the biopsy, respectively) there was a significantly lower (p< 0.05) perception of pain in the patients who received sedo-analgesia (combo-group) compared to those who did not (standard group). Moreover, 100% of the patients in combo group who had previously undergone this procedure without premedication, reported that they would prefer sedoanalgesia for the subsequent procedures, thus showing the effectiveness of this combination also in relieving anticipatory anxiety. Finally, the histological specimen was found to be high in quality, as defined by standards.

Table 1.

Summary/Conclusions: Administration of oral analgesia and anxiolysis is a safe and feasible option to be used in outpatient setting: sedo-analgesia is very effective in reducing pain during the biopsy and diminishes the anticipatory anxiety related to a painful procedure. Patients should have the possibility to choose between local anaesthesia alone or sedo-analgesia plus local anaesthesia.
Aims: To assess cost-effectiveness of ATGAM (horse antithymocyte globulin) in comparison to rabbit antithymocyte globulin (r-ATG) in the treatment of moderate to severe aplastic anemia (sAA) patients in Sweden.

Methods: A semi-Markov state-transition cohort model was developed to estimate long-term (up to 5 years) clinical and economic outcomes for patients with AA receiving either ATGAM or r-ATG as first-line IST treatment. The following key assumptions were included in the model: responders who relapse are assumed to be re-treated with no expected change in survival. Patients who do not respond to first-line treatment move onto a second-line treatment comprised of either IST, IST + etiopromib or hematopoietic stem cell transplantation (HSCT). Although response rates are lower, those who respond to second-line treatment are assumed to have the same outcomes as those who responded to first-line. Patients who continue to not respond receive standard supportive care with a significant decrease in expected survival. Efficacy data for ATGAM and r-ATG were obtained from published literature. Adverse events were not included due to lack of evidence of any difference between the two comparators. Medication, administration, and disease management costs were obtained from published literature, publicly available sources and clinical expert opinion. As resource utilization for disease management changes over time and differs considerably between responders and non-responders, three distinct phases have been included in the model: short-term (first 6 months post-IST administration), medium-term (6-12 months) and long-term (greater 1 year), for patients in either of the response categories.

Results: Response to treatment was calculated to be seen in 67% of ATGAM patients’ vs 35% in r-ATG (accounting for mortality). Over 5 years, the model estimated that patients gained 4.15 life-years (3.28 quality-adjusted) on ATGAM vs 3.52 (2.56) on r-ATG. Short-term disease management costs were estimated to be SEK 800,144 (€96,816) in responders vs SEK 1,264,016 (€139,041) in non-responders. Medium and long-term costs also followed the same pattern. Overall costs (drug plus disease management), were significantly lower for patients receiving ATGAM vs r-ATG; making ATGAM cost-saving by being both more effective and less costly than r-ATG. When considering treatment costs only (including cyclosporine and HSCT), the model estimated a cost of SEK 107,097/life-year gained (approx. €11,781) and SEK 135,655/quality-adjusted life-year (approx. €14,922), showing ATGAM is highly cost-effective. The analysis showed that when treatment and disease management costs are considered, ATGAM dominates r-ATG as the gain in QALYs and LYs are achieved at a lower cost. Therefore making ATGAM cost-saving with greater health benefits in comparison to r-ATG.

Summary/Conclusions: Due to improved treatment response, survival, and quality of life outcomes, the model shows that ATGAM is at least more cost-effective, if not cost-saving, in comparison to r-ATG for the treatment of patients with aplastic anemia.

E1462

A CLINICAL AUDIT OF NUTRITIONAL SCREENING AND SUPPORT OF HOSPITALIZED PATIENTS WITH HEMATOLOGIC DISEASES

A. Stamoul1, A. Liaskas1, I.-G. Tzanninis1, E. Kanioura1, D. Politis1, L. Pouli1a, N.-A. Viniou1, K. Konstantopoulos2, P. Diamantopoulos1.1
11st Department of Internal Medicine, Hematology Unit, Laikon General Hospital, National and Kapodistrian University of Athens, 2Clinical Nutrition Department, Laikon General Hospital, Hematology Department, Laikon General Hospital, National and Kapodistrian University of Athens, Athens, Greece

Background: Poor food intake is a common problem in patients with hematologic diseases. Recurrent infections and chemotherapy complications are some of the possible causes. Malnutrition is correlated to slow recovery, prolonged hospitalization, and higher mortality. Audits about the nutritional support of hospitalized patients may detect significant failures in patient care and help towards the correct application of the international guidelines.

Aims: We performed a prospective observational audit on hospitalized patients with hematologic diseases to investigate their nutritional status and whether they received the appropriate nutritional support.

Methods: The initial population consisted of 122 consecutive patients with hematologic diseases admitted from March 31, 2016 to June 8, 2016 in two Hematologic Units of a Tertiary University Hospital in Athens, Greece. We designed a special questionnaire based on the Malnutrition Universal Screening Tool (MUST) with additional questions on demographic, somatometric and medical data (Table 1). The questionnaire was applied by 6th-year medical students to all patients within 48 hours of admission. Patients were classified as high, intermediate, and low-risk per the MUST score and were reassessed at prede- fined intervals. We examined food intake and nutritional interventions (nutritional supplements, enteral or parenteral nutrition) applied.

Results: Ninety-three patients were included in the final analysis (5 refused to participate, 22 were excluded due to short-term hospitalization, 2 were absent during reassessment). Forty-one (38%) patients had a MUST score ≥2 (high risk) but none of them received nutritional supplements. One patient was supported with parenteral nutrition (Table 1).

Patients receiving nutritional support, N (%) | 1 (1)*

Recorded food intake (last 5 days), N | | |
| Increased | 1 (1)* |
| Decreased | 38 (41.1) |
| Normal | 36 (38.9) |
| Serum albumin levels on admission/discharge, g/dl (median, range) | | |
| 41 (2.9-4.2) |
| Other variables: estimated food intake in 3 days, reduced appetite, type of diet, calorie intake, duration of hospitalization, ECOG score, recent surgery, dysphagia, nausea, malnutrition, infections, neurological deficits, head trauma etc. | | |

Summary/Conclusions: Our audit revealed a lack of nutritional support of the hospitalized patients. A meeting with the involved health professionals was organized and an oral presentation of the results and the possible causes (lack of sensitization of the staff, high regimen cost, shortness of staff) was performed. Proposals to change the current situation were made such as detection of high risk patients by medical students and further assessment by a nutritional specialist. A brief MUST-based questionnaire was also proposed to be used for all patients upon admission. A re-audit was programmed and is already in progress.
E1463
ASSESSING REAL-WORLD TREATMENT PATTERNS, OUTCOMES AND RESOURCE USE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) POST AUTOLOGOUS STEM CELL TRANSPLANT ACROSS EUROPE
1Mid-Yorkshire Hospitals NHS, Wakefield, 2Adelphi Real World, Bollington, United Kingdom, 3Celgene International, Boudry, Switzerland

Background: Autologous stem cell transplant (ASCT) is the standard of care for first-line (1L) treatment (tx) for patients (pts) with MM deemed of suitable fitness to safely undergo the procedure. More recently introduced tx options have significantly increased the life expectancy of pts with MM and continue to provide further promise for the future in this devastating disease. The increasing therapeutic armamentarium the MM pathway allows for varied tx patterns providing both potential differences in outcomes and healthcare resource use (HCRU).

Aims: The aim of the analysis was to determine current management of pts in the post ASCT setting, assess outcomes of pts and HCRU.

Methods: A retrospective chart review was conducted in France, Germany, Italy, Spain and the UK. Data collection took place in Q1 2017. Physicians provided data on consecutive pts with MM who had undergone an ASCT as part of 1L tx on or after 1st January 2014, to specifically examine the HCRU post 1L ASCT. Data collected pertained to pt characteristics, tx patterns, duration of tx and outcomes (including time to progression (TTP) and best response achieved (IMWG updated criteria), HCRU in terms of hospitalizations, additional supportive drugs prescribed and healthcare professional (HCP) visits. Pt records included in this interim analysis were completed by Feb 17th 2017, with data collection continuing in all countries.

Results: 214 record forms have been reviewed to date. Pts' mean age at diagnosis was 59 (±7.8 SD) years; 43% female and 57% male. Mean duration from diagnosis, to receiving an ASCT was 9.6 months (±13.3 SD). Of the pts included in the study, 62%, 28% and 8% had received 1st, 2nd and 3rd line tx respectively. In the 1L setting, 72% of pts did not receive any drug therapy post ASCT, 21% received consolidation and 8% maintenance therapy. Of the pts who did not receive maintenance therapy, 42% and 34% went onto receive 2L and 3L drug therapy respectively; whereas, only 24% of pts who received maintenance therapy went onto 2L, and none onto 3L. The most frequently prescribed regimens at 1L maintenance were Lenalidomide (82%), Bortezomib (12%) and Thalidomide (10%). TTP from start of 1L tx was 22.2 months (±11.1 SD) for pts not receiving maintenance and 33.0 months (±8.1 SD) for pts receiving maintenance. Overall 43% of pts achieved a sCR and CR, 51% achieved a VGPR and PR. During the period from 1L post ASCT to start of 2L, 54% of pts required to achieve one additional response—i.e., the multiple of treat-
ed patients to responders. We assumed response is not evaluated prior to 3 months, per National Comprehensive Cancer Network (NCCN) guidelines. Therefore, the cost of achieving an additional response was estimated as the product of NNT and 3-month cost, based on US Wholesale Acquisition Costs (WAC) and recommended dosing for each TKI from US prescribing information (USPI).

Results: To achieve one expected response, the NNT is 1.7 (95%CI: 1.5-1.9) patients for ponatinib, 3.8 (3.4-14.8) for nilotinib, 4.2 (2.2-11.1) for dasatinib, and 4.5 (3.4-6.7) for bosutinib (based on CCyR of 60%, 26%, 24% and 22%, respectively). With a 3-month WAC for ponatinib of $49,683, nilotinib: $33,892, dasatinib: $33,897 and bosutinib: $36,045, the estimated 3-month cost per response achieved is $82,600 ($73,100-$95,500) for ponatinib, $130,000 ($108,000-$161,000) for nilotinib, $141,000 ($75,300-$377,000) for dasatinib, and $164,000 ($124,000-$240,000) for bosutinib.

Summary/Conclusions: Using published, synthesized efficacy estimates, the NNT to achieve response with ponatinib in TKI-refractory CP-CML is less than with dasatinib or bosutinib despite a higher WAC. The lowest estimated 3-month cost per response achieved. Therapy choice should, however, consider both treatment cost and the benefit-risk profile of the individual patient.

E1465
THE COST-EFFECTIVENESS OF PEGASPARAGASE FOR FIRST-LINE TREATMENT OF ACUTE Lymphoblastic LEUKAEMIA: A COST-UTILITY ANALYSIS
1Shire, London, United Kingdom, 2Shire, Cambridge, United States, 3University Hospital of Wales, Cardiff, 4University of Manchester, Manchester, United Kingdom

Background: Asparaginase is a key component in the multi-agent chemotherapeutic regimen for the treatment of children, adolescents, and adults with acute lymphoblastic leukaemia (ALL). Compared to native asparaginase (native ASP), pegaspargase (PEG-ASP) has a longer half-life, can be given less frequently, and is less immunogenic, which leads to fewer hypersensitivity reactions. In the UK, patients with newly diagnosed ALL are treated with PEG-ASP followed by Erwinia-derived asparaginase (ERW-ASP) in cases of hypersensitivity, based on the UKALL protocols. Although native ASP is no longer used as the first choice of asparaginase therapy, it was the standard of care before PEG-ASP was available. A cost-utility analysis (CUA) was conducted to evaluate overall cost-effectiveness of PEG-ASP in comparison to native ASP when utilized as part of antineoplastic combination therapy for treating newly diagnosed ALL in children, young people, and adults.

Aims: To evaluate the cost-effectiveness of a treatment strategy including PEG-ASP in a multi-agent in patients with newly diagnosed ALL compared to regimens that include native ASP.

Table 1.
Results: The base-case scenario demonstrated that PEG-ASP followed by ERW-ASP dominated (i.e., was both less costly and more effective than) native ASP followed by ERW-ASP in adults, children, and the whole (combined) population (Table). Scenario analyses highlighted the robustness of the cost-effectiveness results. Differences in total QALYs between PEG-ASP and native ASP were driven primarily by the difference in hypersensitivity rates.

Summary/Conclusions: This analysis demonstrates that PEG-ASP, as part of multi-drug chemotherapy, is a cost-effective treatment option compared to native ASP for treating ALL in children, young people and adults with newly diagnosed ALL.

E1466

IMPACT OF VENETOCLAX ON THE QUALITY OF LIFE OF PATIENTS WITH RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA: RESULTS OF A PHASE 2, OPEN-LABEL STUDY OF VENETOCLAX (ABT-199/ GDC-0198) MONOTHERAPY

W. Wierda1,2, K. Saal1, L. Noe2, R. Kamalakar2, J. Gdovin2, M. Verdugo2, S. Kim2, R. Humerickhouse2, S. Stilgenbauer3

1The University of Texas MD Anderson Cancer Center, Houston, 2AbbVie Inc, North Chicago, United States, 3Department of Internal Medicine III, Ulm University, ULM, Germany

Background: Chronic lymphocytic leukemia (CLL) is associated with reduced health-related quality of life (HRQoL), with progressive severe fatigue being a particularly relevant burden. Disease-related symptoms, toxic effects of therapy, and the awareness of living with an incurable disease can have a profound impact on HRQoL. Venetoclax (VEN) is an oral BCL-2 inhibitor that has demonstrated deep and durable responses in relapsed/refractory (R/R) CLL patients.

Aims: To assess whether Venetoclax has a sustained impact on health related quality of life among patients with relapsed/refractory CLL based on a second interim analysis (first interim results through week 24) of patients treated with VEN monotherapy.

Methods: Patients ≥18 years of age with R/R CLL received VEN monotherapy until disease progression, unacceptable side effects, or discontinuation for any other reason. Patient-reported HRQoL measures included the EORTC QLQ-C30 and EORTC QLQ-CLL16, which were assessed at Baseline (BL), at 4 weeks and every 12 weeks thereafter. Mean change in the HRQoL measures from BL to each assessment are reported. Clinical relevance was based on minimum important difference (MID) of values from BL at different assessment points. The lower bound of 5–10 point changes, considered a ‘little’ change for EORTC-QLQ-C30 was used as MID acceptance for both measures.

Results: Clinically meaningful improvements from BL were observed early and were sustained throughout week 96 in VEN treated patients in the EORTC-QLQ-C30 global health status and the role, social, and emotional functioning scales. Improvements in VEN treated patients in EORTC-QLQ-CLL16 disease effects, social problems, and future health worries scores were statistically significant and exceeded the MID at all assessment points. Furthermore, early and sustained improvements in fatigue through week 96 were seen in both EORTC-QLQ-C30 and EORTC-QLQ-CLL16 (Table 1). The changes observed in patient EORTC-QLQ-CLL16 future health views were considered large (>20 points) at Weeks 12, 24, and 48.

Table 1.

Summary/Conclusions: These updated interim results suggest that patients receiving VEN monotherapy experienced early and sustained clinically relevant improvement in several key aspects of functioning and HRQoL for up to 96 weeks in a very symptomatic and difficult to treat patient population. These results are important to consider when making treatment decisions in the R/R settings.

E1467

WHICH HAEMATOLOGICAL CONDITIONS CAN THIRD YEAR MEDICAL STUDENTS RECOGNISE INTERPRETING FULL BLOOD COUNT RESULTS?

S. Lovato1,2, J. Arnold1,2

Summary/Conclusions: These updated interim results suggest that patients receiving VEN monotherapy experienced early and sustained clinically relevant improvement in several key aspects of functioning and HRQoL for up to 96 weeks in a very symptomatic and difficult to treat patient population. These results are important to consider when making treatment decisions in the R/R settings.

E1468

LONGITUDINAL ASSOCIATIONS BETWEEN HEALTH-RELATED QUALITY OF LIFE AND HEALTHCARE UTILIZATION IN AL AMYLOIDOSIS

M. Baylis1, T.P. Quock2, S.D. Guthrie2, M.K. White1, R.L. McCausland1

1Optum, Lincoln, 2Prothena Biosciences Inc, South San Francisco, United States

Background: Light chain (AL) amyloidosis is a rare, complex disease associated with significant organ dysfunction, disability, and death. AL amyloidosis patients interact with the healthcare system in a myriad of ways; however, few studies have quantified healthcare utilization (HCU) in this condition.

Aims: To prospectively examine the association between health-related quality of life and healthcare utilization among patients with AL amyloidosis.

Results: Twenty-four patients participated in the study. Most participants were males, with a median age of 69 years (range: 36-85). The majority of participants had AL amyloidosis type 2 (42%), followed by type 1 (38%) and type 3 (20%). The median duration of disease was 3 years (range: 1-12). The median number of hospitalizations was 3 (range: 0-7) and the median number of emergency department visits was 1 (range: 0-5). The median number of primary care visits was 4 (range: 0-10) and the median number of specialist visits was 3 (range: 0-10).

Summary/Conclusions: This group of medical students found it difficult to correctly diagnose some of the haematological conditions presented, even though they had studied all the conditions before, however the use of a ‘Team Based Learning’ approach where students could discuss the cases in small groups improved their results. Interestingly for two conditions, for CML and Multiple myeloma the number of correct answers was the same for i-RAT and t-RAT, possibly the students who responded correctly during the i-RAT were concentrated in fewer groups. To the author’s knowledge this is the first study on the effect of applying the Team Based Learning method to haematology teaching. This study showed that TBL could be a useful teaching tool to improve teaching of haematological conditions in medical schools, however the size of the sample was small and the results should be validated with a bigger study.

Postgraduate, London North West Healthcare NHS Trust, 1Postgraduate, Imperial College London, London, United Kingdom
Methods: A non-interventional, longitudinal online study was conducted among patients with AL amyloidosis who were recruited with assistance from patient advocacy groups. Initial (n=341) and six-month follow-up (n=226) surveys assessed demographics, disease and treatment characteristics, and health-related quality of life (HRQoL), measured by the SF-36v2® Health Survey physical and mental component summary scores (PCS and MCS). HCU (e.g., outpatient patient doctors' visits, emergency room [ER] visits, hospitalizations, and insurance coverage) was measured during the six-month follow-up. Prevalence of HCU and its bivariate associations with patient characteristics were evaluated. Multivariable logistic regression models were used to test for associations between HRQoL and having an ER visit or hospitalization in the past six months.

Results: Overall, visits with specialists and other healthcare providers during the previous six months were nearly ubiquitous (92.0% and 94.6%, respectively). Collectively, 56.0% of patients reported having ≥1 ER visit or hospitalization. ER visits and hospitalizations were not associated with the numbers or types of organs affected by the disease or the duration of disease. There were significant associations between PCS and ER visits (p<0.05) and between both PCS and MCS and hospitalizations (p<0.05 for all) based on multivariable analyses.

Summary/Conclusions: There is a lack of real-world evidence regarding HCU among AL amyloidosis. This research identified longitudinal associations between HRQoL and HCU, indicating there is potential for using HRQoL surveys as screening tools to predict future HCU for AL amyloidosis patients. The development of prediction models for HCU in AL amyloidosis should consider incorporating HRQoL, as well as disease staging and treatment type.

E1469
SAFETY, FEASIBILITY AND EFFECTIVENESS OF ELECTRICAL MUSCLE STIMULATION IN HOSPITALIZED PATIENTS UNDERGOING AUTOLOGOUS OR ALLOGENIC STEM CELL TRANSPLANTATION AND INTENSIVE CHEMOTHERAPY
D. Kadan-Mulinveda1, A. Klostermann1,1, M. Bewarner1, J. Bitterbriinger1, M. Pfreundschuh1
1Innere Medizin I, Universitätsklinikum des Saarlandes, Homburg, Germany

Background: Autologous and allogeneic stem cell transplantation (HSCT) or intensive chemotherapy are the only treatment option for many patients with haematological malignancies. Even after complete remission many patients are physically and psychologically impaired because of intensive treatment and weeks of immobilisation. Electrical muscle stimulation (EMS) is a verified training tool to prevent muscle decline in seniors and helps improving physical performance in patients with chronic diseases.

Aims: This prospective, randomized and controlled study tested the safety, feasibility and efficacy of EMS in 72 patients (EMS=42, control=30) undergoing autologous HSCT (n=21), allogeneic HSCT (n=17) and intensive chemotherapy (n=34).

Methods: A Myopuls 2000 device (Curatec Services Gmbh) was used. Targeted training time was 15 minutes 5 days a week on both thighs and arms from start of therapy (T1) to time of discharge (T2). Adverse events and treatment adherence were documented. Impact on psychological and physical functioning was evaluated using the Multidimensional Fatigue Inventory (MFI), the EORTC QLQ-C30, the Short Physical Performance Battery and the 6 Minute Walking Distance at T1 and T2.

Results: Seven patients died in the EMS- (n=4) and control-group (n=3). 6 of 42 EMS patients withdrew because of sepsis (n=4) or loss of motivation (n=2). 32 patients from the EMS group completed our study with 22 accomplishing ≥65% of the pre-set training time. EMS related adverse events were hypoesthesia (11%) and muscle pain (n=2). No bleeding events (WHO bleeding scale=1) or ventricular arrhythmias occurred. Difference in 6-minute walking distance between both groups was 23 meter (p=0.2). SPPB test results differed by one point (p=0.08). MFI and EORTC QLQ-C30 both favoured the EMS group, but showed no statistical significance.

Summary/Conclusions: EMS is feasible and safe in patients undergoing intensive chemotherapy regimens. It also may improve physical fitness, fatigue and quality of life, indicated by favourable test results in the EMS group. To verify positive effects of EMS in patients with haematological malignancies, further research is needed, with more patients and sham EMS stimulation.

E1470
MYELOMA PATIENT VALUE MAPPING: A DISCRETE CHOICE EXPERIMENT
J. Galinsky1,1, S. Fifer2, S. Richard1
1Research, Myeloma UK, Edinburgh, United Kingdom, 2Research, Community and Patient Preference Research, Sydney, Australia

Background: Myeloma is a life threatening haematological cancer. Although myeloma is responsive to treatments, there remains no cure. In recent years, there have been improvements in survival due to the use of high dose therapies, stem cell transplant, and other novel therapies. However, while myeloma patients are living longer, they are also living with symptoms and treatment related side effects. Therefore, myeloma patients face difficult decisions about the benefits and risks of treatment. The purpose of this study was to assess myeloma patient preferences for treatment.

Aims: The study aimed to answer the following questions: What treatment attributes do myeloma patients value? What is the relative importance of different treatment attributes? Is there a minimum acceptable risk they are willing to accept? What risk-benefit trade-offs characterise patients’ decision-making around treatment options, including not to treat? What, if any, influences and predictive factors are found in the way patients assess benefits and risk?

Methods: Participants were 475 Myeloma patients in the UK. Data were collected using discrete choice experiments (DCEs) through an online survey. The DCEs presented patients with a traditional treatment choice experiment (e.g., treatment A vs treatment B), focusing on the clinical benefits of treatments and the associated risks. The attributes and levels of the attributes were selected based on previous research, literature review and expert opinion. The DCE data were modelled using a Latent Class Model (LCM), and the effect of demographic characteristics were also examined.

Results: Findings revealed two classes (groups) of patients with different preferences for treatments. Patients in class one placed greater importance on overall survival and mild-to-moderate side effects, whereas patients in class two placed greater importance on how the treatment was administered and the associated risks for treatment. The attributes and levels of the attributes were selected based on previous research, literature review and expert opinion. The DCE data were modelled using a Latent Class Model (LCM), and the effect of demographic characteristics were also examined.

Summary/Conclusions: Findings from this study suggest that not all myeloma patients value the same treatment features equally. This finding has important implications for the healthcare policy decision-making process and could be used to inform discussion around the value of new myeloma medicines. For example, to establish more patient-aligned endpoints in clinical trials or as evidence which is incorporated into the Health Technology Assessment process.

E1471

COST-MINIMIZATION ANALYSIS OF RITUXIMAB SUBCUTANEOUS FORMULATION VERSUS INTRAVENOUS ADMINISTRATION OF RITUXIMAB FOR THE TREATMENT OF NON-HODGKIN’S LYMPHOMA IN THE REPUBLIC OF MACEDONIA
1Roche Macedonia DOOEL Skopje, 2ISPOR - Republic of Macedonia Regional Chapter, Faculty of Pharmacy, Ss. Cyril and Methodius’ University of Skopje, 3Clinical Department, University Clinic of Hematology, Skopje, Macedonia, 4Outpatient Clinic, 5Clinical department, University Clinic of Hematology, Skopje, Macedonia, 6The Former Yugoslav Republic Of

Background: Rituximab, an anti-CD20 monoclonal antibody, in combination with chemotherapy is a standard of care for non-Hodgkin’s lymphoma (NHL), in which intravenous (IV) infusion dose of 375mg/m2 body surface area (BSA) over one hour, administered by intravenous (IV) infusion, or fixed dose of 1400mg administered as subcutaneous formulation (rituximab SC). Intravenous infusion of rituximab typically lasts for three to four hours, while subcutaneous application last approximately five to seven minutes. The evidence to support the use of rituximab SC as an alternative to rituximab IV is primarily based on the phase III, randomised, non-inferiority, open-label SABRINA study. Recent studies demonstrated therapeutic and pharmacokinetic non-inferiority of rituximab SC to rituximab IV.

Aims: The aim of the study was to identify and compare the total costs of subcutaneous (SC) vs intravenous (IV) administration of rituximab for the treatment of NHL patients in the Republic of Macedonia.

Methods: Cost-minimization analysis was used to evaluate pharmacoeconomic impact of the use of subcutaneous vs intravenous administration of rituximab in the treatment of NHL patients. The total of 220 NHL patients (mean body surface area 1.9 m2, middle aged 59.6 years) were enrolled in the study. Evaluated healthcare resources included drug treatment costs, infusion chair occupying cost, active Healthcare Professional time cost and consumable disposals.

Results: Direct costs of administering one course of rituximab, including cost of drug, cost of administration and cost of consumables in all treatment phases (premedication, medication and post medication), for intravenous administration of rituximab were 162€ compared to 154€ for subcutaneous administration of rituximab. Average time for intravenous administration is 6 hours, 12 minutes and 13 seconds, compared to 10 minutes and 13 seconds for subcutaneous administration. Subcutaneous rituximab incurred less non-drug related costs than intravenous rituximab under the observed clinical practice: 14.62€ vs 1.76€ regarding active healthcare professional time and 10.10€ vs 1.2€ as infusion chair occupying cost.

Summary/Conclusions: Subcutaneous administration of rituximab is a cost-saving therapy in comparison with intravenous administration of rituximab for the treatment of NHL patients in the Republic of Macedonia.
E1472
QUALITY OF LIFE AND ABILITY TO WORK OF PATIENTS WITH CHRONIC MYELOGENOUS LEUKEMIA TREATED WITH THYROSINE KINASE INHIBITORS
B. Sidi Mohamed El Amine1,*, H. Asma1, Z. Zahia1, M. Naima2, M. Nemra3
1Hematology department, Universitary hospital of Sidi Bel Abbès, Sidi Bel Abbès, 2Hematology department, Universitary hospital of Tiemcen, Tiemcen, 3Hematology department, Hospital of Mascara, Mascara, Algeria

Background: Thyrosine kinase inhibitors (TKIs) are now standard treatment for chronic myelogogenous leukaemia (CML), but little is known about quality of life (QoL) of the patients.

Aims: The purpose of this study is to evaluate QoL of CML patients receiving TKIs, a disease requiring strict daily compliance with taking these drugs orally, as well as regular clinical and biological controls.

Methods: The study included patients with CML followed in three hospitals in west Algeria between 2004 and 2016. The measure of QoL was performed by the tool of functional assessment of chronic illness therapy (Functional Assessment of Chronic Illness Therapy, FACIT) for leukemia. We have established QoL scores given by the questionnaire, FACIT, consisting of three levels: TOI for leukemia trial outcome index, FACT-G for general score, and FACT-LEU for the total score of leukemia. Specific areas of the questionnaire were associated with QoL of patients such as fatigue and ability to work. The correlation between the total score and QoL scores was assessed using Spearman’s test. The test is significant if p<0.05.

Results: 67 patients with CML have agreed to answer to the questionnaire of QoL, medications in use, and their side effects. The mean QoL of the patients was 93.7 (out of 124 total points) for the TOI, 77.2 (out of 108) for the FACT-G, and 128.9 (out of 176) for the FACT-LEU. Patients who presented with TKIs side effects had a low score of QoL (p=0.0006), especially when these effects are severe (p=0.003). Stopping TKIs medication was noted in 41.3% of patients with severe side effects. Severe fatigue was observed in 14 (22.9%) patients, having low QoL scores in all scales (p<0.0001). 44 (65.8%) patients were able to work with higher QoL scores in the three FACIT scales (p=0.0001, Spearman correlation).

Summary/Conclusions: QoL is an important aspect in the management of CML, its assessment is necessary and must be regular. The ability to work and fatigue are important components of QoL of patients receiving TKIs and should be specifically taken into account during the treatment. Adverse effects of TKIs can interfere with QoL of patients and can lead to discontinuation of CML therapy.

E1473
QUALITY OF LIFE AND EMPLOYMENT AFTER AN HEMATOPOIETIC STEM CELL TRANSPLANTATION IN A MEXICAN POPULATION
L. Rivera-Fong 1, A. Riveros Rosas1, C. Benjet1, L.M. Valero Saldaña2, R. Robles García1,*, L. Traeger3, S. Rivas-Vera2,*, J.L. Aguilar Ponce4, O. Galindo Vázquez2, B.L. Acosta Maldonado2
1Psicología y Salud, Universidad Nacional Autónoma de México., 2Hematology, National Cancer Institute, Mexico City, Mexico, 3Hematology, Harvard University, Massachusetts, United States, 4Oncology, National Cancer Institute, Mexico, 5Psicología, Universidad Nacional Autónoma de México., Mexico City, Mexico

Background: Hematopoietic stem cell transplantation (HSCT) is a consolidation therapy for multiple hematological malignances and its goal include patients achieve levels of quality of life (QOL) similar that general population. However, studies developed in Europe and United States have shown that patients on long-term follow-up after HSCT reported lower levels of QOL, more unemployment and lower household income than before the procedure. These relationships have not been examined in Mexican HSCT patients.

Aims: To describe the QOL (EORTC-QLQ), level of employment and household income in Mexican patients on follow-up after HSCT

Methods: This was a cross-sectional study with patients ≥18 years old with at least one year of follow up after HSCT at the National Cancer Institute, Mexico. Results: 30 participants were included, with a median age of 34 years (range 25-67), 56% male, and 41% married. Regarding educational level 68.7% had basic education, 25% had a college education and 6.3% postgraduate education. Mean time after HSCT was 36 months, 10% had active chronic graft versus host disease (GVHD). Patients reported moderate to high levels of QOL (Table 1). With respect to employment, 52% had a job (56% had a full time job, 13% work part-time and 31% had an informal job) and 48% were unemployed (50% could not find a job and 50% did not want to have a job). Finally, 56% had lower household income than before HSCT.

Summary/Conclusions: Mexican patients showed similar or higher levels of QOL in comparison with samples from other countries, with the exception of higher impact in emotional QOL and better social QL in our sample. Additionally, a substantial minority of patients were unemployed and over half had lower household income after HSCT. More work is needed to identify risks associated with changes in QOL, employment status and income among long-term survivors of HSCT.

E1474
ANTHRACYCLINE INCREASES THE RISK OF DEVELOPING DIABETES IN B CELL LYMPHOMA
H.-C. Lin1,*, W.-L. Hwang1, C.-L. Teng1
1Division of Hematology/Medical Oncology, VTaichung Veterans General Hospital, Taichung, Taiwan, Republic of China

Background: Treatments of R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisone) or R-CHOP like regiments have made B cell lymphoma to be one of the most curative hematological malignancies. Among the effective chemotherapeutic agents in B cell lymphoma treatment, anthracycline plays an important role. However, anthracycline associated bone marrow suppression and cardiotoxicity limit its clinical application. Whether anthracycline would further increase the risk of developing diabetes in B cell lymphoma remains unclear.

Aims: The aim of this study was to compare the cumulative incidences of diabetes in B cell lymphoma patients treated with and without anthracycline. We also investigated the dose effect of anthracyline on diabetes development. Additionally, whether anthracycline would increase the severity and complication of diabetes in B cell lymphoma patients were also studied.

Methods: We conducted this population-based study by using Taiwanese National Health Insurance Research Database. From 2004 to 2011, medical records from a total of 3984 B cell patients were analyzed. To understand whether anthracyline therapy was associated with more diabetes in B cell lymphoma, we compared the cumulative incidence of newly diagnosed diabetes between patients with (n=3147) and without (n=637) anthracyline treatments. Impact of anthracyline on diabetes was further studied by multivariate Cox proportional hazard regressions in a dose-dependent manner.

Results: Log-rank test did not show the difference of cumulative incidences of newly diagnosed diabetes between B cell lymphoma patients with and without anthracyline treatments (p=0.1448). However, anthracyline remained associated with more diabetes [hazard ratio (HR): 1.59; 95% confidence interval (CI): 1.05–2.39; p=0.0278] after adjustment for age, gender, and comorbidities. Moreover, cumulative anthracyline doses of 253-400mg (HR: 1.94; 95% CI: 1.23–3.05; p=0.0043) and 401-504mg (HR: 1.83; 95% CI: 1.11–3.01; p=0.0180) increased the incidence density of diabetes in a dose-dependent manner (p=0.0438). Notably, patients with and without anthracyline treatment had simlarly adapted diabetes complications severity index alteration (0.58±1.89 vs 0.75±1.85; mean±standard deviation), suggesting anthracyline did not deteriorate outcome of diabetes in B cell lymphoma patients (p=0.4924).

Summary/Conclusions: Anthracycline therapy was responsible for more diabetes in B cell lymphoma in a dose-dependent manner. More intensive blood sugar monitoring and control should be recommended to B cell lymphoma patients, especially those who received anthracycline treatment.

E1475
THE COST-EFFECTIVENESS OF LENALIDOMIDE PLUS DEXAMETHASONE FOR THE TREATMENT OF RELAPSED OR REFRACTORY MULTIPLE MYELOMA IN CHINA
J. Lu1*, S. Hu2, P. Xu3, Y. Feng2
1Peking University People’s Hospital, Peking University Institute of Hematology, Beijing, 2Fudan University School of Public Health, Shanghai Health Development Research Center, 3Cellgene China, Shanghai, 4Department of Pharmacy, Beijing Hospital, Beijing, China

Background: The introduction of lenalidomide plus dexamethasone (RD), and bortezomib- and immunomodulatoryContaining regimens, has improved the management of relapsed or refractory multiple myeloma (mMM) in China. However due to the absence of both head-to-head (direct) comparative efficacy and local drug evidence, stakeholders still face hard choices to make when choosing one therapy over another. Indirect treatment comparisons and health economic modeling can help support local decision-making by enabling the incorporation of country-specific unit cost data, in the comparison of cost-effectiveness of one treatment vs another where treatments have not been directly compared in clinical trials.

Aims: To assess the cost-effectiveness of RD relative to bortezomib/dexamethasone (VD) and bortezomib/cyclophosphamide/dexamethasone (VCD) for mMM in Chinese patients.

Methods: The Markov-based decision analytic model was constructed to simulate lifetime health benefits and direct medical costs associated with RD, VD, and VCD for mMM in Chinese patients. A systematic literature review was conducted (in both Chinese and English databases, from 2005 to 2016) to obtain efficacy data of the three treatment regimens. The risk of progressive disease associated with RD and VD were estimated from available Chinese trials. The efficacy of VCD and the mortality associated with progressive disease after treatments with RD and VD were lacking in China, therefore were estimated from the published international randomized clinical trials. Published quality of life data was adapted to Chinese mMM patients with health utility adjustment. The model took into account (i) drug acquisition costs, (ii) treatment administration costs, (iii) Chinese urban hospital setting and (iv) adverse events management costs based on a survey of seven MM centers across China, and (v) mMM management costs estimated from a Chinese real-world hospital setting. Quality-adjusted life years (QALY) and direct medical costs in the model were discounted at 3% per annum. Base case analysis calculated incremental cost-effectiveness ratio (ICER) per QALY for RD relative to VD and VCD, respectively from the Chinese healthcare payer’s perspective. One-way sensitivity analysis and probabilistic sensitivity (PSA) with 5,000 Monte Carlo simulations assessed the impact of the model uncertainty on the cost-effectiveness of RD. A scenario analysis was conducted by meta-analyzing the published international randomized trials for the efficacy associated with RD, VD, and VCD, to verify the base case analysis.

Results: Based on the model simulation without discounting survival outcomes over a lifetime horizon, RD could obtain longer average PFS years than VD (2.37 vs 0.78) and VCD (2.37 vs 1.36). RD was associated with longer duration of response (DOR) compared to VD (1.41 vs 1.30) associated with lower costs ($94,060 vs $72,173 vs $244,220) than both VD and VCD. The ICERs per QALY for RD relative to VD ($149,706) and VCD ($150,774) were less than the cost-effectiveness threshold of China (three times of estimated 2016 China GDP per capital $166,920/QALY, ¥1 = €0.138). The cost-effectiveness of RD relative to VD and VCD was below the willingness-to-pay threshold associated with the progressive disease after treatment. The scenario analysis generated comparable ICER per QALY associated with RD relative to VD ($120,974) and VCD ($117,191), therefore supports the robustness of base case analysis.

Summary/Conclusions: The local data-based health economic model estimates that RD could gain longer PFS and OS with acceptable cost-effectiveness, when compared to VD and VCD in Chinese mMM patients.

E1476
DEVELOPMENT OF A NEW HAEMATOLOGICAL MALIGNANT PATIENT-REPORTED OUTCOME MEASURE FOR USE IN CLINICAL PRACTICE: HM-PRO
P. Goswami1,*, S. Salek1, T. Ionova2, E. Oliva3, A. Fielding 4, M. Karakantza5, T. Board, Cardiff, United Kingdom

Background: Health-related quality of life (HRQoL) of patients with haematological malignancy (HM) is greatly affected by the disease and the treatment and thus has not been captured in a systematic manner in clinical practice.

Aims: The aims of this study were to identify issues important to patients with HM and development of a new patient reported outcome measure for use in daily clinical practice.

Methods: A conceptual framework was developed using preliminary literature search and discussions with physicians and patients. Patients with HM were then recruited to produce a comprehensive item pool from which a new instrument was developed. The generated items were then discussed in the data definition panel meeting to be included in the prototype version of the HM-PRO. Subsequently, a panel of experts and a panel of patients were asked to rate the items of the prototype HM-PRO for its language clarity, completeness, relevance and scaling followed by cognitive interviews with the patients to pilot test the HM-PRO.

Results: The preliminary literature search revealed that there is no PRO specifically developed for patients with HM for use in daily clinical practice. The conceptual framework comprised of two main themes: QoL (impact); and symptoms. 129 patients (male=78; mean age=61.1 years; SD=15.3; median age=64.9 years; age range=18-88 years; diagnosis –AML, ALL, CML, MM, ANHL, NHL, HL, MPN, and MDS) with mean duration of the HM of 3.6 years (SD=4.3; and range= 19-days-23 years) from 5 haematology centres were interviewed to identify the issues important to HM patients. A prototype version of HM-PRO was developed after data definition panel meeting with 34 items in impact category (Part A) and 23 items representing disease symptoms (Part B). Nine- member panel of experts and 7-member panel of patients, rated the items and discussed them for its language clarity, completeness, relevance and scaling to reach consensus. 60 patients (male=36; mean age=63.8 years; SD=16.61; median age =69.2 years; and age range =18-91 years) with mean duration of the HM of 4.9 years (SD=6.4; and range= 14-days-26 years) were recruited for the pilot testing where 34 of which were involved in cognitive interviews. 92% of the patients reported that the statements were easy to understand and all issues important to them were covered; 95% stated that they were able to respond spontaneously and expressed their willingness to complete the instrument during their visit to the clinic; 97% reported that the statements were easy to read; 98% did not wish to delete any item; and 88% did not feel the need to add any item.

Summary/Conclusions: The findings of the content validation, pretesting and cognitive interviews indicate that HM-PRO possesses a strong content validity in different HMs, includes all the issues important to these patients and the statements are easy to read, understand and respond to spontaneously. HM-PRO will undergo further psychometric testing to support its psychometric properties across different types of HMs.

E1477
OVARIAN TISSUE CRYOPRESERVATION IN PEDIATRIC AND ADOLESCENT PATIENTS UNDERGOING CANCER CHEMOTHERAPY AND/OR HEMATOPOIETIC STEM CELL TRANSPLANTATION
A. Kinoshita1,*, R. Ooyama1, D. Keino 1, Y. Matsuoka1, Y. Koto1, T. Mori1, N. Suzuki1, A. Nakayama1, N. Suzuki1,2,3
1Pedicatric Hematology/Oncology, 2Department of Obstetrics and Gynecology, St. Marianna University School of Medicine, Kawasaki, Japan

Background: Ovarian tissue cryopreservation (OTC) and subsequent re-implantation is the only option available for fertility preservation in prepubertal females, but this approach remains unestablished in pediatric and adolescent patients with cancer. After the experience of OTC for more than 200 patients with primary ovarian failure and more than 50 patients with breast cancer in our center over 5 years, we have started OTC for pediatric and adolescent cancer patients since 2015.

Aims: The main outcome variables are safety and benefits of OTC in pediatric and adolescent patients with undergoing cancer chemotherapy and/or hematopoietic stem cell transplantation. Methods: From December of 2015 to February of 2017, OTC was performed in 6 girls (median age 14 years, range 11-15): 2 patients with myelodysplastic syndrome, 2 with lymphoma, 1 with acute lymphoblastic leukemia, and 1 with refractory immunodeficiency. Indications for OTC were 5 hematopoietic stem cell transplantation and 1 stimulating chemotherapy. Two patients with myelodysplastic syndrome and 1 with immunodeficiency received no previous chemotherapy and the other 3 had received prior chemotherapy. Laparoscopy was used to collect a pair of ovaries that was frozen by vitrification method. Results: Ovarian tissue cryopreservation in 6 infants and prepubertal patients were studied without major postoperative complications and this procedure did not delay chemotherapy or hematopoietic stem cell transplantation. Histological analysis of ovarian tissue revealed prordominal follicles, even in the patients with previous cancer chemotherapy. No malignant cells were identified. Median post-harvest survival of ovarian tissue revealed primordial follicles, even in the patients with previous cancer chemotherapy. No malignant cells were identified. Median post-harvest survival of ovarian tissue has been 3 years.
follow-up was 9 months (0-14) and all patients were alive. Hormonal results were evaluable for 3 patients; 2 patients were in premature ovarian insufficiency. Re-implantation of ovarian tissue has not yet been performed.

Summary/Conclusions: Although OTC and subsequent re-implantation is experimental, this approach may be the best method for restoration of ovarian function and fertility preservation in pediatric and adolescent cancer patients. A risk of reseeding malignant cells is a problem still to be conquered.

E1478

A MULTI-DISCIPLINARY APPROACH TO CHEMOTHERAPY PRESCRIBING AT NEWCASTLE UPON TYNE HOSPITALS NHS FOUNDATION TRUST S. Gabriel1,*, G. Jones2, C. Cox2, S. Blakey2, M. Lannon2 1Northern Centre for Cancer Care- Pharmacy, 2Northern Centre for Cancer Care-Haematology, Newcastle upon Tyne Hospitals NHS Trust, Newcastle upon Tyne, United Kingdom

Background: Newcastle Upon Tyne Haematology service has made numerous changes in recent years to provide streamlined care for patients, focusing on reduced wait times & improve quality of care. The original pathway was costly in time, involving several waits for the patient: for urgent venepuncture, physician consultation, prescribing of chemotherapy, specialist pharmacist screening of prescriptions & then a separate trip to pharmacy for dispensing. Patients then returned home & waited for a call from the Clinical Nurse Specialist (CNS) to confirm if blood results were appropriate for chemotherapy administration. If a dose adjustment was required the drug was wasted & patients needed to return to hospital for another prescription. Pharmacy waiting times for oral outpatient chemotherapy or supplementary medications are approximately 30 minutes.

Aims: We introduced a weekly multi-disciplinary chemotherapy prescribing meeting in 2013 with the aim of improving prescribing safety, minimizing time spent prescribing in clinical & reducing patient waiting times. Present at each meeting is a Haematology Specialist Pharmacist, Haematology CNS, Consultant & Specialist Registrar. Chemotherapy is planned a week in advance on ChemCare (an electronic chemotherapy prescribing package). Chemotherapy is prescribed & immediately screened by the pharmacist; oral chemotherapy is collected from pharmacy by a CNS prior to clinical. All prescription queries are resolved during this meeting. Deferred oral chemotherapy can be returned to pharmacy stock, minimizing waste. Intraavenous chemotherapy is pre-planned with authorisation on the day if treatment if the patient is fit to proceed.

Methods: In line with the care pathway in Newcastle, we focused on delivery of care to myeloma patients receiving oral chemotherapy, including setting up a nurse-led clinic. Data have been collected to assess service impact, particularly on patient satisfaction. The latter was assessed using a patient survey. Between July-Dec 2014, 66 patients received oral chemotherapy in the Myeloma Consultant-led clinic, Lenalidomide based regimens accounted for 86% of the oral regimens prescribed. On average, 7 patients per week were on maintenance therapy. During this period 8% of chemotherapy courses were deferred due to low blood counts or side-effects. Drugs were not wasted due to the pharmacy agreement.

Results: A patient satisfaction survey was undertaken from Jan-June 2015, post-introduction of the nurse-led clinic paired with the MDT chemotherapy prescribing meeting. Patients were asked about a wide-range of quality parameters. Results showed 89% of patients noted a reduction in wait times & 89% felt they spent more time in consultations as a result. All patients noted they spent more time with the nurse specialist & benefited from not attending pharmacy. All patients rated the service as more efficient.

Summary/Conclusions: The MDT approach to prescribing & dispensing oral chemotherapy & supportive medication has streamlined our way of working & led to greater efficiency for both staff & patients. The new model has changed how patients are seen & assessed and minimised drug wastage. Drugs were not wasted due to the pharmacy agreement. All patients rated the service as more efficient.

E1479

FINANCIAL TOXICITY OF THE MANAGEMENT OF MULTIPLE MYELOMA B. Sidi Mohamed El Amine1,*, H. Asma1, O. Fouzia1, S.A. Najet1, Z. Zahia1 1Haematology department, Universitary hospital of Sidi Bel Abbés, Sidi Bel Abbes, Algeria

Background: Advances in supportive care and the development of novel treatment have helped to double the life expectancy of patients with newly diagnosed multiple myeloma (MM). Financial toxicity is increasingly recognized as adversely affecting the quality of life and medication adherence, and patients with MM may be particularly vulnerable because of extended treatment duration.

Aims: Our aim was to measure financial toxicity and its effects on patients undergoing treatment for MM.

Methods: Between October 2016, and January 2017, we did a cross-sectional survey of individuals receiving at least 3 months of ongoing treatment for MM at our department. The survey included the 11-item COST measure (financial toxicity score range 0-44). A paper survey was offered to eligible patients on arrival for routine follow-up visits or treatment, and participants were asked to complete the survey before their visit or phone call. Data were postponed by two psychologists. The COST questionnaire was validated with internal consistency (Cronbach’s coefficient) and item correlation (Pearson’s r coefficient) tests, especially those of Quality of life (EORTC QL Q30).

Results: Of 47 patients approached for the study, 44 individuals completed the survey and 40 (91%) were insured. Analysis of the internal consistency of the COST questionnaire showed an overall Cronbach’s alpha coefficient of 0.84. According to COST data, 26 (59, 1%) patients have a score<22. Patients with financial difficulties have a negative impact on their quality of life (P=0, 02, r=0, 32), and low scores of physical and role functioning (P<0,001, r >0, 5), 29 (68%) patients feel financially stressed, and 23 (52, 3%) did not control their financial situation. After a logistic regression, lower household income (P=0,009) and Poor response to treatment (P=0, 0037) were associated with higher financial burden as measured with the COST score.

Summary/Conclusions: Despite insurance and free care, financial toxicity is common in many myeloma patients, especially those with lower income and refractory disease. Strengthened collaboration among patients and health-care stakeholders is needed to promote healthcare reforms that promote high value and affordable myeloma care.
### Sickle cell disease

**E1481**

**DISEASE SEVERITY AND SLOWER PSYCHOMOTOR SPEED IN ADULTS WITH SICKLE CELL DISEASE**

E. Novelli1,2, D. Jorgensen2, A. Metti2, M. Butters2, C. Rosano2

1Medicine, Vascular Medicine Institute, University of Pittsburgh, BST E1240, 200 Lothrop St., Pittsburgh, 2University of Pittsburgh, Pittsburgh, United States

**Background:** Psychomotor slowing is common in children with sickle cell disease (SCD), but little is known about its severity in adult patients. While the primary risk factor for psychomotor slowing in stroke, there has been mounting evidence that cognitive impairment also occurs in patients without a history of overt or silent stroke. Risk factors for cognitive impairment in patients with SCD without stroke are, however, not completely known, particularly in relationship to the SCD genotype.

**Aims:** We conducted a cross-sectional study to quantify psychomotor slowing, measured with the Digit Symbol Substitution Test (DSST), a pencil and paper test of executive function, in relationship with disease severity in adult patients with SCD attending an outpatient clinic. We also examined whether demographic, behavioral, physiologic, and pathologic factors that are known to be related to SCD severity and cognitive function in other settings are also related to psychomotor speed in these patients.

**Methods:** Genotype was used to group patients with SCD (n=88, age: 36.3 years, 33 males) in “severe” (homozygous for the mutated sickle hemoglobin HbS [HbSβ°], or compound heterozygous with βthalassemia [HbSβ+-thal]) and “moderate” groups (compound heterozygous for HbS, with either HbC [HbSβC] or βthalassemia [HbSββ+-thal]). Standardized DSST scores based on published norms were used to define mild cognitive impairment, defined as ≤1.5 standard deviations (SD) below the DSST T-score (T-scores had a mean of 50 and SD of 10).

Data on demographics, hematological parameters, hydroxyurea and opiate intake, stroke (including silent cerebral infarcts (SCI)) and transfusion history were collected concurrently with DSST. Analyses were repeated after exclusion of patients with a history of stroke (n=12). Age-adjusted p-value was calculated with logistic regression for all variables except age (unadjusted) and DSST T-score (already adjusted for age, sex and education in calculation of T-score).

**Results:** Among our patients, 56 (63%) had a “severe” genotype and 32 (37%) had a “moderate” genotype. Mild cognitive impairment was detectable in both the “severe” and the “moderate” group (30% and 9%, respectively, age-adjusted p=0.15). Compared to the “moderate” group, those in the “severe” group, had significantly lower DSST scores (age, sex and education adjusted p-value<0.006), independent of adjustment for factors that differed between groups: hemoglobin, ferritin, hydroxyurea use, blood pressure parameters and stroke history. Results were similar after excluding patients with stroke.

**Summary/Conclusions:** Psychomotor slowing in SCD differs in relationship to genotype; this difference appears unrelated to history of stroke or severity of anemia and other risk factors examined cross-sectionally. Although relatively infrequent, mild cognitive impairment was also detectable in adult patients with a less severe genotype. Longitudinal studies of SCD should include all diseases genotypes, and examine factors that would reduce the risk of cognitive impairment in each subgroup.

---

**E1482**

**MONITORING OF CHRONIC HEPATIC DAMAGE IN SICKLE CELL DISEASE: LONGITUDINAL OBSERVATION OF A COHORT OF ADULT PATIENTS**

V.M. Pinto1, B. Gianesin1, M. Balocco1, P. Carrara1, G.L. Forni1,2

1Haematology-Centro Microcitromia Anemie Congenite, Ospedale Galliera Genova, Genova, Italy

**Background:** Acute vaso-occlusive events (VOCs) in Sickle Cell Disease (SCD) is an important cause of hepatic damage which can result in catastrophic consequences as acute hepatic failure and contribute to early mortality. In addition, sickle hepatopathy may be the consequence of SCD’s treatment as liver iron overload or viral hepatitis due multiple blood transfusions that these patients require over their lifetime. Therefore both SCD itself and related therapies may lead liver to fibrosis/cirrhosis.

**Aims:** We evaluated liver fibrosis using Transient Elastography (TE) in patients with SCD, exploring possible correlation with clinical, laboratory and imaging findings in longitudinal way.

**Methods:** SCD patients with at least one stiffness evaluation were retrospectively evaluated in the decade 2006-2016 using biochemical markers (liver damage, cholestasis, liver synthetic capacity, iron overload, viral hepatitis and hemolytic index), TE and liver imaging (ultrasound, MRI-R2*).

**Results:** 37 adult patients were evaluated: 32% HbSS, 68% HbSβ°, median 39yrs, 46% male, median stiffness 6.6 KPa IQR: 5.1-9.1 KPa (Table). There were not differences of stiffness value for gender, genotype. A positive moderate correlation was observed between TE and serum ferritin values (R\(^p=0.43, p=0.008\)), ALT (R\(^p=0.42, p=0.01\)), AST (R\(^p=0.49, p=0.022\)), conjugated bilirubin (R\(^p=0.59, p<0.001\)), ALP (R\(^p=0.51, P=0.002\)); a positive strong correlation was observed between TE and GGT (R\(^p=0.79, p<0.001\)), negative moderate correlation with the albumin (R\(^p=0.47, p=0.048\)). We found that the group of patients on eritroexchange programmes had a value of stiffness lower than the group transfused (p=0.007). No significant finding was found between stiffness and LIC (R(p=0.11, p=0.67). For 24 patients all record were available at time of first observation until last follow up (f.u.): 75% HbSβ°, median age 39.5yrs, male 42%, median f.u. 6 yrs, median stiffness 7.3 KPa IQR: 5.3-11.9 KPa. At the first evaluation we documented a significant positive-moderate correlation of TE with serum ferritin (R\(^p=0.43, p=0.037\)), AST (R\(^p=0.54, p= 0.006\)), conjugated bilirubin (R\(^p=0.52 values 0.009\) and positive-strong correlation with GGT (R\(^p=0.68, p=0.001\)), these parameters except of ferritin (Rp\(^=0.3, p=0.15\) and AST (R\(^p=0.39, p=0.058\)) have maintained the correlation with last f.u.; albumin and ALP showed a significant strong correlation only at f.u. (albumin R\(^p=0.64, p=0.004\); ALP R\(^p=0.7, p=0.0017\)). To remove factors associated with liver fibrosis we also conducted this analysis in the subset of patients HCV negative without liver iron overload: 26 patients, HbSβ° 73%, median age 40.5yrs, male 50%, median f.u. 6 yrs, median values of stiffness 6.1 KPa IQR: 4.6-7.4 KPa. All significant correlations previously described were confirmed also in this group. Three patients in this cohort presented stiffness value according to F4 METAVIR since their first evaluation: all these patients showed pauci-symptomatic disease in terms of VOCS, however they had a severe hepatic damage due to sickle cell disease.

Summary/Conclusions: Early identification of chronic hepatic disease sometimes pauci-symptomatic in terms of VOs can but able to lead to advanced stage and progressive fibrosis is crucial for suitable clinical management to avoid cirrhosis in SCD patients. The combination of TE with specific serum markers (GGT, ALP, albumin) is a valid tool to early detection of sickle hepatopathy.

E1483

MICROSTRUCTURAL ANALYSIS OF RETINO-CHOROID LAYERS USING OPTICAL COHERENCE TOMOGRAPHY IN ADULT PATIENTS WITH SICKLE CELL DISEASE

G. Graziaidei1, L. Dell’Arti2, G. Bartesseli3, F. Viola4, L. Riva1, E. Carini1, S. Francconi1, A. Invernizzi2, L. Duca7, M.D. Cappellini8

Aims: to analyze macular alterations in patients with Sickle Cell Disease (SCD) by spectral-domain optical coherence tomography (SD-OCT), using the automated software for retinal segmentation; b) to investigate relationship between OCT abnormalities and the severity of proliferative sickle cell retinopathy (PSR). c) to elucidate the role of potentially contributory systemic factors on the development of macular thinning.

Methods: This is a prospective, observational case-control study. Ophthalmological examination, fluorescein angiography and SD-OCT were performed. Central and temporal retinal layers were measured by the SD-OCT Automatic Segmentation software. SCD eyes were divided into two groups based on the presence of visible macular thinning areas. Clinical data and blood samples were collected.

Results: Thirty consecutive adult SCD outpatients were studied (median age 38.7±9.89 (M.F 12:18), including 9 patients with Sickle Cell Anemia (SCA), 17 with Sickle Cell Trait (SS) and 14 Thalassemia and 4 Hbs/Hbc. One Hbs/Hbc was not considered due to retinal detachment and severe refractive defect. Nineteen out of 59 eyes (32.2%) and 13 out of 30 SCD patients (43%) were noted to have patchy areas of macular thinning on SD-OCT, mostly seen temporally to the fovea. Among these patients, 6 had SCA, 4 had β-Thalassemia and 3 Hbs/Hbc. More severe PSR was present in 16/59 eyes (29%); the prevalence of temporal macular thinning was higher (10/16) in eyes with more severe PSR (62.5%). Both inner and outer retinal layers thinning of the foveal region and of the central and temporal macula was found in the overall SCD patients compared with normal controls (p<0.001). SCD eyes with patchy retinal thinning showed significant reduction of inner nuclear layer (INL) and outer plexiform layer (OPL) in the temporal region. Univariate analysis revealed a significant correlation between patchy areas of severe retinal thinning on OCT and SCD need for transfusions, need for chelation, HbF, ferritin, and transferrin saturation (p<0.05). Further multivariate regression analysis was performed in order to analyse ΝΑΤΕΜ CT (Closure Time), MCF (Maximum Clot Firmness), EXTEM CT, MCF and FIBTEM CT, MCF. Brain imaging as well as brain MRI. Measurements of fibrinogen, D-Dimers, antithrombin III, proteins S and C were performed (SIEMENS BCS) and thromboelastography ROTEM® was performed in order to analyse NATEM CT (Closure Time), MCF (Maximum Clot Firmness), EXTEM CT, MCF and FIBTEM CT. MCF, Brain imaging as well as brain MRI. Measurements of fibrinogen, D-Dimmers, antithrombin III, proteins S and C were performed (SIEMENS BCS) and thromboelastography ROTEM® was performed in order to analyse NATEM CT (Closure Time), MCF (Maximum Clot Firmness), EXTEM CT, MCF and FIBTEM CT.

Background: Retinopathy is one of the ophthamological complications of patients with Sickle cell disease (SCD), due to microvascular occlusions; occasion-ally, proliferative sickle cell retinopathy (PSR) can lead to severe vision loss.

Method: Aims: a) to analyze macular alterations in patients with Sickle Cell Disease (SCD) by spectral-domain optical coherence tomography (SD-OCT), using the automated software for retinal segmentation; b) to investigate relationship between OCT abnormalities and the severity of proliferative sickle cell retinopathy (PSR). c) to elucidate the role of potentially contributory systemic factors on the development of macular thinning.

MCF, Brain imaging as well as brain MRI. Measurements of fibrinogen, D-Dimers, antithrombin III, proteins S and C were performed (SIEMENS BCS) and thromboelastography ROTEM® was performed in order to analyse NATEM CT (Closure Time), MCF (Maximum Clot Firmness), EXTEM CT, MCF and FIBTEM CT. MCF, Brain imaging as well as brain MRI. Measurements of fibrinogen, D-Dimers, antithrombin III, proteins S and C were performed (SIEMENS BCS) and thromboelastography ROTEM® was performed in order to analyse NATEM CT (Closure Time), MCF (Maximum Clot Firmness), EXTEM CT, MCF and FIBTEM CT. MCF, Brain imaging as well as brain MRI. Measurements of fibrinogen, D-Dimers, antithrombin III, proteins S and C were performed (SIEMENS BCS) and thromboelastography ROTEM® was performed in order to analyse NATEM CT (Closure Time), MCF (Maximum Clot Firmness), EXTEM CT, MCF and FIBTEM CT.
4/161 (1.6%), positive D-Dimers in 57/59 (96.6%), decreased protein S in 10/61 (16.3%) and decreased protein C or 13/61 (21.3%). NATEM MCF was increased in 27/61 (44.3%) patients while EXTEM MCF was increased in 3/61 (50.8%) patients. Patients with a history of TEE had higher mean values of NATEM-MCF and EXTEM-MCF and those differences were statistically significant (p=0.023, and p=0.011 respectively). There was a statistically significant association between the presence of ischemic lesions in brain MRI and the history of TEE (p=0.01). On the contrary, the history of ACS was not correlated with the presence of ischemic lesions in MRI. Chronic Hydroxyurea treatment did not correlate with the absence of ischemic findings in brain MRI. Among patients with ischemic lesions those who were already on chronic hydroxyurea treatment had a shorter NATEM-CT compared to patients without treatment. In patients with ischemic lesions in MRI and a history of TEE NATEM-MCF and EXTEM MCF were higher (p=0.03, x0.03, respectively).

Summary/Conclusions: The presence of microschemic encephalopathy is very common in SCD patients and is associated with a history of TEE, which is also frequent in SCD. There seems to be a permanent activation of the coagulation mechanism in SCD. In SCD patients with SCIs and a history of TEE, apart from clotting factors and natural inhibitors there seems to be a contribution of platelets and cellular elements, possibly sickle cells. The impact of chronic hydroxyurea treatment on the pathogenesis of silent infarcts and TEEs needs further evaluation.

INVASIVE BACTERIAL INFECTIONS IN GAMBIAN PATIENTS WITH SICKLE CELL ANEMIA IN AN ERA OF WIDESPREAD PNEUMOCOCCAL AND HAEMOPHILUS INFELUENZA TYPE B VACCINATION
G. Soothill1,*, S. Darboe2, G. Bah3, L. Bolaníndé4, A. Cunnington5, S. Anderson2
1Royal Free Hospital, London, United Kingdom, 2Medical Research Council Unit Gambia, Fajara, Gambia, 3Imperial College London, London, United Kingdom

Background: Bacterial infections cause significant morbidity and mortality in patients with sickle cell anemia, especially in populations without reliable access to antimicrobial prophylaxis and treatment. The limited understanding of penicillin prophylaxis and vaccination for Streptococcus pneumoniae and Haemophilus influenzae type b in resource-rich settings has minimised the additional risk of invasive bacterial infections associated with sickle cell anemia. However, these interventions are not routinely implemented in much of Africa, despite this region having the greatest burden of disease, with over 80% of people with sickle cell anemia born on the continent. The Gambia has well established vaccination programmes for pneumococcal and Haemophilus influenzae type b, which is rare in the region. There is little data on the identity of bacterial infections in African sickle cell anemia populations, and we believe (until this study) there were no data from countries in the region adopt pneumococcal and Haemophilus influenzae type b vaccination programmes, they may see a change in the spectrum of pathogens found in sickle cell anemia patient populations. Local research may be needed to determine appropriate antimicrobial treatment and prophylaxis regimens for patients with sickle cell anemia.

Results: Pathogenic bacteria were cultured from blood in 11 of the 131 admissions (8.4%, 95% CI 4.5-14.1%). The most frequent organism isolated was Salmonella typhimurium (6/11; 54.5%), followed by Staphylococcus aureus (2/11; 18.2%) and other enteric Gram-negative pathogens (2/11; 18.2%) and there was one case of Haemophilus influenzae non-type b bacteremia (1/11; 9.1%). No cases of bacteremia caused by Streptococcus pneumoniae or Haemophilus influenzae type b were identified. The most common diagnosis causing the admission was vaso-occlusive crisis (53/161; 32.9%), followed by infective complications including pneumonia (16/161; 9.9%) and osteomyelitis (12/161; 7.5%). The median length of admission was five days and the median age of patients was five years (IQR: 2-13 years). A new diagnosis of sickle cell anemia was made during the admission in just under half of patients.

Summary/Conclusions: The predominance of non-typhoidal Salmonella and other enteric Gram-negatives as the causative agents of invasive bacterial infections in our study is striking. Despite its success in resource-rich settings, penicillin may not be the optimal prophylaxis for sickle cell anemia patients already vaccinated for pneumococcal and Haemophilus influenzae type b in The Gambia. For sickle cell anemia patients with suspected bacterial sepsis, empirical treatment must be effective against both non-typhoidal Salmonella and Staphylococcus aureus, and account for local resistance patterns. As other countries in the region adopt pneumococcal and Haemophilus influenzae type b vaccination programmes, they may see a change in the spectrum of pathogens found in sickle cell anemia patient populations. Local research may be needed to determine appropriate antimicrobial treatment and prophylaxis regimens for patients with sickle cell anemia.

E1488
THE ASSOCIATION OF IGF-1 AND IGFBP-3 SERUM LEVELS AND GENE EXPRESSION WITH THE PATHOGENESIS OF INFLAMMATION IN SICKLE CELL DISEASE
N. basuli1, F. karahan2, E. ak3, S. Unal4,5
1Pediatric, meris University Pediatric, 2Mersin University Pediatric Oncology Department, 3Mersin University Pediatric Hematology Department, Mersin, Turkey

Background: Sickle cell disease (SCD) is one of the chronic inflammatory diseases Serum markers of inflammation have provided evidence for a state of chronic inflammation in sickle cell disease (SCD). Inflammation promotes endothelial adherence to sickle erythrocytes.

Aims: We aimed to investigate the serum insulin-like growth factor 1 (IGF-1) and insulin-like growth factor binding protein 3 (IGFBP-3) levels and gene expression in the pathogenesis of inflammation in sickle cell disease and to determine its role in painful crises.

Methods: A total of 71 patients aged 2 to 18 years, who were followed with the diagnosis of SCD in our department, were included in the study between April 2012 and April 2013. Patients were divided into two groups; Group 1: Patients who had a painful crisis during the study (41 patients, mean age: 11.5 years) and Group 2: Patients who were in steady state during the study (30 patients, mean age: 11 years). Blood samples were taken from the patients for complete blood count, serum levels of C-reactive protein (CRP), interleukin-1 β (IL-1 β), interleukin-6 (IL-6), tumor necrosis factor-alpha (TNF-α), IGF-1, IGFBP-3 and IGF-1, IGFBP-3 gene expression.

Results: When the patients in both groups were compared in terms of serum IGF-1 level; serum IGF-1 levels were normal in all patients (100%) in group 2 and 33 patients (80.5%) in group 1, and the difference was considered to be statistically significant (p < 0.001). When the groups were compared in terms of serum IGFBP-3 level; serum IGFBP-3 level in Group 2 was found to be significantly lower in Group 1 (p <0.001). Also, when the patients were examined for IGF-1 and IGFBP-3 gene expression, no significant difference was found between the groups (Table 1). A negative correlation was found between leukocyte level and IGF-1 in group 1, and IGF-1 gene expression and CRP in group 2. Serum IGFBP-3 and IL-6 levels were found to be significantly lower in patients without any painful crisis than those with painful crisis in the last year (p <0.05).

Table 1.
Summary/Conclusions: The clinical manifestations of SCD were thought to be associated only with hemoglobin polymerization for a long time. However, recent studies have shown that SCD is a chronic inflammatory disease. The pro-inflammatory cytokines and IGF are in a state of equilibrium in the human body. It has been reported that IGF-1 plays a major role in the production of NO, which is produced in the endothelium and causes a vasodilatory response, and that it increases antioxidant systems and reduces oxidative stress, thereby decreasing inflammation by reducing pro-inflammatory cytokines. In our study, we found that the serum levels of IGF-1, an important growth factor that has not been studied previously in SCD and has recently been evaluated on the effects of inflammation, decreased in SCD patients with painful crisis compared to patients in steady state. It was also found that the levels of inflammatory cytokines, evaluated during the same period, such as IL-6 and TNF-α are increased. In conclusion, IGF-1 was thought to play a role especially in the pathogenesis of acute inflammation in SCD.

UNIVERSAL NEWBORN SCREENING FOR SICKLE CELL DISEASE: PRELIMINARY RESULTS OF THE FIRST YEAR OF A MULTICENTRIC ITALIAN PILOT PROJECT

M. Martella1, L. Cattaneo2, G. Viola1, S. Azzena1, A. Cappellari1, E. Baraldi3, C. Zorloni2, N. Masera2, A. Biondi2, G. Basso1, R. Colombatti1,1, L. Sainati1

1Clinic of Pediatric Hematology Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, Italy, Padova, Italy.

Methods:

The frequency of visits limits this option for individuals in rural areas with SCD. In subsequent years. Thus, in additional children with SCD were referred from the difficult. Hydroxyurea, the only drug-FDA-approved to modify the course of SCD, requires monthly laboratory assessments in the first year and every 3 months in subsequent years. In conclusion, patients living in the rural PeeDee region, decrease the burden of care and expense of travel for affected families and improve Hydroxyurea acceptance and uptake.

Background:

Sickle cell disease (SCD) is the most common monogenic disease worldwide. Although it is most prevalent in Africa, in parts of the eastern Mediterranean and Asia, the result of this disorder is also continuously increasing in central and northern Europe. It is established that early detection and appropriate prophylactic measures prevent potentially fatal complications and many European countries have already introduced newborn screening programs for SCD. In Italy it is estimated that 6.5% of the total population is represented by carriers of hemoglobinopathies, nevertheless, there isn’t a national newborn screening program for SCD nor a plan to establish it. Selective newborn screening programs for SCD are currently active in three regions of Italy, and a pilot universal newborn was terminated due to lack of funding. Hydroxyurea was included in the SCD protocol for the local pediatric group for the telehealth clinic who had been designated as “lost to follow up (LTFU).” The clinics were originally scheduled monthly however three clinics were cancelled during the first 16 months and a total of 13 clinics were conducted. They were 64 total visits scheduled of which 50 visits were conducted. The overall no-show rate of 14% (range 0-34%) and six clinics had a no-show rate of 0%. The scheduling rate was 78% (range 60-100%). The primary aim was to assess the feasibility and acceptability of a telehealth clinic measured by patients' and families' adherence to scheduled appointments. Of the 19 patients, 13 (68%) (19) have continued participating in clinic (defined as attending more than 3 clinics in the 16-month period). Prior to starting the telehealth clinic, 10 of the 19 patients had only been seen once in the previous calendar year and 5 of those patients had not been seen in >18 months. Three new patients were started on Hydroxyurea. Two additional referrals to the telehealth clinic were made during the first 13 months (young adults with SCD who had been LTFU for over 3 years). These young adults were seen once by telehealth and then referred to MUSC for the young adult clinic.

Summary/Conclusions: The pediatric SCD telehealth clinic met its primary aim and has continued monthly operations. Hydroxyurea initiation has improved chronic care through the state sickle cell network, (SC)2. This approach will well as acute care through the state sickle cell network, (SC)2. This approach will well as chronic care through the state sickle cell network, (SC)2. This approach will also use a technology-based approach to increase education of providers.

References:

Performing with a grant from Team for Children.
The plasmatic hemoglobin (cell-free hemoglobin - Hb) was measured by using (Bantu / Bantu + HC) and 54 without (Bantu / Bantu - HC), respectively.

Methods: SCA.

Aims: To provide a recommendation for newborn screening program for SCD in Italy.

Methods: A panel of experts was identified by Italian Society of Thalassemia and Hemoglobinopaties (SITE) and Italian OncoHematology Pediatric Association (AIEOP). The panel has rigorously reviewed the literature (from 1990 to 2016), the existing recommendations/guidelines of other countries where newborn screening program for SCD is already exists and the results of SCD-CARE system (Recommendations Assessment, Development and Evaluation) was used to score levels and grades of evidence. The working group provided the draft guideline, and the final version has been revised by external (international) reviewers and the national patients association (UNITED).

Results: The recommendations were divided into five sections according to the newborn screening program as well as: 1) testing of newborns and specific screening methods, 2) evaluation of screening results for a definitive diagnosis, 3) enrollment of affected newborns in comprehensive care programs, 4) evaluations of the efficacy of follow-up and interventions, and assessment of the benefit to the patient, family, and society. The on line access for recommendations will be available for clinicians and healthcare providers.

Summary/Conclusions: The recommendations for SCD newborn screening program will be an important tool (i) in discussion of strategic new born screening panel at national level; (ii) to early identify patients to be treated in comprehensive SCD centers and (iii) to produce epidemiological data required for future design of SCD map in Europe.

E1492

GENETIC HEMOLYTIC MARKER IN SICKLE CELL ANAEMIA

P. Pereira Nascimento1,*, L. Souza Torres1, D. Grunig Humberto da Silva 1, J. Viviane Okumura1, E. Belini Junior2, C. Lopes de Castro Lobô3, and C. Regina Bonini-Domingo3

1Departamento de Biologia, Instituto de Biociências, Letras e Ciências Exatas - Ilicte/UNESP - São José do Rio Preto, São José do Rio Preto, 2Medicina - UFMS/CPFL, Universidade Federal de Mato Grosso do Sul, Três Lagoas, and 3HEMORIO, Instituto de Hematologia Arthur de Siqueira Cavalcanti, Rio de Janeiro, Brazil

Background: The heterogeneity and complexity of the phenotypic profile among individuals with sickle cell anemia (SCA) is one of the principal factors of current research. The SCA, a homozygous condition for Hb S, is a hereditary haemolytic anemia with severe clinical consequences. The intravascular hemolysis is a chronic clinical subphenotype and has been associated as an independent risk factor related to complications such as pulmonary hypertension, leg ulcer and more recently with progress of vasculopathies. Researches has already shown that the heterogeneity of the hemolytic profile can be due to the presence of different beta S-globin gene cluster haplotypes among the individuals, which suggests the participation of genetic factors in the characterization of this subphenotype. Thus, search for genetic variants has been a promising strategy to assist in the individualization of treatments, and favoring clinical evolution. Recent studies showed that the presence of at least one rs7203560 SNP allele (G) of the NPRL3 gene play a protective role at hemolysis in individuals with SCA, suggesting this variant as a genetic marker of hemolysis. Our objective were to evaluate the association between different genotypes of the SNP rs7203560 and the intravascular hemolysis in patients with SCA.

Methods: We evaluated 76 Brazilian people with SCA, all with a Bantu / Bantu haplotype profile, and in a steady state. The patients were divided into two groups according to Hb levels (HC) 22 vs low Hb levels (HC) 54 without (Bantu / Bantu - HC), respectively. The plasmatic hemoglobin (cell-free hemoglobin - Hb) was measured by enzyme-linked immunosorbsent assay (ELISA) to evaluate intravascular hemolysis. The association between categorical variables (with or without use of HC and genets SNP genotypes) and cell-free Hb levels was performed by univariate covariance analysis (GLM), followed by Fisher’s Post Hoc, considering the gender and age covariates. Statistical software was used and assumed p <0.05 as significant.

Results: Evaluating the recessive model (GG / GT versus TT), we found a significant difference between the different genotypic patterns (p=0.026), and not for the dominant model. Therefore we performed an analysis of the association of SNP in the variation of cell-free Hb levels and hemolysis markers commonly used as hemolysis parameters (relative reticulocytes, the enzymes lactate dehydrogenase and aspartate aminotransferase and unconjugated bilirubin), and we found that the individuals genotypic profile was responsible for 50.7% of the VS-Sw (V5k < 0.50%) in improving pain management, suggesting that the SNP may play a role in characterizing the hemolytic profile of our patients with SCA.

Summary/Conclusions: The SNP here studied is located in the intronic region of the NPRL3 gene, where the main regulatory elements of the alpha globin cluster (HS-48, HS-30 and HS-33) are also found. Studies have already suggested that the protective effect of the G allele of the SNP on the hemolytic profile is probably related to the role of this genetic variant in the expression of the alpha globin genes. Its promising that additive analyzes in other ethnic groups and models of hemolytic anemias, such as those of an acquired character are realized. This is one of our next step in the attempt to suggest this variant as a genetic marker capable of assisting in the characterization of the hemolytic and prognostic profile of people with SCA.
Table 1.

Summary/Conclusions: This is the first study highlighting key healthcare practice data for the small but significant number of SCD Day Hospital/Infusion Units around the globe. Our data suggest that among institutions with SCD-DH/IU there is no consensus regarding clinical practice or data collection. We conclude that there is a significant need to further evaluate SCD DH/IU patient-based value, and to develop operational standards / benchmarks to ensure dissemination, adaptability, and sustainability of these alternative care models.

REDUCED SERUM HAEMOPEXIN LEVELS IN HAEMOGLOBIN SC DISEASE OCCUR INDEPENDENTLY FROM THE DEGREE OF HAEMOLYSIS

F. Vendrame1,6, L. Marani1, S. Saad1, F. Costa1, K. Fenrini1
1Hematology and Hemotherapy Center, Unicamp, Campinas, Brazil

Background: In intravascular haemolysis, saturation of haptoglobin leads to haemoglobin oxidation and the release of free haem, whose main scavenger is haemopexin. In sickle cell mice, excess free haem has been shown to cause vaso-occlusion that can be reversed by haemopexin, implicating that knowledge on how haemolysis changes haemopexin production may influence the applicability of clinical use of haemopexin for sickle cell disease and other haemolytic states. Recent studies have reported reduced haemopexin levels in children with sickle cell disease (Santigo et al., 2016) and adults with beta thalassemia (Vinci et al., 2016) in association with elevated haem levels, thus suggesting haemopexin decreases due to chronic haemolysis. No data are available in adults with milder sickling disorder haemoglobin SC (HbSC) disease.

Aims: In this study, we examined haemolytic markers, haem, and haemopexin levels in samples from HbSC patients with varying degrees of haemolysis in comparison with healthy subjects with no abnormal haemoglobins (HbAA group).

Methods: Forty HbSC patients (age range 25-68 years, 15 men) and forty HbAA controls (age range 18-66 years, 28 men) participated in this study. Exclusion criteria were pregnancy, other cause of haemolysis, history of blood transfusion or sickle cell pain crisis in the past 3 months. Venous blood samples were collected for complete blood counts (Advia 2120, Siemens) and measurement of lactate dehydrogenase (LDH), bilirubin (Roche Hitachi), and haemopexin (Abcam) levels. Statistical analysis was performed by odds ratio (OR).

Results: As expected, serum LDH, total and indirect bilirubin, and reticulocyte counts were increased in HbSC patients (P=0.0001). Despite this, no significant difference in total circulating haem was found between HbSC and HbAA (39±2.6 vs 35±1.8 μM, respectively, P=0.30), contrary to what has been reported in other haemolytic diseases. Haemoglobin (Hb) was higher in the HbAA group compared to the HbSC group (15±0.2 vs 12±0.3 g/dL), and considering World Health Organization definitions of anaemia for men (Hb below 13g/dL) and women (Hb below 12g/dL), 20 (50%) patients in our HbSC cohort were anaemic, thus fulfilling criteria for compensated haemolysis. HbSC patients with compensated haemolysis were not significantly different from their anaemic counterparts, with similar reticulocyte counts, LDH, bilirubin, haemoglobin (9.83±9.48 vs 7.73±9.813 ng/dL, P=0.10), and total haem levels (33.92±2.4 vs 37.55±2.9 μM, P=0.30). We also found an unexpected negative correlation between haemoglobin and haemopexin, r=-0.42 (Pearson), P=0.007.

Summary/Conclusions: Despite the putative importance of reduced haemopexin in the pathophysiology of sickle cell disease, HbSC patients do not always present with haemopexin deficiency, regardless of the intensity of the haemolytic state, and possibly due to a lesser importance of intravascular haemolysis. Our data support that non-anaemic HbSC patients may be equally affected by haemolysis, but intravascular haemolysis does not predominantly regulate haemopexin production. We suggest that excessive free haem and low haemopexin probably represent a lesser contribution to the pathophysiology of complications found in this subgroup of sickling disorders.

E1495

ASSOCIATION OF TOLL-LIKE RECEPTOR 2 GENE POLYMORPHISM WITH THE INCIDENCE OF BACTERIAL INFECTIONS IN SICKLE CELL DISEASE

K. Tozatto-Maio1,2,3, R. Girot4, C. Manaselvan5,6, M. Bennabi5,6, A. Ruggieri1,2, B. Cappelli1,2, R. Krishnamoorthy5, B. Pinto Sinhões5, I. Diagne4, E. Guckman1, R. Tamouza56
1Eurocord, Université Paris 7, Paris, France, 2Monacord, International Observer on Sickle Cell Disease, Centre Scientifique de Monaco, Monaco, Monaco, 3Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, Brazil, 4Hôpital Tenon, 5Inserm U1160, Université Paris 7, Paris, 6Hôpital Henri Mondor, Créteil, France, 7Pediatrics Unit, Centre Hospitalier National d’Enfants Albert Royer, Dakar, Senegal

Background: Despite antimicrobial prophylaxis and immunization, bacterial infection remains a leading cause of morbidity and mortality in sickle cell disease (SCD) patients. Functional hyposplenia/asplenia partially explains their susceptibility, since even young SCD children with functional spleen are at raised infectious risk. Toll-like receptors (TLR), that recognize pathogen molecular patterns, are at the forefront of immune protection. The interaction between TLR and infectious diseases in SCD patients has never been explored.

Aims: To evaluate if functional polymorphisms in TLR confer susceptibility/resistance to infections in SCD.

Methods: 160 SCD patients followed either in France (n=104) or Senegal (n=56) with recorded history of infections were tested for SNPs in TLR-1, TLR-2, TLR-4, TLR-6 and TLR-10 by TaqMan S-nuclease assay for their association with infectious history. Comparisons between groups were evaluated by x² or Fisher exact T-test with Bonferroni corrections of P-value (Pc); associations were measured by odds ratio (OR).

Results: 70 patients were positive for at least one bacterial infectious episode (IP) and 84 had no infection (NIP). Eleven IP had more than one episode of infection. Median age was 25 years (range 4-49) for IP and 23 years (range 3-52) for NIP with no distribution bias in gender (p=0.24). All patients had vaccinations against Streptococcus pneumoniae and Haemophilus influenza B, and patients under 10 years had received penicillin prophylaxis. Endotoxigenic agent was identified in 58 cases with encapsulated bacteria (EB) occurring in 35; the most common agents consisted of Mycobacterium tuberculosis, Streptococcus pneumoniae, Salmonella spp, Escherichia coli and Klebsiella pneumoniae. Sites of infection included respiratory tract (n=24), bone and joints (n=21), blood stream (n=17), uterine tract (n=11), central nervous system (n=8) and abdominal (n=5). TLR-2 rs4966480 TA genotype was less represented in IP than in NIP [45% vs 98%, OR=0.02, 95%CI=0.01-0.09, Pc<0.003] and in particular TLR-2 rs4966480 TA genotype was significantly less frequent in the group of patients infected by EB as compared to NIP+IP with other known endotoxigenic agents [51% vs 85%, OR=0.19, 95%CI=0.08-0.44, Pc<0.003]. Other TLR SNPs, genotype and haplotype showed no significant difference between groups.

Summary/Conclusions: rs4966480 TA genotype apparently confers protection against infections especially for EB. Given the previously demonstrated association of AA genotype with exacerbated expression of inflammatory cytokines as well as association of T allele with lower expression of cytokines it is tempting to postulate that TA genotype can be considered as a compromise between deleterious effects of over inflammatory response (TLR-2 AA genotype) and under response (TLR-2 TT genotype) to infectious agents. Such balanced selection effect is probably reflected by the observed deviation from HWE.

Stem cell transplantation - Clinical

E1496
HIGH PROGNOSTIC VALUE OF PRE-SCT MOLECULAR MINIMAL RESIDUAL DISEASE ASSESSMENT BY WT1 GENE EXPRESSION IN AML TRANSPLANTED IN CYTOLGIC COMPLETE REMISSION
A. Candoni1,*, M.E. Zannier1, E. Bertoli1, F. De Marchi1, E. Simeone1, C. Fili1, D. Lazzarotto1, G. Ventura1, E. Toffolli1, N. Rabassi1, C. D’Onofrio1, C. Comuzzi1, R. Fanin1
Division of Hematology and SCT, University Hospital, Udine, Udine, Italy

Aims: We analyzed the outcome of allogeneic Stem Cell Transplantation (allo-SCT) in AML patients according to molecular Minimal Residual Disease (MRD) at the pre transplantation (pre-SCT) workup, assessed by the quantitative expression evaluation of the panleukemic marker Wilms’ tumor gene (WT1), according to LeukemiaNET validated method.

Methods: 122 consecutive AML patients received allo-SCT while in cytologic Complete Remission (cCR), between 2005 and 2016, at our Center. The median age at SCT was 53 years (18-70). The quantitative analysis of the WT1 gene expression (bone marrow samples) was available in 100% cases, both at diagnosis (100% overexpressing WT1 with a mean of 8607±8187 copies/10^4 Abelson and before allo-SCT (1/12) in 26% of MRD-WT1-negative and 41/122-44% MRD-WT1 positive cases at the pre-SCT workup.). We evaluated post-SCT Overall Survival (OS), Disease Free Survival (DFS) and Relapse Rate, according to MRD-WT1 pre-SCT status.

Results: Both post-SCT OS and DFS were significantly better in patients who were MRD-WT1 negative (WT1<250 copies) at the time of SCT compared with those who were MRD-WT1 positive (WT1>250 copies), with a median OS and DFS not reached in the MRD-WT1 negative group and 9 and 8 months, respectively, in the MRD-WT1 positive group (OS log-rank p<0.0001; hazard ratio [HR]=4.26; 95% confidence interval [CI]=2.0-9.1; DFS log-rank p=0.0001; HR=3.73; 95% CI=2.0-6.72). The relapse rate after allo-SCT was 15% (12/81) in pre-SCT MRD-WT1 negative cases and 44% (18/41) in MRD-WT1 positive cases (p=0.00073). At univariate analysis, MRD-WT1 negativity before allo-SCT and grade <2 acute GVHD were significant prognostic factors for improved OS and DFS. However, at multivariate analysis, MRD-WT1 negativity before allo-SCT was the only independent prognostic factor for improved OS and DFS.

Summary/Conclusions: These data show that pre-allo-SCT molecular MRD evaluation through WT1 expression is a powerful predictor of post-SCT outcome (OS, DFS, relapse rate). Patients with both cCR and a MRD-WT1 negativity before allo-SCT have a very good outcome with a very low relapse rate and better survival. The pre-SCT MRD-WT1 strafication in AML is a valuable tool to identify patients, transplanted in cCR, who are at high risk of relapse and who could be considered for conditioning regimen intensification and/or for post-SCT immunomodulation, immunosuppression, azacitidine or new target drugs.

E1497
GOOD IMMUNOLOGICAL RESTORATION IN ADULTS WITH ACUTE LEUKAEMIA AFTER ALFA-BETA TCR/CD19+ DEPLETED HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) AND T-CELL DEPLETION BETWEEN MAY 2011 AND DECEMBER 2016
L. Prezioso1, S. Bonomini1, C. Schifano1, A. Monti1, I. Manfra1, A. Spolzino1, G. Sammarelli1, L. Craviotto1, M. Sassi2, M. Soli2, F. Aversa1
1CAL HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) and 2Prognosis Analysis, University of Palermo, Palermo, Italy

Background: Haplo-HSCT based on the infusion of high numbers of T cell depleted (TCD) hematopoietic progenitor cells and no post-transplant immunosuppression controls both graft rejection and GVHD in patients with acute leukemia. One major remaining issue is the delay in the post-transplant immunological restoration because of the minimal residual T lymphocytes in the graft and in vivo ATG-linked T cell depletion. Current studies are focussing on rebuilding posttransplant immunity to improve clinical outcomes separating GvHD from favourable donor immune responses. Selective elimination of αβ+T cells retains in the graft NK, dendritic cells, monocytes and γδT lymphocytes. Under this approach, a rapid immunological reconstitution and very promising outcome have been reported in pediatric patients.

Aims: With the aims of confirming these results in adults, we tested this approach in adults with acute leukemia.

Methods: Thirty-two patients, median age 51 years (range 19-74), with AML (n=21), ALL (n=11) entered to study. Twenty were in CR (12 CR1; 8 CR2), 12 in advanced-stage disease at transplant. Consisting of ATG 1.5mg/kg from day -13 to -10, Treosulfan 12 gr/sqm from -9 to -7, Fludarabine 30mg/sqm from -6 to -2 and Thiotaape 5mg/kg on days -5 and -4. PBPCs from haplo-donor (3 mothers, 9 siblings, 13 sons/daughters and 7 cousins) under went ATG-linked T cell depletion between May 2011 and December 2016. No post-transplant immunosuppression was given. Ganciclovir was given over the conditioning regimen in the 22 patients who were CMV seropositive; L-AmB was used as anti-mold active prophylaxis over the neutropenic phase.

Results: Grafts contained a median of 11x10^6/kg (range 5-19) CD34+ cells, 4.3x10^5/kg CD3-Tcells/kg (range 1-36), 4.9x10^5/kg (range 0.4-62) αβ-T cells, 4x10^5/kg CD8/Tcells/kg (range 1-34), 5x10^4/kg B cells/kg (range 1.5-32) and 22x10^5/kg CD56/NKcells/kg (range 5-91). All patient achieved a full donor sustained engraftment. Median time to reach 500 neutrophils and 20,000 platelets was 13 (range 10-18) and 11 days (range 6-30), respectively. Two patients developed and died from severe acute GVHD. One of them had received the highest dose of αβ+T cells (3.7x10^6/kg) and the second one affected by 6GPDH deficiency experienced a late onset hepatic GvHD. Eight patients had skin limited grade II aGVHD that required short course steroids. Only two patients have so far developed mild cGvHD that recovered completely after steroid and cyclosporin treatment. Tending to confirm our working hypothesis, there was a rapid, sustained increase in peripheral blood T-cell subpopulations (Fig. 1). Naïve and memory T-cell subsets increased significantly over the first year after transplantation. B-cell reconstitution was rapid and sustained and immunoglobulin serum levels normalized within 3 months. CMV reactivation occurred in 1 of the 30 patients who were at risk (p=0.041) and 2 or more CMV reactivations. One with unfavorable serology (donor negative into recipient positive) developed and died of CMV disease 8 months after transplant. Relapse was the main cause of failure (8/12 in relapse, 3/20 in CR). NRM was 15% (4/12 in relapse, 4/20 in CR), 13 patients survive at a median follow-up of 29 months (range 5-53).

Figure 1.

Summary/Conclusions: The infusion of αβ/CD19-depleted grafts confirmed a fast immunological reconstitution also in adults. Relapse is still a major concern in patients already in relapse at transplantation.

E1498
UNMANIPULATED HAPLOIDENTICAL TRANSPLANTATION CONDITIONING WITH BUSULFAN, CYCLOPHOSHAMIDE AND ANTI-THYMOMOGLUBIN FOR ADULT SEVERE APLASTIC ANEMIA: GOOD OUTCOME AND PROGNOSIS ANALYSIS
Z. Xu1, L. Xu1,*, F. Wang1, X. Mo1, T. Han1, W. Han1, Y. Chen1, Y. Zhang1, J. Wang1, Y. Wang1, C. Yan1, Y. Sun1, F. Tang1, X. Zhang1, X. Huang1
1Peking University People’s Hospital, Peking University Institute of Hematology, Beijing, China, Beijing, China

Background: Severe aplastic anemia (SAA) is a life-threatening disorder for which allogenetic hematopoietic stem cell transplantation (HSCT) is the available curative approach. Recently, more and more studies have focused on the feasibility of haplo-identical transplantation in SAA patients because of donor availability. Our team evaluated the outcomes of this intervention in a series of patients who were transplanted in a cytologic stage (HSCt) in adults with acquired severe aplastic anemia (SAA), we conducted a retrospective analysis.

Methods: A total of 49 SAA adults received haplo-identical transplantation without in vitro T-cell depletion between May 2011 and December 2016. A total of 47 cases surviving for more than 28 days achieved donor myeloid engraftment. The median time for myeloid engraftment was 13 (range, 10-21) days and for platelet was 17.5 (range, 7-101) days with the cumulative incidence of 93.88±0.17%. The cumulative incidence of grade II-IV and III-IV acute graft-versus-host disease (aGvHD) were 20.89±0.35% and 4.17±0.08%, respectively.
For patients who survived more than 100 days, the incidence of chronic graft-versus-host disease (cGVHD) were 14.9±4.0% and 27.4±0.77%, and that of extensive cGVHD were 2.57±0.07%, and 7.8±1.29% at 1 year and 3 year. With a median follow up of 20.1 (2.1-70.1) months for alive patients, 3-year estimated overall survival (OS) and failure-free survival (FFS) were both 92.5±5.7%. Multivariate analysis showed hematopoietic cell transplantation-specific comorbidity index (HCT-CI) score ≥3 was significantly associated a worse 3-year survival outcome (86.0% vs 50.0%, P=0.035, Hazard ratio [95% Confidence interval]: 6.266 [1.139-34.463]).

Summary/Conclusions: Haplo-identical transplantation without in vitro T-cell depletion conditioning including BU/CY+ATG is a feasible strategy for adult SAA patients, with successful engraftment, acceptable GVHD, and inspiring survival outcomes. HCT-CI might be an outcome predictor in these patients.

Figure 1.

Summary/Conclusions: It is possible to conduct autotransplants for patients with MS employing non-frozen peripheral blood stem cells and outpatient conditioning. Additional information is needed to assess the efficacy of these procedures in the treatment of patients with MS.
Patients were endoscopically evaluated at time of GVHD diagnosis and follow-up. Treatment characteristics are provided in Table 1.

Results: All 13 patients experienced clinical responses, which were confirmed by endoscopies and in mucosal biopsies. 10 patients (77%) achieved a clinical response within 28 days, and half of these were complete responses. At last follow-up 10 patients (77%) had achieved sustained complete responses, 2 patients (15%) had responded partially and 1 patient (8%) suffered disease progression. 7 patients (54%) were alive after a median follow up of 35 weeks. The causes of death were transplantation related toxicity, GVHD in other target organs and infectious complications. Increased relative counts of CD25++/CD127low regulatory T-cells prior to treatment were observed in peripheral blood of 7 of 9 evaluable patients, and the relative counts decreased in all 7 patients during follow-up.

Summary/Conclusions: Our results indicate that vedolizumab may effectively treat steroid refractory cases of intestinal GVHD and is well tolerated. The mechanism of action is believed to be inhibition of allo-reactive T-cells interacting with intestinal endothelial cells. It is unclear why regulatory T-cells were increased in our steroid refractory GVHD patients and subsequently normalized. This might initiate a response to the alloreactive inflammation and subsequent redistribution to affected tissues and/or its resolution after successful treatment.

E1502

RISK FACTORS, OUTCOMES AND CHARACTERIZATION OF ‘AUTOLOGOUS GRAFT VERSUS HOST DISEASE’: THE MAYO CLINIC EXPERIENCE

T. Arangustoa1, J. Pulidoa1, M.M. Patnaika1, M.R. Litzowa1, D.A. Gaspina1, N. Duma1, F.K. Buoqa1, D. Martina1, W.J. Hoggan1, G. Goyal1, J.S. Lehman1, S.K. Hashmi1, S.S. Kenderian1
1Hematology/Medical Oncology, Mayo Clinic, Rochester, United States

Background: Graft versus Host Disease (GVHD) is a common complication of allogeneic stem cell transplantation (SCT) which is caused by the recognition of recipient antigens by the donor T lymphocytes. Acute GVHD remains a major cause of morbidity and mortality and half of the cases are refractory to steroids. The development of GVHD after autologous SCT (ASCT) is a poorly understood phenomenon. While some experts suggest that such an entity does not exist, some ASCT recipients develop clinical and histo-pathological changes similar to GVHD after allogenetic SCT.

Aims: In this analysis, we aimed to elucidate the factors that affect the outcomes of patients with autologous GVHD.

Methods: This is a retrospective analysis of patients that received ASCT at Mayo Clinic between January 2006 and December 2016. Autologous GVHD was defined as the development of clinical and histo-pathological findings indicative of GVHD in ASCT recipients, as determined by pathology review. Survival was estimated and compared using the Kaplan Meier and Log Rank tests. The study was approved by the institutional review board.

Results: Between 2006 and 2015, 3,891 consecutive patients underwent ASCT. Of these, 35 patients (0.9%) developed symptoms suggestive of GVHD warranting biopsies. In 19 of these 35 patients (54%), the histopathological changes were consistent with GVHD. The most common underlying disease in patients with developed GVHD was myeloma (14 patients, 73.7%) and the most common conditioning regimen used was melphalan (16 patients, 84.2%). The median age at ASCT was 61.9 (range 49.2-72.6) years and the median number of prior therapeutic regimens was 2 (range 1-7). GVHD management was similar to GVHD after allogeneic SCT.

CNS DEMYELINATION AFTER HAPLO-HSCT AND ITS ASSOCIATION WITH THE IGG INTRATHecal SYNTHESIS INDEX AND ANTI-MYELIN Oligodendrocyte Glycoprotein Antibody in CerebroSPinal Fluid

X. Zhao1, Q. Wang1, J. Zhang1, X. Zhu1, Y. He1, L. Xu1, W. Han1, H. Chen1, Y. Chen1, F. Wang1, J. Wang1, Y. Zhang1, X. Mo1, Y. Chen1, Y. Wang1, Y. Chang1, L. Xu1, K. Liu1, X. Huang1, X. Zhang1
1Peking University Institute of Hematology, Peking University People's Hospital, Beijing, China

Background: Haploidentical haemopoietic stem cell transplant (haplo-HSCT) is an upfront and effective therapy for haematological patients, but it usually has many complications such as neurological complications. As one of the neurological complications following haplo-HSCT, immune-mediated demyelinating diseases of the central nervous system (CNS) seriously affect the patient quality of life. However, the incidence, risk factors and pathogenesis of CNS demyelination are not very well understood.

Aims: To analyse the incidence, risk factors, and prognosis of CNS demyelination after haplo-HSCT.

Methods: A study was conducted in 1,526 patients who underwent haplo-HSCT between January 2013 and June 2016. The definition of CNS demyelination during haplo-HSCT was confirmed by neurologic signs, MRI abnormality corresponding to the neurologic signs, abnormal CSF studies and the presence of systemic GVHD or the response to immunosuppressive therapy (Grauer O et al. Brain. 2010; 133(10): 2852-2865, Chronic graft versus host disease.

Summary/Conclusions: Our results indicate that vedolizumab may effectively treat steroid refractory cases of intestinal GVHD and is well tolerated. The mechanism of action is believed to be inhibition of allo-reactive T-cells interacting with intestinal endothelial cells. It is unclear why regulatory T-cells were increased in our steroid refractory GVHD patients and subsequently normalized. This might initiate a response to the alloreactive inflammation and subsequent redistribution to affected tissues and/or its resolution after successful treatment.

Table 1.
100 and 2-years TRM, based only on HCT-CI, had AUCs of 56.4 and 58.6, respectively. The introduction of both albumin and CrCl, separately or combined, resulted in incremental improvement in AUC, topping at 66.1 (+17% increase) and 63.2 (+8% increase), for day-100 and 2-years TRM, respectively (Figure panel b). The improvement was maintained in all conditioning and donor subgroups.

**Results:** Thirty patients developed CNS demyelination after haplo-HSCT. The cumulative incidences of the diseases at 100 days, 1 year and 2 years post transplantation were 0.6%, 1.6% and 2.3%, respectively. The mean age at the time of presentation was 26.5 years (range, 10-52 years), and the mean time from transplant to the onset of neurolologic symptoms was 216 days (range, 17-844 days). Nineteen patients received a corticosteroid pulse, five patients received immunoglobulin, and six patients received supportive treatment and an immunosuppressive regimen in immune responsive symptoms improved in all patients. The mean duration from the time of improvement to deterioration was 5 days (±4). In univariate analysis, we found that BBB permeability and the CrCl IgG intrathecal synthesis index were related to the occurrence of CNS demyelination (p=0.1). In multivariate analysis, the CrCl IgG intrathecal synthesis index (OR=1.017, 95% CI: 1.003-1.031, p=0.019) and CrCl myelin oligodendrocyte glycoprotein antibody (OR=12.059, 95% CI: 1.141-127.458, p=0.038) were independently associated with the onset of CNS demyelination. We also studied the possible pathogenesis of CNS demyelination. Immune reconstitution (the cell proportion of CD19+B cells, CD3+ T cells, CD4+ T cells), the count of leukocytes, lymphocytes, monocytes and platelets, as well as the level of immunoglobulins A, G and M +30 days, +60 days, and +90 days after HSCT showed no significant differences between CNS demyelination and no demyelination (P>0.05). The probabilities of overall survival showed no significant differences between patients with and without demyelination.

**Summary/Conclusions:** The CrCl IgG intrathecal synthesis index and CrCl myelin oligodendrocyte glycoprotein antibody are independently risk factors for the onset of CNS demyelination after haplo-HSCT and have no influence on long-term survival. Immune reconstitution may not be pathogenesis of CNS demyelination.

**BASELINE CREATININE CLEARANCE AND ALBUMIN ARE POWERFUL RISK FACTORS FOR ALLOGENEIC TRANSPLANTATION RELATED MORTALITY**

**R. Shouval1, N. de Jong2, J. Fein1, E. Braakman2, A. Broers2, J. Kuipers2, R. Shouval1,**

1Hematology Division, Chaim Sheba Medical Center, Tel-HaShomer, Ramat-Gan, Israel, 2Department of Hematology, Erasmus University Medical Center, Rotterdam, Netherlands

**Background:** The course following allogeneic hematopoietic stem cell transplantation (HSCT) varies between individuals. Baseline comorbidities, commonly scored by the Hematopoietic Cell Transplantation-Comorbidity Index (HCT-CI), are important determinants of transplant risk. However, their prognostic utility varies and only partially accounts for transplantation-related mortality (TRM). Standard pre-HSCT laboratory carries objective physiologic information which can be used for TRM risk estimation.

**Aims:** Determine the value of pre-HSCT estimated creatinine clearance (CrCl), albumin, and alkaline phosphatase (Alk-p) for TRM prediction.

**Methods:** The study population included 1,217 patients from two European centers. Indications for transplantation and conditioning regimens were diverse. Donors were either HLA-matched sibling donors (54%), matched unrelated donors (30%), or 9/10 HLA-mismatched unrelated donors (15%). The impact of CrCl, albumin, and Alk-p on TRM was evaluated in a univariate and multivariate analysis.

**Results:** Patients had a median age of 55 years and HCT-CI scores of 0 (24%), 1-2 (39%), and >3 (37%). A cut-off of CrCl≤60 ml/min, albumin<3.5 g/dl, and Alk-p>180 IU/l corresponded with 8.8%, 8.3%, and 6.5% of the population, respectively. CrCl and albumin were associated with increased risk and higher cumulative incidence of TRM, disease status, donor-recipient sex mismatch, donor type, cytomegalovirus serostatus, and conditioning intensity. Relapse was considered a competing event for TRM. The predictive benefit of adding the laboratory markers to the HCT-CI score was estimated by calculating the area under the receiver operating curves (AUC) of TRM prediction models, with and without the markers.

1-2 years TRM prediction for the model which includes both CrCl and albumin were 56.4 and 62.5% respectively, significantly better (p<0.001) than for the model based only on HCT-CI, which had AUCs of 56.4 and 58.6, respectively. The introduction of both albumin and CrCl, separately or combined, resulted in incremental improvement in AUC, topping at 66.1 (+17% increase) and 63.2 (+8% increase), for day-100 and 2-years TRM, respectively (Figure panel b). The improvement was maintained in all conditioning and donor subgroups.

**E1505**

**CYTOGENETIC AND MOLECULAR RISK FACTORS AT DIAGNOSIS ARE OVERCOME BY WT1 AND FLOW CYTOMETRY-BASED PRE TRANSPLANT MINIMAL RESIDUAL DISEASE ASSESSMENT IN ADVANCED ACUTE MYELOID LEUKEMIA PATIENTS**

**F. Guolo1, P. Minetto1, P. Minetto1, M. Clavio1, F. Galaverna2, D. Guardo1, M. Clavio1, D. Guardo1, E. Coviello1, N. Colombo1, N. Colombo1, F. Ballerini1, F. Ballerini1, M. Miglino1, C. Di Grazia1, A. M. Riaolă2, R. M. Lemoli2, M. gobbi1, M. Miglino1, R. M. Lemoli2, M. gobbi1, A. Bacigalupo2, 1Clinic of Hematology, Department of Internal Medicine (DIME), University of Genoa, 2Division of Hematology and Bone Marrow Transplantation, IRCCS AOU San Martino-IST, Genova, Italy

**Background:** Allogeneic bone marrow transplantation (BMT) offers the only chance of cure for patients with advanced acute myeloid leukemia (AML). High levels of pre BMT minimal residual disease (MRD) have been reported to predict relapse risk in patient transplanted in first complete remission (CR). WT1 expression levels and multicolor flow cytometry (MFC) are the most common tools to evaluate MRD.

**Methods:** Here, we analyzed the role of pre-BMT MRD assessment as predictor for the post-transplant relapse risk in patient transplanted beyond first CR.

**Aims:** We retrospectively analyzed the outcome of 92 consecutive AML patients receiving allo-BMT in 2nd (CR2) or 3rd (CR3). Pre-BMT MRD was evaluated by WT1 expression and MFC. Median age at transplant was 45 years. Disease phase was CR2 in 63 patients (68%) and CR3 in 29 (32%). Risk group according to European Leukemia Net (ELN) at diagnosis was low in 28 patients (30%), intermediate in 44 (48%) and high in 20 (22%). Sixty-six patients (71%) received myeloablative conditioning, whereas 26 (29%) were conditioned with reduced intensity regimen. Stem cell source was HLA-identical sibling in 16 (20%), haploidentical (HAPLO) in 24 (26%) and alternative donor in 50 (54%). Median follow-up was 64 months (95% CI 39.8-88.2 months). A positive MRD FMC was defined by the presence of at least 1x10-6 residual leukemic cells at four or eight (since 2011) color flow cytometry. WT1 copy number at diagnosis and at the time of allo BMT was assessed by real-time quantitative PCR of WT1. Of the patients, 54% were WT1 positive at diagnosis and 44% at the time of allo BMT.

**Results:** WT1 levels of pre BMT minimal residual disease (MRD) have been reported to predict relapse risk in patient transplanted in first complete remission (CR). WT1 expression levels and multicolor flow cytometry (MFC) are the most common tools to evaluate MRD.

**Aims:** We retrospectively analyzed the outcome of 92 consecutive AML patients receiving allo-BMT in 2nd (CR2) or 3rd (CR3). Pre-BMT MRD was evaluated by WT1 expression and MFC. Median age at transplant was 45 years. Disease phase was CR2 in 63 patients (68%) and CR3 in 29 (32%). Risk group according to European Leukemia Net (ELN) at diagnosis was low in 28 patients (30%), intermediate in 44 (48%) and high in 20 (22%). Sixty-six patients (71%) received myeloablative conditioning, whereas 26 (29%) were conditioned with reduced intensity regimen. Stem cell source was HLA-identical sibling in 16 (20%), haploidentical (HAPLO) in 24 (26%) and alternative donor in 50 (54%). Median follow-up was 64 months (95% CI 39.8-88.2 months). A positive MRD FMC was defined by the presence of at least 1x10-6 residual leukemic cells at four or eight (since 2011) color flow cytometry. WT1 copy number at diagnosis and at the time of allo BMT was assessed by real-time quantitative PCR of WT1. Of the patients, 54% were WT1 positive at diagnosis and 44% at the time of allo BMT.

**Conclusions:** Pre- transplant estimated creatinine clearance (CrCl) and albumin are powerful risk factors for TRM. Deviations from normal ranges were frequent in our cohort, making them useful prognostic markers. We report for the first time the role of CrCl in HSCT prognostication, rather than the traditional HCT-CI cut-off of Creatinine >2mg/dL, which is rare in HSCT population (<1% in our cohort). We also corroborate albumin’s important prognostic role. Incorporation of these simple biomarkers can improve pre-transplant risk stratification and potentially be used as a tool for treatment personalization.
number/Abl copy number 250x10^4 was used as cut-off value for abnormal WT1 expression.

**Results:** Relapse occurred in 30 patients (33%) and two years non-relapse mortality was 29%. Three-year estimate of OS was 47.9% (median19 months). The survival probability was significantly affected by donor source (better for HAPLO, p<0.05), ELN at diagnosis (better for ELN low risk, p<0.01), MRD status, p<0.05 for WT1-based MRD, p<0.03 for MFC based MRD) and CR status at BMT (better for CR2, p<0.05). Specifically patients transplanted in a MRD negative status had comparable OS irrespectively of ELN at diagnosis (2-years OS of 62.2% and 52.7% among MFC MRD negative patient with ELN risk low or intermediate/high, respectively, Fig.1). The predictive value of MRD resulted independent from all other analyzed variables, although patients with positive MRD undergoing HAPLO BMT had a slightly better outcome. Multivariate OS analysis revealed that MRD status (evaluated by any method) was the only independent predictor of OS (p <0.05 for both). Pre BMT MRD was also a strong predictor of cumulative incidence (CI) of relapse in competitive risk analysis (p<0.01 and <0.03, respectively, for WT1 and MFC MRD). Multivariate CI of relapse analysis showed that donor source and MRD significantly influenced relapse risk (p <0.05 and <0.01, respectively).

**Figure 1.**

**Summary/Conclusions:** Pre transplant MRD evaluated by both WT1 and MFC in bone marrow samples is a reliable predictor of relapse risk and OS which can overcome the ELN risk stratification at diagnosis. Pre BMT MRD negative patients had a significantly better OS, compared with MRD positive ones. MRD positive patients showed an increased risk of relapse, irrespectively of having a low ELN risk at diagnosis. In patients undergoing BMT beyond CR1 pre-BMT MRD status confirms its prognostic relevance and may help in selecting stem cell source. Pre-BMT MRD evaluation may also help in choosing pre-emptive therapeutic strategies.

**Background:** Allogeneic stem cell transplantation (allo-SCT) represents an increasingly important curative treatment strategy in adults with acute myeloid leukemia (AML), consequent upon both the increased availability of unrelated donors and the advent of reduced intensity conditioning (RIC) regimens. Although optimal outcomes are achieved in patients transplanted using an unrelated donor matched at 10/10 HLA-A, B, C, DRB1, DQ alleles it remains the case that many undergo transplantation using a donor matched at only 9/10 HLA alleles.

**Aims:** There are limited data concerning the impact of specific HLA mismatches on patient outcome and we therefore interrogated the EBMT database in order to characterize the impact of mismatch on transplant outcome.

**Methods:** 937 patients with AML in CR1 or CR 2 underwent transplantation utilizing a RIC regimen using a 9/10 mismatched unrelated donor between 2001-2015. Of these 264 were transplanted using a donor mismatched at HLA-A, 127 were mismatched at HLA-B, 292 mismatched at HLA-C, 180 mismatched at HLA-DQ and 74 mismatched at HLA-DRB1. 85% of patients received in vivo T cell depletion.

**Results:** The 2 year leukemia free survival (LFS) for the whole cohort was 45% and the 2 year overall survival (OS) was 50%. The corresponding non-relapse mortality (NRM) was 26%. Relapse incidence was non-different among patients transplanted with 9/10 HLA-A, B, C, DRB1 and 9/10 HLA-A, B, C, DRB1, DQ mismatched donors (11% vs. 12%, respectively). Overall survival was comparable irrespective of the number of mismatched HLA-A, B, C, DRB1, DQ alleles.

**Summary/Conclusions:** To our knowledge this is the largest to date studying the impact of specific HLA mismatch on the outcome of adults undergoing a RIC allograft from an adult unrelated donor. Recipients of HLA-A, B, C, DRB1 and DQ mismatched allografts demonstrated equivalent outcomes.

**Patient:donor CMV disparity is an important adverse prognostic factor in HLA mismatched transplants. These data have the potential to inform donor selection in allo-mandatory adults with AML undergoing a RIC allograft who lack a 10/10 matched donor.**

**E1507**

**PRE-EMPTIVE THERAPY WITH IFN-α-2B FOR ACUTE LEUKAEMIA PATIENTS WITH HIGH RISK OF RELAPSING TENDENCY POST ALLO-HSCT**

X. Lin 1, A. Wang 2, F. Chen 1, X. Ma 1, X. Sun 3, X. Zhu 1, H. Qiu 3, J. Jin 3, S. Xue 1, D. Wu 1,2, X. Tang 1,2

1The First Affiliated Hospital of Soochow University; Jiangsu Institute of Hematology; Institute of Blood and Marrow Transplantation; Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

**Background:** Relapse remains the most frequent cause of treatment failure and mortality. According to the data of CIBMTR, relapse has become the leading cause of death following allo-HSCT. The high risk patients with more advanced disease, have a relapse rate of 40–80%. Therefore, prevention and treatment of relapse post allo-HSCT is the most likely approach to improve survival of these patients. It is well known that IFN-α had been widely used in the field of antitumor. Recently it is shown that IFN-α also play an important role in immune modulation to enhance the effect of GVL.

**Aims:** To determine the efficacy and safety of IFN-α-2b pre-emptive therapy for acute leukemia(AL) patients with relapsing tendencies after allogeneic hematopoietic stem cell transplantation (allo-HSCT).

**Methods:** Retrospectively analyzed 986 acute leukemia patients undergoing allo-HSCT from Jan, 2006 to Mar, 2014 in our hospital. After allo-HSCT, 986 AL patients were periodically monitored the minimal residual disease(MRD) including: bone marrow smear, leukemia-associated immunophenotype (LAIP), leukemia specific or related fusion genes, and donor chimerism through multi-parameter detection to evaluate disease status. Patients were given IFN-α -2b 3 million units / day by subcutaneous injection for preemptive treatment once a relapse tendency was detected, such as: increasing proportion of blast in bone marrow between 3–5%, or MRD>1.0x10^-3, or leukemia specific fusion gene transfrom negative to positive, or dynamic increasing copy number of WT1 more than 200 copies/10^4 abl, or decreasing of donor chimerism(≤ 90%). There were 98 patients who presented increasing tendency of MRD and were enrolled in this study. Among them, 31 patients received IFN-α-2b 3 million units / day by subcutaneous injection for preemptive treatment, and 67 patients received non-IFN-α-2b therapy such as: withdraw immunosuppressant, traditional DLI or DC-CIK immunotherapy.

**Results:** There were no significant differences in disease characteristics between two groups. For the 31 patients who received IFN-α-2b pre-emptive therapy(IFN group), the median time of IFN-αtreatment was 60 days (range: 5–720 days), Twenty five patients had responsed to the treatment without prophylactic treatment, and 6 patients were responded to the treatment (RR response rate 80.6%). 2 patients developed to hematological relapse again after temporary response; 3 patients had no response and eventually progressed to hematological relapse. Regarding 67 patients who received non-IFN-α-2b therapy (non-IFN group), the median time of IFN-αtreatment was 60 days (range: 5–720 days), Twenty five patients had responded to the treatment without progressing to hematological relapse (response rate 80.6%). 2 patients developed to hematological relapse again after temporary response; 3 patients had no response and eventually progressed to hematological relapse. Regarding 67 patients who received non-IFN-α-2b therapy (non-IFN group), the median time of IFN-αtreatment was 60 days (range: 5–720 days), Twenty five patients had responded to the treatment without progressing to hematological relapse (response rate 80.6%). 2 patients developed to hematological relapse again after temporary response; 3 patients had no response and eventually progressed to hematological relapse.

**Discussion:** Considering the benefit and safety of IFN-α-2b, it is recommended to implement the preemptive therapy for the patients at high risk of relapse.
free survival rate (LFS) of IFN group were 47.0%±13.9% and 38.7%±13.1% respectively. However, the 5-yr OS and LFS of non IFN group were 14.5%±10.7% and 12.5%±9.4% respectively. The difference were significantly (P=0.000, P=0.002 respectively). Patients with GVHD had significantly better response than patients without GVHD (88.9% vs 33.8%, P=0.043, P=0.05).

Summary/Conclusions: IFN-α-2b pre-emptive therapy can effectively prevent high-risk patients with relapsing tendencies for disease progression post allo-HSCT. Further large-scale investigation is warranted.

E1508
PREDICTING SURVIVAL AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION. THE GATMO SCORE
1Hematology, Transplant Unit, Hospital Universitario Austral, Derqui, 2Hematology, Transplant Unit, Hospital Italiano de Buenos Aires, 3Hematology, Transplant Unit, Instituto Alexandre Fleming, 4Hematology, Transplant Unit, Fundacion Favaloro, 5Hematology, Transplant Unit, Hospital Alemán, Buenos Aires, 6Hematology, Transplant Unit, Hospital Italiano de La Plata, La Plata, 7Hematology, Transplant Unit, Fundaleu, Buenos Aires, 8Hematology, Transplant Unit, Hospital Privado de Cordoba, Cordoba, 9Hematology, Transplant Unit, Sanatorio Andorena, 10Hematology, Transplant Unit, Hospital Britanico, Buenos Aires, 11Clinica Medica, Hospital Universitario Austral, Derqui, Argentina, 12CIBIMTR, Department of Medicine, Medical College of Wisconsin, Milwaukee, United States

Background: Several attempts to predict mortality after autologous stem cell transplantation (ASCT) have been made, like Hematopoietic Stem Cell Transplant Comorbidity Index (HCT-CI) score, originally described by Sorror for allogeneic HSCT. There is no score applicable to the clinical practice that integrates comorbidities with other patient characteristics.

Aims: To describe a comprehensive score that combines comorbidities with other factors and analyse the impact of this score in OS and NRM after ASCT in a cohort of patients transplanted in Argentina.

Methods: We retrospectively reviewed a cohort of 1453 medical records of adult patients who received an ASCT in our centres between October 2002 and August 2016, for Multiple Myeloma or Lymphoma. We compared NRM and Relapse with CI, OS with KM and long term MVA with fine-Gray or Cox regression. We included in the score all the factors that remained significant after MVA for NRM, and assigned a score of 1 if the Hazard ratio (HR) was around 2 (1.5-2.5) and 2 if it was around 3 (2.6-3.5).

Results: Mean age was 50.7 years (range 15-74); 57% were male, 52% had Multiple Myeloma, 29% Non Hodgkin Lymphoma and 19% Hodgkin Lymphoma. Forty-seven percent were in CR, 50% in PR and 3% SD/ PD; 14% received three or more chemotherapy lines before transplant (heavily pre-treated). Regarding comorbidities, 62% had low HCT-CI score (score 0), 26% intermediate risk (1-2) and 12% high risk (≥3). Median follow up was 1.1 years (range 5-85), with all patients having a neutrophil count <1x10^9/l. The reasons for ICU admission included sepsis (n=12), severe mucositis/colitis (n=11), renal failure (n=10), respiratory distress (n=9), liver failure (n=1). The median number of days spent in ICU was 9 (range 2-16). Five patients required single organ support (non-invasive ventilation, 2; inotrope support, 2; haemofiltration; 1) and 2 required only management of...

Summary/Conclusions: We found that GATMO score had a significant association with long term OS due to an increase in NRM. All end-point risks increased proportionally with the score. This observation should be confirmed in larger series.

E1509
A RETROSPECTIVE ANALYSIS OF PATIENT CHARACTERISTICS AND RISK FACTORS FOR ADMISSION TO THE INTENSIVE CARE UNIT (ICU) FOLLOWING HIGH DOSE CHEMOTHERAPY AND AUTOLOGOUS STEM CELL TRANSPLANTATION (HDC-ASCT)
L. Jeyaraj Nallathambi1,*, T. Freeman1, S. Williams1, V. Potter1, R. Benjamin1, K. Cuthill1, S. Devereux1, P. Patten1, D. Yallop1, S. kassam1
1Haematology, Kings college hospital, London, United Kingdom

Background: HDC-ASCT is a standard treatment modality for patients with myeloma and lymphoma. It carries a low, but significant risk of morbidity and mortality. Given that the upper age limit for patient selection continues to increase, it is important to have an objective way of assessing patient suitability for HDC-ASCT. Admission to the ICU is an ominous clinical event post HDC-ASCT and carries a high risk of mortality. There are currently no standard assessment tools to predict the risk of morbidity and mortality.

Aims: To review the incidence and cause of ICU admission in patients receiving HDC-ASCT and identify pre-transplant factors that may be predictive of transplant morbidity and mortality.

Table 1.

Methods: All patients receiving HDC-ASCT for myeloma and lymphoma at King’s College Hospital, London between July 2015 and December 2016 were included. Data cut off was 1st February 2017. Electronic patient records were used to collect data on baseline patient characteristics, comorbidities and performance status. The Charlson comorbidity index (CCI) and haematopoietic cell transplantation comorbidity index (HCTCI) were calculated. Univariate analysis of variables was performed using Graph Pad Prism version 5.03. A p value <0.05 was considered significant.

Results: 169 patients received HDC-ASCT. The median age was 58 years (23-74). Patient characteristics are shown in the table (See Image). Thirteen patients (7.6%) required ICU admission at a median of 14 days post cell infusion (range 5-85), with all patients having a neutrophil count <1x10^9/l. The reasons for ICU admission included sepsis (n=12), severe mucositis/colitis (n=11), renal failure (n=7), hypotension and arrhythmias (n=7), respiratory distress (n=4), liver failure (n=1). The median number of days spent in ICU was 9 (range 2-16). Five patients required single organ support (non-invasive ventilation, 2; inotrope support, 2; haemofiltration; 1) and 2 required only management of...
fluid balance. Six patients required multi-organ support (non invasive ventilation/ intubation, haemofiltration and inotropic support) and all died. Four patients died within 30 days of HDC-ASCt and had not engrafted neutrophils at the time of death. Two patients died late at day +120 and day +93 post HDC-ASCt. The latter had both successfully engrafted neutrophils but subsequently became neutropenic. Causes of death were neutropenic sepsis (3), cerebrovascular accident (1) and autologous sepsis (1) versus host disease (1). By univariate analysis none of the baseline parameters, comorbidities or conditioning regimens were predictive of ICU admission. The only parameter for which there was a trend for significance was baseline cardiac ejection fraction (EF) <50% (p=0.05). Three patients that required ICU has an EF <50% and 2 were on heart failure medications prior to HDC-ASCt. Two of these 3 patients died.

Summary/Conclusions: In this retrospective series, the risk for ICU admission and death following HDC-ASCt was 7.6% and 3.5% respectively. All patients requiring more than one organ support died. The only predictor of ICU admission but this would need confirmation in a larger series. Patient selection remains challenging with no definite tool to predict ICU admission or death.

E1510

AUTOLOGOUS STEM CELL TRANSPLANTATION WITH BENDA-EAM (BENDAMUSTINE, ETOPOSIDE, CYTARABINE, MELPHALAN) IN AGGRESSIVE NON HODGKIN AND HODGKIN’S LYMPHOMA

T. Noeslinder1, R. Simanek1,1*, M. Panny1, E. Koller1, M. Moestl1, F. Keil1
1Hematology and Oncology, Hanusch Krankenhaus, Vienna, Austria

Background: Autologous Stem Cell Transplantation (ASCT) is standard of care in relapsed diffuse large B-cell lymphoma (DLBCL) and other lymphoproliferative disorders (relapsed Hodgkin’s disease, 1st line mantle cell lymphoma (MCL) or T-cell lymphoma). BCNU, Etoposide, Ara-C, Melphalan (BEAM) is a standard conditioning regimen, but BCNU is known to be associated with interstitial pneumonia (range 2 to 20%) and an increased risk of death compared with other regimens.

Aims: Therefore a less toxic conditioning protocol might improve the results in lymphoma patients. Bendamustine showed promising results in B- and T-cell lymphoma and dose escalation is safe and feasible. Here we report promising results with bendamustine replacing BCNU in the BEAM regimen described as Benda-EAM, previously published in a phase two dose finding study (Visani, Blood 2011).

Methods: Forty-one patients with Hodgkin’s (HL)(n=9) or Non-Hodgkin (n=32) lymphoma were consecutively treated with Benda-EAM (bendamustine on two consecutive days at a dose of 200mg/m² per day). Eleven patients were diagnosed with DLBCL, ten patients with MCL, six patients with follicular lymphoma (FL), three patients with T-cell lymphoma (TCL) and two patients with greyzone lymphoma (GZL). Twenty-seven patients were male and fourteen female with a median age of 52 years (range 22-71) and 25% were above the age of sixty. The median lines of previous therapies were 2 (range 1-4).

Figure 1. All patients had chemosensitive disease and before transplantation, 34 patients (83%) were in complete (CR) and 7 (17%) in partial remission (PR). A median number of 4.20*10⁶CD34+ cells/kg (range: 1.60-13.30) were infused. All patients showed engraftment with a median time to achieve an absolute neutrophil count >1*10⁹/L of 10 days (range 8-13) and to platelets >20*10⁹/L of 12 days (range 7-110). The median time of fever was 5 days (range: 0-15). The median number of days on G-CSF was 7 (range 4-15) and in median 2 units of red blood cells and 5 units of platelets to be transfused. The median duration of hospitalization was 25 days. The most common grade 3 and 4 toxicities during the whole treatment period were diarrhea (n=10), mucositis (n=7), infections (n=9) and febrile neutropenia (n=6), followed by nausea (n=4) and cardiac toxicities (n=3). No severe pulmonary or renal toxicities were observed and no transplant related mortality occurred. After a median follow-up of 43 months 22 patients (56%) are still in CR, while 19 patients (44%) showed a relapse. The median time of 3 relapses were (range 2-29 months). Until today nine patients received an additional allogeneic transplantation. Eleven patients (27%) have died (3 DLBCL, 3 HL, 2 MCL, 1 GZL, 1 TCL and 1 FL), all due to lymphoma progression. Thus the 1- and 2-year PFS are 73.2% and 57.9% and the 1- and 2-year OVS 85.4% and 79.4%, respectively.

Summary/Conclusions: In conclusion Benda-EAM is feasible with a quite promising outcome. Currently an international randomized phase II trial comparing Benda-EAM with BEAM is recruiting. So far fifty-five of 110 planned patients are randomized and first results are expected for 2018.

E1511

THROMBOTIC MICROANGIOPATHY WITH CONCOMITANT AGVHD AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: RISK FACTORS, SEVERE OUTCOME AND TREATMENT EXPERIENCE

X. Liu1, Q. Wang1, Y. He1, X. Zhu1, J. Zhang1, L. Xu1, W. Han1, H. Chen1, Y. Chen1, F. Wang1, J. Wang1, Y. Zhang1, X. Mo1, Y. Chen1, Y. Wang1, Y. Chang1, Y. Lü1, X. Xu1, W. Zhang1
1Peking University People’s Hospital, Beijing, China

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT)- associated thrombotic microangiopathy (TA-TMA) is a significant complication after allo-HSCT. acute graft-versus-host disease (aGVHD) is one of the risk factors for the occurrence of TA-TMA, and some patients may develop both. Although there has been sufficient information available on aGVHD and TA-TMA, TMA with concomitant aGVHD after allo-HSCT remains not well understood.

Aims: To explore the possible risk factors for the occurrence and mortality of TMA with concomitant aGVHD and to investigate outcomes and treatments of this disorder after allo-HSCT.

Methods: This study was based on patients who underwent allo-HSCT at Peking University People’s Hospital from January 2008 to December 2016. We included patients who showed refractory diarrhea and underwent enteroscopy and biopsy. The diagnosis of TA-TMA and aGVHD were mainly based on the probable-TMA criteria (Byung-Sik Cho et al. Transplantation 2010;90:918-926) and endoscopic appearance and histologic findings (Thomas Hematopoietic Cell Transplantation, Fifth Edition, 2016), respectively.

The potential factors affecting TMA with concomitant aGVHD occurrence and markers associated with the death of these patients were identified using univariate and multivariate Cox analysis. The cumulative incidence of relapse, non-relapse mortality (NRM), overall survival (OS) and disease-free survival (DFS) were estimated using the Kaplan-Meier method and were compared by the log-rank test.

Results: Among all 3,992 allo-HSCT recipients, 276 patients showed refractory diarrhea and underwent enteroscopy; of these patients, 50 (1.33%) were diagnosed with TMA with concomitant aGVHD and were enrolled in the case group, and 150 (5.80%) were enrolled in the control group. The two groups matched well with regard to baseline characteristics. Based on the nested case-based control study, grade III-IV aGVHD (P=0.000), AKI (P=0.033) and hypertension (P=0.028) were significant independent risk factors associated with the occurrence of TMA with concomitant aGVHD. Considering the case group only, our data suggested that a haptoglobin level below normal (P=0.013), a maximum volume of diarrhea >2500 ml/d (P=0.015) and bloody diarrhea (P=0.049) were significant markers for death in both univariate and multivariate analysis. Among the case group and control group, the 9-year OS rates were 52% and 81% (P=0.001), respectively; the 9-year DFS rates were 50% and 65% (P=0.345), respectively; the 9-year cumulative incidence rates of NRM were 44% and 11% (P=0.001), and those of relapse were 6% and 19% (P=0.010), respectively. To further study the treatments of patients with TMA and aGVHD, we calculated the OS and found that plasma exchange (PE) use (PE=0, 62.5%; PE 0, 36.9%; P=0.156) had no significant influence on the patient outcome.

Summary/Conclusions: This study demonstrated that patients diagnosed with TMA with concomitant aGVHD after allo-HSCT had a significantly lower OS, higher NRM, and a lower incidence of relapse. The risk factors associated with the occurrence and mortality of TMA with concomitant aGVHD may help us assess the prognosis of patients. The findings also suggested that PE use may be ineffective to these patients.

E1512

SIGNIFICANCE OF MINIMAL RESIDUAL DISEASE MONITORING BY QUANTITATIVE RT-PCR IN CORE BINDING FACTOR AML ON TRANSPLANTATION OUTCOMES

B. Oran1,*, K. Patel2, D. Marin1, Q. Bashir1, S. Ahmed1, A. Alousi1, S. Ciurea1, J. Chen1, K. Rezvani1, U. Popat1, E. Shpall1, R. Champlin1
1Stem Cell Transplantation and Cellular Therapy, 2Hematopathology, The University of Texas MDACC, Houston, United States

Background: Despite the well-defined role of minimal residual disease (MRD) monitoring in core binding factor (CBF)-AML after intensive chemotherapy, there has been, to date, a paucity of data assessing the clinical utility of MRD monitoring before allogeneic stem cell transplantation (H SCT).

Aims: We investigated the prognostic impact of MRD monitoring by real-time quantitative polymerase chain reaction (RT-PCR) for RUNX1/RUNX1T1 and
CBFB-MYH11 transcript levels at HSCT on transplant outcomes in AML patients with CBF abnormalities.

Methods: We included 61 AML patients with CBF at diagnosis that underwent their first HSCT in complete remission (CR) from January 2007 through May 2016. Of 61, 19 (31%) had t(8;21) chromosomal translocation and 42 (69%) inv(16)(p13;q22). Disease status at HSCT was CR1 in 19 (31%) and CR2 in 42 (69%). Disease-free survival (DFS) was defined as absence of peripheral blood blasts, normal bone marrow with normal peripheral blood, and normal CAs. We performed on reverse-transcribed RNA for the CBFB-MYH11 fusion transcripts. Fusion (RUNX1/RUNX1T1 and CBFB-MYH11) and internal control (ABL1) transcript levels were detected simultaneously and quantitative results were expressed as the percent ratio of fusion to ABL1 transcript levels (fusion/ABL1 ratio).

Summary/Conclusions: This study showed that long-term transplant outcomes in SAA patients with CAs at diagnosis were excellent. Moreover, CAs at diagnosis did not affect the clinical outcome including clonal evolution to other hematologic malignancies after SCT in adult SAA.

E1514
PROGNOSTIC VALUE OF PET/CT PRIOR TO AUTOLOGOUS HCT IN RELAPSED / REFRACTORY LYMPHOMA
M. Damlaj1,2,*, G. Syed3, G. Gmati1, H. Salama1, K. Abuelgasim1, M. Al-Zahrani1, S. Ghazi3, A. Hejazi2, A. Alaskar1
1Oncology, King Abdulaziz Medical City, 2King Abdulaziz International Medical Research Center (KAMRC), 3King Abdulaziz Medical City, Riyadh, Saudi Arabia

Background: Positron Emission Tomography /Computed Tomography (PET/CT) is emerging as a powerful prognostic tool in the management of Hodgkin Lymphoma (HL) and Non-Hodgkin Lymphoma (NHL). A number of retrospective single center cohorts have reported that a positive PET/CT prior to autologous Hematopoietic Stem Cell Transplantation (HCT) is an adverse factor associated with higher relapse risk. However, important heterogeneity is noted in these studies due to differences in timing of PET/CT prior to HCT as well as different metabolic activity threshold (i.e. Deauville ≤2 vs ≥3). At our institution, we perform PET/CT within 4 weeks prior to HCT and after all intended salvage therapy is administered.

Aims: We sought to further investigate the prognostic value of PET/CT in relapsed / refractory lymphoma patients prior to HCT.

Methods: After due IRB approval, patients who received autologous HCT at our institution for relapsed / refractory lymphoma between 2010 - 2016 were included. All variables were retrospectively extracted. PET/CT reports were reviewed and metabolic activity was assigned per Deauville criteria. Patients with primary CNS lymphoma were excluded. Refractory disease indicates disease progression prior to completing planned first line therapy. Categorical and continuous variables were compared using Chi-squared and Wilcoxon tests, respectively. Time to end point analysis was computed using the method of Kaplan and Meier with log rank tests. Competing events were computed using Grey’s method considering non relapse mortality as a competing event for relapse. Analysis was computed using JMP software, version 11.

Results: A total of 53 patients underwent HCT for relapsed / refractory lymphoma with 80% of the cohort having HL. Median follow up of the entire cohort was 26.8 months (0.6-70.5). Cumulative incidence of relapse (CIR), progression free survival (PFS) and overall survival (OS) at 2 years was 37.9%, 56.1% and 74.8%, respectively. A PET/CT status pre-HCT. A total of 47 patients had pre-HCT PET/CT and were evaluable for further analysis. Median time from PET to HCT was 17 days (6-59). There were no significant differences between the cohorts based on age at HCT, gender, underlying diagnosis, relapsed/refractory status, time to relapse, number of salvage regimens, number of salvage cycles, use of immunotherapy as part of salvage and post HCT immunotherapy use as maintenance. Considering Deauville ≤2 as complete metabolic response (CMR), 2-year CIR was 16.7% vs 60.5% for PET negative vs PET positive patients (p=0.0021). 2-year PFS was significantly higher in PET negative vs PET positive patients at 72% vs 39.5%, respectively (p=0.035). 2-year OS was similar irrespective of PET status (p=0.49). Considering Deauville ≤2 as CMR, there was only a trend towards decreased CIR for metabolically negative scans (p=0.096). Significance of these results remained unchanged after excluding NHL cases. B. Relapse post HCT: Median time to Hodgkin post HCT for patients...
was 109 days (55-395) vs 271 days (55-440) for PET positive vs PET negative patients, respectively. Mortality post relapse was 57% with the remaining patients achieving long term disease control with immunotherapy alone (57%), allogeneic HCT (29%) and combination chemotherapy (14%). Median follow up of patients with long term disease control was 1093 days (177-1271). Causes of death post HCT relapse was progression of disease in all cases.

Summary/Conclusions: Despite inherent limitations of this analysis, we present a number of important observations: 1. Deauville score ≤3 is an appropriate cutoff for metabolic activity pre-HCT and is associated with significantly decreased relapse and improved PFS. 2. PET positive status will better identify patients who may benefit from maintenance strategies post HCT. 3. Time to relapse in PET positive patients is significantly shorter highlighting the need for early initiation of pre-emptive maintenance therapy. 4. Long term disease control is possible in a high proportion of patients despite relapse post HCT. These important observations require further study.

Figure 1.

Summary/Conclusions: UCBT showed good OS with the low incidence of NRM even in patients with high HCT-CI scores. These results indicate that a single unit umbilical cord blood might be a promising stem cell source for patients with multiple comorbidities. Further studies are needed in order to validate these results.

E1517

LOW DOSE POSTTRANSPLANTATION CYCLOPHOSPHAMIDE CAN ENHANCE THE PROTECTIVE EFFECT OF ATG /G-CSF ON GVHD: RESULTS OF A PHASE II PROSPECTIVE TRIAL

Y. Wang1,*, Y.-J. chang1, X.-J. Huang1

1Peking university people’s hospital, beijing, China

Background: Anti-thymocyte globulin (ATG)/granulocyte colony-stimulating factor (G-CSF)-represented regimen produces essentially universal engraftment with limited relapse and favorable survival, albeit with relatively high rates of graft-versus-host disease (GVHD), especially after HCT from maternal donor or collateral relatives. While use of high-dose, post-transplant cyclophosphamide (PT/Cy) results in low rates of GVHD and favorable immune reconstitution, although with higher rates of relapse and somewhat high rates of graft failure. Thus, novel strategies are needed to refine each approach: under Beijing protocol including ATG and G-CSF, reducing GVHD without abrogating GVL effect is a major priority.

Aims: In order to benefit patients at high risk of developing GVHD without abrogating engraftment and GVL effects, we sought to develop a novel procedure in TCR haplo-HCT with intensified conditioning containing ATG and G-CSF followed by lower-dose of PT/Cy. In addition, the current study attempt to establish a murine model and focus on Treg cells to clarify the immunological mechanisms for GVHD prevention by the new strategy.

Methods: We performed a prospective pilot study of HLA haploidentical cell transplantive intervention (HCT) from maternal or collateral donors with intensified conditioning including G-CSF and ATG, followed by two lower doses of PT/Cy (14.5mg/kgx2 doses; designated as Group A). Outcomes were compared with those of 160 controls from matched-pair analysis who undergo haploidentical HCT from other donors than mother or collateral relatives at the same time period (Group B) as well as with those of 46 historical controls undergoing HCT from mother or collateral relatives at earlier time period (Group C). In addition, the current study attempt to establish a murine model and focus on Treg cells to clarify the immunological mechanisms for GVHD prevention by
the new strategy. Trial registration: The study is registered at www.clinicaltrial.gov as NCT02412423.

Results: We found that low dose PT/Cy combined with ATG could alleviate GVHD in mice and could increase the number of Treg cells while have no effect on CD4+ or CD8+ T cells. A total of 40 patients with myelodysplastic syndrome (MDS) and leukemia undergoing haploidentical HCT from maternal or collateral donors were enrolled in the study. The cumulative, 100-day incidence of acute GVHD, grades II-IV, in Group A (17%; 95% CI, 5%>29%) was significantly lower than both that in Group B (33%; CI, 25%>41%; P=0.04) and that in Group C (56%; CI, 42%>70%; P<0.001). The 1-year probabilities of NRM (5%; CI, 0%-12%), OS (84%; CI, 88%>100%), and LFS (83%; CI, 70%>96%) in Group A were similar to that in Group B, but was significantly lower than that of Group C (28%; CI, 15%>41%; P=0.006; 65%; CI, 51%>79%; P=0.02; and 65%, CI, 51%>79%; P=0.04; respectively).

Summary/Conclusions: Low dose PT/Cy can enhance the protective effect of ATG/G-CSF on GVHD. Conditioning with ATG/G-CSF and low-dose PT/Cy might be a feasible option for patients undergoing HLA haploidentical, T-cell replete HCT, in particular for those with high GVHD risk.

E1518
HEPATITIS B REACTIVATION IN HEMATOPOIETIC STEM CELL TRANSPLANTATION: 22 YEARS EXPERIENCE OF A SINGLE CENTRE
N. Obara1, Y. Hasegawa1, S. Chiba1, Z. Baslar2, T. Soysal2,*
1Internal Medicine, 2Hematology, Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Reactivation of inactive viruses is an important complication of haematopoietic stem cell transplantation (HSCT). Suggestion of strategies to combat this problem will probably decrease transplant related mortality and morbidity.

Aims: Aims of this study is to evaluate the clinical progress and risk factors for reactivation in HSCT patients who were infected with hepatitis B virus (HBV) with the prospect of developing recommendations for a better clinical care.

Methods: Patient files and electronic records of 561 patients who received HSCT between 1994 and 2015 at the Bone Marrow Transplantation Center of Cerrahpasa Medical Faculty were retrospectively evaluated. A total of 66 patients with HBsAg (n=15; 12 autologous, 3 allogeneic) and anti HBC IgG positivity (n=51; 29 autologous, 22 allogeneic) were included in the study. Cases were grouped according to transplant types (autologous or allogeneic) and anti-HBc antibody positivity (anti-HBs positive or negative) to calculate relative risks and cumulative incidences of HBV reactivation.

Results: Four (%26) of the 15 patients with HBsAg positivity showed HBV reactivation in an average of 13 months following HSCT. While cumulative incidence of reactivation was 7% at day 60, it went up to 16% and 44% at days 270 and 730 following HSCT, respectively. In Anti HBC IgG positive group, allogeneic HSCT (n=22) was a higher risk factor for reactivation (31.8%) than autologous HSCT (n=29, 6.8%). Relative risk of reactivation in the allo-transplanted patients who were anti-Hbc IgG positive and anti-HBs negative was 6.8 when compared to anti-HBc IgG positive patients (n=51, 55% vs 13, 10% (95% CI, 1.3-46.5)). Cumulative incidence of reactivation in anti-Hbc IgG positive anti-HBs negative patients (isolated anti Hbc IgG positivity) was 11% at day 10 day, 33% at day 133, 50% at day 400 and going up as high as 75% at day 940.

Summary/Conclusions: The results of our study indicate that HBsAg positive patients undergoing autologous or allogeneic HSCT should receive prophylaxis at least one year posttransplant. Anti-Hbc IgG positive patients carry the risk of reverse seroconversion, with receivers of allogeneic HSCT having higher risk than those of autologous HSCT. Patients who are anti-Hbc IgG positive and anti-HBs negative should receive prophylaxis for HBV if allo- geneic HSCT is to be performed. However, close follow-up seems to be acceptable rather than a prophylactic treatment for anti-Hbc IgG positive patients undergoing autologous HSCT.

E1519
ALLOGENIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION FROM HAPLOIDENTICAL DONOR WITH POST-TRANSPLANT CYCLOPHOSPHAMIDE WAS RELATED TO LESS INPATIENT COST COMPARED TO CORD BLOOD TRANSPLANTATION
N. Kurt1,*, Y. Yokoyama1, T. Kato1, H. Nishikii1, M. Sakata-Yanagimoto1, N. Obara1, Y. Hasegawa1, S. Chiba1
1Department of Hematology, University of Tsukuba, Tsukuba, Japan

Background: The number of allogeneic HSCT from alternative donors such as cord blood (CB) and haploidentical donor (haplo) is increasing especially after introduction of post-transplant cyclophosphamide (PT/Cy) as GVHD prophylaxis for haplo. Although comparison of the survival benefit between CB and haplo with PT/Cy has been made by several groups, there is little information about the medical cost and the hospitalization period of HSCT from alternative donors.

Aims: We evaluated the medical costs and the hospitalization period related to allogeneic HSCT in order to clarify the impact of donor sources and other clinical factors on these outcomes.

Methods: Patients (n=134) with hematological malignancies who underwent allogeneic HSCT between January 2013 and December 2016 in University of Tsukuba Hospital were included. The days of the initial hospitalization (from the beginning of the conditioning regimens to discharge), the whole initial inpatient costs and the costs of transfusion during the initial hospitalization were retrospectively analyzed.

Results: The median age of the patients was 46 (range, 16-67) years. The diagnoses were AML (n=66), ALL (n=31), MDS (n=17), lymphoma (n=11), and others (n=9). Twenty-seven patients were transplanted from MRD, 37 from MUD, 22 from haplo with PT/Cy, and 48 with single-unit CB. The median initial inpatient cost was €49179 (IQR, 37030-66923), the median transfusion cost was €11500 (IQR, 9500-15250), and the median length of initial hospitalization was 55 (IQR, 44-75) days. CB showed significantly higher inpatient cost (median, €64852, P=0.008 vs CB), MUD (median, €36998, P<0.001 vs CB), and median (€39262, P<0.001 vs CB) (Figure). Also, the transfusion cost was highest in CB (median, €22750) compared with haplo (median, €12866, P<0.001 vs CB), MUD (median, €12699, P<0.001 vs CB), and MUD (median, €13118, P<0.001 vs CB). The median hospitalization days were 67 in CB, 61 in haplo (P=1.0 vs CB), 46 in MUD (P=0.001 vs CB), and 49 in MUD (P=0.01 vs CB). Among the clinical variables such as diagnoses (acute leukemia or others), refined disease-risk index (low/intermediate/high), donor source (MUD, MUD, haplo, or CB), age, first or second HSCT, intensity of conditioning (RIC or MAC), with or without comorbidity, graft failure, GVHD III-IV, and admission to the intensive care unit (ICU), multiple regression models revealed CB (P<0.001), haplo (P<0.003), graft failure (P<0.001), admission to ICU (P<0.001) and MAC (P<0.05) were the factors that increased the initial inpatient cost. The transfusion cost increased by CB (P<0.001), graft failure (P<0.001), admission to ICU (P<0.001), and MAC (P<0.001). CB (P<0.001), haplo (P=0.003), and GVHD-III IV (P=0.01) were selected as factors associated with longer hospitalization period.

Figure 1.

Summary/Conclusions: Although HSCT from alternative donors was related to the higher initial inpatient cost and longer hospitalization, the impact on those outcomes was more significant in CB than haplo with PT/Cy. The higher inpatient cost of CB was partly attributed to delayed hematological recovery which lead to its larger demand for transfusion. The strategy to improve hematological recovery will be needed to reduce the medical cost especially in CB. The larger scale investigation is necessary for better cost-effectiveness in HSCT.

THE ROLE OF PPARγ EXPRESSION IN PATIENTS WITH AGVHD FOLLOWING ALLOGENEIC HSCT
X. Wu1,*, J. Zhang1, S. Ma1, Y. Ji1, J. Xu1, Y. Xie1, Y. Han1, X. Tang1, C. Fu1, D. Wu1
1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: The acute graft versus host disease (aGVHD) is the main com-
Haploidentical transplantation with myeloablative conditioning regimen could serve as an optional salvage therapy for younger patients with refractory or relapsed non-Hodgkin lymphoma

Aims: To evaluate clinical outcomes of haplo-HSCT in patients with R/R aggressive NHL.

Methods: 23 patients with R/R aggressive NHL who had undergone haplo-HSCT in our center between January 2004 and December 2015 were included, and data were retrospectively analyzed. 25 patients with R/R aggressive NHL who received HLA-matched HSCT during the same period constituted the control group for this analysis. All patients received myeloablative conditioning (MAC) regimen, which was administrated to lower than mild aGVHD (grade 1 to 2) patients. Expression of IFNγ and T-bet increased in aGVHD patients and were negatively correlated with PPARγ mRNA expression (P<0.05). The expression of MLR shows that PPARγ agonist rosiglitazone above concentration of 25µM had dose-dependent inhibition effect to proliferation of lymphocytes.

Summary/Conclusions: Low expression of PPARγ is associated with aGVHD occurrence and degree. PPARγ agonist can inhibit the proliferation of lymphocytes, which may be a new way to treat aGVHD.

E1521

OUTCOMES OF ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH ACUTE MYELOID LEUKEMIA HARBORING INV(3)/t(3;3) WITH OR WITHOUT CHROMOSOMAL ABNORMALITIES

Aims: To evaluate outcomes of allo-HSCT in patients with AML.

Methods: Clinical data were collected from the registry database of the Japan Society for Hematopoietic Cell Transplantation. We selected patients with AML harboring inv(3)(i3.3), who were aged ≥16 years and who underwent their first transplantation between January 2000 and December 2014. We analyzed outcomes as overall survival (OS), relapse, and relapse mortality (NRM) for the patients underwent allo-HSCT. OS was estimated using the Kaplan-Meier method and compared using the log-rank test. Relapse and NRM were considered as competing risk and were compared using the Gray’s test. In a multivariate analysis, the Cox proportional hazard model was used to analyze OS. The following variables were considered: age, sex, disease status at allo-HSCT, time from diagnosis to transplant, inv(3)/(q21;q26.2)/t(3;3)(q21;26.2) was identified in 66 patients. The median age of patients who underwent allo-HSCT was 33 years (range, 16-58). Twenty-three patients had received transplant from haploidentical donors, while twenty-five patients received transplant from HLA-matched donors, of which included 13 ISD and 12 MUD.

Results: Of 15025 patients with AML who were aged ≥16 years and who underwent their first transplantation, inv(3)(i3.3) was identified in 66 patients. The median age of patients who underwent allo-HSCT was 33 years (range, 16-58). Twenty-three patients had received transplant from haploidentical donors, while twenty-five patients received transplant from HLA-matched donors, of which included 13 ISD and 12 MUD. Chemoresistant disease at transplantation was more common in the haplo-HSCT group as compared to that in the HLA-matched HSCT cohort (P=0.005). No significant between-group differences were observed with respect to distribution of age and sex, histological subtype, bone marrow involvement, aapro score, chemotherapy regimen and relapse after ASCT.

Type of 3q abnormality.

Results: 65 patients under allo-HSCT and 10 healthy controls were enrolled in study. Peripheral blood (PB) of patients was collected at 15 days, 30 days, 60 days, and 90 days after allo-HSCT. The mRNA expression of PPARγ, IFNγ, T-bet was detected by the real-time PCR. Furthermore, we conducted mixed lymphocyte reaction (MLR) to detect the proliferation of active lymphocytes under different concentration of PPARγ agonist.

Results: Among 65 patients after HSCT, aGVHD occurred in 45 patients. Expression of PPARγ mRNA in healthy controls were significant lower than that in patients after allo-HSCT within 90 days (P<0.05). The expression of PPARγ mRNA hold steady in non-GVHD patients within 90 days after allo-HSCT, and was significantly lower in GVHD group than in non-GVHD group (P<0.05). PPARγ expression in severe aGVHD (grade 3 to 4) was lower than mild aGVHD (grade 1 to 2) patients (P=0.05). The expression of IFNγ and T-bet increased in aGVHD patients and were negatively correlated with PPARγ mRNA expression (P<0.05). The expression of MLR shows that PPARγ agonist rosiglitazone above concentration of 25µM had dose-dependent inhibition effect to proliferation of lymphocytes.

Summary/Conclusions: Low expression of PPARγ is associated with aGVHD occurrence and degree. PPARγ agonist can inhibit the proliferation of lymphocytes, which may be a new way to treat aGVHD.

E1522
Summary/Conclusions: These findings revealed that AML with inv(3)/t(3;3) had dismal outcome even after allo-HSCT. Multivariate analysis suggested that a myeloablative conditioning regimen might improve the transplantation outcome.

E1523

PHARMACOKINETICS (PK) OF PROPYLENE GLYCOL-FREE MELPHALAN HCL (PG-FREE MEL) IN MULTIPLE MYELOMA (MM) PATIENTS UNDERGOING AUTOLOGOUS TRANSPLANTATION (AHCT)

P. Han1, B. Dhakal1, A. D’Souza1, R. Thompson1, M. Hamadani1, M. Pasquini1, S. Chhabra1

1Medical College of Wisconsin, Milwaukee, United States

Background: Melphalan (MEL) is the most commonly used conditioning agent in AHCT for MM and exhibits a dose response relationship (Nath CE Br J Clin Pharmacol. 2010 May; 69(5):484). PG-free MEL (Evomela™) has longer stability in solution, results in a slightly higher systemic exposure compared with standard MEL and eliminates propylene glycol administration during high dose melphalan-based conditioning. This agent was shown to be bioequivalent to conventional melphalan leading to successful myeloablation and engraftment in MM pts receiving AHCT with no transplant related mortality or unexpected toxicity leading to its FDA approval (Hari P Biol Blood Marrow Transplant. 2015 Dec; 21(12):2100). Published studies thus far have used PG-free MEL in 2 consecutive daily doses of 100mg/m²/day while a single daily conditioning dose of 200mg/m² (MEL200) is most commonly used in clinical practice.

Aims: Determine the safety and PK variability of high dose PG-free MEL 200mg/m² in patients undergoing AHCT for MM

Methods: Open-label phase II study in which 10 serial blood samples at specific time points for the PK evaluation of melphalan were collected immediately prior to and after receiving single 200mg/m² dose of PG-free MEL on day -2 as a part of 21 day conditioning protocol. The primary objective was a descriptive analysis of melphalan PK while secondary objective included the response rates, engraftment and the toxicity and safety profile of PG-free MEL conditioning.

Results: As of Feb 2017, a total of 24 pts. were enrolled (63% male) with a median age of 67 years (range 46-72), including 23 (96%) who received upfront AHCT and 1 (4%) after relapse (Figure 1). High-risk cytogenetics was present in 6 (25%) pts 25% were in ISS stage 3. Disease status at transplant was complete remission (CR) and PR in 50% and PR in 8 (33%). AHCT was performed entirely as outpatient in 25%.

PK data are available for the first 12 pts at this time. Wide variability in MEL exposure was noted with maximum plasma concentration (Cmax) of 10.100 ng/ml, median Cmax 7750ng/ml (range, 5220-10,100) and median area under the concentration- time curve (AUC) of 561500 ng.min/ml (range, 771000-254000). Mean AUC was 549000 ±155000). No grade 4 non-hematologic toxicities or gastrointestinal toxicities were observed including in patients with Cmax >10,000 (upper quartile of distribution) or AUC >625000. All patients are alive and post-transplant responses in those with at least 100 days of follow up indicate sCR/CR in 60% and VGPR in 30%.

![Figure 1](image_url)

Summary/Conclusions: PG-Free MEL can be safely administered as a single 200mg/m² in conditioning with a favorable toxicity profile. Considerable variability in the PK parameters of high dose MEL indicate that PK directed MEL dosing could be used to optimize MEL exposure. The safety profile of PG-free MEL indicates no increase in mucosal toxicity or adverse events seen even in subjects with highest levels of MEL exposure. For patients in the lowest quartile of AUC, increased PG-free MEL doses up to 20 to 40% over 200mg/m² may be safely attempted without additional toxicity if PK directed dosing is used to ensure adequate MEL exposure and utilize the dose response effect of MEL.
removing, both CD4+ and CD8+ subpopulations remained low and these patients were prone to develop relapse. These findings underscore a putative function of CD8+ T-cells in eliminating post-transplant residual disease and maintaining the patients disease free.

E1525

COMPARISON OF TECAM AND BEAM HIGH-DOSE CHEMOTHERAPY FOLLOWED BY AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPANTATION IN LYMPHOMA: EFFICACY AND TOXICITY

F. Sahin1,*, P. Patir1, N. Akad Soyer1, R. Durusoy2, G. Saydam1, M. Tobu1, M. Tombuloglu1, F. Vural1
1Hematology, Ege University Hospital Internal Medicine, 2Public Health, Ege University, Bornova, Turkey

Background: High-dose chemotherapy conditioning regimens followed by autologous hematopoietic stem cell transplantation (AH SCT) generally provide good results in relapsed and refractory lymphomas.

Aims: Limited data are available to guide the choice of conditioning regimen before AH SCT for patients with lymphoma. We evaluated the efficacy and safety of TECAM and BEAM regimens as conditioning with autologous stem cell support in patients with relapsed/refractory lymphomas.

Methods: From July 2011 to October 2016, 64 pathologically confirmed lymphoma patients underwent AH SCT with BEAM (n=32) or TECAM (n=32) regimens in Hematology Division of Ege University Faculty of Medicine. Patients considered as high risk at diagnosis or with relapsed or refractory diseases were eligible for AH SCT. The two groups were well matched in terms of age, gender, histology. Patients were conditioned with TECAM (thiotepa [40mg/m2 x four days], etoposide [200mg/m2 x four days], cyclophosphamide [60mg/kg x one day], cytarabine [200mg/m2 x four days] and melphalan [80mg/m2 x two days]) or BEAM (carmustine [300mg/m2 x one day], etoposide [200mg/m2 x four days], cytarabine [200mg/m2 x four days] and melphalan [140mg/m2 x one day]) regimens.

Results: The estimated 22-months overall survival for the TECAM and BEAM groups were 53% and 63%, respectively (p=0.41). The estimated 22-months progression-free survival in the BEAM group (59%) was relatively lower than the TECAM (74%) group, but the differences were not significant (p=0.98). Cardioxicities were relatively more common in the BEAM group. No differences were observed in the time to hematopoietic recovery, the duration of hospitalization, hematological and nonhematological toxicities.

Summary/Conclusions: We conducted a single-center retrospective on lymphoma patients undergoing AH SCT, comparing efficacy and toxicity of TECAM and BEAM conditioning regimens. These two regimens are all optional high-dose chemotherapy with favorable efficacy and acceptable toxicity.

E1526

GENETIC MARKERS OF THE NEUTROPIA DURATION AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA

E. Nazarova1,*, M. Horobryh2, V. Shardakov1, N. Zorina2, N. Minaeva3, I. Paramonov1
1Laboratory of Immunology of Leukemia, 2Department of chemotherapy and bone marrow transplantation, 3Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

Background: The successes achieved in the treatment of multiple myeloma (MM) in the past few years, associated with the use of high-dose chemotherapy, and with the use of new drugs. Using high regimes with subsequent autologous hematopoietic stem cells (auto-HSCT) has increased both overall and progression-free survival of patients with MM, as well as improved quality of life. In most cases, patients in the early post-transplant period have severe toxic and infectious complications, which require resource-intensive supportive care. The duration of the period of hematopoiesis hypoplasia is dependent on many factors, and an average of 14-16 days. In turn, the attachment of infectious complications in some cases adversely affect the duration of neutropenia.

Aims: To evaluate the possible association of the immune response genes mutation status to the duration of neutropenia after autologous transplantation of peripheral blood stem cells in patients with multiple myeloma.

Methods: The study included 19 patients with multiple myeloma at the age of 32 to 67 years (median - 52 years) who underwent autologous transplantation of hematopoietic stem cells after conditioning regimen with high-dose melphalan. Among surveyed: 8 men and 11 women. In accordance with staging for Durie-Salmon (DSS) system in patients following stages of MM were installed: stage 1A in one patient (5.2%), stage 2A - in 12 patients (63.2%), stage 2B - in two patients (10.5%) and stage 3A - in four patients (21.1%). In the pre-transplantation period, partial remission of the disease was achieved in seven patients (36.8%), very good partial remission - in eight patients (42.1%) and complete response in four patients (21.1%). Genotyping of polymorphisms of the innate immune response genes TLR2 (rs5743708), TLR3 (rs3775291), TLR6 (rs5743810), TLR9 (rs5743836), IL18 (rs2856841), IL2 (rs2069762), IL4 (rs2243250), IL6 (rs1800795), IL10 (rs1800871), IL17A (rs2275913), CD14 (rs34424920), TNFa (rs1800629), FCGR2A (rs1801274) was performed by polymerase chain reaction with allele-specific primers (Life, Russia) at the time of diagnosis.

Results: Depending on the duration of the neutropenia period all examined are divided into two groups. The first group included 10 patients with MM who have early observed recovery (within the first 13 days, 11-13 days), the number of leukocytes ≥1000 cells per ml after auto-HSCT. The second group consisted of nine patients with agranulocytosis held more than two weeks (≥14 days, 14-19 days). When comparing the genotyping data found that a longer period of neutropenia after autologous HSCT was significantly associated with the presence in genotype of MM patients homozygous wild-type allele A gene IL17A at position -197 (OR 13.15, 95%CI: 0.60-288.34, p=0.03) and with a predominance of heterozygous mutant allele C of the gene IL1B at position -31 (OR 8.17, 95%CI: 1.03-67.94, p<0.05).

Summary/Conclusions: Our findings point to immune response genes involved in the rate of recovery of hematopoiesis in MM patients after autologous HSCT. Identification of the wild-type allele in intron gene IL17A (G-197A) and mutant allele in intron gene IL1B (T-31C) will predict the risk of prolonging the period of agranulocytosis and, consequently, the risk of post-transplant complications, and develop a personalized strategy of managing them.

E1527

SUCCESSFUL TREATMENT WITH GRANULOCYTE TRANSFUSION AND EARLY NEUTROPHIL ENGRANAGEMENT IN ALLOGENIC TRANSPLANT PATIENTS WITH FEBRILE NEUTROPENIA

A. Ünal1,*, L. Kaynar1, N. Kem1, A. Birekül1, E.E. Turak1, S. Sivgin1, B. Eser1, M. Çetin1
1Erciyes University Medical School, Kayseri, Kayseri, Turkey

Background: Febrile Neutropenia is very severe and urgent early complication after bone marrow transplantation before engraftment. Infection delays engraftments. In this study we retrospectively evaluated the effect and outcome of Granulocyte transfusion on febrile neutropenia and neutrophil engraftment in patients receiving allogeneic transplantation.

Aims: Between 2015-2016, five patients receiving allogeneic bone marrow transplantation (BMT) were treated with granulocyte transfusion at the time of febrile neutropenia before engraftment. The reasons for the use of the granulocyte transfusion were prolonged febrile neutropenia episode.

Methods: Five AML patients underwent allogeneic transplantation. Three of them transplanted from match sibling donors, one from unrelated donor, and one from (7/10) mismatch mother (haploidentic transplant). They had febrile neutropenia before engraftment. They were given antibiostics. Before granulocyte transfusion, on the 13th-18th days of transplantation, their neutrophil counts were 0.03-0.08x10^3/dl.

Results: We started Granulocyte transfusion for three days. Granulocyte was collected from unrelated and same blood groups donors. Mean infused gran-
ulocyte counts were 3.6x10^9/1 (1.3-4.6x10^9/1) at day. Twenty-four hours after granulocyte transfusion, mean neutrophil counts were 0.6x10^3/dl (0.4-0.9x10^3/dl). Neutrophil counts were 2.6 x 10^3/dl (1.7-2.6 x 10^3/dl), after 48 hour. After 72 hours, neutrophil counts were 3.4x10^3/dl (2.1-4.5x10^3/dl). After 4th days of granulocyte transfusion, neutrophil counts were normal levels (>0.5x10^3/dl).

Summary/Conclusions: Granulocyte transfusions during the febrile neutropeinia, helped to better overcome febrile neutropeinia periods in allotransplant patients before engraftment. In addition, granulocytes transfusion also may help early neutrophil engraftments.

DEFIBROTIDE FOR THE PREVENTION AND TREATMENT OF HEPATIC VENO-OCCULSIVE DISEASE AFTER HEMATOPOietIC STEM CELL TRANSPLANTATION; A SINGLE CENTER EXPERIENCE
B. Antmen1,2, I. Sasmaz2,2, B. Karagun1, M. Serbest1
1Pediatric Bone Marrow Transplantation Unit, Department of Pediatric Haematology, Adana Acibadem Hospital, 2Pediatric Haematology, Cukurova University, Adana, Turkey

Background: Hepatic veno-occlusive disease (VOD) is a common and serious complication of hematopoietic stem cell transplantation (HSCT) in children. We aimed to assess prospectively the use of prophylactic defibrotide in pediatric patients undergoing HSCT.

Aims: We aimed to assess prospectively the use of prophylactic defibrotide in pediatric patients undergoing HSCT.

Methods: In this study, 113 patients who underwent HSCT were given defibrotide prophylaxis as 25mg/kg per day in four divided intravenous infusions over 24h, starting on the same day as the pretransplantation conditioning regimen. The mean duration of use of defibrotide is 25 days as a prophylaxis.

Results: In this study, 113 patients were recruited, 66 male patients and 47 female patients, with the average of 9.1 years, range 1-20; 8% infants, 55% children and 37% adolescent. There were 50 patients with thalassemia major, 41 patients with leukemia (11%), one patient with aplastic anemia, one patient with Diamond-Blackfan anemia, two patients with congenital dyserythropoietic anemia, one patient with osteopetrosis, four patients with familial hemophagocytic lymphohistiocytosis, two patients with severe immune deficiency and one patient with Kostman syndrome. All transplants were allogeneic. No serious side effects were seen. In eight patients developed clinical VOD (Seattle criteria). In these patients, defibrotide dose was increased to a treatment dose of 40-60mg/kg per day. One infant patient with Kostman syndrome died due to hepatic and pulmonary veno-occlusive disease. After 36 months of follow up, 7 patients who developed VOD are being well and no patient have transplant related complications.

Summary/Conclusions: Hepatic veno-occlusive disease, which is caused by hepatitis and sinusoidal vessel endothelium damage, can occur early after HSCT, and in its severe form, may lead to liver failure, hepatorenal syndrome, portal hypertension, and eventually death from multorgan failure. In this prospective study, we demonstrated that the use of defibrotide is safe and effective in preventing and treating VOD in pediatric patients at high risk.

E1529
ACUTE RENAL IMPAIRMENT IN ALLOGENEIC STEM CELL TRANSPLANT RECIPIENTS, A PREDICTOR OF MORTALITY
A.J. Mahdi1, D. Foxwell2, G. Scoot1, D. Davies1, K. Wilson1, W. Ingram1
1Department of Haematology, 2Department of Nephrology, University Hospital of Wales, Cardiff, United Kingdom

Background: Allogeneic stem cell transplant (ASCT) remains the only curative option in many malignant and non-malignant conditions. There remains however, no significant morbidity and mortality. One risk, acute kidney injury (AKI), can result from drug toxicity and/or haemodynamic instability from sepsis and/or graft vs host disease (GVHD). Existing reports on the impact of AKI have concentrated on patients undergoing mainly myeloablative (MA) conditioning alone, whilst those undergoing reduced intensity conditioning (RIC) transplants have reported outcomes from limited patient numbers.

Aims: To investigate the incidence, causes and consequences of AKI in patients undergoing ASCT, including survival.

Methods: The prospectively maintained database of the South Wales Blood and Marrow Transplant programme which serves 77% of the Welsh population, was interrogated to identify patients undergoing ASCT from January 2010 to January 2015. Patients received ciclosporin as GVHD prophylaxis to 100 days post ASCT and weaned thereafter in the absence of GVHD. Serum creatinine and derived estimated glomerular filtration rate (eGFR) acted as the main assessment of renal function. The Acute Kidney Injury Network classification was used to define AKI. Causes of AKI were assigned after independent review of clinical notes and relevant laboratory data. Patients undergoing second ASCT were excluded. Statistical analysis was carried out using SPSS, version 23 including COX regression and Kaplan-Meier survival analysis.

Results: A total of 229 patients were identified (MA-n=35, 15%; RIC-n=194, 85%). Acute myeloid leukaemia was the most common indication (n=103, 45%). Mean age at ASCT was 51 years (18-72 years). Median follow up after ASCT was 2.19 years (range 9 days-6.6 years). Overall survival to 100 and 365 days was 93% and 74% respectively. Pre-existing renal impairment was uncommon (mean eGFR 92ml/min, range 45-143ml/min). During the first 100 days, no differences were seen in mean eGFR in survival vs non-survival groups (75 and 80ml/min respectively, p=0.23). Amongst all patients, AKI incidence in the first 100 days was greater in the non-survival group (93.2% vs 80.6%, p=0.02). On multivariate analysis, AKI event in the first 100 days and HLA mismatch (<8/8) were independent factors predicting mortality (p=0.02 and p=0.04 respectively).

Recent race and gender, ASCT indication, number of hypertensives, BMI, SAT status, donor sex, stem cell source and conditioning regimen (MA vs RIC) were not statistically significant (p>0.05). Within the first year of ASCT, pre-terminal AKI was noted in 29% (n=23) of all patients dying (n=59) with sepsis accounting for 60% of these (n=36). For non-relapse causes of death (n=15). Of the patients alive, only 11 (8%) had chronic renal impairment. Chronic GVHD was associated with these patients (73%) one of whom was dialysis dependent.

Summary/Conclusions: AKI is a very common post ASCT. Chronic renal failure is uncommon in long-term survivors. AKI is however a prominent event preceding death. Consistent with other reports AKI and HLA mismatch correlated inferior outcomes. Poor survival from AKI probably reflects physiological strain from other complications (e.g. sepsis and GVHD). Early recognition and treatment of AKI are important measures in the supportive care of patients with AKI.

E1530
PREDICTIVE INDEXES FOR ALLOGENEIC HEMATOPOietIC STEM CELL TRANSPLANTATION; A SINGLE-CENTER EXPERIENCE
J. Zanabili Al-Sibai1,*, M.P. Palomo Moraleda1, A.J. González Huerta1, T. Arias Fernández1, L.R. Morais Bras1, C. Castañón Fernández1, A. Solé Magdalena1, S. González Muñiz1, A.P. González Rodríguez1
1Hematology, HUCA, Oviedo, Spain

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is often associated with complications such as graft-versus-host disease (GVHD), resulting in poor outcome, relapse and death. Introduction of reduced intensity conditioning (RIC) regimens and improvements in supportive care, have allowed offering allo-HSCT to more and older patients (pts). A balanced risk-benefit approach of candidates for allo-HSCT is the key for maximized chances of cure with acceptable quality of life.

Aims: Compare the potential utility of two pretransplant predictive models: PAM (pretransplant assessment of mortality, Parimón et al, AIM 2006) and HCT-CI (HCT comorbidity index; Sorror et al, Blood 2005). In our cohort of pts.

Methods: We retrospectively studied 154 pts, 86 (55.8%) were males with a median age of 51 years (range: 15-68), who underwent allo-HSCT in our center between May 2005 and December 2014. Patients' baseline diseases were: acute myeloblastic leukaemia (24%), multiple myeloma (22.7%), non Hodgkin lymphoma (11.7%), acute lymphoblastic leukemia (11%), myelodysplastic syndrome (9.1%), chronic lymphocytic leukemia (5.2%), Hodgkin lymphoma (3.9%), aplastic anemia (3.9%), myelofibrosis (3.9%), chronic myeloid leukemia (1.3%), Waldenström macroglobulinemia (1.3%) and others (1.8%). Eighty (51.9%) pts received cells from matched siblings, seventy (45.5%) from unrelated donors and the remaining (2.5%) pts received RIC regimens. Stem cell source were: peripheral blood (n=86), bone marrow (n=63) and umbilical cord (n=5). Median and maximum follow-up were 31 and 228 months, respectively.

Figure 1. Results: After allografting, 57.1% pts had complications, the most frequent were: infections (45.5%), followed by nephrotoxicity (25.3%), hepatotoxicity (12.3%), pulmonary toxicities (9.7%) and cardiotoxicity (3.9%). Eighty-two per cent of pts with high/intermediate risk group of PAM score presented complications versus 46% of pts included in low/intermediate risk (p<0.001). Regarding GVHD, 41.6% and 31.2% of pts developed aGVHD (grades II to IV) and cGVHD, respectively. PAM score was a good predictor for aGVHD risk; 38.1% of pts with low/intermediate risk had aGVHD versus 59.3% of pts with high/intermediate risk (p<0.001). Median follow up of 26% of NRMs included infections (45.8%), hemorrhage (10%), pulmonary toxicities (16%), second neoplasia (14.6%), GVHD (6.2%), cardiotoxicity (2%) and hepatic toxicity (2%); PAM score effectively risk-stratified pts for NRM: 17%, 24.7%, 45%, and 50%
in the low, intermediate, high and very high risk groups, respectively, showing a clear distinction by categories (p<0.038) (figure 1). Refraining reale, 44 (28.6%) patients. Neither PAM nor HCT-CI were good predictors for relapse. However, HCT-CI was not good predicting complications, GVHD, NRM or relapse.

Summary/Conclusions: In our series of pts, risk-groups based on PAM score provided much better discrimination of post-HSCT complications, aGVHD (II-IV) and NRM than HCT-CI model. None of the indexes were acceptable predictors of relapse. Furthermore, correlation between both indexes was poor.

E1531
ROLE AND TIMING OF HEMATOPOIETIC CELL TRANSPLANTATION FOR HIGH-RISK PERIPHERAL T-CELL LYMPHOMAS
H. Huang1,*, Y. Jiang2, Q. Wang3, T. Xu1, X. Chen1, Z. Jin1, D. Wu1
1Soochow University, Suzhou, China

Background: Peripheral T-cell lymphomas (PTCLs) often carry poor outcomes with conventional chemotherapy, and hematopoietic cell transplantation (HCT) can benefit patients with PTCL. Recent retrospective studies have reported that autoHCT as consolidation can offer a durable survival benefit in high-risk patients with first complete or partial response, and alloHCT could result in long-term disease control for relapsed and refractory patients.

Aims: To explore questions about the optimal timing for stem cell transplantation and relative efficacy of auto-HCT versus alloHCT.

Methods: We conducted a retrospective review of 67 patients with peripheral T-cell lymphoma who underwent autologous HCT (autoHCT, n=43, median age 40 years) or allogeneic HCT (alloHCT, n=24, median age 36.5 years) from 2004 to 2016.

Results: With a median follow-up of 27 months, 5-year PFS and OS of auto-HCT patients were 49% and 57%, respectively. Among alloHCT recipients, the 5-year PFS and OS were 54% and 55%, respectively. When considering incidence of disease relapse or progression (CIR) and nonrelapse mortality (NRM), the 5-year CIR and 1-year NRM of alloHCT recipients were 38% and 18%, respectively, and 58% and 7% of autoHCT patients, respectively. There were no differences between autoHCT and alloHCT on 5-year PFS (P=0.499), OS (P=0.566), CIR (P=0.555) and NRM (P=0.202). When specifically examining recipients in primary refractory disease, 3-year PFS rates of autoHCT and alloHCT were 20% and 49% (P=0.054), 3-year OS rates were 20% and 53% (P=0.042), respectively.

Figure 1.

Summary/Conclusions: This analysis shows that HCT can benefit patients with high-risk PTCL in both remission and primary refractory setting. The outcomes did not differ significantly between autoHCT and alloHCT approaches, but alloHCT recipients in primary refractory disease resulted in significantly better outcomes than autoHCT patients. So, we favor proceeding to alloHCT if patients with PTCL in primary refractory disease.

E1532
IMPACT OF BASELINE BILIRUBIN ON SURVIVAL IN PATIENTS WITH HEPATITIS VIRAL-OCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME RECEIVING DEFIBROTIDE: POST-HC ANALYSIS OF EXPANDED-ACCESS PROTOCOL FINAL DATA
P. Richardson1,*, A. Smith2, B. Triplett3, N. Kerman4, S. Grupp5, J. Antin6, L. Lehmann7, S. Giralt6, W. Liang9, R. Hume9, W. Tappe9, R. Soiffer7
12 nd Congress of the European Hematology Association

Background: Veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) is an unpredictable, potentially life-threatening complication of hematopoietic stem cell transplantation (HSCT) conditioning. VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved in the European Union to treat severe hepatic VOD/SOS post-HSCT and in the United States to treat hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT. Prior to approval, defibrotide had been available in the United States via an expanded-access program.

Aims: A post-hoc analysis of final data from the defibrotide expanded-access program was used to explore Day +100 survival post-HSCT based on bilirubin-level categories at the time of study entry.

Methods: Patients in the defibrotide expanded-access program had VOD/SOS diagnosed by investigators using Baltimore criteria (bilirubin ≥2mg/dL and ≥2 of: hepatomegaly, ascites, ≥5% weight gain), modified Seattle criteria (≥2 of: bilirubin >2mg/dL, hepatomegaly, or ascites and/or ≥5% weight gain), or biopsy; bilirubin >2 was not required for modified Seattle criteria or biopsy. MOD (mod. The Children’s Hospital of. After informed consent, defibrotide treatment (25mg/kg/day) was recommended for ≥21 days. Here, Day +100 survival was explored by bilirubin level at study entry using categories that are part of the European Society for Blood and Marrow Transplantation (EBMT) proposed grading scale for adults (≥2 to <3mg/dL, ≥3 to <5, ≥5 to <8, and ≥8), as well as bilirubin <2mg/dL, which is not part of the scale but has been reported in children with VOD/SOS.

Results: There were 1000 HSCT patients enrolled, between December 2007 and September 2016, with a confirmed diagnosis of VOD/SOS and receiving ≥1 dose of defibrotide, 512 patients had MOD. Median age was lowest in patients with bilirubin <2 (44.5 years); 19% of patients median age in the bilirubin ≥2 to <3 group (53.5% of patients) and 13.5 in the ≥3 to <5 group (20.4% of patients); median age in other groups ranged from 15 to 17 years. Kaplan-Meier estimated Day +100 survival in all HSCT patients was 58.9%, with 85.6% in patients with BR <2; other bilirubin groups were older and survival estimates decreased (Table 1). In the pediatric (aged ≤16 years) and adult (aged >16 years) patients, patterns were similar (Table 1). Estimated survival rates were lower for patients with MOD across all groups. Of all 1000 HSCT patients with confirmed VOD/SOS, 210 (21%) had treatment-related AEs (TRAEs). The TRAEs in ≥2% of patients were pulmonary hemorrhage (4.6%), gastrointestinal hemorrhage (3.0%), epistaxis (2.3%), and hypotension (2.0%).

Table 1. Day +100 Survival (Kaplan-Meier, N=1000).

Summary/Conclusions: This post-hoc analysis found that higher bilirubin levels were generally associated with lower Day +100 survival. These results should be interpreted with caution, as only 1 EBMT criterion was analyzed. MOD was also associated with lower Day +100 survival. The results suggest that diagnosis and treatment of VOD/SOS, before bilirubin becomes markedly elevated, may be associated with improved outcome.

Support: Jazz Pharmaceuticals.

LONG-TERM FOLLOW-UP OF A PROSPECTIVE TRIAL OF INTENSIFIED CHEMO-IMMUNOTHERAPY WITH AUTOLOGOUS OR ALLOGENEIC STEM CELL TRANSPLANTATION IN PATIENTS AFFECTED BY PERIPHERAL T-CELL LYMPHOMA
1Department of Hematology, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, 2Hematology, Azienda Ospedaliero Universitaria Città della Salute, Turin, 3Hematology, Ospedale Papa Giovanni XXIII, Bergamo, 4Statistical Department, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, 5Hematology,
cancellations for donor-related reasons and the following factors: donor sex, grounds and inability to contact the donor. We examined associations between donor attrition rates and causes of cancellation among BBMR donors are recruited from blood transplant centres (TCs) and to UK TCs via the Anthony Nolan registry.

Data reported by international registries on donor attrition is scarce and mainly focused on attrition at the VT stage. BBMR donors are recruited from blood transplant centres (TCs) and to UK TCs via the Anthony Nolan registry.

Methods: Three patients relapsed after auto SCT and were subsequently allografted and cyclophosphamide. Patients in clinical remission with HLA identical donors and donor availability, the majority of patients allografted had donor reasons accounted for 38% of cancellations (n=216, 6.8% of requested donors), of which 69% (n=148) happened for medical reasons, 27% (n=59) for uncontuctable donors. The medical reasons for withdrawal were varied but the most frequent health issues were obesity and cardiovascular disease. Analyses of factors affecting donor reasons showed that donor sex and time on the register were not associated with donor fitness or withdrawal rate. Age had no impact on donor pull-out, but it was significantly associated with medical eligibility and donors who were older than 35 years were more likely to be cancelled. Donor pull-out rates were significantly associated with blood donor reliability score (p=0.029, score 5 vs others). In 48 cases (8%) there were mixed reasons where TCs had other donor options and pursued them because of issues such as donor availability for ideal dates or CMV mismatches.

Summary/Conclusions: In our registry patient-related issues accounted for more than half of cancellations at a late stage in the stem cell donor pathway. Cancellations for donor reasons were unusual (6.8% of requested donors), which figure compares favourably with international data (12.4% of requested donors, WMDA Annual Report 2015). This is likely due to the fact that most BBMR donors are regular donors: few donors withdrew for personal reasons, few were rejected as a donor. Medical reasons for cancellation were the most frequent cause of cancellation for donor reasons. Further work is underway to allow earlier or reduced deferral of medically unsuitable donors such as control of high blood pressure and to explore personal reasons which cause donors to withdraw. This study should provide reassurance to TCs that BBMR provide reliable and accessible stem cell donors.

E1535
POLIMORPHISM IN TGFB1 GENE PREDISPOSES TO RELAPSE AND DEVELOPMENT OF ACUTE GRAFT-VERSUS-HOST DISEASE GRADES III-IV

N. Meggyesi1,*, P. Kovy1, V. Telek1, K. Balassa1,2,*, A. Griffiths3, D. Winstone1, Y. Li1, V. Rocha1,2, R. Pawson1,2

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the most effective treatment option for certain hematologic malignancies. Cytokines play a well established role in the mechanism of acute GvHD (aGvHD), which is one of the most significant complications and the main transforming growth factor B1 (TGFB1) is one of the inflammatory cytokines, which play a pivotal role in the development of aGvHD.

Aims: The aim of this study was to investigate the role of TGFB1 -1347C>T polymorphism in the outcome of HSCT.

Methods: We examined the association of recipient and donor TGFB1 -1347C>T and allo-HSCT outcome in a cohort of 419 adult patients who underwent first allo-HSCT between January 2007 and December 2013 at our single center. 217 patients received stem cells from their siblings, 202 patients from matched unrelated donors (MUD). For identification of TGFB1 rs1800496 genotypic and allelic phenotype DnaLightCycler melting curve analysis (LightCycler 480II, Roche Diagnostics) was performed.

Results: We did not find any association between recipients’ TGFB1 -1347C>T polymorphism and HSCT outcome. However, in patients whose unrelated donors carried homozygous TGFB1 -1347TT variant, aGvHD grades III-IV occurred more frequently (aGvHD grade III-IV: 28.9% vs aGvHD grade 0-II: 9.6%, p=0.006). Similar finding was observed on a subgroup of patients with acute leukemia: in aGvHD grade III-IV 37.5%, while in grade 0-II 11.5% of patients had TT genotype (p=0.022). Donor TT genotype did not influence the relapse rate significantly. Patients with MUD carrying TT genotype had lower overall survival (OS) that of donors bearing at least one C variant, but the difference did not reach the level of significance (OS at 40 month for CC and CT variant donors: 45.3% and for TT donors: 26.2%). In case of sibling donors, we did not find association between recipient or donor genotype and aGvHD, but relapse rate was increased if donor had at least one T variant (n=115, 67.9% vs 32.1%, p=0.028). Significant differences in OS between the subgroups with different genotypes were not observed.

Summary/Conclusions: Our findings suggest that TGFB1 -1347C>T polymorphism in HSCT donors might influence the development of aGvHD in unrelated and the relapse rate in related HSCT.

E1534
UNRELATED DONOR ATTRITION AT A LATE STAGE: THE BRITISH BONE MARROW REGISTRY EXPERIENCE

K. Balassa1,2,*, A. Griffiths3, D. Winstone1, Y. Li1, V. Rocha1,2, R. Pawson1,2

Background: The success of searches for unrelated stem cell donors (UDs) relies on the existence of large international donor registries and the availability and reliability of donors on the register. Donor attrition at the verification typing (VT) or late stage results in delay of transplant and can adversely affect patient outcomes. The British Bone Marrow Registry (BBMR) provides UDs to international transplant centres (TCs) and to UK TCs via the Anthony Nolan registry. Data reported by international registries on donor attrition is scarce and mainly focused on attrition at the VT stage. BBMR donors are recruited from blood donors and may differ in their reliability from non-blood donors included in existing reports.

Aims: To investigate donor attrition rates and causes of cancellation among finally selected or backup BBMR donors at the post-VT stage.

Methods: Data on requests for work-ups from April 2002 to December 2016 were extracted from BBMR databases and donor notes and were analysed retrospectively. The reasons for cancellation were categorised: cancellation initiated by the donor (recipient’s) mixed reasons. Within donor reasons we distinguished 3 categories: donor medical reasons, donor withdrawal on personal grounds and inability to contact the donor. We examined associations between cancellations for donor-related reasons and the following factors: donor sex, age at time of donation/cancellation, time on the register and donor reliability score. The reliability score relates to blood donation and runs from 1 (best) to 5 (worst), increasing if a donor fails to attend appointments for blood donation.

Results: A BBMR final/backup donor was selected for 3184 stem cell or lymphocyte collections. 82% of the requests (n=2613) were completed. Out of the 571 (18%) cancelled cases the reason for cancellation was not available for 5 cases. Overall more than half of the cancellations (502, 33%) were initiated by TCs mainly due to patient death, deterioration or alternative donor choice. Donor reasons accounted for 38% of cancellations (n=216, 6.8% of requested donors), of which 69% (n=148) happened for medical reasons, 27% (n=59) for donor pull-out on personal grounds and 4% (n=9) due to uncontuctable donors. The medical reasons for withdrawal were varied but the most frequent health issues were obesity and cardiovascular disease. Analyses of factors affecting donor reasons showed that donor sex and time on the register were not associated with donor fitness or withdrawal rate. Age had no impact on donor pull-out, but it was significantly associated with medical eligibility and donors who were older than 35 years were more likely to be cancelled. Donor pull-out rates were significantly associated with blood donor reliability score (p=0.029, score 5 vs others). In 48 cases (8%) there were mixed reasons where TCs had other donor options and pursued them because of issues such as donor availability for ideal dates or CMV mismatches.
E1536
EARLY AND LATE LOSS OF PROTECTIVE ANTIBODY LEVELS AGAINST MEASLES, MUMPS AND RUBELLA IN PATIENTS GIVEN ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION
J. Bücheholz1,2, E. Haralambieva2, M.G. Manz1, U. Schanz1, A.M. Müller1,1Hematology, 2Pathology, University Hospital Zurich, Zurich, Switzerland

Background: Live-vaccines should be avoided in the early period following allogeneic hematopoietic cell transplantation (HCT), due to a possible uncontrollable proliferation of the attenuated strains. The post HCT immune system is severely compromised by pharmacological immunosuppression and disruption of lymphoid tissues by conditioning and donor T cell alloreactivity. Patients frequently lost their antibody-based immunity against measles, mumps, and rubella after receiving allogeneic HCT.

Aims: Here, we studied the dynamics of antibody (AB) titers against measles, mumps, and rubella post-HCT.

Methods: We retrospectively analyzed serial AB titers in 240 patients who underwent allogeneic HCT from related and unrelated HLA-matched donors from 2002-2014 at our center. AB titers against measles, mumps and rubella were measured prior to HCT, at 6 months (m), and every year (y) post-HCT.

Results: Most patients had protective AB titers (measles 90%, mumps 86%, rubella 92%) prior to HCT. AB protection against mumps was lost in a substantial proportion of patients after HCT (protective AB titers in 72%@1y, 56%@5y, 50%@8y), comparing to AB against measles, which persist more frequently (protective AB titers in 85%@1y, 74%@5y, 73%@8y). We found a faster lost of protective AB in the first years for patients given a myeloablative condition (MAC) in comparison to patients with reduced condition (RIC), but the proportion of seropositive patients became more equal over time (Figure 1 displays the percentage of seropositive patients to Measles AB given MAC or RIC during 8 years post-HCT). The proportion of patients who retained protective AB titers at 5y post-HCT was higher in recipients of mobilized peripheral blood compared with bone marrow (BM) grafts (measles p=0.01, mumps=0.06, rubella p=0.08).

For rubella, absolute AB titers were available. Patients with lymphoid malignancies, ongoing GVHD and pharmacological immunosuppression had a steeper decline of rubella AB titers as compared to patients with myeloid malignancies.

Summary/Conclusions: We found a marked decline of AB titers post-HCT with loss of protection in a substantial proportion of patients. Surprisingly, BM grafts did not provide better AB protection post-HCT, despite their higher content of (donor) plasma cells. Together with the observations that (i) patients with lymphoid malignancies (who have received (B-) lymphocyte targeted therapies prior to HCT) had lower AB levels, while (ii) those given reduced intensity conditioning have a higher percentage of protective AB levels in the first years, our data suggest, that residual host plasma cells significantly contribute to AB production during the first years post-HCT. In opposite, the loss of protective AB levels in later years after transplantation was independent of the toxicity of the conditioning regime and may be a effect of weakening signaling for host plasma cells or late donor alloreactivity.

E1537
MICA AND NKG2D POLYMORPHISMS HAVE A SIGNIFICANT IMPACT ON GRAFT VERSUS HOST DISEASE AFTER HLA-MATCHED HEMATOPOIETIC STEM CELL TRANSPLANTATION.
M.-J. Apithy1,2, A. Charbonnier2, J. Desoutter1, P. Morel2, J.-P. Marolleau2, N. Guillaume1

1Hematology and Histocompatibility, 2Hematology and cellular therapy, University Medical Center, AMIENS, France

Background: MICA (MHC class I polypeptide-related sequence A) is a highly polymorphic gene closely linked to the HLA-B locus. It encodes a cell stress inducible glycoprotein, which mediates an activatory signal towards the NKG2D receptor expressed on NK-cells, CD8+ T-cells and NKT-cells. MICA polymorphisms have been shown to influence NKG2D signaling. Indeed, a methionine to valine change at position 129 in exon 3 categorized the MICA alleles into strong (MICA-129 met) and weak (MICA-129 val) binders of NKG2D receptor. NKG2D binds to two ligands: MICA and NKG2D. 5 repetitions of CTC at 1 additional nucleotide insertion (G) in exon 5 designates the MICA A5.1 alleles with a premature stop codon. Moreover, NKG2D polymorphisms identified alleles associated with a low (NK3 C/C and NK4 C/C) or high cytotoxic activity (NK3 G/G and NK4 T/T).

Aims: In this study, we hypothesized that polymorphisms at the MICA and NKG2D loci are associated with adverse outcomes in HSCT.

Methods: Here, we evaluated whether recipient MICA and donor NKG2D polymorphisms (respectively MICA-129, MICA A5.1 and NK3, NK4 C4) could influence the incidence of acute and chronic graft-vs-host disease (GVH), overall survival (OS) and relapse free survival (RFS) on 124 patients undergoing allogeneic hematopoietic stem cell transplantation using an HLA-matched donor (10/10).

Results: In an univariate model, recipient MICA A5.1 heterozygosity (p=0.030) and donor NK4 C/C polymorphism (p=0.013) are associated with the increase of incidence of acute GVH (grade I to IV). Recipient MICA A5.1 heterozygosity is also associated with chronic GVH (p=0.04) while Recipient MICA-129 val/val tends to be a risk factor of chronic GVH without being statistically significant. These polymorphisms have no significant impact on OS and RFS in our study (median of follow up=15 months; range 0.2-49 months).

Summary/Conclusions: Our data suggest that a MICA or NKG2D low activity status can be related to an increase of acute GVH according to a mechanism that remains to be elucidated, maybe by a low cytotoxic activity on recipient dendritic cells.

Figure 1.

Summary/Conclusions: We found a marked decline of AB titers post-HCT with loss of protection in a substantial proportion of patients. Surprisingly, BM grafts did not provide better AB protection post-HCT, despite their higher content of (donor) plasma cells. Together with the observations that (i) patients with lymphoid malignancies (who have received (B-) lymphocyte targeted therapies prior to HCT) had lower AB levels, while (ii) those given reduced intensity conditioning have a higher percentage of protective AB levels in the first years, our data suggest, that residual host plasma cells significantly contribute to AB production during the first years post-HCT. In opposite, the loss of protective AB levels in later years after transplantation was independent of the toxicity of the conditioning regime and may be a effect of weakening signaling for host plasma cells or late donor alloreactivity.

STEM CELL TRANSPLANTATION WITH MYELOABLATIVE CONDITIONING USING TIMED SEQUENTIAL BUSULFAN IMPROVES OUTCOMES IN OLDER AML AND MDS PATIENTS
B. Oran1, R. Saliba1, S. Ahmad1, A. Alousi1, S. Ciurea1, C. Hosing1, L. Khouri1, D. Marin1, A. Olson1, Q. Bashir1, Y. Nielo1, K. Rezvani1, P. Kebrbaei1, B. Valdez1, E. Shpall1, B. Andersson1, R. Champlin1, U. Popat1, 1Stem Cell Transplantation and Cellular Therapy, The University of Texas MDACC, Houston, United States

Background: We previously reported 6% 100 day NRM with a MA fludarabine (Flu) and busulfan (Bu) in older patients with a median age of 60 years. MA dose of Bu in this timed sequential (TS) regimen was administered over a longer period of time. To assess its impact on survival, we compared the outcomes of older patients treated with the TS Bu (TS cohort) and the reduced intensity conditioning with Flu/Bu regimen, which is used as standard (ST) for older patients at our center ST cohort.

Aims: To assess its impact on survival, we compared the outcomes of older patients treated with the TS Bu (TS cohort) and the reduced intensity conditioning with Flu/Bu regimen, which is used as standard (RIC cohort) for older patients at our center.

Methods: Patients in the TS cohort received Flu 40mg/m2/d followed by IV Bu daily for 4 days (day -6 to -3) with IV-Bu dose adjusted to achieve a total Bu course AUC of 20,000μmol-min based on PK studies. Patients in the ST cohort received Flu 40mg/m2/d followed by IV Bu daily for 4 days (day -6 to -3) dosed to achieve AUC of 16,000μmol-min based on PK studies. Patients treated with the TS Bu (TS cohort) and the reduced intensity conditioning with Flu/Bu regimen, which is used as standard (RIC cohort) for older patients at our center.

Results: Overall survival (OS) and progression free survival (PFS) were significantly better in the TS-MAC cohort. This was due to a reduction in the disease progression without any increase in the TRM. After adjusting for other covariates, the multivariate analysis for PFS confirmed a reduction in the disease progression without any increase in the TRM.

Table 1.

Summary/Conclusions: The myeloablative timed sequential Bu regimen improves survival and appears promising in older patients with AML/MDS. The myeloablative timed sequential Bu regimen improves survival and appears promising in older patients with AML/MDS.
Background: Recently, haploidentical hematopoietic stem cell transplantation (HSCT) poses an alternative option for patients without a suitable donor. Erciyes Pediatric BMT Center is the first pediatric center for haploidentical HSCT with depletion of TCRαβ (+) in Turkey.

Aims: We would like to share our pediatric experience with a follow up period of over five years.

Methods: All children who underwent haploidentical HSCT in our center from December 2012 to February 2017 were included in the study. Total 51 haploidentical HSCT in 44 children (17 relapsed/refractory AML, 9 relapsed/refractory ALL, 4 SAA, 4 HLH, 2 Fanconi aplastic anemia, 2 Griselli syndrome, 1 JMML, and 5 SCID) were performed. Transplantation-related mortality (TRM) was 13.7%. The regimen included ATG, Fludarabine, Thiotepa, Melphalan, Mycophenolate mofetil (MMF) was given as GvHD prophylaxis if the graft contained <5 x10^9/kg TCRαβ (+).

Results: The mean of collected CD34 cells were 18.60 (range 3.98-43.66) x 10^6/kg. The graft had a purity of 99.9% TCRαβ depletion with a median of 0,257 (range 0.003 to 1.47) x 10^9 TCRαβ cells. The median engraftment days for myeloid and platelet were both 12th day of HSCT (range 7 to 28, 9 to 33 day) respectively. Grade II skin GvHD was detected in 8 patients, and treated with steroids without any further complications. However grade III, and grade IV gastroenteritis and GvHD were observed in three patients. Although the patients with gastrointestinal GvHD were treated with steroid, bendocid, cyclosporine, MSC; one patient did not respond and died. MMF was given as GvHD prophylaxis in 36 patients and 15 patients did not receive any immune suppressive drug. The mean day of discharge was 34th day of HSCT. The long term follow up immunological reconstructions were performed in 18 patients. The analysis of the immune reconstitution of the patients transplanted in haploidentical HSCT group showed a rapid immune reconstitution for CD3+ T cells 732 (range 128-2432)/mm3; for CD4+ helper T cells 92 (range 1–419)/mm3; CD8+ cytotoxic cells 310 (range 95-2235)/mm3 at 28th day of HSCT. Twenty nine patients are currently alive, with a median follow up of 22 months (range 1 to 49 months). Overall survival was 65.9% in these group.

Summary/Conclusions: Our primary results underline that haploidentical HSCT with depletion of TCRαβ (+) can be an option in experienced center in countries which unrelated donor programs are not satisfactory, as in Turkey. The availability of a haploidentical donor in most families is a potential advantage. Moreover probably more potent graft-versus-tumor effect can be induced with haploidentical HSCT.
drugs for GVHD was performed in all cases. Defibrotide was subsequently administered as monotherapy in 5 cases, in combination with rituximab and/or plasma exchange in 7, and with other agents in 5 others (2 vincristine; 1 eculizumab; 1 bevacizumab; 1 mesenchymal stromal cells). Complete resolution of TA-TMA (CR) was achieved in 11 episodes (65%), and associated with a reduced all-cause mortality: 18% of CR cases (2/11: 1 multiorgan failure and/or another cause). The study engaged a total CD34+ subset (420 vs 385, 8% vs 3/8, 38%; P=0.027) and early-onset TA-TMA (9/11, 82% vs 2/6, 33%; P=0.046).

Summary/Conclusions: TA-TMA is a severe endothelial dysfunction syndrome for which, beyond the complement inhibitor eculizumab, treatment is not well established. Defibrotide has proven to be safe and effective in sinusoidal obstruction syndrome. Here, we provide encouraging evidence suggesting that defibrotide, as monotherapy or in combination with other agents, may also have a role in the treatment of TA-TMA. Our data show complete resolution of TA-TMA in two thirds of cases, and even higher in those with early treatment and early onset forms of the disease. Validation of single-center experience in prospective controlled studies should be warranted.

### E1542

PRE-TRANSPLANT COMORBIDITY AS AN OUTCOME PREDICTOR IN HEMATOPOIETIC CELL TRANSPLANTATION FOR SEVERE APLASTIC ANEMIA

S.-N. Lim1,*

1Internal Medicine, Haeundae Paik Hospital, Busan, Korea, Republic Of

Background: In the context of allogeneic hematopoietic cell transplantation (allo-HSCT), comorbidities are an important risk factor. Use of the hematopoietic cell transplantation-specific comorbidity index (HSCT-CI), which was modeled to effectively capture comorbidity and predict post-transplant outcomes. HSCT-CI had been evaluated in a cohort of patients with a variety of hematologic malignancies. However, it was not validated in a cohort of adult patients with non-hematologic malignancies.

Aims: We performed multi-center retrospective study to validate the prognostic impact of HSCT-CI on transplant outcomes in a cohort of aplastic anemia patients undergoing allo-HSCT.

Methods: We applied the HCT-CI to 140 patients with severe aplastic anemia (SAA) who underwent allogeneic HCT at the Asan Medical Center, Seoul, and Haeundae Paik Hospital, Busan, Korea between April 1995 and March 2013. Required data were retrieved from Asan medical center and Haeundae Paik Hospital BMT Registry Database. We stratified the patients based on comorbidities, as assessed by HCT-CI. Post-transplant outcomes were evaluated in terms of overall survival (OS) and event-free survival (EFS). Event was defined as graft failure including primary and secondary, relapse, donor lymphocyte infusione, and death.

### Results:

The median age of including patients was 31 year-old (range: 31-61 year-old) and male was 81 patients (58%). HCT-CI score was 0 in 92 patients (65.0%), 1-2 in 34 (24.3%) and ≥3 in 14 (10.2%). The most prevalent comorbidity captured by the HCT-CI was infection (n=20, 14%) followed by moderate/severe hepatic comorbidity (n=10, 7%). During a median surviving post-HCT follow-up period of 45.5 months (range, 4-1,178.4 months), 32 patients (24%) died and 20 (14%) experienced primary or secondary graft failure. The 10-year probability of OS and EFS was 73.4% and 68.3%, respectively. OS and EFS was significantly different according to HCT-CI score; the OS for HCT-CI 0, 1-2, and ≥3 at 4 years was 84.1%, 68.6%, and 60.6%, respectively (P=0.007). The EFS for HCT-CI 0, 1-2, and ≥3 at 4 years was 76.5%, 60.0%, and 56.3%, respectively (P=0.019). Multivariate analysis after adjustment for other variables demonstrated that higher HCT-CI score were associated with increased OS and EFS as judged by increasing hazard ratio compared to patients with HCT-CI score of 0 (Table 1).

### Summary/Conclusions:

In conclusion, our data indicate that the presence of pre-transplant comorbidty assessed by HSCT-CI may predict worse outcomes after allo-HSCT in severe aplastic anemia.

### E1543

EFFICACY AND SAFETY OF FILGRASTIM BIOSIMILAR COMPARED TO FILGRASTIM ORIGINATOR IN THE STEM CELL MOBILIZATION AND HEMATOPOIETIC ENGRAFTMENT IN PATIENTS UNDERGOING STEM CELL TRANSPLANTATION

M. López-Parra1,*, M. Baile1, J. Dávila1, J.C. Caballero1, Á. Veiga1, N. Arratibel1, F. López-Cadenas1, L. García-Martín1, M. Salinero1, N.C. Gutiérrez1, O. López-Villar1, M.D. Caballero1, R. García-Sanz1

1Hematology, University Hospital of Salamanca, Salamanca, Spain

### Background:

Neupogen® is the original Filgrastim used for peripheral blood stem cell mobilization (PBSC) in patients and donors selected for stem cell transplantation (SCT). Nivestim® is a Filgrastim biosimilar approved for the same indications as Neupogen®.

### Aims:

To evaluate the efficacy and safety of Nivestim® in the PBSC mobilization for harvesting and hematopoietic SCT.

### Methods:

Retrospective, controlled, observational study conducted at the University Hospital of Salamanca between January 2008 and March 2015. The study included 365 patients candidates for ASCT and 217 healthy sibling donors for allo-SCT who underwent PBSCs mobilization. Nivestim® (Amgen Europe BV, Breda, NL) was administered for mobilization at standard doses until SEP2012, while Nivestim® (Hospira, Maidenhead, UK) was used from that date. Among PATIENTS, 145 were mobilized with Nivestim® and 220 the originator Neupogen®. Patient characteristics between groups were similar, although lenalidomide was more frequently used in the Nivestim® group, as it corresponds to more recent transplants. The mean number of CD34+ cells/μl in the peripheral blood after 4 days of mobilization treatment was not significantly different (Neupogen® 73.2, SD=113.0; Nivestim® 84.5, SD=151.0, p=0.015), but the mean of the total CD34+ collected cells was 4.75. SD=4.41 in the Neupogen® and 6.35±6.42 in Nivestim® group (p=0.01), with a larger number of apheresis procedures needed in the Neupogen® group (1.39, SD=0.65 vs 1.24, SD=0.45, p=0.02). The mobilization failure rate was slightly higher with Nivestim® (22%) than with Neupogen® (16%), although it was attributed to a more frequent use of lenalidomide. Most patients underwent ASC: 87% and 92% patients in the Neupogen® and biosimilar groups, respectively. There were no statistically significant differences in hematopoietic recovery and trans-
plant-related toxicity. The median hospitalization time (20, range 14-70 vs 20, range 14-53, p=0.72) and the consecutive number of re-admissions after discharge (27% vs 35%, p=0.35) were also similar between Neupogen® and Nivestim® groups. In the group of HEALTHY DONORS, 95 were mobilized with Neupogen® and 122 with Nivestim®. Donor characteristics were equivalent between groups, and no severe adverse events were registered in any of them. Mean of CD34+ cells collected/kg of recipient body weight was 7.62x10^6, SD=3.45x10^6 for Nivestim® vs 6.26±10^6, SD=2.71±10^6 Neupogen® (p=0.002), but the minimal target cell dose (2x10^6/kg) was collected in all donors. 8.5% of donors mobilized with Nivestim® failed to achieve the optimal cell dose (4x10^6/kg) compared with 13% in the Neupogen® group (p=0.25). All recipients were successfully transplanted. All donors for haploidentical transplants (N=25) were mobilized with Nivestim®; none with Neupogen®. There were no other transplant differences. Platelet and neutrophil engraftment were comparable between the two groups, as well as for transfusion requirements and infectious complications after transplant. The incidence of grade 1 to 4 acute graft-versus-host disease was not different (Nivestim®65.5% vs Neupogen® 67.7%; p=0.7). The hospitalization period was similar in Neupogen® and Nivestim® groups, (30 days, range 16-102; 30 days, 16-136, respectively).

Summary/Conclusions: Although prospective data are still required, our study supports that the use of the Filgrastim biosimilar Nivestim® has a similar efficacy and safety as mobilization agent compared with the originator Neupogen®.

E1544 PERIPHERAL BLOOD STEM CELL DONATION IN OLDER SIBLING DONORS: IS IT SAFE?
K. Balassa1, A. Peniket1, R. Danby1, R. Pawson1
1Department of Haematology, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

Background: The introduction of reduced intensity conditioning regimens has led to an increase in allogeneic haematopoietic stem cell transplantation (HSCT) in older patients with a consequent increase in age of family members who are asked to donate HSCs for them. Such donors are expected to have more comorbidities than younger donors and careful assessment of their suitability to donate is required.

Aims: The aim of this study was to assess the frequency and nature of issues concerning the eligibility of related peripheral blood stem cell donors as seen at Churchill Hospital, Oxford between 2012 and 2016. We wished to examine the influence of age and the nature of any extra interventions required to establish donor suitability.

Methods: For clinical data collection donors’ notes were reviewed and analysed retrospectively. A similar template was used in all cases for sibling donor selection and screening.

Results: During the study period 90 related donors were screened, of whom 1 declined to proceed because of his concerns regarding G-CSF safety, 2 were excluded due to pre-existing medical conditions and 2 were defined medically inadmissible during work-up, and finally 85 donors donated PBSCs to their relatives (36% of allogeneic HSCT performed at our centre). The median donor age was 51 years (range 25-71, n=17 over 60). Nearly half of the donors (44%) took regular medications. Two thirds (67%) suffered from at least one significant comorbidity (25% hypertension, 24% back problems, 16% asthma, 9% cardiovascular conditions, 9% diabetes mellitus, 8% autoimmune disease). The presence of comorbidities was significantly associated with age (p=0.033), 59% travelled abroad, of whom 14% visited a malarial area within a year of a donation. Based on donors’ history or examination findings, 47% needed extra blood tests on top of the mandatory tests before the clearance, including malaria (31%) and haemoglobinopathies screening (13%). 6% underwent specific haematology investigations e.g. BMA, molecular studies. Additional imaging studies were performed in 13%. In 16% specialist opinion was sought from other specialties with concerns regarding donor fitness or safety. 13 out of 85 cases were handled as planned deviation from our standard eligibility criteria. Two donors needed central venous access for stem cell collection. The collected median CD34+ dose was 5.73x10^6/kg (range 1.76-22.45). Collection was completed in one day in 54%, in two in 44% and in three in 2%. Male (p=0.017) and younger donors (p=0.041) were more likely to achieve stem cell yield in one day collection. The stem cell dose was higher for collections being successful in one day (median 6.5 vs 5.03, p<0.001). Citrate related toxicity was the most common complication of the apheresis procedure (52%). The only documented serious complication affected a 69-year old donor who was hospitalized on 3rd day of G-CSF treatment with chest and abdominal pain and troponin rise, but investigations excluded acute coronary syndrome or other significant acute pathology and she managed to donate successfully with no further issues.

Figure 1.

Results: A median follow up was 5 months (0.3-63). A median time between allo-HSCT and DLI was 3 months (1.5-64). 100% donor chimerism was achieved in 17 patients with MC from 26 (65%). A median number of infusions
was 2 (1-5). There were 5 (19%) graft failures. Acute GVHD appeared in 8 (32%), all of them grade 3; chronic GVHD occurred in 7 (27%). Patients with a MC had better overall survival 77.6% than patients with relapse after allo-HSCT (22%). Remission was achieved in 16 (48%) patients with relapses. However, 5 patients relapsed again. Acute GVHD was developed in 8 cases (22%). Nineteen patients died from relapse and 1 patient died from aGVHD in remission. Two patients are free of relapses in patients with MC and in patients with relapses was 78.6% and 26.2%, respectively.

Summary/Conclusions: The prognosis of hematological malignancies is poor if relapse is established after allo-HSCT. DLI protocol as preventive therapy must be created for improving long-term results in high risk patients. 1Prevention is better than cure.

E1546
MEMORY T CELLS DONOR LYMPHOCYTE INFUSIONS AFTER HAPLOIDENTICAL STEM CELL TRANSPLANTATION AS A SAFE PROCEDURE TO IMPROVE T-CELL RECONSTITUTION
S. Cortez 1, R. De Paz1,*, M. Gasior1, A. Martinez1, Y. Mozo2, B. Rosisch2, J. Valentín1, A. Sastre2, A. Pérez 2
1Hematology, 2Pediatric Hematology-Oncology, Hospital Universitario La Paz, Madrid, Spain
Background: Hematopoietic stem cell transplantation (HSCT) is a potential curative treatment for patients with hematologic malignant diseases. Haploidentical transplantation with extensive ex vivo T cell depletion of the graft, has demonstrated to prevent graft versus host disease (GVHD), but the major disadvantage has been the development of graft failure, relapse and infections due to delayed immune reconstitution. A selective T cell depletion method that removes T cells expressing CD45RA+ in haploidentical donor lymphocytes, which are responsible for GVHD, as well as preservation of memory T cells CD45RO, is a novel therapy that may provide functional T cells with anti-infection, anti-leukemia and anti-rejection properties.

Aims: We describe the outcome of CD45RA+ cell depletion of donor lymphocytes infusions, in patients with severe infections with mixed chimerism, severe infections and high risk of relapse after hematopoietic stem cell transplantation.

Methods: Patients with hematologic diseases with poor prognosis who lacked an HLA matched donor were included. The recipients received a CD45RA-depleted haploidentical transplantation, on day 0 they received a first graft with a median CD34+ cell dose of 6.4x10⁶/kg (range: 3.9x10⁶/kg-9.3x10⁶/kg), on day +1 they received a CD45RA-depleted graft. After transplantation studies of chimerism, quantification of lymphocyte subsets as well as control for viral infections were made to all patients.

Results: We present the results of six patients with a median age of 11 years (range: 3-18 years), diagnosis included B-Cell acute lymphoblastic leukemia (n=2), T cell acute lymphoblastic leukemia (n=1), acute myeloblastic leukemia (n=2), aplastic anemia (n=1), these patients received a selective CD45RA-depleted haploidentical transplantation. During the follow up after HSCT, three patients had persistent lymphopenia, four patients developed infections caused by CMV, norovirus, HHV-6, BK virus and toxoplasma, one patient had increasing levels of mixed chimerism and one had graft failure. These patients were treated with infusions of 16 aliquots of cryopreserved CD45RA+ haploidentical donor lymphocytes, the CD45RA+ cells depletion was made using the clinMACS system. The median dose of CD45RA+ cells was 1,02x10⁷/kg, starting at a dose of 1x10⁷/kg, this dose was increased every 21 days. The CD45RA+ cell dose was a median of 0.0045x10³/kg (range: 0-1.6x10³/kg). All the procedures were well tolerated, neither adverse events nor GVHD were noticed. After the DLI, a progressive increase in T cells count were observed.

Summary/Conclusions: In our experience DLI enriched for CD45RO+ memory T Cell is a promising and safe strategy for patients with severe viral infections and risk of relapse after haploidentical HSCT, these cells have demonstrated to trigger the CD4 and CD8 T cell reconstitution, which will help reduce risk of relapse with a low risk of GVHD. However further studies are needed in order to support this therapy.

FLAG REGIMEN WITH IDARUBICINE AS CYTOREDUCTION THERAPY BEFORE ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH REFRACTORY ACUTE MYELOID LEUKEMIA
L. Wang1,*, R. Devillier1, X. Fan1, W. Tang1, S. Harbi2, N. Vey2, J. Hu1, D. Blaise2
1School of Medicine, Lomonosov Moscow State University, 2Department of Hematological Oncology and BMT, National Hematology Research Center, Moscow, Russian Federation
Background: Chimerism analysis is one of the main methods to monitor the bone marrow engraftment or disease relapse after allogeneic bone marrow transplantation. Routine test is based on differences in the length of short tandem repeats (STR) from the donor and the recipient. However, chimerism estimation is complicated by stutter PCR peaks appearing due to irregular DNA polymerase activity. Generally, these sequences are 4 nucleotides shorter than a specific marker and may concur with a specific sequence of recipient’s DNA, hindering chimerism estimation based on that locus. This problem seems to be especially serious in case of a sex-matched sibling BMT when most of the alleles for donor and recipient are the same. One may suggest to limit the use of these markers for the cases with stutter-bands comparable with donor allele peak height. Therefore, the absence of “stutter-peaks free” markers hinders mixed chimerism estimation at the point of low recipient hematopoiesis output.

Aims: To identify the contribution of stutter-bands to the total amount of PCR-product and to derive universal formulas for the chimerism calculation excluding stutter percentage.

Methods: Genomic DNAs of donors and patients were isolated from bone marrow samples. Chimerism was assessed by the STR-PCR analysis (polymerase chain reaction with a panel of primers for loci of short tandem repeats) with COrDIS Plus multiplex kit for amplification of 19 polymorphic STR-markers and amelogenin loci. The fragment analysis was performed on a 2130 Genetic Analyzer. The data processing was accomplished using GeneMapper v4.0 software. Informative loci were chosen beforehand comparing pretransplant

Figure 1.
INTRODUCING PLERIXAFOR TO IMPROVE MOBILIZATION IN MULTIPLE MYELOMA PATIENTS WHO BEHAVE AS POOR-MOBILIZERS IS COST-EFFECTIVE CONSIDERING THE WHOLE MOBILIZATION AND TRANSPLANT PROCEDURE

C. Chabannon1,*, A.-G. Le Corroller-Soriano 2, R. Touzani2, A.-M. Stoppa3, C. Hamard1, A. Granata1
1Centre de Therapie Cellulaire. Departement de Biologie du Cancer, Institut Paoli-Calmettes, 2ESSEIM, Inserm, 3Departement d’Oncohematology, Institut Paoli-Calmettes, Marseille, France

Background: Plerixafor, a CXCR4-antagonist, is efficient to improve CD34+ cell mobilization and collection in candidates for autologous transplantation who behave as poor-mobilizers. The cost of the drug is however of concern. Published medico-economics studies were mostly conducted in the US, and few including detailed and comprehensive micro-costing of the collection and transplantation process; conclusions may thus not apply to European countries where cost structures are different. Aims: To compare costs and effectiveness of plerixafor-free and plerixafor-replete management strategies for multiple myeloma patients who behaved as poor-mobilizers after adequate administration of a standard rhG-CSF mobilization regimen. Methods: Sixty patients diagnosed with multiple myeloma were consecutively identified during years 2009-2011, immediately before and after EMA granted marketing authorization for plerixafor. Poor-mobilizers were defined as having a number of PRBC and platelet transfusions were identical in the two groups. Aims: To describe the experience in our center in allogenic transplantation with mismatched unrelated donor stem cell transplantation showed high engraftment rates, low rates of severe acute and chronic GVHD and comparable overall survival, non-relapse mortality and relapse rates. We suggest that T cell-replete haploidentical transplantation is a safe and acceptable alternative when a matched unrelated donor is unavailable.
Aims: Several biological mechanisms may contribute to graft failure. Immuno-
logical rejection of the graft is known as a major cause of graft failure. Graft
failure may also be caused by septicemia, viral infections, drug toxicity and so
on. These events have been frequently occurred just before engraftment, and
we often experience fluctuation of blood levels of immunosuppressive drugs.
Here, we analyzed an association between blood levels of Tacrolimus (Tac)
before neutrophil engraftment and neutrophil engraftment.

Methods: Between January 2011 and Jury 2016, 76 patients received single-
unit CBT at our institutions. We analyzed 59 patients for whom Tac was used for GVHD prophylaxis including Tac and Mycophenolate mofetil (MMF) combi-
nation (n=26) and Tac with an additional short Methotrexate (sMTX) (n=33). Sixteen patients who underwent second or third CBT and a patient for whom Tac was not used for GVHD prophylaxis were excluded. We also excluded a patient whose Tac concentration we didn’t check more than two times a week. Tac was started at a dose of 0.02mg/kg/day by continuous i.v. infusion. Tac blood concentrations were monitored at least three times a week before engraft-
ment, and dosages were adjusted to maintain serum levels about 10-20 ng/ml.

Results: Of the 59 patients, 48 patients achieved neutrophil recovery at a median of 22 (range 13-35) days. Two patients died before engraftment from severe PIR and active infection. Nine patients (18.6%) experienced graft failure. Patients who could maintain Tac level above 12ng/ml during the second week after CBT (Tac high group) had an incidence of graft failure of 4.8%, which was significantly lower than the 26.3% seen in the other patients (Tac low group) (p<0.01). Patients for whom Tac and MMF were used (MMF group) had an incidence of graft failure of 3.8%, which was significantly lower than the 26.3% seen in the other patients (Tac low group) (p<0.01). Combined of these factors, the patients of Tac high group and MMF group even if the patient were included of Tac low group.

Summary/Conclusions: Low levels of Tac blood concentration were signifi-
cantly associated with the incidence of graft failure of the patient for whom Tac with an additional sMTX were used for GVHD prophylaxis. Before engraftment, frequent checks of the Tac blood concentration and maintaining the drug level should be considered for these patients.

THE EXPRESSION OF TOLL-LIKE RECEPTORS GENES IN PATIENTS WITH LYMPHOID MALIGNANCIES AFTER AUTOLOGOUS PERIPHERAL BLOOD STEM CELL TRANSPLANTATION

J. Rybka1, B. Jaźwiec1, K. Wicherska-Pawłowska1, R. Poręba2, K. Kulickowski1, T. Wróbel1

1Hematology, 2Internal Medicine, Wroclaw Medical University, Wroclaw, Poland

Background: Peripheral blood stem cell transplantation (PBSCT) is one of the
main strategies for the treatment of malignant hematological diseases. Toll-like receptors (TLRs) are present on various immune cells including natural
killer cells, monocytes, macrophages, T lymphocytes and B lymphocytes. Ten
different TLRs have been evaluated in humans. TLRs play a central role in
immunological surveillance and in the initiation of the inflammatory response. The expression of TLRs genes and their association with outcome in patients treat-
ment with PBSCT remains unclear.

Aims: The objective of the current study was to investigate association between
expression of TLRs genes and hematopoietic recovery and rate of infections in
patients treated with PBSCT.
Methods: The evaluation of TLRs expression genes were performed in 40 patients who underwent PBSCT. The median age of patients was 54 years (range: 25-65 years). There were 15 patients with multiple myeloma (MM), 20 patients with non-Hodgkin lymphomas (nHLs) and 5 patients with Hodgkin lymphoma (HL). Peripheral blood samples were taken before megachemotherapy with autologous stem cell transplantation and at time of hematopoietic recovery in patients after PBSCT. Relative expression of TLRs receptors was assessed by real-time PCR using inventoried TaqMan® Assays from Life Technologies/ThermoFisher. Beta glucuronidase (GUSB) served as endogenous control. Reaction was performed in 7500 Real Time PCR instrument (LifeTechnologies) using Gene Expression MasterMix (LifeTechnologies/ThermoFisher). Comparative Ct method (**) was used to compare expression among patients and with healthy controls. Statistical analysis was conducted using STATISTICA 12 software (StatSoft, Polska). For quantitative variables arithmetic means (X) and standard deviations (SD) of estimated parameters were calculated in the analysed groups. Distribution of variables was examined using tests of skewness and kurtosis. In cases of independent quantitative variables with the normal distribution the statistical analysis took advantage of t test for unlinked variables. In cases of variables manifesting distribution distinct from the normal one, for independent quantitative variables U test of Mann-Whitney was used. For dependent quantitative variables of the normal distribution, the t test for linked variables was applied. In cases of quantitative dependent variables with the distribution distinct from normal, the pair sequence test of Wilcoxon was applied. In order to define a relationships between the studied variables, correlation analysis was performed. Results: The mRNA expression of TLR2 and TLR9 was significant higher in patients after PBSCT than before PBSCT procedure (ΔCt TLR2 1,409±1,0461 vs 1,7877±1,4974 and ΔCt TLR9 117,853±1,0870 vs 289,788±271,98) (p<0,05). We observed that expression of TLR9 was significant higher in patients with bacterial and fungal infection after PBSCT in comparison to group without infection after PBSCT (ΔCt TLR9 117 of 10.414±870 vs 289,788±271,98) (p>0,05). Moreover we found significant positive correlation between expression of mRNA of TLR9 and neutrophil recovery after PBSCT (r=0,4075; p=0,023).

Summary/Conclusions: In conclusion our findings suggest that TLRs could be useful markers in outcome in patients treated with PBSCT. This observation should be validated by larger study.

TIMING OF DEFIBROTIDE INITIATION POST-DIAGNOSIS OF HEPATIC VENO-OCCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION: EXPANDED ACCESS PROGRAM FINAL DATA

S. Grupp1, P. Richardson2,*, A. Smith3, N. Kernan4, J. Antin5, L. Lehmann6, S. Giralt7, W. Liang8, R. Hume8, W. Tappe8, R. Soiffer6

1Pediatric Oncology, The Children’s Hospital of Philadelphia, Philadelphia, 2Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, 3Division of Pediatric Blood and Marrow Transplantation, University of Minnesota, Minneapolis, 4Pediatric BMT Service, Memorial Sloan Kettering Cancer Center, New York, 5Stem Cell Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, 6Center for Stem Cell Transplantation, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, 7Memorial Sloan-Kettering Cancer Institute, New York, 8Jazz Pharmaceuticals, Inc., Palo Alto, United States

Background: Hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) is an unpredictable, potentially life-threatening complication of hematopoietic stem cell transplantation (HSCT). VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved to treat severe hepatic VOD/SOS post-HSCT in the European Union and to treat hepatic VOD/SOS with renal and/or pulmonary dysfunction post-HSCT in the United States. Prior to approval in the United States, defibrotide had been available via an expanded-access program.

Aims: To perform an exploratory post hoc analysis of final data from the expanded-access program on the impact of defibrotide on Day +100 survival of timing of initiation of defibrotide after diagnosis of VOD/SOS in HSCT patients.

Methods: In an expanded-access study, patients diagnosed with VOD/SOS (per Baltimore criteria, modified Seattle criteria or biopsy) with or without renal/pulmonary MOD after HSCT or chemotherapy received defibrotide 25mg/kg/d in 4 divided doses for a recommended ≥21 days after patients provided informed consent. For these exploratory analyses, Day +100 survival rates in HSCT patients were examined post hoc by time from VOD/SOS diagnosis to start of defibrotide for (1) all patients before/after days 1, 2, 3, 4, 7, and 14, using Fisher’s exact test and (2) patients starting defibrotide on a particular day before/after days 1, 2, 3, 4, 7, 10, 14, comparing event-free survival rates for all days (P<.001), except Day 14 (2.6% of patients started defibrotide before Day 14). The trend test for particular initiation days also showed a significant trend over time for higher Day +100 survival with earlier defibrotide initiation post-diagnosis in both the overall HSCT group and MOD subgroup (P<.001). Adverse events (AEs) and serious AEs occurred in 70.8% and 53.4% of patients, respectively. Other than VOD/SOS and MOD, the most common AE was hypotension (11.7%) and most common serious AE was respiratory failure (7.3%).

Summary/Conclusions: In this exploratory analysis of final study data, earlier defibrotide initiation post-VOD/SOS diagnosis significantly improved Day +100 survival, confirmed by the Cochran-Armitage test (P<.001). No specific day provides a clinically meaningful cutoff for better Day +100 survival, suggesting that later intervention retains value if treatment must be delayed.

RED BLOOD CELL DISTRIBUTION WIDTH (RDW) AS AN ACUTE GRAFT VERSUS HOST DISEASE PREDICTOR MARKER IN ALLOGENIC STEM CELL TRANSPLANTATION

B. Robredo1, F. Sarton1, M.A. Duran1, A. Gutierrez1, A. Sampol1, L. Lo Riso1, J.M. Sanchez-Raga1, B. Lopez Andrade1

1Hematology, Hospital Universitario Son Espases, Palma Mallorca, Spain

Background: The red blood cell distribution width (RDW) is a common parameter for measuring anisocytosis in the study of anemia. Recently it has been regarded as a surrogate marker of inflammatory and adverse outcome in several diseases. Acute graft-versus-host disease (GVHD) is a common complication of allogeneic hematopoietic cell transplant (allo-HSCT) which is related to inflammation in the context of damage of the host tissue and the release of inflammatory cytokines. We decided to study the utility of this potential inflammatory marker in the setting of GVHD in the allo-HSCT.

Table 1.
Aims: RDW values were evaluated at the day of infusion (RDW0), we choose this point in time to evaluate the tissue injury and inflammation secondary to the conditioning regimen, in order to evaluate if there is a major incidence of GVHD.

Methods: We retrospectively evaluated 103 patients who had underwent allo-HSCT for different indications at our center, with a median follow up of 12.8 months (0-235) at our center. The population consisted of 59 males and 44 females, the median age was 43.7 years. The RDW was collected from the hemogram at the day of the HSCT cell infusion, before it was performed (table 1). The IBM SPSS STATISTICS program was used for all statistical analyses. Differences were considered statistically significant when \( p < 0.05 \). The median of RDW values in our study was of 16.4 (11.2-38.5). The areas under the receiver operating characteristic (ROC) curves of RDW were \( \leq 18.4 \) and \( > 18.4 \) for the selection of the increased RDW cutoff. We evaluated the association of increased RDW (>18.4) with the development of GVHD. A survival analysis of the association of different levels of increased RDW was performed. A subgroup analysis of the Haploidentical HSCT patients (N=13) was also evaluated.

Figure 1.

Results: The presence of increased RDW >18.4 was strongly associated with an increased risk of developing acute GVHD (\( p=0.009 \)) being present in 80% of the patients. In the haploidential HSCT subgroup an increased RDW >16 was associated with acute GVHD. (\( p=0.044 \)). There was no association of chronic GVHD with elevated RDW at day 0 (\( p=0.563 \)). The survival analysis didn’t found an association of high RDW levels with mortality or survival (\( p=0.301 \)) but a tendency to an increased survival was show between the RDW level subgroups. Where a higher RDW seems to have a better survival, but this should be evaluated in a wider sample.

Summary/Conclusions: RDW at day 0 is a feasible predictor factor of Acute GVHD, most likely as a secondary surrogate marker of inflammation secondary to the conditioning regimen. The presence of other factors contributing to the RDW increase (secondary to other comorbidities) cannot be ruled out, but by itself RDW it’s an easy and affordable prognosis marker for aGVHD that should be further evaluated.

E1556

COMPARISON OF THE BEEAM CONDITIONING REGIMEN AND THE BEAM CONDITIONING REGIMEN IN THE AUTOLOGOUS TRANSPLANTATION FOR HL AND NHL

S. Lozenov1,2, P. Ganeva1, B. Spassov1, Y. Petrov1, G. Arnaudov1, G. Mihaylov1
1NSHAITHD, Sofia, Bulgaria
2Department of Transfusion Medicine, Medical University of Sofia, Sofia, Bulgaria

Background: The BEAM has established itself as a standard of care conditioning regimen in the autologous lymphoma HSCT setting for most transplant centres in Europe. Yet however various other regimens are being compared with it in order to achieved better safety profile, better OS and DFS, in order to improve results with chemorefractory and unfavourable patients. One such regimen is BeEAM (bendamustine, etoposide, cytarabine, melphalan).

Aims: We aimed to compare the efficacy of the BEAM and BeEAM conditioning regimens and to compare there myelotoxicity profile.

Methods: We evaluated retrospectively 114 patients, receiving auto-HSCT at the National Specialized Hospital for Active Treatment of Hematological Diseases in Sofia for relapsed/refractory HL or NHL for the period from 1.01.2013 to 1.07.2016 with a follow-up of patients up to 1.11.2016. 92 of the patients received BEAM and 22 received BeEAM. 2 and 3 year OS and DFS were compared, CR rates and the average time periods to hematological recovery.

Results: The OS at 2 and 3 years respectively was 86.1%, 86.1%, for BeEAM and 78%, 71% for BEAM, the DFS at 3 years was 76.4% in BeEAM and 73.2% for BEAM, provided that the differences did not have statistical significance. The CR rate was 63.63% in the BeEAM group versus 50% in the BCU group. 22.72% of the patients receiving BeEAM in SD or in diseases progression achieved CR versus 10.86% respectively for the BEAM group. The mean time to hematological recovery for neutrophils was 11.27 days (BeEAM) versus 10.24 days (BEAM) and 12.64 days (BeEAM) versus 11.12 days (BEAM) for platelets.

Summary/Conclusions: BeEAM appears to be a non-inferior alternative conditioning regimen to the standard BEAM, it shows a trend towards higher myelotoxicity, but also a trend towards better short-term results in chemoresistant patients.

E1557

DOUBLE UMBILICAL CORD BLOOD TRANSPLANTATION IN ADULTS: CORRELATION OF ALLELE-LEVEL HLA MATCHING WITH OUTCOME AND WHICH CORD BLOOD UNIT WILL BECOME DOMINANT

M. Weslendorf1,2, D. Hogge1, K. Song1, S. Narayanan1, S. Nante1, R. Broady1, M. Barnett1, C. Tozza1, A. Gervio1, Y. Abou Mourad1, D. Sanford1, M. Power1, D. Forrest1, S. Heather1, N. Thomas1
1Leukemia/BMT Program of BC, Vancouver General Hospital, Vancouver, Canada

Background: Umbilical cord blood (UCB) has been used for alternative donor transplantation for the past 3 decades. Graft failure is not uncommon due to higher degrees of histoincompatibility between recipient and UCB units and fewer hematopoietic precursors in the product. To improve engraftment rates, especially in larger (i.e. adult) patients (pts), two UCB units can be used. Double UCB transplantation (DUCBT) is being utilized at many centres although it has been noted that, while both units may contribute to engraftment, only one unit becomes “dominant” – i.e. persists to provide long-term hematopoiesis. A variety of predictors of which unit will become dominant have been suggested, primarily the unit that is more closely HLA-matched or the unit with the highest total nucleated cell (TNC) count.

Aims: To determine the likelihood of engraftment, incidence of GVHD, influence of TNC count and HLA mismatch on survival and selection of the dominant cord following DUCBT in adults with high-risk hematologic disorders.

Methods: A retrospective review was performed of adult pts undergoing DUCBT at the referral centre for British Columbia. Recipients signed informed consents for all clinical trials in which they participated. HLA typing at A, B, C and DRB1 loci was done on all pts using high-resolution allele-level testing (HRT). HRT was available at these 8 loci for both UCB units in 25/31 pts; for the remaining units, class I typing was done by serology. UCB units selected had to be ≥4/6 match at A, B (serologically) and DRB1 (by HRT). Combined TNC count for the units had to be ≥30x10^6/kg recipient weight. Conditioning was Flu Darabine 40mg/m2 x4 and TBI 150 cGy x8; GVHD prophylaxis was Tacrolimus/Mycophenolate. Pts received G-CSF 300 mcg s.c. daily from day +1. Outcomes were compared using Fisher’s exact test.

Results: Between 06/09 and 09/16, 31 pts underwent DUCBT - 11 males, 20 females with median age 50 years (range 19-59). Diagnosis was acute myeloid leukemia (AML; n=12), acute lymphoid/mixed phenotype leukemia (n=7), chronic lymphoproliferative disease (n=5), MDS (n=4) or other (n=3). All 31 pts recovered ANC>0.5x10^9/L at median of 20 days (range 14-72). Platelet count reached >20x10^9/L in 26/31 pts at median of 38 days (range 24-188). Acute GVHD developed in 26/31 pts (84%) and chronic GVHD in 17 of the 26 pts (65%) that survived to day +100. Seventeen pts (55%) remain alive, in contin-
uous remission at median follow-up of 3 years (range 0.5-7.0). Ten pts (32%) experienced non-relapse mortality from GVHD (5 pts), infection (4 pts) or unknown cause (1 pt). Four pts (13%) had relapsed at 3.5, 10 and 12 months. Outcomes for pts when the best cord unit match was 0-2 antigen-mismatched (Ag-MM) were superior (8/12 alive and well) to those pts when the best unit was 3Ag-MM (3/9 alive and well; p=0.20). Unexpectedly, 6/9 pts whose best unit was ≥4 Ag-MM are alive and well. Information on the dominant cord was available on 19 pts (Table 1); in 15/19 pts, the dominant cord was the same or a better HLA match compared to 4/19 with a dominant cord that was an inferior HLA match (p<0.001). However, the TNC was of less importance with the lower TNC unit being dominant as frequently as the higher TNC unit for each HLA match category (Table 1).

Table 1.

**Summary/Conclusions:** DUCBT is effective in adults with life-threatening hematologic disorders. With current UCB inventories, conditioning therapies and supportive care, graft failure is rare - even in adults. The sharing rate between the UCB unit and the patient is a better predictor than the TNC regarding which unit will become dominant. Pts receiving well-matched UCB units (0-2 Ag-MM) may have better outcomes than pts receiving 3 Ag-MM units although successful outcomes can be seen even with a high degree (>4 Ag-MM) of HLA incompatibility.

**E1558**

**CLINICAL ANALYSIS OF HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR 46 ACTIVE RELAPSED AND REFRACTORY ACUTE PEDIATRIC LEUKEMIA**

L. Yuan1, S. Xue1, J. Wang1. 1Department of Hematology, Aerospace Center Hospital, Beijing, China

**Background:** Given the dismal prognosis for relapsed and refractory (R/R) acute leukemia, many physicians discourage offering hematopoietic stem cell transplantation (HSCT) to adults with bone marrow (BM) blasts over 25%. Therapeutic recommendations for pediatric subjects with a similar situation are not available.

**Aims:** With no significant alternative managing options for these patients, more data are required to make an informed and patient tailored decision.

**Methods:** We retrospectively analyzed the preliminary outcome of 46 active R/R pediatric AML or ALL patients (aged 16 ALL relapsing at the time of the study) with transplants between 2012 and 2016. Median age at HSCT was 13 years. Active R/R disease was all confirmed by cytogenetic/molecular genetics and aggressive clinical course. Median bone marrow blasts was 46.4% (5-99%). Of note, 27 patients had over 50% blasts in BM, The earliest transplants were conditioned with conventional Bu/Cy or TBI/Cy regimen, thereafter, all received intensified conditioning including FLAG/TBI (N=21), FLAG/Bu/Cy (N=2) and CLAG/Bu/Cy (N=10). Immuno-suppressive agents withdrawal started since day 30 if no acute GVHD occurred. The use of post-HSCT intervention including donor lymphocytes infusion and intraluke-2 injection were performed to reduce relapse. Median follow-up of the whole cohort was 19 months (3-53 months).

**Results:** Forty-five (97.8%) achieved CR following HSCT. One died of infection before engraftment. All 3 death occurred before 90 day due to relapse. Transplant-related mortality at year 1 was 15.2%. Acute GVHD incidence was 49.3% (grade III 20.4%), chronic 59.5%. Relapse was the major cause of treatment failure and occurred in 28.3% of patients at a median of 1 year post HSCT. Two-year overall survival and leukemia-free survival were 44.8±9.5% and 27.6±9.5%, respectively. Survival of AML patients was superior to those of ALL. Refractory disease in ALL patients were equivalent to those with relapsed refractory AML which not in ALL. Blast percentage ≥50% in the BM pre-HSCT, TBI based conditioning and chronic GVHD proved to be favorable prognostic features.

**Summary/Conclusions:** This may validate decision making on if this special group of patients should receive HSCT as salvage treatment.

**E1559**

**POST-TRANSPLANT HIGH-DOSE CYCLOPHOSPHAMIDE AFFECT T-CELL RECONSTITUTION IN BONE MARROW, BUT NOT IN PERIPHERAL BLOOD STEM CELLS RECIPIENTS**

E. Mikhailtsova1, 2, M. Drokov1, J. Davydlova2, L. Kuzmina1, N. Popova1, D. Pliska1, V. Veselyeva1, O. Koroleva1, Z. Konova1, N. Kapranov2, I. Galtsева2, E. Parovichkina1, V. Savchenko1. 1BMT department, 2Laboratory of immunophenotyping, National Research Center for Hematology, Moscow, Russian Federation

**Background:** Hematopoietic stem cell transplantation (HSCT) the only curative therapy for many patients with hematologic malignancies. Occurrence of complications and mortality after allo HSCT still high and it's strongly associated with immune reconstitution. Despite the wide-spread of Post-Transplant High-Dose Cyclophosphamide (PTCy) immune reconstitution and immunological safety of this method is still poorly understood.

**Aims:** Evaluate immune reconstitution profile in patients who received HSCT with and without PTCy.

**Methods:** 62 patients who underwent allogeneic PBSC in our institution were analyzed in 2 groups; patients with PTCy (n=28) and without PTCy (n=34). The total cohort had 21 males and 40 females, and had median age of 33 years (range 18-61). All patients had hematological malignancy. 21 patients underwent myeloablative conditioning and 41 patients non-myeloablative. In 41 patients received bone marrow transplant. The GVHD prophylaxis consisted of a combinations of ATG-PTCy-CsA-MMF (n=10), ATG-PTCy (n=5), Mono- CsA (n=1), ATG-CsA-MMF-MTX (n=20), CsA-MTX (n=2), ATG-CsA-MTX (n=2), CsA-MMF-MTX (n=1). In 21 patients received PSCS. The GVHD prophylaxis consisted of combinations of ATG-PTCy-CsA-MMF (n=4), ATG-PTCy (n=8), ATG-CsA-MMF-MTX (n=8), ATG-CsA-MTX (n=1). 21 patients had progression disease before transplantation, this could affect the results. Immune reconstitution profile was tested via serial flow cytometry analysis of peripheral blood on day +1, +30, +60 and +90 after allo-HSCT. Anti-CD3 FITC, anti-CD16PE, anti-CD56 PE, anti-CD45 Per-CP-CY5.5, anti-CD4 PE-Cy7TM, anti-CD19 APC, anti-CD16 PE-Cy7, anti-CD62L FITC (BD Biosciences, USA); anti-CD14PE, anti-CD16PE, anti-HLA-DR APC (ebioscience, USA) were used to defined white blood cells subsets.

**Results:** In a bone marrow recipients the number of CD4+ cells was significantly lower when using PTCy (see Figure 1). On day 14 CD4+ cells count for bone marrow recipients was 42,6±29,99; on day 30 - 114,29±42,36; on day 60 – 140,81±52,53; on day 90 - 126,83±26,12. On day 14 CD4+ cells count for PBSC recipients for treatment failure was 47,47±19,99; on day 11 months (range 5-48); 15/36 (41%) of relapsed patients suffered aGvHD stage III/IV; 6/36 (17%) experienced non-relapse mortality from GVHD (5 pts), infection (4 pts) or infection (1 pt). Four pts (13%) have relapsed at 3, 5, 10 and 12 months. On day 60 – 140,8±58,22; on day 90 - 162,93±62,94. At the same time when using the PBSC transplant number of CD4+ cells was not significantly different.

**Figure 1. Short-term reconstitution in BM and PBSC recipients with and without Post-HSCT-Cy.**

**Summary/Conclusions:** Lymphocyte recovery was inparred for the PTCy groups in the immediate post-HSCT period but quickly recovered. The mechanism of induction of immune reconstitution using PTCy on the + 3 + 4 day is limited to deletion of alloreactive T-cell clones, but also affects other leukocyte subpopulations (B cells, monocytes, granulocytes). The use of PTCy at +3, + 4 a day is immunologically safe method for prevention of GVHD.

**E1560**

**OUTCOMES OF PATIENTS RELAPSING FOLLOWING ALLOGENIC STEM CELL TRANSPLANTATION FOR AML IN FIRST CR: SINGLE CENTER EXPERIENCE**

D. Pastori1, 2, P. Carluccio1, M. Delia1, A. Ricco1, A. Russo Rossi1, M. S. De Candia1, A. Mestice1, V. Carluccio1, V. P. Gagliardi1, S. D’Agostino1, C. Pasciolla1, F. Albano1, G. Specchia1. 1Hematology with Transplantation-University Policlinico, Bari, Italy

**Background:** Allogeneic stem-cell transplantation (SCT) is a curative therapy for patients with AML but disease relapse continues to be the most common reason for treatment failure. There is no standard therapy for relapse after SCT and treatment results are very poor. Treatment options range from supportive care through chemotherapy and donor lymphocyte infusion (DLI) up to a second SCT from the same or a different donor.

**Aims:** We report a retrospective study of 36 patients AML relapsed patients following allogeneic stem cell transplantation in first CR.

**Methods:** Between 2000 and 2016, 130 adults with AML in first CR underwent allo-SCT. We identified 46/130 patients (27%) who had relapsed and proceeded to review the management and outcomes of these patients; the incidence of relapse was 20% and 54% after myeloablative and reduced intensity conditioning, respectively. The median time to disease relapse after allo-SCT was 11 months (range 5-48); 15/36 (41%) of relapsed patients suffered aGVHD grade II-IV or extensive cGVHD. At time of relapse 15/36 (41%) patients were still taking immunosuppressive treatment, which was immediately suspended.
Results: The patients were subdivided into three groups according to the salvage treatment received palliative/supportive care (PSC group, n=9, 25%), intensive chemotherapy alone (CHT group, n=18, 50%) and chemotherapy with immunotherapy (donor lymphocyte infusion or second SCT) (IT group, n=9, 25%). Median age at the start of treatment from relapse was 10, 20 and 25 days in the PSC, CHT and IT groups, respectively. In the CHT group, 3 patients (16%) died of primary graft failure during reinduction chemotherapy. In the IT group, 6 (66%) pts achieved a second CR after chemotherapy and DLI/second allo-SCT and 3 (34%) died of treatment toxicity. In the whole patients sample, median overall survival (OS) was 7 months (range 2-74), being 4, 5, 13 months in the PSC, CHT and IT group, respectively. Estimated 1-year and 2-years overall survival was 10%, 15%, 40% and 0%, 0%, 12% in the PSC, CHT and IT groups, respectively. In our experience, 3 independent factors for a longer OS after chemotherapy and immunotherapy have been identified: the absence of previous acute or chronic GvHD (HR=2.7,p<0.001), a longer interval between the allo-SCT and relapse than 12 months (HR=1.2, p=0.005) and age less than 40 years (HR=1.3, p=0.005).

Summary/Conclusions: This study shows that salvage chemotherapy (with DLI or second allo-SCT) provides the best results and should be offered, whenever possible, to patients with AML who relapse after allo-SCT performed in first CR. Patients undergoing chemotherapy alone had a poorer outcome. Our results underline the need to schedule a prospective protocol combining cytoreductive treatments and immunotherapy in patients in AML relapsing after allo-SCT.

Background: Patients with refractory HL after autologous SCT generally have poor clinical outcomes with available therapies and by far, allogeneic SCT represents the only strategy with a curative potential.

Methods: Patients with refractory HL undergoing stem cell transplantation (SCT) have become the standard of care for refractory/relapsed Hodgkin lymphomas (HL), leading to durable responses in approximately 50% of relapsed patients and a minority of refractory patients. Patients with refractory HL after autologous SCT generally have poor clinical outcomes with available therapies and by far, allogeneic SCT represents the only strategy with a curative potential.

Aims: We examined allogeneic transplantation outcomes patients with HL. Chemorefractory following last salvage treatment.

Results: 39 patients with HL who received allogeneic SCT in chemorefractory disease, from 2000 to 2016 were retrospectively studied. The median age was 34 years (range 16-57 years) and 23 (59%) were male. The majority of patients (80%) had a prior autologous SCT. Most (90%) patients received reduced-intensity conditioning, 59% received matched sibling donor and 41% matched-unrelated donor grafts.

Results: 36 patients survived beyond 100 days and were evaluable for chronic GVHD of whom 22 (61%) remained free of cGVHD and 14 (39%) developed cGVHD. The disease at day 100 post transplant was reported in 36 out of 39 evaluable patients. 7 (19%) achieved a CR, 11 (31%) had a PR, 15 (42%) a stable disease and 3 (8%) had progressive disease. Following transplantation 30 (77%) patients have relapsed or progressed at a median time of 12.7 months (range 1-39 months) post-transplant. With a median follow-up of 28 months (range 3-95 months) 7 patients remain alive in complete remission, 2 are in stable disease and 26 have died. The Kaplan-Meier estimates PFS at five years was 18%. 6 patients (18%) died of non-relapse mortality (NRM) at a median of 300 days (range 28 days - 40 months) following transplantation. The causes of death included infection (n=2), GVHD (n=3), multi-organ failure (n=1).

Summary/Conclusions: Allogeneic SCT seems to be a viable option for patients who are refractory to salvage chemotherapy, especially because better results are obtained when this treatment is applied earlier. Despite the reduction of NRM and GVHD, disease relapse still represents the major issue in the setting of allogeneic SCT failure. The availability of novel agents resulting in objective responses may eventually result in increased eligibility for allogeneic SCT.

Results: Oral mucositis (OM) is one of the main complication during stem cell transplantation (SCT). It has an incidence varies between 47-100%. Numerous prevention strategies have been studied. However, the recommendations of the international guidelines have low evidence to back them up. Cryotherapy is used to reduce OM in conditions that use Melphalan. In our center, we have the cryotherapy implemented in our OM prevention protocol since 2012.

Aims: The main aim is to compare the results in terms of incidence and severity of OM measured according to World Health Organization scale in patients in whom cryotherapy was applied and in whom it was not applied as well as the necessity of using morphine and parenteral nutrition. The secondary endpoint is to analyze the occurrence and duration of fever and documentation of infection.

Methods: We used a cohort of patients with plasma cell dyscrasias who underwent autologous stem-cell transplant with conditioning melphalan 200, Busulfan-Melphalan 140 or melphalan 100 in hemodialysis regimen in which cryotherapy was not applied (2007-2011) and another cohort in which was applied since 2012 (2012-2016).

Results: The baselines characteristics can be seen in table 1. All patients in both groups had OM. In the cryotherapy and non-cryotherapy groups, the distribution was respectively: grade I 20% vs 16%, grade II 40% vs 10.8%, grade III 31.4% vs 59.4% and grade IV 8.5% vs 13.5%. We observed a reduction in the incidence of severe mucositis (grade III and IV) in the group in which cryotherapy was used against the cohort in which it was not (40% vs 72.9%, p=0.005). The need for morphine was also lower in the cryotherapy cohort (64% vs 72% p=0.149). The use of parenteral nutrition was lower in the non-cryotherapy group (8.5% vs 13.5%, p=0.7). The prevalence of fever was predominant in the cryotherapy group (51% vs 43%, p=0.48), but and infection was documented on more occasions in cryotherapy group (27% vs 81%, p=0.04). The median number of days the patients were discharged from the cryotherapy group was lower (+14 vs +15 median days, p=0.39) and the mortality at day 100 was higher in the non-cryotherapy group (0% vs 8%, p=0.24).

Decreased mucositis degree was associated with both univariate and multivariate analysis only with cryotherapy (p=0.01 and p=0.0003). Hazar ratio was 0.81 (IC 95% 0.06-0.55).

Table 1.

Summary/Conclusions: In our center, cryotherapy reduces significantly the severity of mucositis. The use of morphine and parenteral nutrition and other complications do not present such a drastic decline, probably because they influence the gastrointestinal mucositis, which is not combated with cryotherapy. With this results, we are encouraged to continue to include cryotherapy in our protocols.

Results: Reduced incidence of primary graft failure in patients undergoing haploidentical stem cell transplantation: a single center experience.

Aims: Reduced incidence of primary graft failure in patients undergoing haploidentical stem cell transplantation (HSCT). It has an incidence varies between 47-100%. Numerous prevention strategies have been studied. However, the recommendations of the international guidelines have low evidence to back them up. Cryotherapy is used to reduce OM in conditions that use Melphalan. In our center, we have the cryotherapy implemented in our OM prevention protocol since 2012.

Methods: We used a cohort of patients with plasma cell dyscrasias who underwent autologous stem-cell transplant with conditioning melphalan 200, Busulfan-Melphalan 140 or melphalan 100 in hemodialysis regimen in which cryotherapy was not applied (2007-2011) and another cohort in which was applied since 2012 (2012-2016).

Results: The baselines characteristics can be seen in table 1. All patients in both groups had OM. In the cryotherapy and non-cryotherapy groups, the distribution was respectively: grade I 20% vs 16%, grade II 40% vs 10.8%, grade III 31.4% vs 59.4% and grade IV 8.5% vs 13.5%. We observed a reduction in the incidence of severe mucositis (grade III and IV) in the group in which cryotherapy was used against the cohort in which it was not (40% vs 72.9%, p=0.005). The need for morphine was also lower in the cryotherapy cohort (64% vs 72% p=0.149). The use of parenteral nutrition was lower in the non-cryotherapy group (8.5% vs 13.5%, p=0.7). The prevalence of fever was predominant in the cryotherapy group (51% vs 43%, p=0.48), but and infection was documented on more occasions in cryotherapy group (27% vs 81%, p=0.04). The median number of days the patients were discharged from the cryotherapy group was lower (+14 vs +15 median days, p=0.39) and the mortality at day 100 was higher in the non-cryotherapy group (0% vs 8%, p=0.24).

Decreased mucositis degree was associated with both univariate and multivariate analysis only with cryotherapy (p=0.01 and p=0.0003). Hazar ratio was 0.81 (IC 95% 0.06-0.55).
Aims: The aim of the study was to evaluate the incidence and risk factors of primary graft failure (PGF) in patients with lymphoma who underwent haploidentical hematopoietic stem cell transplantation (haplo-HSCT) compared to those of HLA-matched HSCT in alternative sources of stem cells for allo-HSCT.

Methods: We retrospectively analyzed 40 consecutive patients who underwent HSCT from 2014 to 2016: unmanipulated for 20 adults and graft engineering for 20 children (CD34 selection/CD45RA depletion, n=14). The stem cell source was mobilized peripheral blood in all cases. GCSF was systematically used from day 5 until engraftment. We used descriptive statistical methods for analysis.

Results: Patient characteristics are described in Table 1. Conditioning regimen was Bu-Flu-Cy (n=18, adults), Thio-Bu-Flu (n=2, adults), Flu-Mel-Thio for all pediatric patients. ATG was used in 6 children and TLI in 14 children. All adult patients were given PT-Cy. Only one adult patient had high titer donor specific anti HLA antibodies and was desensitized with plasma exchange, Rituximab and IVIG before transplantation. All patients engrafted before day 28 and no PGF diagnosis was established in our serie. We found that 4 patients (3 children, 1 adult) required a boost of CD34 selected graft from the same donor for secondary GF and poor graft function.

Summary/Conclusions: PGF incidence described in literature is 5-10%, we did not find any primary graft failure in our serie. Desensitization therapy appeared to be effective in one patient with anti HLA antibodies. All CD34 boosts were performed for secondary graft failure/poor graft function due to treatment toxicities or viral infections. Unfortunately, analysis of causes and risk factors for secondary GF requires a larger number of patients to be determined.

RESULTS OF HAPLOIDENTIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION IN PATIENTS WITH LYMPHOMA: A SINGLE CENTER EXPERIENCE

Z. Gulbas1,*, D. Cekdemir1,2, I. Dora1,2, E. Er1,2
1Hematology and Hemotherapy, 2Pediatric Hemato-oncology, Hospital Universitario La Paz, Madrid, Spain

Background: Hematopoietic stem cell transplantation (HSCT) is an alternative for patients without HLA matched donors. However, primary graft failure (PGF) and graft versus host disease are still limitations derived from allogeneity due to HLA mismatch. T cell depleting approaches (in-vivo with post-transplant cyclophosphamide (PT-Cy) or ex-vivo with graft engineering) and surveillance for anti HLA antibodies are strategies intended to reduce these complications. PGF has a high mortality, and treatment with a second graft is not well defined in terms of donor, source, graft engineering or conditioning.

Aims: Our objective is to describe the incidence and risk factors of PGF and treatments if needed.

Methods: We retrospectively analyzed 40 consecutive patients who underwent HSCT from 2014 to 2016: unmanipulated for 20 adults and graft engineering for 20 children (CD34 selection/TCRαβ depletion, n=14; and CD34 selection/CD45RA depletion, n=14). The stem cell source was mobilized peripheral blood in all cases. GCSF was systematically used from day 5 until engraftment. We used descriptive statistical methods for analysis.

Results: Patient characteristics are described in Table 1. Conditioning regimen was Bu-Flu-Cy (n=18, adults), Thio-Bu-Flu (n=2, adults), Flu-Mel-Thio for all pediatric patients. ATG was used in 6 children and TLI in 14 children. All adult patients were given PT-Cy. Only one adult patient had high titer donor specific anti HLA antibodies and was desensitized with plasma exchange, Rituximab and IVIG before transplantation. All patients engrafted before day 28 and no PGF diagnosis was established in our serie. We found that 4 patients (3 children, 1 adult) required a boost of CD34 selected graft from the same donor for secondary GF and poor graft function.

Summary/Conclusions: PGF incidence described in literature is 5-10%, we did not find any primary graft failure in our serie. Desensitization therapy appeared to be effective in one patient with anti HLA antibodies. All CD34 boosts were performed for secondary graft failure/poor graft function due to treatment toxicities or viral infections. Unfortunately, analysis of causes and risk factors for secondary GF requires a larger number of patients to be determined.

COLLECTION OF PERIPHERAL BLOOD HEMATOPOIETIC PROGENITOR CELLS (PBPC) FROM HEALTHY DONORS: 15 YEARS SINGLE CENTER EXPERIENCE

B. Aguado1,*, E. Jimenez Barral1, A. Arriero1, J. Cornago1, Y. Paz1, I. Vicuña1, V. Gomez1, R. de la Camara1, A. Figuerola1, A. Alegre1
1Hematology, H.U. La Princesa, Madrid, Spain

Background: Hematopoietic stem cell transplantation (HCT) is, nowadays, a consolidated therapy within the treatment of multiple hematological pathologies. In the last two decades, the main method of obtaining hematopoietic progenitor cells is blood leukapheresis after mobilization with granulocyctic colony growth factors (G-CSF).

Aims: To describe the experience of our center in apheresis of healthy family donors in the last 15 years. Furthermore, analyze the influence of different variables on the procedure and the yields obtained.

Methods: retrospective analysis was performed on 189 hematopoietic progenitor cell collection (HPCC) from January 2002 to December 2016. The study was carried out at Apheresis Unit, Hospital de La Princesa, Madrid, Spain. Progenitor cells mobilization was performed with G-CSF in all cases at a dose of 10mg/kg b.w. Apheresis device was COBE Spectra in all cases and citrate was the anticoagulant used for all the apheresis procedures. All donors were carefully evaluated and informed on the donation procedure and signed an informed consent for apheresis. The venous access used was mostly peripheral venous access in antecubital veins, and in only 7 cases (3.7%) central venous catheter was required. Donor details studied were age, sex, AB0 group, number of apheresis, number of CD34+ per kilogram collected, and processed volume.

Results: among the 189 donors, 85 were females and 104 were males (45% vs 55%). The hematologic pathologies that motivated transplantation were, in order of frequency, Acute Myeloid Leukemia (AML) (40.2%), Myelodysplastic Syndrome (MDS) (13.8%), Acute Lymphoblastic Leukemia (ALL) (10.1%), Hodgkin’s Lymphoma (HL) (8.5%), Non-Hodgkin’s Lymphoma (NHL) (6.3%), Multiple Myeloma (MM) (5.3%), Chronic Myeloid Leukemia (CML) (4.2%), other (11.8%). Among donors most of recipient AB0 group was A and in 123 of all cases (65%) donor and recipient had the same group. Median weight of donors was 74 Kg and in recipients was 70.5 Kg. Median age of our donors was 50 and median age of recipients was 51 years. Twenty donors were >65 years (10.6%) and 10 were >70 years (5.3%). Median of processed volume was 13 liters, but if we stratify that volume by recipient’s weight, in those whose were heavier than 100 kg, median of processed volume was 18 liters. Two apheresis procedures were performed only in ten donors. Of these, 2 were older than 70 years (20% of total donors over 70 years of age) compared to 8 under 70 years of age (4.5% of all patients in that age range). The median of CD34+ /kg collected, and processed volume.

Summary/Conclusions: donor age and weight discrepancy with recipient were the factors that significantly affected PBPC collection. These factors had also an impact in the amount of liters of volemia processed, although in most cases only one apheresis procedure was enough. Adverse effects of apheresis for PBPC collection were the same as for other apheresis procedures such as those related to venous access, almost always peripheral one and citrate toxicity.

Table 1.

Summary/Conclusions: PGF incidence described in literature is 5-10%, we did not find any primary graft failure in our serie. Desensitization therapy appeared to be effective in one patient with anti HLA antibodies. All CD34 boosts were performed for secondary graft failure/poor graft function due to treatment toxicities or viral infections. Unfortunately, analysis of causes and risk factors for secondary GF requires a larger number of patients to be determined.

E1564

RESULTS OF HAPLOIDENTIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION IN PATIENTS WITH LYMPHOMA: A SINGLE CENTER EXPERIENCE

Z. Gulbas1,*, D. Cekdemir1,2, I. Dora1,2, E. Er1,2
1Bone Marrow Transplantation Department, 2Anadolu Medical Center, Kocaeli, Turkey

Background: Allogeneic hematopoietic stem-cell transplantation (allo-HSCT) is a potentially curative treatment for a variety of hematologic malignancies and nonmalignant hematologic disorders. However, only about a third of candidates for allo-HSCT have HLA-matched siblings. For patients who lack HLA-matched siblings, partially HLA-mismatched (haploidentical) related donors are good alternative sources of stem cells for allo-HSCT.

Aims: In this retrospective, single center study we evaluated safety and efficacy of haploidentical allo-HSCT compared to those of HLA-matched allo-HSCT in patients with lymphoma.

Methods: A total of 81 lymphoma patients (Hodgkin and Nonhodgkin) with a mean age of 42 years who underwent allo-HSCT (HLA matched n=46, haploidentic n=35) between July 2010 and July 2016 were analyzed. All patients received Cyclophosphamide (Cy) 50mg/kg i.v. on days +3 and +4. All patients initiated CsA day +5, and then adjusted according to the plasma levels. In addition to CsA, all haploidentical allo-HSCT recipients received MMF until day +35.

Results: There were no significant differences in age, sex, diagnosis, disease status up-front HSCT, or transplant characteristics between the groups except a higher median number of stem cells infused in haploidentical group (p=0.004). The median follow-up was 13 months for haploidentical group and 12 months for HLA-matched group. Outcomes of patients are summarized in Table 1.
E1566

ALLORESPONSES OF HUMAN T-CELLS FROM ADULT PERIPHERAL BLOOD AND UMBILICAL CORD BLOOD ARE DIFFERENTIALLY IMPACTED BY LENALIDOMIDE - IMPLICATIONS FOR AHSCT

C. Besley1, E. Kotsiou1, R. Petty1, A. Sangaranigam2, C. Chelala2, E. Ghazaly1, R. LeDieu1, J. Gribsen1, J. Davies1
1Centre for Haemato-Oncology, 2Centre for Tumour Biology, Barts Cancer Institute, London, United Kingdom

Background: Immunomodulatory drugs (IMiDs), such as lenalidomide provide a tool to enhance both direct anti-tumor and graft-versus-tumor effects after allogeneic haematopoietic stem-cell transplantation (AHSCT). However, early clinical experience with IMiDs after AHSCT using adult peripheral blood (APB) as a stem cell source has been limited by induction of graft-versus-host disease. Characterization of the mechanisms by which IMiDs can modulate allosresponsive T-cells from different cell sources could facilitate more effective use of these drugs in the setting of AHSCT.

Aims: To use in vitro modelling to identify changes in allosresponsive of APB and umbilical cord blood (UCB) T-cells after exposure to the widely used IMiD lenalidomide.

Methods: We have used multi-parameter flow cytometry and gene expression profiling to perform an in-depth characterisation of the phenotypic and genotypic effects of clinically relevant concentrations of lenalidomide treatment on T-cells during allogeneic co-culture. Using GCSF-mobilised APB (GMPB), steady state APB and UCB PBMC as responder cells in allogeneic co-culture we have been able to compare the differential effect of lenalidomide on these three cell sources. Allogeneic responder cells were labelled with CFSE (carboxyfluorescein diacetate succinimidyl ester) to allow quantification of allo-proliferation. Responder T-cell subsets including naive, memory, activated, cytotoxic and regulatory were interrogated. Functional effects of lenalidomide treatment including cellular capacity to produce cytokines, degranulate and exert direct cytotoxicity was also assessed. RNA was extracted from highly purified proliferative and non-proliferative CD8+ T-cell fractions following a combination of magnetic and flow-sorting and gene expression changes assessed by Affymetrix whole genome array and qRT-PCR.

Results: We demonstrate that lenalidomide increases net alloproliferation of APB T-cells by selectively enhancing allospecific proliferation of CD8+ T-cells. These CD8+ T-cells have enhanced effector memory differentiation, are enriched for polyfunctional effectors, and have a distinct gene expression profile with altered expression of key immunoregulatory genes and pathways. This effect on CD8+ T-cell proliferation was seen across all 3 cell sources. Importantly a differential effect on CD4+ T-cell responses was observed depending on cell source. Lenalidomide treatment of APB results in no change in CD4+ T-cell proliferation overall, but leads to reduced frequencies of CD4+ regulatory T-cells (Treg). In contrast lenalidomide treatment of GMPB resulted in a significant increase in CD4+ T-cell proliferation, with no effect on Treg cell frequencies. Most strikingly, although lenalidomide treatment of UCB T-cells during allostimulation results in a similar increase in alloreactive effector CD8+ T-cells, it also reduces allospecific proliferation of CD4+ T-cells and selectively expands frequencies of Treg, resulting in a net reduction in UCB T-cell alloproliferation.

Summary/Conclusions: Our findings show that lenalidomide has a qualitatively different impact on T-cell responses from different cell sources, with a potentially tolerogenic effect on UCB T-cells. These findings have important implications for the future use of IMiDs in the setting of AHSCT.

E1567

USING MARKER GENES ANALYSIS INSTEAD OF MLR ASSAY FOR IDENTIFICATION OF FUNCTIONAL CD4+FOXP3+ REGULATORY T CELLS IN GVHD PROPHYLAXIS

1Division of Transfusion Medicine, Department of Medicine, Taipei Veterans General Hospital and National Yang-Ming University School of Medicine, 2Institute of Biological Chemistry, National Taiwan University, Taipei, 3Department of Life Science, Fu-Jen University, New Taipei City, Taiwan, Republic of China

Background: There are two types of CD4+CD25+Foxp3+ regulatory T cells (Treg), natural Treg cells (nTreg): developing in thymus, and induced Treg cells (iTreg) arising from CD4+ naïve T cells. The Treg cells have been considered important for maintenance of immunological tolerance and correlate with the occurrence of GVHD in some studies. Establishing a quick method to identify the functional iTreg cells is worthy of focusing. Five to ten percent Tregs could be found in human CD4+ T cells and should be expanded via classical in vitro culture. Therefore, using qPCR for marker genes analysis instead of MLR (mixed lymphocyte reaction) assay is an important issue.

Methods: Mouse splenocytes were prepared from mouse spleen. Human PBSC were prepared from peripheral blood (PB) of healthy donors by Ficoll-Hypaque density gradient centrifugation. All T cells were isolated by negative selection, then CD4+naïve T cells were harvested. CD4+ naïve T cells were activated with anti-CD3/CD28 beads in the presence of IL-2, TGF-β and retinoic acid (RA) containing RPMI1640 medium. The protocol is showed in Fig. 1.

Results: Seven genes for qPCR analysis were used to identify the functional iTreg cells. We used the different proportions of iTreg cells in total naïve T cells for 7 genes expression analysis and MLR assay to investigate the relationship between different expression profile of iTreg cells and functional. iTreg cell gene expression analysis were shown in Fig2. It indicated that the different proportion of iTreg cells could show the different expression profile of these genes. Obviously, the FoxP3 gene expression increased in a great level. Based on our previous

Figure 1.
experiments, iTreg cells induction could be TGF-b1 dependent. After different amount of TGF-b1 induction, the genes expression profile also showed the coincidence of the data in Fig.2 (Fig.3). Using the same iTreg populations, MLR assay have been investigated for 5 days. The T cell suppression percentage would be dependent on the iTreg cells proportion (Fig.4A and B). It indicated that the gene expression levels can represent the biological function of iTreg cells. It’s the better way to identify the iTreg cells. Further, we have used PBMC for Treg cell induction, the marker genes expression analysis also showed in Fig.5. After comparing with IL-2 cultured T cells, the genes expressions revealed the difference in between iTreg cells and un-induced T cells.

Summary/Conclusions: Our study showed that MLR assay should spend 3 to 5 days for identification of the functional iTreg cells, however, the marker genes analysis took only one day for that. Besides, MLR assay is a more complicated method than qPCR analysis. Using simple analysis for human iTreg cells functional identification could save the time for clinical application and might prevent GVHD occurrence effectively.

OXIDANT-ANTIOXIDANT SYSTEM IN PATIENTS WITH MULTIPLE MYELOMA

L. Aleksanian1,*, L. Rybakova1, S. Kapustina1, S. Gritsaev2, S. Bessmeltsév2
1Biochemistry laboratory, 2Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Multiple myeloma (MM) is one of the most widespread malignant B-cell lymphoproliferative disorders and is characterized by a clonal proliferation of atypical plasma cells in bone marrow or, less frequently, in extramedullary locations synthesizing monoclonal immunoglobulins. Currently, autologous hematopoietic stem cell transplantation (auto-HSCT) is recognized as the standard method of treatment for young patients (≤65 years old) with MM. Moreover, the best auto-HSCT results are observed in patients who have received new medication (thalidomide, bortezomib, and lenalidomide) during induction therapy and who have achieved at least a very good partial response, which leads to a significant increase in overall survival. However, studies reflecting the impact of this kind of treatment on the dynamics of oxidant-antioxidant indicators are virtually non-existent. At the same time, the possibility of treating developing diseases by prescribing medication makes the problem highly relevant.

Aims: The aim of the study was to investigate the state of OS-AOS in patients with MM during auto-HSCT.

Methods: We studied 20 patients (11 men and 9 women, mean age 49 years) who followed auto-HSCT after high-dose melphalan. The control group consisted of 50 age- and sex-matched healthy persons. The plasma levels of malonic dialdehyde and ceruloplasmin as well as activities of superoxide dismutase and catalase were measured by standard biochemical techniques. In erythrocytes, the level of non-protein thiol groups was studied. The state of OS-AOS was investigated in each patient four times: before and after conditioning with melphalan, at the moment of maximal leucocyte decrease and after complete reconstitution from cytopenia.

Results: We have found the features of impaired balance in OS-AOS in MM patients before as well as in course of auto-HSCT. The level of malonic dialdehyde in MM patients was not significantly different from that in the control group. At the same time, ceruloplasmin plasma level as well as catalase activity were significantly increased in patient group (p<0.05), whereas the level of non-protein thiols groups was decreased in MM (p<0.05). The results of our study have shown, that an imbalance of OS-AOS is frequently seen in MM patients and, possibly, could influence the course of auto-HSCT.

Summary/Conclusions: The results of the study indicate a high frequency of occurrence of disturbance of the condition of OS-AOS in patients with MM. The imbalance in the functioning of this system is not entirely eliminated in the process of treating the patients with MM using auto-HSCT. The question of the necessity and methods of the possible correction of OS-AOS in patients with MM, particularly during auto-HSCT, requires further study.

E1569

SURFACE RECEPTOR EXPRESSION PROFILE DEFINES ALLOREACTIVE DONOR CD8+ T-CELLS AFTER MURINE ALLOGENIC HEMATOPOIETIC CELL TRANSPLANTATION

Background: Acute graft-versus-host disease (aGvHD) is a severe and often life-threatening inflammatory complication of allogeneic hematopoietic cell transplantation (allo-HCT). aGvHD is mediated by alloreactive donor T cells attacking the gastrointestinal tract, liver, and skin of the host. Efficient strategies to improve aGvHD-related morbidity and mortality will rely on more precise methods than preemptive immunosuppression to consistently predict aGvHD and abrogate disease manifestation without exposing patients to an unwarranted risk for infectious complications. Recent insights into the multistep-pathophysiology of aGvHD provide a good basis for the development of new tests to identify individual patients at risk before the onset of aGvHD.

Aims: As pathologic T cell responses rely on spatiotemporally defined programs of T cell activation, acquisition of effector functions, and homing to GvHD target tissues it appeared attractive to assess receptor expression profiles of peripheral blood T cells as potential predictive markers.

Methods: Therefore, we characterized the surface receptor expression profile of peripheral blood donor lymphocytes early after allo-HCT in two independent murine models across minor histocompatibility antigens (miHAg) with multicolor flow cytometry. C57Bl/6 (H-2b, Thy1.1+) or B10.D2 (H-2d, Thy1.1+) T cells plus bone marrow cells were transplanted in conditioned (8Gy) miHAg mismatched BALB/c (H-2b, Thy1.2+) and syngeneic C57Bl/6 (9Gy) or BALB/c (H-2d, Thy1.1+) recipients. To identify suitable predictive markers, we compared the expression pattern of allo-HCT recipients to syngeneic HCT recipients and untreated wild type controls.

Results: Comparing a panel of T cell surface receptors, we found the homing markers CD44, integrin, and E-selectin ligand highly up-regulated on allogeneic peripheral blood donor CD8+ T cells at peak time points of cell migration. The combination of these homing markers with the activation markers CD25 and CD69 at later time points and low expression levels of L-selectin allowed to define alloreactive donor T cells.

Summary/Conclusions: Based on this data we propose that alloreactive CD8+ T cells can be identified in miHAg allo-HCT recipients upon their homing receptor expression pattern as soon as six to ten days before the onset of aGvHD.
**Thalassemias**

**E1570**

**SOLUBLE FORM OF TRANSFERRIN RECEPTOR IS ASSOCIATED WITH AGE AT DIAGNOSIS AND RISK OF THERAPEUTICAL INTERVENTION AND IRON OVERLOAD IN PATIENTS WITH NON-TRANSFUSION-DEPENDENT THALASSEMAIA**

A. Meloni1,*, A. Spasiano 2, P. Ricchi2, L. Pistoia1, A. Carrà 3, C. Cosmi 4, R. Rosso5, A. Scaccetti6, V. Positano1, R. Righi7, S. Renne8, A. Pepe1

**Background:** The soluble transferrin receptor (sTfR), that fully reflects the marrow erythropoietic activity, was found to have not only a striking diagnostic accuracy in predicting the risk of extramedullary haematopoiesis (EMH), but also in scoring disease severity in non-transfusion-dependent thalassemias (NTDT).

**Aims:** We retrospectively evaluated the relationship between sTfR and some fundamental events in the life and in the management of patients with NTDT.

**Methods:** We considered 111 NTDT patients with four genetic entities of NTDT: homozygous or compound heterozygous state for β-thalassemia, triplicated α chain disease, α/β-thalassemia, and thalassemia intermedia. sTfR was measured by the T2* Magnetic resonance Imaging (MRI) technique.

**Results:** The group with homozygous or compound heterozygous for β-thalassemia had the higher sTfR levels. sTfR values were negatively related to age at diagnosis (R=−0.462, P<0.0001) and to age at first transfusion (R=−0.703, P<0.0001). ROC curve analysis showed that a sTfR value of 5.3 mg/L could differentiate β-TM patients with PH risk with 90% sensitivity, 75 U/mL could differentiate β-TM patients with PH risk with 90% sensitivity, and in unsplenectomized patients a significant positive correlation was found between sTfR values and spleen diameter (R=0.572, P=0.0001). sTfR values were negatively related to age at starting chelation therapy (R=−0.564, P=0.044). Patients never chelated showed significantly lower sTfR values than patients under chelation therapy (see Figure). sTfR values were significantly correlated with serum ferritin levels (R=0.321, P=0.0001), but no with LIC values.

**E1571**

**LOW SERUM FERRITIN LEVELS DO NOT PROTECT FROM CARDIAC AND HEPATIC IRON OVERLOAD IN PATIENTS WITH THALASSEMAIA MAJOR**

A. Meloni1,*, A. Spasiano2, P. Ricchi2, L. Pistoia1, A. Carrà3, C. Cosmi4, R. Rosso1, A. Scaccetti6, V. Positano1, R. Righi7, S. Renne8, A. Pepe1

**Background:** The estimation of serum ferritin levels is the most commonly employed test to evaluate iron overload in Beta Thalassemia Major (TM).

**Aims:** The aim of this multicenter study was to assess the distribution of serum ferritin levels in a cohort of well-treated TM patients and the possible protective role of really low levels versus iron accumulation in the heart and in the liver.

**Methods:** We considered 1548 TM patients regularly transfused and chelated consecutively enrolled in the MIOT (Myocardial Iron Overload in Thalassemia) Network. Myocardial and hepatic iron burdens were quantified by the T2* technique. For the heart a multislice approach was adopted in order to calculate segmental and global T2* values. Hepatic T2* values were converted into liver iron concentration (LIC) values.

**Results:** A group of patients was enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) network and underwent hepatic iron overload assessment by the T2* Magnetic resonance Imaging (MRI) technique.

**Summary/Conclusions:** To measure the levels of IMA in 45 children and adolescents with β-TM compared with 30 healthy controls and assess its relation to lipid peroxidation, vascular complications and subclinical atherosclerosis.

**Methods:** β-TM patients without symptoms of heart disease were studied focusing on transfusion history, chelation therapy, serum ferritin, malondialdehyde (MDA) and IMA levels. Echocardiography was performed and carotid intima-media thickness (CIMT) was assessed.

**Results:** IMA and MDA levels were significantly higher in β-TM patients compared with controls (p<0.001). IMA was higher among patients with heart disease and pulmonary hypertension (PH) risk than those without. Serum IMA and MDA levels were elevated among patients with serum ferritin >2500 µg/L compared with patients below this cutoff. TM patients compliant to chelation had a significantly lower IMA levels than non-compliant ones.

**Figure 1.**

**Summary/Conclusions:** Low serum ferritin values, even in the normal range, do not per se exclude cardiac and hepatic iron overload, although decreasing the risk. Before to consider a reduction of the chelator dose in patients whose serum ferritin levels have reached the target, a MRI scan should be performed in order to measure iron levels in the different organs.
91.4% specificity and positive predictive value of 75% and negative predictive value 97%; area under the curve 0.883 (95% confidence interval 0.752-0.959).

In addition, the cutoff of IMA at 17.5 uM/l could differentiate β-TM patients with heart disease with 80.5% sensitivity, 88.9% specificity and positive predictive value of 96.7% and negative predictive value 73.3%; area under the curve 0.887 (95% confidence interval 0.750-0.962). Significant positive correlations were found between IMA levels and disease duration (r=0.311, p=0.045), white blood cell count (r=0.322, p=0.031), serum alanine aminotransferase (r=0.388, p=0.01) and aspartate aminotransferase (r=0.382, p=0.037). IMA and MDA levels were positively correlated (r=0.503, p=0.001) and there was a significant positive correlation between these two markers and serum ferritin (IMA; r=0.645, p<0.001 and MDA; r=0.567, p<0.01) among TM patients. IMA levels were positively correlated to TRV (r=0.621, p=0.008), while negatively correlated to ejection fraction (r=0.412, p=0.014) and fractional shortening. Both IMA and MDA were positively correlated to CIMP (r=0.607, p<0.001 and r=0.597, p<0.001, respectively).

Summary/Conclusions: Our results highlight the role of oxidative stress in the pathophysiology of vascular complications in thalassemia. IMA could be useful for screening of β-TM patients at risk of cardiopulmonary complications and atherosclerosis because its alteration occurs in early subclinical disease.

E1573
SERUM N-TERMINAL PRO-BRAIN NARIURETIC PEPTIDE LEVEL AND ECHOCARDIOGRAPHIC TISSUE DOPPLER ABNORMALITIES IN PATIENTS WITH BETA THALASSEMA MAJOR
M. El-Tagui1, I. Mahmoud2, H. Agha3, S. Mohamed1, M. El-Ghamrawy1, 1Pediatrics, 4Clinical and Chemical Pathology, Faculty of Medicine, Cairo University, Cairo, Egypt.

Background: Heart disease remains the major cause of morbidity and mortality in thalassemia patients. Multiple pathologies have been implicated in the development of cardiac dysfunction in these patients including: cardiac iron overload leading to right ventricular diastolic then left ventricular systolic dysfunction, chronic anemia and tissue hypoxia. Because congestive heart failure is the main cause of death in these patients, early recognition of cardiac dysfunction may be useful in modifying therapy in a timely manner. Tissue Doppler imaging (TDI) is an echocardiographic method that is able to measure the tissue velocity of the blood flow at the heart ventricles and it is commonly used to assess the myocardial function.

Methods: Thirty beta thalassemia major patients with a mean age of 12.93±2.07 years regularly followed up at Pediatric Hematology Clinic, Cairo University and thirty aged matched healthy control subjects were included. Conventional, M-Mode and TDI echocardiography were performed to all patients and control subjects in addition to cardiac magnetic resonance (CMR) for studied patients. Serum NT-proBNP level was measured using enzyme linked immunosorbant assay (ELISA).

Results: Tissue doppler imaging revealed a significant difference of ratio of the early (e') to late (a') right ventricular filling velocities (RV e'/a' ratio) between cardiac iron overloaded patients reflecting early diastolic dysfunction in cardiac iron overloaded patients. Myocardial performance index of left ventricle (LV_TEI index) by TDI showed significant difference in cardiac iron overloaded patients compared to non cardiac iron overloaded patient (mean 0.59 ± 0.04 with p-value 0.003) indicating decrease in ventricular relaxation due to iron overload and restrictive cardiomyopathy. SerumBNP level was significantly higher among patients compared to controls (mean 99.18± 72.43pg/ml versus 18.93± 9.65pg/ml respectively with p-value< 0.001) and among cardiac iron overloaded patients compared to non cardiac iron overloaded (mean 212.31±57.18pg/ml versus 64.75±26.69pg/ml respectively with p-value<0.001). We found positive correlation between level of BNP and frequency of the blood transfusion/year, RV/e'a and LV TEI_TDI index with (p value 0.006, <0.001 and 0.030 respectively) denoting early diastolic impairment in asymptomatic thalassemia patients.

Summary/Conclusions: Asymptomatic thalassemia major patients under chelation therapy may have diastolic and or systolic dysfunctions that could not be detected by conventional echocardiography but could be highlighted by TDI. CMR, TDI and serum BNP level measurement are promising tools for accurate assessment of cardiac functions and iron overload in thalassemia patients.

PRENATAL DIAGNOSIS OF HEMOGLOBINOPATHIES IN NORTHERN GREECE. 15 YEARS REPORT
S. Theodoroudi1, N. Prapas2, A. Sotiriadis2, A. Athanasiadis2, T. Daglis2, O. Karakasidou1, E. Skatharoudi 1, D. Adamidou1, M. Economou1, A. Teli1, B. Delaki3, E. Voskaridou 3, A. Balassopoulou 3, T.-A. Vyzantiadis 4, 1Thalassemia Unit, 2Obstetric Department, Hippokration General Hospital, Thessaloniki, 3Thalassemia Centre, Laikon General Hospital, Athens, 4Microbiology Department, 4Obstetric Department, Aristotelion University, Thessaloniki, Greece

Background: Hemoglobinopathies constitute the most frequent monogenic disorders worldwide and thalassemias are the most frequent genetic disorders. In Northern Greece the frequency of h-B thalassemia is 0.45% of the population are carriers of the Hb S mutation. The rate of β-thal carriers could be as high as 15-20% in some areas. The risk of giving birth to an affected child depends on the incidence of the thalassemic gene and this may vary from 1/24 to 1/150 in married couples. The National Program for prevention of Thalassemia was established in 1973. Through population screening and prenatal diagnosis programs Greeks and immigrants are screened and counseled.

Aims: We report our findings on prenatal diagnosis of thalassemias and hemoglobinopathies in Northern Greece over a 15 year period (2001-2015).

Methods: During the 15 year period, a total of 33,837 subjects were screened and examined. We included couples at risk for β-TM and as couples with sickle cell disease. 3,659 couples were screened for hemoglobinopathies. In 371 couples both partners carried an abnormal Hb gene and counseling was offered and 329 pregnancies were found at risk of giving birth to an affected child. The genes interactions were in 245 pregnancies at risk for thalassemia major offsprings and 84 for sickle cell disease ones. Prenatal diagnosis was attempted from 12 weeks of gestation (n=298), in few cases by amniotic fluid sampling (n= 21) collected at 16-18 weeks. Few late comers were tested by fetal blood sampling at 20 week of gestation (n=5). The remaining 42 pregnancies involved couples who were double heterozygotes for mutations that did not cause severe clinical disease and were exempted from prenatal diagnosis. The gene interactions were as follows β-thal / α thal, β-thal in combination with Hb E-Saskatoon or D-Punjab, HbE/HbE, Hb E-Saskatoon /with carrier of HbS, and Hb O / Hb O. β-thal or α thal in combination with D Punjab, Hb Brugg/β-thal, silent β-thal silent β-thal. 91% of the couples were of Greek origin, and 9% were immigrants from North Africa, Asia, America and Eastern Europe.

Results: The number of births per year ranged from 8 in 1998 to 125 in 2006. The overall number of liveborn was 450. Of those affected, 240 were thalassemia major and 210 were sickle cell disease. The national Thalassemia Prevention Program has effectively decreased the incidence of the thalassemia major and sickle cell syndromes in our country and in our region.
was a strong relationship between ferritin and LIC values (R=0.656, P<0.0001) while in patients with steatosis the correlation was moderate (R=0.428, P=0.05).

Table 1.

Summary/Conclusions: Our data show that liver steatosis affected also patients with NTDT and should be suspected in presence of a ALT/AST ratio >0.89. Recently, serum ferritin thresholds to predict clinically relevant liver iron concentrations for guiding chelation therapy when MRI is unavailable in patients with (NTDT) have been provided. Our data show that the presence of liver steatosis may lead to overestimate the magnitude of iron burden and may be responsible for anticipating or exceeding chelation treatment in patients with NTDT in absence of a LIC evaluation.

CIRCULATING CELL-FREE DNA (cfDNA) AND INEFFECTIVE ERYTHROPOIESIS IN BETA-THALASSEmia INTERMEDIA
D. Tavazzi1, G. Graziadei2, A. Marcon2, L. Duca2, I. Nava2, M.D. Cappellini1,*, M. Sampietro3
1Dip. Scienze Cliniche e di Comunità, Università degli Studi di Milano, 2Dipartimento di Medicina Interna, Fondazione IRCCS Cà Granda Policlinico di Milano, 3Dip. Fisiopatologia Medico-Chirurgica e dei Trapianti, Università degli Studi di Milano, Italy

Background: Low concentrations of circulating cell-free DNA (cfDNA) are found in the plasma of healthy individuals and increase in a number of conditions, from autoimmune diseases and trauma. The mechanisms of release of cfDNA in the bloodstream are not fully understood: DNA could originate from cells undergoing apoptosis/necrosis in tissues or from cells released in the blood and subsequently lysed. Also the tissue origin of cfDNA is mainly unclear. It has been suggested that cfDNA, at least after bone marrow transplantation, could be mostly of hematopoietic origin. This finding prompted us to explore whether cfDNA is increased in patients with ineffective erythropoiesis (IE), a condition characterized by the over-proliferation and lysis/removal of erythroid precursors. This situation is common in thalassemias, mainly in non transfusion-dependent patients (NTDT).

Aims: The present study was designed i) to evaluate the behaviour of cfDNA in IE caused by beta-thalassemia, and ii) to assess whether cfDNA could be useful to quantify IE.

Methods: We studied 49 beta-thalassemia intermedia (TI) patients (mean age 41 years, range 16-65), 23 of whom were splenectomized. No evidences of tumor, trauma or autoimmune diseases have been observed in any patient at the time of the study. Eighteen healthy subjects were also included as control group. The study was approved by the local ethical committee. DNA was extracted by QIAgen silica-based micro-spin columns from 200 mL of K3EDTA plasma, and its concentration determined fluorometrically using the fluorescent dye PicoGreen. Biochemical and hematologic parameters were determined in all patients as a part of laboratory routine. Reticulocytes and peripheral erythroblasts (EBL) were counted by automated procedures. Soluble transferrin receptor (sTfR) and growth differentiation factor 15 (GDF15) were also measured by immunometric ELISA assays.

Results: In the 49 patients studied, plasma cfDNA concentrations ranged from 6.3 to 93.1 ng/mL and are significantly higher than in controls (median 21.8 vs 10.4, P<0.0001). Comparing non splenectomised (non-SPX) patients, we observed a significant increase of cfDNA in the SPX group (median 29.4 vs 19.3 ng/mL, P=0.0085). In the whole TI group, cfDNA concentration was significantly correlated with EBL (P<0.0001), LDH (r=0.52, P=0.0001) and AST (r=0.58, P<0.0001). Correlations of cfDNA were also observed with sTfR (r=0.45, P=0.0014) and GDF15 (r=0.56, P<0.0001). Notably, correlations with EBL (r=0.75, P<0.0001), AST (r=0.58, P=0.0036) and unconjugated bilirubin (r=0.54, P=0.0083) were observed only within the SPX group and not in non-SPX.

Summary/Conclusions: In this study we found that plasma cfDNA rises in TI patients compared to controls. Its concentration appears to correlate with both the amount of IE based on high number of EBL and the lysis of circulating erythroid precursors (both increased after splenectomy). We obtained preliminary evidences that circulating cfDNA concentration may be a suitable indicator of erythropoietic activity in TI patients. Results need to be extended on larger samples of patients’ population to investigate the possible use of plasma cfDNA as a feasible and reliable biomarker to describe/monitor the severity of IE and TI complications.

E1577
LEFT VENTRICULAR HYPERTROBECULATION BY CARDIAC MAGNETIC RESONANCE IN THALASSEmiA INTERMEDIA PATIENTS: FREQUENCY AND PROGNOSTIC ROLE
A. Meloni1,*, F. Macaione2, L. Pistola1, S. Pulini1, V. Santamaria2, M. Benni5, L. Sardella4, A. Barison1, G. Peritore2, V. Postiano1, S. Novo4, A. Pepe1

Background: Differentiation of left ventricle non-compaction (LVNC) from hypertrobeculated LV due to a negative heart remodeling in thalassemia intermedia (TI) can depends on the selected CMR criterion. The recently proposed Piga’s criterion (NC/C ratio threshold of >2.5, Am J Haem 2012) seems to have a low specificity to identify the true LVNC in TI. Anyway, the Piga’s criterion could easily detect a negative heart remodeling in TI patients.

Aims: The aim of our study was to prospectively assess whether the Piga’s criterion had a prognostic role for adverse cardiovascular outcomes in TI patients.

Methods: We studied prospectively 168 TI patients (81 males, mean age 38.32±11.61 years) consecutively enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network. Standard cine steady-state free precession sequences were acquired and used for the calculation of biventricular function parameters (short-axis) and for the calculation of the thickness of the non-compacted and the compacted myocardium (three diastolic long-axis views) in all 16 segments. The maximal NC/C ratio was considered. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis.

Results: Eight patients were excluded because a cardiac complication was present at the first CMR. The baseline mean age of the considered 161 TI patients was 38.32±11.61 years and 81 patients were males. The study population was divided into two groups: patients with Piga’s positive criterion (n=15, 9.31%) and with Piga’s negative criterion (n=146, 90.68%). No significant differences were found between the two groups in terms of demographic features and CMR parameters. The mean follow-up time was 57.50±21.87 months. Sixteen new cardiac events were recorded: 1 heart failure, 10 supraventricular arrhythmias and 5 pulmonary hypertension. Due to numerical reasons, it was possible to perform a Cox regression analysis only for arrhythmias and cardiac complications globally considered. Patients with Piga’s positive criterion had a significant higher risk of developing arrhythmias (hazard ratio=HR=7.19, 95% CI=2.02-25.51; P=0.002) and cardiac complications (HR=3.66, 95% CI=1.18-11.36, P=0.025). The figure shows the Kaplan-Meier survival curves. The Piga’s positive criterion remained a significant prognosticator also in a multivariate models including previous and resolved events (14 cardiac complications, of which 7 arrhythmias) (HR for arrhythmias=23.67; HR for cardiac complications=7.09).

Summary/Conclusions: Based on our data a NC/C ratio >2.5 provides prognostic information for patients with TI about the risk of developing cardiac complications.

E1578
NITRIC OXIDE DYSREGULATION IN BETA-THALASSEMIa MAJOR: RELATION TO PULMONARY HYPERTENSION
M. Elshinawy1,2, A. Elnegg3, A. Ghanem3, M. Wagdy4
1Pediatric Hematology, Sultan Qaboos University Hospital, Muscat, Oman, 2Pediatric Hematology, Faculty of Medicine, 3Hematology, Medical Research Institute, 4Clinical Pathology, Faculty of Medicine, Alexandria, Egypt

Background: Pulmonary hypertension (PH) is emerging as one of the most devastating complications of beta-thalassemia major. Chronic hemolysis and iron overload constitute a major source of strong oxidative stress. Free heme radicals and red cell membrane elements resulting from hemolysis have a negative effect on the intrinsic nitric oxide (NO) production and arginine availab
ability. Deficiency of both biochemical mediators promotes vasoconstriction of the pulmonary vasculature resulting in further endothelial dysfunction, with subsequent intensified reduction of nitric oxide. The role of nitric oxide dysregulation is well-studied in non-transfusion dependent thalassemias and in sickle cell disease, but yet not very well-characterized in beta thalassemia major.

Aims: The aim of our work is to study the relation between intrinsic nitric oxide level and the evolution of pulmonary hypertension in beta thalassemia major.

Methods: This is a case-control study, including all patients with beta thalassemia major above 12 years of age, undergoing follow up in pediatric hematology unit and in medical research institute, university of Alexandria, Egypt throughout a period of 6 months form 1st of July till 31st of December 2016. All patients were screened for pulmonary hypertension by echocardiography, and those who have high tricuspid regurgitant jet velocity (TRJV >2.5m/sec.) underwent cardiac catheterization.

Results: The present study included 52 thalassemic patients, 28 males and 24 females aged between 11 and 26 years. The patients were subdivided into two groups (17 patients with pulmonary hypertension (PH), proven by cardiac catheterization and 35 patients without pulmonary hypertension). Nitric oxide level (measured by ELISA) was significantly lower in patients as a whole compared to controls [median of 19 micromol/L versus 30 micromol/L (P=0.02)]. Similarly, nitric oxide was significantly lower in PH group compared to non-PH patients (P=0.001). In addition, there was a statistically significant negative correlation between serum NO level and serum ferritin level in all patients (r=-0.444, p=0.001).

Summary/Conclusions: In conclusion, NO reduction might contribute significantly to the development of pulmonary hypertension in patients with beta thalassemia major. This effect could be related to the degree of hemolysis, iron overload and the duration of disease. Further studies on the adverse pathophysiological effects of nitric oxide deficiency in beta thalassemia major e.g. its relation to coagulopathy and platelet aggregation are recommended.

SPECKLE-TRACKING ECHOCARDIOGRAPHY FOR DIAGNOSIS OF EARLY MYOCARDIAL DISEASE IN EGYPTIAN BETA THALASSEMIA MAJOR PATIENTS

A.A.C. Tantawy1,*, N.M. Habeeb2, N.H. Elshenoff2, E.M. Hasan1, A. Abdelhameed1
1Pediatric Hematology & Oncology, 2Cardiology department, faculty of medicine, Ain Shams University, 3Pediatric Hematology & Oncology, Ain Shams University, Cairo, Egypt

Background: The new parameters of cardiac function, derived from two-dimensional speckle-tracking echocardiography could be useful for an early diagnosis of cardiac involvement in transfusion dependent β-TM patients.

Aims: In this cross sectional study, our goal was to detect early myocardial disease in transfusion dependent β-TM patients using Echocardiography (Speckle Tracking Echo) to assess its specificity and sensitivity in comparison with cardiac MRI T2*.

Methods: This cross sectional study included 30 transfusion dependent β-thalassemia patients aged between 11-20 years recruited from the Pediatric Hematology and Oncology Unit, Children Hospital, Ain Shams University. All included patients were subjected to detailed medical history(including transfusion, chelation, hepatitis C virus history with calculation of mean serum ferritin in last 2 years) Radiological investigation included Echocardiography (Tissue Doppler and Speckle Tracking),MRI T2* were done.Cardiac affection by speckled was defined as decreased longitudinal strain less than 11 percentage or affection of any segment less than 11 percentage.

Results: Cardiac affection by speckled echocardiography was found in 10 patients(33.3%), 8 of them (80%) had normal ejection fraction and normal shortening fraction, while 9 had iron overload by Cardiac MRI T2*. Patients with mean serum ferritin level <2000 nmol/L in the last 2 years prior evaluation showed a significantly lower longitudinal strain (GLPSLAx) (P=0.043) which was further proved by a significantly negative correlation with the mean serum ferritin (P=0.002). No significant differences were found between both spelemonorized and non spelemonorized patients as regard speckle tracking echocardiographic measures. The ROC curve analysis revealed that GLPSLA4G a cutoff value of ≤21% was able to detect β-thalassemia patients having myocardial disease by cardiac MRI T2* with a sensitivity of 87.50% and specificity of 63.64%. Patients with cardiac iron overload by MRI T2* had significantly lower GLPSLAx &GLPSA4C and higher Ao Diam than those without cardiac iron overload (P=0.016, P=0.008, P=0.047 respectively). No significant difference between beta thalassemia patients with cardiac affection and those without cardiac affection as regard the duration of the disease, type and compliance of chelation therapy.

Summary/Conclusions: Although, Magnetic Resonance Imaging T2* technique holds high diagnostic accuracy for cardiac iron overload, its routine use is limited by its high costs, poor availability. We demonstrated in this study an abnormal global longitudinal strain despite preserved LV systolic functions among BTM patients; thus speckle tracking echo techniques might be considered as an alternative effective method to detect early myocardial disease before evident systolic dysfunction.

E1581

EFFICACY, SAFETY AND GENETIC BASIS OF VARIABILITY OF RESPONSE TO HYDROXYUREA THERAPY IN BETA THALASSEMIA: A SYSTEMATIC REVIEW

S. Khaliq1,*, E. Ismail1, A. Tantawy1, A. Adly1, E. Ismail1, A. Ahmed1, N. Yousef1
1Pathology, fauji Foundation Hospital/Foundation University Medical College Rawalpindi, 2Hematology, Hemophilia Centre, Rawalpindi, Pakistan

Background: Pharmacological agents such as hydroxyurea promote fetal hemoglobin production via a reactivation of β-genes. In β-thalassemia there is an imbalance in globin chains which could be ameliorated by the newly synthesized α-chains which neutralize the excess α-chains and therefore improves symptoms.

Aims: Systematic review of literature to evaluate the efficacy, safety and the genetic basis of variability of response to hydroxyurea therapy in beta-thalassemia patients.

Methods: Research sources used were: MEDLINE (PubMed), EMBASE (Ovid) and Cochrane from June 1993 till June 2016. Eligible articles were reviewed and data including patients’ characteristics, duration of treatment, outcome, toxicity and impact of genetic mutation on response to hydroxyurea therapy was extracted. Major responders were those who became transfusion independent after hydroxyurea treatment, partial responders had significant decline in transfusion requirements, poor responders did not respond to hydroxyurea therapy. Statistical analysis software package 16 was used for data analysis.

Results: Thirty eligible studies comprising of a total of 1822 patients with beta thalassemia were identified. Of these (n=9, 30%) evaluated the effect of hydroxyurea therapy on beta thalassemia major patients, (n=11, 33.3%) evaluated beta thalassemia intermediate patients while (n=10, 34%) included both beta thalassemia major and thalassemia intermedia patients. Mean age of patients was 13.5 years. Mean duration of hydroxyurea therapy was 3.4 years. The mean ±SD of hydroxyurea was 10mg/kg per day (1.15mg/kg). Table I showing number and percentage of patients having major, partial and poor response to hydroxyurea therapy. Only (n=12, 38%) studies evaluated the role of underlying genetic mutation on hydroxyurea response, out of these (n=6, 50%) studies found no significant correlation while (n=6, 50%) showed a positive correlation between common genetic mutations and hydroxyurea response. Hydroxyurea was found to be well tolerated, only (n=09, 01%) had transient myelosuppression.

Summary/Conclusions: Hydroxyurea is an effective and well-tolerated agent in the management of β-thalassemia (both intermedia and major). It reduces blood transfusion requirements either partially or completely in majority of patients. No significant correlation between response to therapy and underlying genetic mutation was found. More studies are required to fully establish the association of genetic mutation to drug response.

EVALUATION OF CONTINUOUS BLOOD GLUCOSE MONITORING METHOD FOR DETECTION OF ALTERATIONS IN GLUCOSE HOMEOSTASIS IN BETA-THALASSEMIA PATIENTS

M. El Samahy1, A. Tantawy1,*, A. Adly1, E. Ismail1, A. Ahmed1, N. Yousef1
1AinShams university, Cairo, Egypt

Background: Glucose metabolism disturbances, among other endocrinopathies, are a common feature of β-thalassemia major (β-TM). Pancreatic iron overload and diabetes mellitus (DM) are common in β-TM patients. However, the relationship between iron stores and glucose disturbances is not well defined. Continuous glucose monitoring system (CGMS) enables more diagnostic accuracy and a better achievement of an optimal glycemic control.

Aims: To assess the pattern of glucose homeostasis in patients with β-TM and detect early impairment in glucose metabolism and prediabetic state in β-thalassemia patients comparing oral glucose tolerance test (OGTT) and CGM system.

Methods: This cross sectional study was conducted on 200 patients β-TM patients. Patients were studied focusing on transfusion history, transfusion index, iron chelation therapy and compliance to chelation. Complete blood picture, markers of hemolysis, serum ferritin and random blood glucose (RBO) were measured. Patients with RBO ≥140mg/dL were subjected to OGTT, insertion of CGMS for 3 days, measurement of fasting C peptide, and serum insulin with calculation of HOMA-IR and assessment of HA1c.

Results: Screening with RBO revealed that 20 patients (10%) had RBO ≥140mg/dL. Using OGTT, 7 (3.5%) patients were in the diabetic range, 7 (3.5%) had normal OGTT while 6 (3%) had impaired glucose tolerance. The CGMS showed that 7 (3.5%) patients had IGT (6.5%) and 13 patients had diabetes
mellitus. The percentage of diabetic patients diagnosed by CGMS was significant lower than that with OGTT (p= 0.012). According to CGMS readings, 10 of the 13 patients with diabetes had abnormal HbA1c readings of diabetic range (6.5-9.9%) while 5 of the 7 patients with impaired glucose tolerance had HbA1c readings in the prediabetic range (5.5-6.1%). Serum ferritin were significantly higher among patients with RBG ≥ 140mg/dL (p= 0.001). It was noted that 65% of patients were noncompliant and 75% of patients on desferrioxamine therapy had RBG ≥ 140mg/dL. There was a significant positive correlation between HbA1C% and FBG among the studied thalassemia patients with elevated RBG≥ 140mg/dL, while HbA1C% was negatively correlated with fasting C-peptide. Serum ferritin was significantly correlated with RBG. As regards GDF-15 data, HbA1C was positively correlated to maximum blood glucose, average blood glucose, SDS blood glucose and area under the curve≥140mg/dL. The only significant independent factor for elevated RBG ≥ 140mg/dL was serum ferritin.

Summary/Conclusions: The use of CGMS in the diagnosis of early glycemic abnormalities (prediabetes) among patients with β-TM appears to be promising and superior to other known diagnostic modalities namely OGTT and HbA1c.

E1584
ASSOCIATION OF SP1 POLYMORPHISM IN THE COLLAGEN TYPE I ALPHA -1 (COL1A1) GENE WITH OSTEOPROSIS IN CHILDREN WITH BETA-THALASSEMIA
M. Hesham1,*, N. Khalifa2, M. Zakaria1, N. Elbazz2, D. AbdElmonem2
1Pedicatria, 2clinical pathology, Zagazig University Hospital, Zagazig, Egypt

Background: Osteoporosis is a progressive bone disease that is characterised by a decrease in bone mass and density that leads to an increased risk of fracture. Early detection of mutation at the Sp1-binding site on the COL1A1 gene is mandatory in order to initiate preventive therapy before the occurrence of fracture. The main target of our study was to investigate the possible relation between beta-thalassemia patients and RBG ≥ 140mg/dL.

Aims: To study the relationship between SP1 polymorphism in the collagen type 1 alpha 1 gene and the development of osteoporosis in patients with Beta thalassemia.

Methods: A prospective case control study was carried out in the Outpatient Clinic of Hematology Unit of Pediatric Department and Clinical Pathology Department at Zagazig University Hospitals on forty thalassemic patients (21 females &19 males) aged 6-18 years during their regular follow-up visits (22 patients with thalassemia major and 18 with thalassemia intermedia) and forty age- and sex-matched healthy children as a control group. All patients and control were subjected to full medical history, thorough clinical examination and laboratory investigations in the form of complete blood count, B12 electrolyses, Calcium level Serum ,alkalin phosphatase, Bone Density by DXA, Serum osteocalcin level and COL1A1 gene polymorphism by using polymerase chain reaction-restriction fragment length polymorphism technique (PCR-RFLP).

Results: There was highly significant difference between thalassemia patients and control group as regards serum levels of calcium, osteocalcin and alkaline phosphatase and DEXA results but no significant difference between thalassemia major and thalassemia intermedia patients. As regard COL1A1 genotype there was high percentage of heterozygous Ss (G/T) and homozygous ss (T/T) genotype in beta thalassemia major 55.63%, 13.67% than thalassemia intermedia 50.6%, 0% respectively. There was significant relation between COL1A1 genotypes and Calcium level (p=0.02). But there was no significant relation between COL1A1 genotypes and osteocalcin, alkaline phosphatase levels and DEXA among studied groups.

Summary/Conclusions: SP1 polymorphism in collagen gene could be of clinical value in identifying the thalassemic patients at risk of developing osteoporosis.

E1585
LEFT VENTRICULAR REGIONAL FUNCTION IN CHILDREN WITH BETA-THALASSEMIA WITH NO CARDIAC MANIFESTATIONS (FOUR-DIMENSIONAL ECHOCARDIOGRAPHIC STUDY)
M. El-Shamsy1,*, O. Tolba 1, W. El-Shehaby1, A. Elshamia 2, A. Fayed3, A. EIKholy 4, E. Eldosoky5
1Pediatrics, Faculty of Medicine, Tanta University, Tanta, 2Pediatrics, Ministry of Health, Basyun, 3Pediatrics, Ministry of Health, Kotor, 4Pediatrics, Ministry of Health, Zelfa, 5Pediatrics, Ministry of Health, Alexandria, Egypt

Background: Early detection of myocardial dysfunction is essential for the management of patients with thalassemia. Four-dimensional echocardiography imaging technique that analyzes the motion of tissues in the heart may be useful for detecting subclinical cardiovascular disease.

Aims: To evaluate the 4-dimensional echocardiographic strain in children with beta thalassemia major and correlate it with other echocardiographic parameters.

Methods: This is a cross sectional cohort study included 200 children, 1-18 years old. They were divided into: One hundred children with β-Thalassemia major with no clinical cardiac manifestations and 100 healthy children as a control, the age was matched with beta-thalassemia major. Complete blood count, serum ferritin and Four-dimensional echocardiographic strains (Longitudinal, Circumferential, Radial and Area strains).

Results: There was no significant difference between the two groups as regard mitral annulus systolic velocity (S wave), E/A ratio and iso-volumic acceleration but there was significant difference as regard to ejection fraction, left ventricle mass, sphericity index and myocardial performance index. The mean values of Left ventricular Strains (Longitudinal, Circumferential, Radial and Area strains) were significantly lower in patients with thalassemia (-14.8±6.1, -8.0±3.8, 32.3±10.6, 19.4±6.6) than controls (-19.1±3.5, -16.2±4.0, 34.7±10.9) but there was a positive correlation with 2-Dimensional strain.

Summary/Conclusions: Strain parameters of the left ventricle obtained by four-dimensional echocardiography can be a novel and promising technique for early detection of left ventricular dysfunction in children with thalassemia.

E1583
THE IMPORTANCE OF SERUM GDF-15 LEVELS TO ASSESS IRON OVERLOAD IN PATIENTS WITH THALASSEMIA MAJOR
M. Ucman1, U. Caliskan2,*, H. Tokgoz2
1Necmettin Erbakan University Erzurum Medical Faculty, Konya, Turkey, 2Pediatrie Hematologie and Oncologie, Necmettin Erbakan University Erzurum Medical Faculty, Konya, Turkey

Background: There is growing interest in noninvasive assessment of iron accumulation in patients with thalassemia major. Magnetic resonance imaging (MRI) have become widely available in recent times.

Aims: We aimed to evaluate the importance of serum GDF-15 levels for monitoring the iron overload in patients with beta thalassemia major.

Methods: Forty-six patients aged between 1 and 25 years were included in the study. Serum levels of GDF-15, ferritin, troponin, AST and ALT were studied.

Results: Serum GDF-15 levels were significantly higher among patients with RBG ≥ 140mg/dL than in normal levels. According to CGMS data, HbA1C was positively correlated to maximum blood glucose, average blood glucose, SDS blood glucose and area under the curve≥140mg/dL. The only significant independent factor for elevated RBG ≥ 140mg/dL was serum ferritin.

Summary/Conclusions: We demonstrated that serum GDF-15 levels were increased in thalassemia major patients. GDF-15 levels is correlated with hepatic iron overload but not cardiac iron overload. It may be due to lower number of thalassemic patients with abnormal cardiac T2* MRI. GDF-15 may be a valuable parameter to assess iron overload in thalassemia major, but further studies are needed.

Background: Hemoglobin (Hb) is a protein responsible for oxygen transportation from lungs to the entire body. It is composed by four globular subunits - the globins - each with a central core containing a heme molecule. Globins are encoded by the α- and β-globin gene clusters located at 16pter13.2 and 11p15.5, respectively. The pattern of globin gene expression during development is precisely controlled by the interaction of cis-regulatory genomic regions (located in close proximity to and far from genes) with trans-activating/silencing factors within permissive chromatin domains. Distal upstream of the α-globin genes there are four multispecies conserved sequences (MC5-R1 to R4) which are critical for the downstream globin gene expression. Deletions removing the α-globin genes and/or their distant MCSs give rise to α-thalassemia, one of the most common genetic recessive disorders worldwide, due to a reduced rate of α-globin chain synthesis. The severity of the pathology is variable ranging from a very mild microcytic hypochromic anemia to a moderately severe anemia associated with the formation of β4 tetramers resulting in HbH disease or an even higher reduction or complete absence of α-chains resulting in hemoglobin Bart’s hydrops fetalis, a condition generally incompatible with life.

Aims: The main objectives of this work were to characterize the molecular lesions underlying ten Portuguese cases of unusual α-thalassemia/HbH disease and to understand their origin and functional consequences.

Methods: After exclusion the most frequent molecular lesions associated with α-thalassemia, Multiplex Ligation-dependent Probe Amplification (MLPA) using the SALSA MLPA P140B HBA kit (MCR-Holland) was used to search for DNA deletions in the subtelomeric region of chromosome 16p. Additionally, specifically designed synthetic MLPA probes, as well as gap-PCR and Sanger sequencing were performed for more accurate deletion breakpoint mapping.

Results: We have found five distinct deletions and one indel, all in heterozygosity. The deletions range from approximately 3.3 to 323 kb and two of them are novel. The three larger deletions remove the entire α-globin cluster whereas the others remove totally or partially the distal regulatory elements keeping the α-globin genes structurally intact. The indel comprises the deletion of the MCS-R2 regulatory element and the insertion of a singular 39 bp DNA fragment possibly originating from a complex rearrangement involving chromosome 3. Finally, no α-globin gene cluster deletion or point mutation were found in a patient with α-thalassemia major, a very unusual case of acquired alpha-thalassemia associated with a myelodysplastic syndrome.

Summary/Conclusions: Our study widens the spectrum of molecular lesions and unusual molecular mechanisms by which α-thalassemia/HbH may occur and emphasizes the importance of diagnosing large α deletions to provide patients with appropriate genetic counseling.

VALUE OF HBA2 IN THE DIAGNOSIS OF BETA-THALASSEMINA MINOR “ATTENTION TO THE GRAY ZONE”

L. Reivais1,2, T. Magalhães Maia1, E. Cunha1, J. Pereira1, A.C. Oliveira1, C. Bento1, M.L. Ribeiro1

1Servicio de Hematologia Clinica, Centro Hospitalar e Universitaritio de Coimbra, Coimbra, Portugal

Background: The hypochromy for the alternative splicing mutation HB?: IVSI-6 (C>T) is the most frequent genotype of beta thalassemia intermediate in our population and was even termed “beta thalassemia intermediate type Portuguese” (Tamagnini et al, 1983). The IVSI-6 (C>T) carriers (heterozygous) are characterized by mild hypochromia and microcytosis, with a moderately increased in HbA2, that may be even less than 3.5%. The correct identification of these carriers is important, especially when facing a couple who intends to have children.

Aims: To evaluate the percentage of individuals with hypochromia and microcytosis and Hb A2 between 3.2% and 3.4%, who are beta thalassemia carriers, alerting for the need to adapt the cut-offs of HbA2 values to the genetic background of different populations.

Methods: Parameterized search of all the consecutive individuals evaluated in our laboratory from January 2007 to January 2016. The inclusion criteria were the simultaneous presence of hypochromia and microcytosis (adjusted to the age) and HbA2 values between 3.2% and 3.4% inclusive. The exclusion criteria were the presence and/or clinical information of sideropenia or sideropenic anemia, hemoglobin variants or alpha thalassemia. Sequencing of the entire HBB gene was performed by Sanger Sequencing.

Results: Respecting the inclusion and exclusion criteria we have identified 43 individuals with hypochromic and microcytic anemia, HbA2 ≥3.2% and ≤3.4%, in which the HBB gene mutations were screened. Among the 43 subjects, nineteen presented HbA2≥3.2% (9/43), eleven HbA2≥3.3% (11/43) and thirteen had HbA2≥3.4% (13/43). The IVSI-6 (C>T) mutation was identified in 2 subjects with HbA2≥3.2% (10%), 5 with HbA2≥3.3% (45%) and 7 with HbA2≥3.4% (54%). No other HBB gene mutations were detected. The remaining individuals are classified as probable alpha thalassemia and suggested continuation of the study, if warranted.

Summary/Conclusions: We have identified 14/43 (32%) individuals as beta thalassemia carriers who, for the conventional cut-off of HbA2 ≥3.5%, would not have been diagnosed. Based on this data, we propose that individuals with hypochromia and microcytosis, with normal or slightly elevated RDW, without sideropenia, with HbA2 between 3.2-3.4%, should be screened for mutations in the HBB gene, in order to rule out beta thalassemia carriers due to Beta+ mutations. As HBB IVSI-6 (C>T) mutation is one of the most frequent beta thalassemia mutations in Portugal, and in Mediterranean basin, it is necessary to deepen in its screening. The classic rule of HbA2 ≥3.5% for the diagnosis of beta thalassemia minor may underdiagnose this pathology and lead to an incorrect genetic counseling.

E1589

DIAGNOSIS OF HEMOGLOBINOPATHIES BY CAPILLARY ZONE ELECTROPHORESIS: EXPERIENCE WITH 925 CASES

P. Tripathi1, H.P. Patil1, R. Saxena1

1Dept of Hematology, All India Institute of Medical Sciences, New Delhi, India

Background: Hemoglobin capillary zone electrophoresis is a relatively newer technique as compared to HPLC for detection of abnormal hemoglobins. We share our first hand experience of using Capillary 2 Flex piercing instrument for diagnosis of hemoglobinopathies as a primary diagnostic modality

Aims: The main aim was to evaluate a new technology for diagnosis of hemoglobinopathy.

Methods: The capillary 2 Flex piercing instrument with Phoresis software for hemoglobin electrophoresis at alkaline pH was evaluated at our centre over a period of 1 year. A total of 925 sample runs were included in the analysis. The equipment was assessed on the following parameters: ease of operation, pre-analytical factors, identification, quantification and precision of hemoglobin variants including the rare variants. Further, we evaluated if capillary zone electrophoresis can be useful as a single method for diagnosis of hemoglobinopathies.

Results: The automation provided by capillary zone electrophoresis eased the problem of errors during sample preparation. The option for low sample volume mode is a great help in samples from children. The instrument could readily identify all common hemoglobins and the diagnosis was straightforward in 829 (90.7%) cases. In the rest 96 (10.3%) cases, the sample was required to be rerun because it lacked Hb A or Hb A2. This posed inconvenience because the electrophoretic zones get displaced and have to be derived after mixing it with normal sample. The machine is not specifically standardized for cord blood samples hence we are not performing tests on neonatal cord blood sample. The instrument could separately identify Hb E from Hb A2 which is a big scorer over HPLC, however, we found mild high Hb A2 both in heterozygous and homozygous Hb E cases (heterozygous Hb E, n-28 mean Hb A2- 3.9% and homozygous Hb E, n- 7 and mean Hb A2- 4.2%) leaving the doubt whether some adducts are still left. Identification of small peaks of Hb H could be difficult and requires other modalities to confirm. Two cases where Hb H was strongly suspected clinically and HB H inclusion test was positive showed small peaks of HB H (1.2% and 0.9% ) on HPLC. Hemoglobins falling into the same zone (eg Hb D- Punjab and Hb Q India) needed identification with second modality. Whenever encountered with problem of identifying certain abnormal peak, we resorted to HPLC for confirmation. Spectrum of hemoglobin variants encountered (n-298 cases, rest 627 showed normal results) in the study is listed in table below.

Summary/Conclusions: Capillary zone electrophoresis is an alternative method for Hemoglobinopathy screening. However, since the diagnosis of Hemoglobin variants mandates confirmation by a second method, HPLC cannot be replaced completely. Based upon the availability, workload and cost effectiveness, any of these two methods can be used as primary modality.

RELEVANT ROLE OF VON WILLEBRAND FACTOR-ADAMS13 AXIS IN HEPATIC ISCHEMIA-REPERFUSION INJURY
Y. Unsono1, 2, H. Matsui3, K. Nishio3, K. Okuchi4, M. Sho3, M. Sugimoto2
1Emergency and Critical Care Medicine, 2General Medicine, 3Surgery, Nara Medical University, Kashihara, Japan

Background: Hepatic ischemia-reperfusion (I/R) injury is a liver damage occurring during liver surgeries such as hepatic resection or transplantation, and denotes the major basis for graft dysfunction after transplantation. Although detailed mechanisms of hepatic I/R injury remain to be clarified, an excessive inflammatory response is thought to play a role in this regard.

Aims: Since recent studies suggest that von Willebrand factor (VWF) plays a pivotal role in a cross-talk between inflammation and thrombosis, we assumed that VWF may be involved in the pathophysiology of hepatic I/R injury. To test this hypothesis, we have used a mouse experimental model of hepatic I/R injury.

Methods: Mice were anesthetized with sodium pentobarbital and a midline laparotomy was then performed on a heating pad. Blood supply for left lateral and median lobes of liver (approximately 70% of the liver mass) was interrupted by cross-clamping the hepatic artery and portal vein with a microvascular atrumatic clip for 90 min. Then a clip was taken off to prevent the reperfusion of hepatic blood flow, which was monitored on the surface of left lateral lobe by Laser Doppler flowmetry (FDL21, Advance Co, Tokyo, Japan). The hepatic blood flow was measured again 24 h after reperfusion and mice were then sacriﬁced to evaluate liver histology and histochemical staining of liver tissue (collagen, neutrophil). VWF, ADAMTS13 activity and liver function tests (ALT, AST, ALP) were tested.

Results: As compared to WT mice, restoration of hepatic blood flow was signiﬁcantly greater in VWF-KO mice at 24 h after reperfusion (WT; 61±17% vs KO; 87±17%, expressed as the percentage of pre-ischemic value). Consistent with the hepatic blood ﬂow, the time-course analysis of serum alanine aminotransferase (ALT) at several time points after reperfusion revealed the lesser liver damages of KO mice (WT, 689±3270 and 1313±621 IU/L vs KO; 3043±1320 and 478±330 IU/L, at 3 h and 24 h after reperfusion, respectively). In addition, histological analysis conﬁrmed that neutrophil inﬁltration in the liver tissue of KO mice was signiﬁcantly reduced as compared to WT mice at 24 h after reperfusion. These impaired hepatic blood ﬂow and ALT values as well ascameraed neutrophil inﬁltration in WT mice were signiﬁcantly improved to an extent comparable to those of KO mice by the bolus injection of recombinant human ADAMTS13 (3 µg/mouse equivalent to 2800 U/kg, n=12) just prior to the I/R operation.

Summary/Conclusions: Our results altogether indicate that VWF-dependent inflammatory responses with neutrophil recruitment at ischemic sites are involved in pathophysiology of hepatic I/R injury, and functional regulation of VWF by ADAMTS13 may serve as a promising therapeutic option for hepatic I/R injury.

THE IMPORTANCE OF THE FULL BLOOD COUNT, JAK II AND ADAMS13 TESTING IN STROKE EVALUATION: A REVIEW OF 619 CONSECUTIVE YOUNG STROKE AND TIA PATIENTS
A. Taylor1, 2, V. Alakbarzade2, A. Chandrathava2, R. Simister2, A. Dados2, M. Mork2
1Haematology, 2Neurology and Stroke Medicine, University College London Hospital, London, United Kingdom

Background: Young ischaemic stroke patients undergo extensive investigations yet around 40% remain of undetermined cause. Complex and costly thrombophilia testing is routinely sent despite limited evidence linking to arterial thrombosis. A full blood count may be ignored but is potentially more helpful in this regard.

Aims: Since recent studies suggest that von Willebrand factor (VWF) plays a pivotal role in a cross-talk between inflammation and thrombosis, we assumed that VWF may be involved in the pathophysiology of hepatic I/R injury. To test this hypothesis, we have used a mouse experimental model of hepatic I/R injury. Methods: Mice were anesthetized with sodium pentobarbital and a midline laparotomy was then performed on a heating pad. Blood supply for left lateral and median lobes of liver (approximately 70% of the liver mass) was interrupted by cross-clamping the hepatic artery and portal vein with a microvascular atrumatic clip for 90 min. Then a clip was taken off to prevent the reperfusion of hepatic blood flow, which was monitored on the surface of left lateral lobe by Laser Doppler flowmetry (FDL21, Advance Co, Tokyo, Japan). The hepatic blood flow was measured again 24 h after reperfusion and mice were then sacriﬁced to evaluate liver histology and histochemical staining of liver tissue (collagen, neutrophil). VWF, ADAMTS13 activity and liver function tests (ALT, AST, ALP) were tested.

Results: As compared to WT mice, restoration of hepatic blood flow was signiﬁcantly greater in VWF-KO mice at 24 h after reperfusion (WT; 61±17% vs KO; 87±17%, expressed as the percentage of pre-ischemic value). Consistent with the hepatic blood ﬂow, the time-course analysis of serum alanine aminotransferase (ALT) at several time points after reperfusion revealed the lesser liver damages of KO mice (WT, 689±3270 and 1313±621 IU/L vs KO; 3043±1320 and 478±330 IU/L, at 3 h and 24 h after reperfusion, respectively). In addition, histological analysis conﬁrmed that neutrophil inﬁltration in the liver tissue of KO mice was signiﬁcantly reduced as compared to WT mice at 24 h after reperfusion. These impaired hepatic blood ﬂow and ALT values as well ascameraed neutrophil inﬁltration in WT mice were signiﬁcantly improved to an extent comparable to those of KO mice by the bolus injection of recombinant human ADAMTS13 (3 µg/mouse equivalent to 2800 U/kg, n=12) just prior to the I/R operation.

Summary/Conclusions: Our results altogether indicate that VWF-dependent inflammatory responses with neutrophil recruitment at ischemic sites are involved in pathophysiology of hepatic I/R injury, and functional regulation of VWF by ADAMTS13 may serve as a promising therapeutic option for hepatic I/R injury.

PERIPHERALLY INSERTED CENTRAL CATHETER (PICC) RELATED THROMBOSIS IN 230 PATIENTS WITH HEMATOLOGICAL MALIGNANCIES: A 6 YEARS SINGLE EXPERIENCE CENTER
M. Baile1, A. Vega1, M. López-Parrá1, M. Sánchez-Barba2, N. Arratibel1, B. Rodríguez1, M. Sastre1, O. Del Rey1, A.A. Martín1, M. Cabrero1, J.R. González-Porras1, J.M. Bastida1
1Hematology, Hospital Universitario de Salamanca, 2Statistic, University of Salamanca, Salamanca, Spain

Background: The use of peripherally inserted central catheters (PICCs) is widely extended in patients with hematological malignancies, not only to be treated with chemotherapy, blood cell transfusions, but also parenteral nutrition support or frequent analytical extractions. However, catheter-related thrombosis is one of its main complications. There are a few studies that evaluate this complication. We reported the experience of the PICC-related thrombosis (PRT) in our center.

Aims: To analyze the incidence of PRT, describe the clinical characteristics and management of these patients and identify the risk factors of PRT.

Methods: We performed a retrospective chart review of 230 adult patients diagnosed with hematological malignancies, in whom, experimented nurses tunneled PICCs with different technique: blinding Seldinger from 2010 to 2014 and guided by ultrasonography (US) from 2015 to 2016. PRT diagnosis was confirmed by Doppler US. Statistical analysis was performed using the SPSS package (v 20).

Results: The median age was 58 years (14-86) and 55.7% of the patients enrolled in the study were male. The most frequent hematological malignancies were: Non-Hodkin’s lymphoma (NHL=105; 45.7%) myeloid malignancies (acute myeloid leukemia and myelodysplastic syndromes=60; 26.1%), acute lymphoblastic leukemia (ALL=22; 9.6%), multiple myeloma (MM=19; 8.3%) and Hodgkin lymphoma (HL=17; 7.4%). In 188 patients (82%), PICC was tunneled when the active disease was presented. Only 51 patients (22%) received thrombophrophylaxis based on low molecular weight heparin (LMWH=27), aspirin (ASA=21) or vitamin K antagonist (VKA=3). PICCs were tunneled guided by US in 127 patients (55.2%), and the main location of tip catheter was in cava-right atrium region (66%). The overall incidence of PRT was 7% (n=16). The main diagnoses related to PRT were ALL (6), NHL (5), HL (3) and MM (1). PICCs were removed within 72 hours of PRT and treated with LMWH to a median of 4 months (range: 1-11). During follow-up, no patient had progression of thrombosis, or pulmonary thromboembolism. Finally, in the univariate analysis ALL, HL and L-ASA had significant impact on...

A STUDY OF VENOUS THROMBOEMBOLISM SUSCEPTIBILITY LOCUS FACTOR XI, ABO AND FIBRINOGEN IN A PORTUGUESE POPULATION SAMPLE
L. Maroco1,*, P. Raheja1, P. Olivera1, V. Pons1, E. Johansson 1, T. Canals1, F. Bosch1, A. Santamaria1,*, P. Martinho3, T. Fidalgo3, A.B. Sarmento2,3, M.L. Ribeiro1,3
1Research Center for Anthropology and Health (CIAS), 2Faculty of Medicine, University of Coimbra, 3Servicio Hematologica Clinica, Centro Hospitalar Universitario de Coimbra, Coimbra, Portugal

Background: Venous thromboembolism (VTE) is a multifactorial disease caused by a genetic background in combination with acquired risk factors and complex gene-environment interactions. VTE results from the development of a thrombus, usually in the deep veins of the leg (deep vein thrombosis, DVT) that can subsequently embolise to the lung (pulmonary embolism, PE). Classical inherited risk factors for VTE in European-ancestry populations include protein C and S deficiencies, factor V Leiden and prothrombin gene mutation (FII G20210A). Several other common and low-frequency susceptibility variants, mainly single nucleotide polymorphisms (SNPs) in loci ABO, FXI, FII, FV, FGG, GP6, KG1, PROC, SLC4A2, STXBP1, TSPAN15 and VWF, have been also found robustly associated with VTE. However, in the Portuguese population, the genetic background for VTE for most of these genetic susceptibility variants remains to be evaluated.

Aims: To investigate the association of five SNPs in the loci ABO (rs2519093 and rs8176719), FXI (rs2036914 and rs2289252) and FGG (rs2066865) with VTE in a sample of Portuguese patients.

Methods: A retrospective (2012-2015) case-control study with 119 cases of unprovoked VTE and 148 healthy controls from the Portuguese population was conducted, to evaluate allele frequencies of the five risk VTE SNPs in the Portuguese population and to assess the association between these alleles and the risk for VTE.

Results: FXI (rs2036914 and rs2289252) and FGG (rs2066865) SNPs were genotyped by real-time PCR with TaqMan probes. ABO rs2519093 and rs8176719 SNPs were genotyped by restriction fragment length polymorphism (RFLP). PLINK software was used to determine the allelic frequencies, concordance with Hardy-Weinberg equilibrium and association between risk alleles and VTE through logistic regression, in the additive model, estimating OR with 95% confidence intervals (95% CI) and p-values. The association between the cumulative number of risk alleles and the risk of VTE was assessed through Pearson χ2 using the Simple Interactive Statistical Analysis software (SISA).

Summary/Conclusions: The results estimated risk allele frequencies in the overall study population sample were: 0.212 for FGG rs2066865 (T), 0.62 and 0.50 for FXI rs2036914 (C) and rs2289252 (T), respectively, and 0.295 and 0.417 for ABO rs2519093 (T) and rs8176719 (C), respectively. The genotype distributions were in agreement with Hardy-Weinberg equilibrium for all SNPs. There was no significant change in allele and genotype frequencies among risk alleles and VTE through logistic regression under an additive model showed that FGG rs2066865 was associated with VTE (nominal p=0.029; OR=1.57, CI 95% 1.05-2.37) as well as ABO rs8176719 (nominal p=0.0064; OR=1.65, CI 95% 1.15-2.36). Both SNPs remain significantly associated even adjusting for age and sex (P=0.019 and P=0.005, respectively) ABO rs2519093 did not reach significant association with VTE in our population sample (P=0.184) as well as FXI rs2036914 and rs2289252 SNPs (P=0.76 and P=0.16, respectively). In addition, there was an increased risk of VTE associated with the increment in the total number of risk alleles: 0 vs 1 risk allele: X2=5.8, p=0.015; 0 vs 2 or more risk alleles: X2=12.2, p=0.00048, (CI=3.36).

Summary/Conclusions: Our data suggest that the alleles FGG rs2066865 T and ABO rs8176719 C may contribute to the VTE susceptibility in the Portuguese population. The absence of significant associations for the remaining loci could be the result of a limited statistical power, consequence of a modest effect size of polymorphisms or lower sample sizes, or because of differences in genetic backgrounds between populations.

PEDIATRIC VENOUS THROMBOEMBOLISM: INCIDENCE, RISK FACTORS AND MANAGEMENT OF HOSPITALIZED PATIENTS IN A TERTIARY CARE TEACHING HOSPITAL
P. Raheja1,*, P. Olivera1, V. Pons1, E. Johansson 1, T. Canals1, F. Bosch1, A. Santamaria1
1Hematology Department, Vall d’Hebron University Hospital, Barcelona, Spain

Background: Venous thromboembolism (VTE) is considered a rare event in childhood. In spite of this, the incidence of VTE is on the rise in hospitalized patients. Medical progress in the treatment of critically ill patients has increased the use of central venous catheters (CVC) and intervention procedures, especially in children with cardiac defects and malignant disease. Therefore VTE is increasingly recognized as a major secondary complication of advanced tertiary care in infants and children.

Aims: To study the incidence, demographics, risk factors, diagnostic tests, therapy, and complications of pediatric acute VTE in our tertiary care hospital.

Methods: A retrospective single-center study of patients<18 years of age who were discharged from January 2014 to December 2016 by using diagnostic codes for acute VTE from our hospital database. We studied demographic characteristics, clinical presentation, diagnostic tests, risk factors, treatment strategies and outcome.

Results: We report an incidence rate of 10.7 cases per 10,000 patient-years (70 acute VTE events / 21,892 discharge cases over a 3-year period). Patients were predominantly male (57%). Mean patient age was 3.3 years, with the greatest proportion of cases (>50%) in the infant group (0-12 months), while children above 1 year comprised 37% and neonates (<1 month) formed 8.6% of our sample. Patients were mostly born at full term (71.4%), although 45.7% of the neonatal and infant cases were premature. Cathereter-related (CVC-VTE) comprised 55.7% of VTE cases. On the other hand, non-cathereter-related (NCR) diagnoses were more frequent intracranial in 35.5% of unprovoked DVT and were treated with anticoagulation therapy. In 19.3% only in 13.1% of our sample. Patients were mostly born at full term (71.4%), although 45.7% of the neonatal and infant cases were premature. Catheter-related (CVC-VTE) comprised 55.7% of VTE cases. On the other hand, non-cathereter-related (NCR) diagnoses were more frequent intracranial in 35.5% of unprovoked DVT and were treated with anticoagulation therapy. In 19.3% only in 13.1% of our sample. Patients were mostly born at full term (71.4%), although 45.7% of the neonatal and infant cases were premature. Catheter-related (CVC-VTE) comprised 55.7% of VTE cases. On the other hand, non-cathereter-related (NCR) diagnoses were more frequent intracranial in 35.5% of unprovoked DVT and were treated with anticoagulation therapy. In 19.3% only in 13.1% of our sample. Patients were mostly born at full term (71.4%), although 45.7% of the neonatal and infant cases were premature. Catheter-related (CVC-VTE) comprised 55.7% of VTE cases. On the other hand, non-cathereter-related (NCR) diagnoses were more frequent intracranial in 35.5% of unprovoked DVT and were treated with anticoagulation therapy. In 19.3% only in 13.1% of our sample. Patients were mostly born at full term (71.4%), although 45.7% of the neonatal and infant cases were premature. Catheter-related (CVC-VTE) comprised 55.7% of VTE cases. DESCRIPTION OF THROMBOTIC EVENTS AND/OR PREGNANCY LOSS IN A COHORT OF HOMOZYGOUS CARRIERS FOR THE C46T POLYMORPHISM IN THE F12 GENE
S. Martin Rodríguez1, L. D. Weiss, with meanings2, R. Vidal1, C. Blas1, J. M. Alonso-Dominguez1, A. García Raso2, P. Llamas1
1Hematology, 2Health Care Institute, Fundación Jiménez Díaz, Madrid, Spain

Background: The intrinsic pathway of coagulation is initiated by a serine protease named factor XII (FXII) in a reaction involving the contact system and triggers fibrin formation through activation of factor XI. In vitro, FXII triggers activation of the classic complement pathway and initiates the fibrinolytic system via plasma kallikrein mediated urokinase activation, whereas in vivo its role is not well established. F12 C46T polymorphism occurs in the 5'-untranslated region of the F12 gene (F12 C46T) is associated with lower levels of FXII. Its frequency varies widely across populations and ethnic groups, ranging from 0.18 in the Spanish population to 0.67 among Japanese. Homozygosity for the C46T polymorphism of the F12 gene has proved to be an independent risk factor for thrombosis and unexplained recurrent spontaneous abortion. However, the precise role of this polymorphism as a thrombotic risk factor is controversial, and the evidence for an association between F12 C46T, venous thromboembolism (VTE) and myocardial infarction is weak.

Aims: To describe the occurrence of thrombotic events and/or pregnancy losses and the existence of other risk factors for thrombosis in a cohort of homozygous individuals for F12 C46T.

Methods: We retrospectively analyzed all the homozygous F12 C46T cases diagnosed in our laboratory from January 2015 to January 2017. Allelic discrimination PCR with TaqMan® probes was performed to detect homozygous individuals for F12 C46T mutation. The following variables were collected: age, gender, race, cardiovascular risk factors (CVRF) (hypertension, diabetes mellitus, dyslipidemia, smoking and overweight), history of cancer, VTE (type, recurrences), arterial thrombosis, familial thrombosis, number of pregnancy losses and other inherited/acQUIRED thrombophilia.

Results: 122 cases were evaluated: 45 (36.8%) male and 77 (63.12%) female. Mean age: 46.2 years (1-86). Race: 65.57% caucasian, 13.1% american, 2.4% black, 1.6% asian, 4.1% other. Decreased factor XII plasma levels were found in 57% of them, with mean factor XII levels 53.73% (27.5-107.5). Overall, 34.48% of the subjects had at least one thrombotic event. Type of thrombosis: 64.4% VTE and 35.6% arterial thrombosis. One (26.7%) or more than one (46.7%) additional thrombotic risk factors were found in patients with any thrombotic event. Presence of one or more CVRF was found in 66.7%. Familiar history of thrombosis was found in 16%, whereas 13% had a recent or active malignant neoplasm. Among women, 28.57% and 12.98% had one and more than one pregnancy loss respectively. Additional thrombotic risk factors were found in 60% of women with recurrent losses. One (43%) or more than one (47%) additional thrombotic risk factors were found in women with any pregnancy loss. Presence of one or more CVRF were found in 30% of them. Familiar history of thrombosis was found in 34.7%, whereas none of them had a recent or active malignant neoplasm.

Summary/Conclusions: 91% of the patients had at least one or more additional risk factors. Nevertheless, up to 26.7% presented no other risk factor than homozygous F12 C46T, suggesting a relevant role in the pathogenesis of thrombosis. According to our results, the risk of abortion could be increased by the presence of homozygosity for F12 C46T, since it was the only thrombotic risk factor found in women with pregnancy losses. Further studies are needed to clarify the real contribution of F12 C46T to thrombosis and pregnancy losses on prospectively selected patients.

ANALYSIS OF CHARACTERISTICS OF HOSPITAL ASSOCIATED THROMBOSIS
Neil Smith1, Charelampos Kartso1
1Haematology, Heart of England NHS Foundation Trust, Birmingham, United Kingdom

Background: Hospital associated thrombosis (HAT) is now commonly monitored but expected targets of HATs remains poorly reported.

Aims: We analysed HATs in our hospital group over a 40 month period to assess any trends or patterns of HAT incidence and characteristics over time.

Methods: HATs were recorded in our hospital group over a 40 month period from 2013-2017. All patients had a medical (non-surgical) index admission with 58.5% admitted as inpatients. Of 394 HAT cases with sufficient data, 80 (20.3%) had a preventable cause, 27 receiving insufficient TP, 9 receiving delayed TP, 26 having no TP given though indicated and 18 not having a VTE risk assessment. Some cases of insufficient TP were deemed unavoidable, 37 patients had contraindications to TP. 166 had TP failure i.e. full TP given and in 102 TP was not indicated. 9 patients were on full anticoagulations at time of index admission.

Summary/Conclusions: HAT rates remain stable and the majority are clinical events by current techniques. Key errors in hospital settings include failure to perform a timely VTE risk assessment and action with appropriate thromboprophylaxis. Full integration of electronic patient records with electronic prescribing modules may reduce further these errors.

THROMBOSIS DURING INFANCY AND NEWBORN PERIOD: AN UNRESOLVED ISSUE
F. Gumruk1,*, S. Aytac1, I. yaman bajin1, B. Kuskonmaz1, S. unal1, S. yigit2, M. yurakok1, M. cetin1
1Pediatric Hematology, 2neonatology department, Hacettepe University, Ankara, Turkey

Background: Reported incidence of thrombosis is higher among newborn infants that can be explained by age related deficiency of anticoagulants, overproduction of procoagulants and deficiency/ dysfunction of fibrinolysis in addition to exposure to multiple risk factors and wide use of catheters which may eventually lead to the transient prothrombotic phenotype in this age group.

Aims: Our aim is to evaluate clinical and laboratory data, risk factors, outcomes of infants (<1-12 months) and newborns (<1 month) with thrombosis in our center.

Methods: Our database revealed 752 children having various types of thrombosis between January 2003 to December 2015 and 77 out of 752 were diagnosed as thrombosis under one year of age. We retrospectively evaluate their clinical and laboratory results as well as the thrombotic events.

Results: There were 51 male and 26 female with a median age of 4 months (0-12 months) in this group. Among 77 thrombotic events 22 (28%) were observed during neonatal period (<1 month) with a male predominancy (n=15, 68%) and from those 22 events 2 were arterial thrombosis (purpura fulminans(1), cerebra(1)) whereas 4 intracardiac, 5 sinusovenous thrombus (deep veins(4), renal veins(3), portal veins(3)) and cerebral(1) veins(1) were noted. In 2(9%) cases of sinusovenous thrombosis was diagnosed on the first day of life and 11 out of 22 patient had underlying risk conditions such as prematurity(3), perinatal hypoxia(2), necrotizing enterocolitis(1), congenital cardiac disorders(3), congenital nephrotic syndrome(1) and adrenal insufficiency(1).Moreover 6 out of these 22 thrombotic cases were associated with the risk factor and 4/22 had infection. Factor V Leiden mutation was found to be homozygous in 1/18 and normal in 17/18. Heterozygous prothrombin 20210A mutation were detected in 1 out of 18 and homozygous MTHFR C677T mutation was found in 3/13 patient. Half of them(12/54) were initially treated with LMWH and TPA were used as a thrombolytic. In 5 case we used anticoagulant treatment. During the follow up period one patient had an amputation, 5 patient deceased; one because of sepsis and the rest 4 had primary disease and thrombosis. The site of location in 55 thrombotic events during the infancy period involved deep venous thrombosis (22), cerebral sinusovenous thrombosis (10),cardiac(8), portal(3), renal(1) veins and cerebral arterial(7), femoral arterial(3), abdominal aortic thrombosis(1).In this group 42(76%) out of 55 had an underlying disorder and most common associated risk factor for this age group was inserted catheter related thrombosis, infection and surgical operations.Initial treatment choice was LMWH in 25(45%) and during the follow up 10 had changed to LMWH. Further 21 resolved, 10 had parsiel thrombosis, 4 deceased and 10 loss to follow up.

Summary/Conclusions: During the first month of life thrombotic complications is 40 times higher than at any other pediatric age. As previously reported venous thrombosis which mainly affect the limbs, the right atrium and renal veins are more frequently seen than arterial thrombosis in newborn infants with a male predominancy is compatible with our findings. In the absence of randomized clinical trials the choice of anticoagulation and the duration of treatment for this age group is still controversy beside the complex mechanism and a high mortality&morbidity rate. Although clinical and laboratory data of neonates were compatible with infants, treatment choices differ between these two groups and it seems that thrombolytic treatment was tend to be used more commonly in the neonates without any complication.

E1599
THE QUALITY COMPOSITION OF SOLUBLE FIBRIN MONOMER COMPLEX FRACTION FOR ACUTE AND POST ACUTE ISCHEMIC STROKE PATIENTS
T. Katrii1,*, T. Vovk1, O. Savchuk1
1Pediatric Hematology, 2neonatology department, Hacettepe University, Ankara, Turkey

Background: Hospital associated thrombosis (HAT) is now commonly monitored but expected targets of HATs remains poorly reported.

Aims: We Analysed HATs in our hospital group over a 40 month period to assess any trends or patterns of HAT incidence and characteristics over time.

Methods: HATs were recorded in our hospital group over a 40 month period from 2013-2017. All patients had a medical (non-surgical) index admission with 58.5% admitted as inpatients. Of 394 HAT cases with sufficient data, 80 (20.3%) had a preventable cause, 27 receiving insufficient TP, 9 receiving delayed TP, 26 having no TP given though indicated and 18 not having a VTE risk assessment. Some cases of insufficient TP were deemed unavoidable, 37 patients had contraindications to TP. 166 had TP failure i.e. full TP given and in 102 TP was not indicated. 9 patients were on full anticoagulations at time of index admission.

Summary/Conclusions: HAT rates remain stable and the majority are clinical events by current techniques. Key errors in hospital settings include failure to perform a timely VTE risk assessment and action with appropriate thromboprophylaxis. Full integration of electronic patient records with electronic prescribing modules may reduce further these errors.
Background: Soluble fibrin monomer complexes (SFMC) are the early marker of thrombophilia that represent the complexes of monomeric fibrin with fibrinogen or their products of degradation (FDP). SFMC levels are not directly affected by therapy with thrombolytic agents. Detection of SFMC formed due to the activation of blood clotting by thrombin reveals a pathological process in the early, preclinical stages.

Aims: We explored the quality difference between the SFMC fraction obtained from acute ischemic stroke patients and one year post acute phase of stroke in the absolutely the same patients.

Methods: SFMC fraction was obtained from each tested groups: 35 healthy donors as well as 66 patients with atherothrombotic ischemic stroke (AIS) and 56 patients with cardiogenic ischemic stroke (CIS) during the acute phase of disease; 56 patients with AIS and 56 patients with CIS one year past acute phase. SFMC were collected from blood plasma of each tested subtypes of ischemic stroke by incubation with 0.78% o-phenanthrolone per 5 min. For Size-exclusion chromatography, SFMC in volume 0.05 ml was used on Healthcare Life Sciences “HLoad 16/60 Superdex 200 pg” column.

Results: Results suggest presence of proteins with Mr from 45 up to 330 kDa in SFMC fraction. The content of SFMC was similar for all stroke fractions with some exception. The difference between results of separation of stroke fractions and fractions obtained from healthy donors was obvious. Mostly the proteins content of the SFMC fraction is similar for stroke and healthy fractions. But amount of the proteins as mean peaks high is different (Figure 1). In fact, the first three peaks which correspond to the 330, 280 and 250 kDa of chromatogram of SFMC are confirmed for all tested fractions and were verified only in their height. Accordingly, the most widely represented variations peaks of SFMC formed even a year after stroke soluble fibrin monomer complex content was higher comparing to the healthy donors index. Healthy donors also had some of these complexes, but in trace amounts. For acute CIS situation was similar as for AIS, but past one year it got closer to healthy donors.

Figure 1.

Summary/Conclusions: It was shown that development of ischemic stroke accompanied by the formation of SFMC in the bloodstream that could take part in disease complication.

E1600 EVALUATION OF A RAPID NANO PARTICLE-BASED LATERAL FLOW IMMUNOASSAY (STIC EXPERT HIT) FOR THE DIAGNOSIS OF HEPARIN-INDUCED THROMBOCYTOPENIA IN A CARDIOTHORACIC HOSPITAL G. Soufla1,*, M. Katafygioti1, S. Georgantis1, T. Kanellopoulou1, T. Kostelidou1

1Biochemistry, Educational and Scientific Centre “Institute Of biology and medicine”, Kyiv, Ukraine

Background: Heparin Induced Thrombocytopenia (HIT) is a severe complication of heparin anticoagulation treatment that could be life threatening. HIT diagnosis is therefore of crucial importance in clinical practice especially for the cardiologic patients that are often exposed to heparin before surgery (e.g. during a PTCI). Laboratory testing for the presence of IgG, IgM and IgG or IgG only antibodies against PF4/Heparin (namely HIT antibodies) along with the 4Ts scoring system (Thrombocytopenia, Time of platelet count fall, Thrombosis, Other cause of thrombocytopenia) is used to evaluate the probability of HIT syndrome. At the Onassis Cardiac Surgery Center the method for routine laboratory testing for HIT comprise Enzyme-linked Immunoassay testing for IgG, IgA, IgM H/PF4 antibodies and Heparin-Induced Platelet Aggregation assay for the presence of platelet activating antibodies.

Aims: We evaluated a rapid nanoparticle-based lateral flow immunoassay (Stic Expert HIT) for assessing the presence of IgG antibodies to PF4/Heparin in patients plasma or serum in cases of emergency diagnosis of HIT needed for patients requiring urgent cardiothoracic surgery over a six-month period.

Methods: Stic Expert HIT, a rapid-nanoparticle based lateral flow immunoassay was performed on plasma from 35 patients from July 2016 until January 2017 and the reading was done independently by two different technicians or biologists. The diagnosis of HIT was confirmed when both H/PF4 ELISA and the 4Ts score were positive.

Results: In 22 cases the Stic Expert was negative for the presence of IgG H/PF4 antibodies in the patients’ plasma and HIT syndrome was easily excluded in combination with the ‘4Ts’. In the rest 13 cases the rapid test provided doubtful results that were considered as positive and then H/PF4 ELISA was performed. Following the ELISA test, 10 out of the remaining 13 patients were found negative for the presence of IgG H/PF4 antibodies, whereas 3 patients were found positive with a relative low O.D. value (0.400). The last 3 patients that were positive for the presence of IgG H/PF4 antibodies by “ELISA” were found not to have HIT syndrome in combination with the ‘4Ts’ scoring system.

Summary/Conclusions: In conclusion the Stic Expert HIT was useful for the quick exclusion of HIT (along with the 4Ts scoring system) when emergency HIT diagnosis is needed in 34% of the cases and then H/PF4 ELISA was performed. The last 3 patients that were positive for the presence of IgG H/PF4 antibodies by “ELISA” were found not to have HIT syndrome in combination with the ‘4Ts’ scoring system.

E1601 AUDIT OF ‘DOOR TO NEEDLE’ TIME IN ADMINISTRATION OF PROTHROMBIN COMPLEX CONCENTRATE TO PATIENTS REQUIRING URGENT REVERSAL OF ANTICOAGULATION S. Elshafei1,*, N. Smith1

1Haematology, Heart Of England Nhs Foundation Trust, Birmingham, United Kingdom

Background: Anticoagulants are used to treat or prevent thrombotic events but their most worrying side effect is major haemorrhage. The British Committee for Standards in Haematology (BCSH) recommend reversal of major/life threatening bleeding in both VKAs and DOACs with Prothrombin Complex Concentrate (PCC).

Aims: We aim to reduce delays in the administration of PCC in our trust and introduce the term ‘Door To Needle’ time (DTN) in the context of anticoagulant reversal.

Methods: We analysed the DTN in bleeding anticoagulated patients defined as time from recognition of haemorrhage to PCC administration. In Heart of England NHS Foundation Trust between May and July 2016, 29 patients were included; 19 patients were taking Warfarin and 10 taking DOACs. All patients received PCC (Beriplex®).

Results: Sixty-nine percent of patients were male and 31% female. The majority (69%) of patients were treated for stroke prevention in AF and 24% had a history of VTE. The two commonest major haemorrhage types were cerebrovascular (including intracranial and subdural haemorrhage) in 36% and gastrointestinal bleeding in 39%. The remaining indications (25%) were pre-urgent procedure/surgery, and soft tissue haematoma. The average time for recognition of haemorrhage was 3 hours 20 minutes (range 4 minutes to 21 hours 27 minutes), and the DTN was 4 hours 50 minutes (range 33 minutes to 13 hours 24 minutes), which means an estimated average of 6 hours 27 minutes (range 2 hours 49 minutes to 13 hours 59 minutes) between hospital admission and receiving PCC. Six of the total number of patients died within 30 days of hospital admission, 4 taking on Warfarin and 2 taking on DOACs.

Summary/Conclusions: This audit demonstrates the continuing delays between recognition of major/life-threatening bleeding events and receiving PCC since previous audits despite raising staff awareness. We plan to introduce the term DTN in the context of anticoagulant reversal, store PCC in the emergency department pharmacy cupboards (as a PoM) as opposed to blood bank, and introduce a reporting system ‘Serious Hazards of Warfarin (SHOW)’ which may further reduce delays, morbidity and mortality.

E1602 THE IMPORTANCE OF PLATELET MEMBRANE FLUIDITY AND OXIDATIVE STRESS IN THROMBOPHILIC COMPLICATIONS ACQUIRED BY CHRONIC MYELOPROLIFERATIVE NEOPLASMS PATIENTS V.M. Popov1,2, M. Andreescu1, M.Omer3, A. Trifa1, F. Mihai1, C. Dragun1, O. Patrinoiu 1, M.G. Moisescu 2, T. Savopol 2, E. Kovacs 2, H. Bumbea 3, V.M. Popov1,*, M. Andreescu1, M. Omer1, A. Trifa1, F. Mihai1, C. Dragun1, O. Patrinoiu 1, M.G. Moisescu 2, T. Savopol 2, E. Kovacs 2, H. Bumbea 3, A.M. Vladareanu2

1Haematology, Comenius University In Bratislava, 2Haematology, University Hospital of Bratislava, 3Haematology, University Hospital of Timisoara, 4Haematology, Medicale University Alba Iulia, Romania

Background: Patients with chronic myeloproliferative neoplasms (MPNs) and chronic myeloid leukemia (CML) have a variety of structural and functional abnormalities of platelets. Many of them have thrombotic or hemorrhage complications. Platelet function is influenced by changes in membrane fluidity (MF) which has an important role in the expression of platelet receptors, modulating the activity of protein membrane.

Aims: The importance of reactive oxidative species (ROS) in alteration function of platelet membrane and expression of platelet receptors in patients with MPNs and CML.

Methods: We present a retrospective study on 36 cases MPN (20 JAK2-positive MPN) and 24 CML admitted in Comenius Clinical Hospital Bucharest. The determination of platelet membrane fluidity was performed by fluorescence anisotropy measurements using as marker 1-(4-trimethylammoniumphenyl)-6-phenyl-1,3,5-hexatriene p-toluenesulfonate (TMA-DPH). We analyzed the fluorescence anisotropy of platelet membrane and correlate the result of with a
Central venous catheters (CVCs) have been widely used in hospitals in treatment of chronic diseases. However, CVC-related venous thrombosis frequency in pediatric age group exact risk factors for CVC related venous thrombosis haven’t been shown yet. Rotational thromboelastography (ROTEM®) measures clot formation and stability and evaluate coagulopathy. Aims: We aimed to predict CVC related venous thrombosis via ROTEM parameters in different age group patients. Methods: Study included patients who required CVC insertion due to any reason and who were not on any anticoagulation treatment during the week before the CVC insertion. On the day of CVC insertion clotting time (CT), clot formation time (CFT), maximum clot firmness (MCF), and alpha angle (AA) were measured for intrinsic (INTEM), extrinsic (EXTEM), and fibrinogen (FIBTEM) pathways via ROTEM. At one week of insertion and at removal of CVC, Doppler ultrasound imaging was performed to the vein that catheter was removed. Results: A total 14 patients were included in the study. Median age was 3.9 years (3-17.8 years). Ten (71%) of the patients had jugular veins, four (29%) patients had femoral CVC. Median duration until removal of CVC was 15.5 days (7-56). Thrombosis was detected in one patient (7%) at first week of CVC insertion (Patient 10). When the the ROTEM parameters were examined, this patient had lowest CT and highest AA in EXTEM, and the highest AA in INTEM, indicating more pro-coagulant status (Table 1). Also patient 14 had similar AA, as patient 10 in EXTEM and INTEM but was not found to develop thrombosis by the 18th day of insertion. However, CVC of that patient wasn’t removed yet.

Summary/Conclusions: USE OF ROTATIONAL THROMBOELASTOGRAPHY TO PREDICT CENTRAL VENOUS CATHER RELATED VENOUS THROMBOSIS IN CHILDREN: PRELIMINARY RESULTS

T. Bayhan1, T. Gungor2, F. Gumruk3, M. Celik1, A. Gunes4, I. Y. Bajcin3, F.N. Kalkan1, S. Unal1

1Department of Pediatric Hematology, 2Department of Radiology, Hacettepe University, Ankara, Turkey

Background: Central venous catheters (CVCs) have been widely used in hospitals in treatment of chronic diseases. However, CVC-related venous thrombosis frequency in pediatric age group exact risk factors for CVC related venous thrombosis haven’t been shown yet. Rotational thromboelastography (ROTEM®) measures clot formation and stability and evaluate coagulopathy. Aims: We aimed to predict CVC related venous thrombosis via ROTEM parameters in different age group patients. Methods: Study included patients who required CVC insertion due to any reason and who were not on any anticoagulation treatment during the week before the CVC insertion. On the day of CVC insertion clotting time (CT), clot formation time (CFT), maximum clot firmness (MCF), and alpha angle (AA) were measured for intrinsic (INTEM), extrinsic (EXTEM), and fibrinogen (FIBTEM) pathways via ROTEM. At one week of insertion and at removal of CVC, Doppler ultrasound imaging was performed to the vein that catheter was removed. Results: A total 14 patients were included in the study. Median age was 3.9 years (3-17.8 years). Ten (71%) of the patients had jugular veins, four (29%) patients had femoral CVC. Median duration until removal of CVC was 15.5 days (7-56). Thrombosis was detected in one patient (7%) at first week of CVC insertion (Patient 10). When the the ROTEM parameters were examined, this patient had lowest CT and highest AA in EXTEM, and the highest AA in INTEM, indicating more pro-coagulant status (Table 1). Also patient 14 had similar AA, as patient 10 in EXTEM and INTEM but was not found to develop thrombosis by the 18th day of insertion. However, CVC of that patient wasn’t removed yet.

**CLINICAL OUTCOMES AND UTILIZATION OF BLOOD BANK RESOURCES OF PATIENTS WITH THROMBOTIC THROMBOCYTOPENIC PURPURA (TTP), HEMOLYTIC UREMIC SYNDROME (HUS), AND OTHER MICROANGIOPATHIC HEMOLYTIC ANEMIA**

Methods: Medical records of these patients treated from 2002-2017 were reviewed. We used the standardized criteria based on the consensus on standardization of terminology in TTP to define clinical response. (Scully et al J Thromb Haemost 2017).

Results: In our series, the causes and number (% of MAHA were TTP-HUS (18.42%), autoimmune disorder-associated MAHA (13.31% i.e. 9 SLE and 4 Sjögren’s syndrome), cancer-related MAHA (4, 9.5%), drug-induced (3, 7.1%), post-transplant and infection-related microangiopathy (4, 9.5%). The average number of PEX sessions required to achieve overall clinical response in TTP, autoimmune-associated MAHA, HUS and drug-induced microangiopathy was 18.2±17.9, 11.5±7.6, 13.0±8.7 and 7.3±6.7, respectively. The mean follow up time was 40.8 months. 5 patient (11.6%) died during the course of treatment in index hospitalization, 12 (27.9%) were refractory to PEX and 24 patients (55.8%) responded to PEX, and 1 patient was lost to follow up. 1 patient relapsed 8 months after achieving clinical remission and was successfully treated with Vincristine. Another patient developed exacerbation and was palliated eventually. For the refractory cases, 7 patients were given Rituximab, 5 achieved clinical response while those who were given Vincristine (n=3) and Cyclophosphamide (n=2), achieved clinical response with a median of 15 days from the time second line agents were used. The 1 year overall survival of those who received second line treatment compared to patients who responded to only PEX and standard of care was 59% and 80% (p=0.051), respectively. The overall 1 year survival of the entire cohort is 74% which is comparable to the Oklahoma registry. The mean length of hospital stay was 30 days (median 27, IQR 22-40). The total number of PRP, PEX, and EX included was $27.797.05. The number of hospital admissions for each patient was 3 (IQR 1-6). In absolute number, platelets significantly increased from 358.9±257.0 /µl to 311.5±210.9/µl (p=0.04), from 290.6±157.6/µl to 1798.7±439.0/µl (p=0.019), and from 16.5±13.6 /µl to 12.9±12.7 /µl (p=0.045), respectively. WBC decreased significantly after rHuEPO administration from 1985.0±520.8/µl to 1798.7±439.0/µl (p<0.05), from 33.2±8.57% to 27.9±5.43% (p<0.05), from 12.9±12.7 /µl to 10.0±5.0 (p<0.05), from 9.5±4.3% to 7.4% (p<0.05), and from 11.8±11.9% to 8.5±7.4% (p<0.05), respectively. The absolute number of CD8+ T cell, NK cell and B cell significantly decreased from 358.9±257.0 /µl to 311.5±210.9/µl (p=0.019) and from 33.2±8.57% to 27.9±5.43% (p=0.05), and from 12.9±12.7 /µl to 10.0±5.0 (p<0.05). Our results show that number of lymphocytes in WBC decreased significantly after rHuEPO administration from 1985.0±520.8/µl to 1798.7±439.0/µl (p<0.05) and from 12.9±12.7 /µl to 10.0±5.0 (p<0.05), from 9.5±4.3% to 7.4% (p<0.05), and from 11.8±11.9% to 8.5±7.4% (p<0.05), respectively. We analyzed peripheral white blood cell subsets in patients who received one bolus administration of recombinant human erythropoietin (HbEPO) to examine the effect of EPO on human immune system.

Methods: One hundred nineteen autologous blood donors (male/female 62/57) in Gunma University Hospital were enrolled in this study after written informed consent. All the patients had no infections or inflammation. Forty nine patients were treated with HbEPO (Epoetin alpha or Epoetin beta (24,000 IU, respectively)) once after blood donation because of low hemoglobin concentration and 70 were not treated. Peripheral blood samples were obtained at the time of the first phlebotomy and after 1 week from the same patient. We measured the number of WBC, lymphocytes, myeloid dendritic cells (mDC), plasmacytoid dendritic cells (pDC), CD4+ T cells, CD8+ T cells, Natural killer (NK) cells, B cells, monocytes, and neutrophils of peripheral blood before and after HbEPO administration by flow cytometry. Absolute number of each cell in peripheral blood before and after treatment was compared. Paired and unpaired Student’s t-test were used to compare absolute counts and percentages of each cell, P values<0.05 were considered significant. This study was approved by the research ethics committee of our hospital.

Results: The number of WBC, mDC, pDC, monocyte and neutrophil did not change significantly. In respect of lymphocyte subsets, absolute number of CD8+ T cell, NK cell and B cell significantly decreased from 358.9±257.0 /µl to 311.5±210.9 (p<0.01) and from 33.2±8.57% to 27.9±5.43% (p=0.05), from 12.9±12.7 /µl to 10.0±5.0 (p<0.05), from 9.5±4.3% to 7.4% (p<0.05), and from 11.8±11.9% to 8.5±7.4% (p<0.05), respectively. Moreover, other B cell subsets, such as transitional B cells, memory B cells and marginal zone B cells, also showed a trend of decrease. However, percentages of naive B cell and IgG/CD27+ B cell in total B cell did not change. These suggest that whole B cell decreased, not a specific subset of B cell. In non treatment group, there was no change of all cell subsets.

Summary/Conclusions: These findings suggested that just one administration of rHuEPO influenced human immune system, especially via reduction of B cell in peripheral blood, with unknown mechanism so far.
Background: At most centers, the majority of patients who request bloodless medicine are members of the Jehovah’s Witness (JW) faith. But, there are no standard, established guidelines to manage pancytopenia in these patients, nor are there many studies to inform optimal treatment approaches. The most troublesome patients who request bloodless medicines are patients with hematologic malignancy. The treatments of these patients are considerable challenges. They have not only problems of severe pancytopenia, but also require intensive chemotherapy. Since 2000, our hospital has been a bloodless center. This study was retrospectively analyzed for hematologic malignancies and aplastic anemia with bloodless treatments in Soonchunhyang university hospital.

Aims: This study was retrospectively analyzed for hematologic malignancies and aplastic anemia with bloodless treatments in Soonchunhyang university hospital.

Methods: A retrospective review of medical records was performed of 44 patients with hematologic malignancies and aplastic anemia who requested bloodless medicine from January 2006 to December 2015 at Soonchunhyang university hospital.

Results: Of 44 patients, 48% were men (n=21) and 52% were women (n=23). The median age of the study population at the time of diagnosis was 62 years (range 18-87). Thirteen patients (29.5%) were acute leukemia, 15 (34.1%) patients with non-Hodgkin’s lymphoma (NHL), 2 (4.5%) patients with aplastic anemia (AA), 6 (13.6%) patients with chronic myeloid leukemia (CML), 4 (9%) patients with myelodysplastic syndrome (MDS) and 4 (9%) patients with multiple myeloma (MM). Thirty one patients were treated with chemotherapies and 13 patients were treated with supportive care only. Among 44 patients 27 were patients were died. Most common cause of attribution to death was anemia (92.5%). And Chief complaint at death was dyspnea (88%). Median survival of acute leukemia was 1 month (95% CI, 0.41-1.59).

Summary/Conclusions: In bloodless treatment, CML, MM and lymphoma had a relatively good prognosis. However, AML, and MDS were shown a poor prognosis. Therefore, further studies are needed to improve survival for bloodless patients with hematologic malignancies.

PREOPERATIVE ANEMIA: A SINGLE INSTITUTION EXPERIENCE IN SPAIN

G. Pinto1, F. Ruiz1, I. Page1, G. Yum1, G. Moreno1

1Hematology, Hospital Ramon y Cajal, Madrid, Spain

Background: Preoperative anemia is considered as a strong predictor of postoperative red cell transfusions, and has also been linked to increased morbidity and mortality in surgical patients, but it is frequently overlooked.

Aims: The objective of this study is measure of real impact of preoperative hematological assessment and optimization of anemic patients in terms of decreasing blood cells transfusions.

Methods: Anemic patients undergoing elective surgery in subgroups of high or low risk of bleeding. All the patients were referred from pre-anesthesia consultation for performing a 4-week hematological protocol in order to optimize the hemoglobin level to a near normal value. We identified the underlying cause of anemia and offered the treatment according to the etiology. The primary outcome was the response to therapy defined as reaching the Hb level >13 g/dL or increasing >2 g/dL from basal level, and the rate of blood transfusion.

Results: Mean age was 70.4 years, with a male-female ratio of 1:2, and the patients were divided into 2 groups according to the bleeding risk: high risk

74% (hip and knee replacement, cystectomy, colostomy, maxillofacial surgery), and low 26% (mastectomy, gynecology or spine surgery), with a median hemoglobin of 10.9% and 10.1%, respectively. A diagnostic workup was performed in order to provide appropriate treatment: iron deficiency anemia (83.9%), anemia of chronic disease (10.3%), folate or vitamin B12 deficiency (5.8%). The patients with iron deficiency anemia received oral (62%) or intravenous (38%), and 38% of patients had to change from oral to intravenous iron by intolerance or poor response. The response to treatment was reached by 44.7% of patients, in an average time of 26.4 days. The rate of blood transfusion was 18% in good responders (0.5 packed red blood cells per patient) and 63% in poor responders (1.6 packed red blood cells per patient).

Summary/Conclusions: This study is the first one to assess the protocol of transfusion strategy of anemic patients in the preoperative period, and the effort to reach a near to normal hemoglobin level, could minimize the amount of red blood cell transfusion the patients will be exposed in the postoperative period. Our data provide evidence about the effectiveness of a prompt evaluation and correction of preoperative anemia in a maximum time of 4 weeks.

RED BLOOD CELLS (RBC) AND PLATELET (PLT) TRANSFUSIONS IN TRANSPLANTED AND NOT-TRANSPLANTED PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

E. Baldoumi1, V. Papadopoulos2, V. Kalaitzidou1, A. Syrigou1, C. Lalayanni1, M. Papadopanasiou1, D. Malliouti1, C. Smias1, I. Sakellari1, A. Anagnostopoulou1, D. Sotiropoulos1

1Haematology Department & BMT Unit, George Papanicolaou Hospital, Thessaloniki, Greece

2Hematology Department, Papageorgiou General Hospital, Thessaloniki, Greece

Background: Patients with hematological malignancies require often and prolonged hospitalisations during the course of their treatment, in part due to increased and frequent transfusion demands.

Aims: The objective of the study was to assess the factors affecting transfusion needs in a Hematology Department (bone marrow transplant unit- BMTU, post-transplant unit-PTU, hematology clinic).

Methods: The patients that were hospitalized between 1/1/2015 and 31/12/2015 were analyzed. Data regarding the underlying disease, the disease status, type of transplant, duration of narrow aplasia and donor-patient blood group mismatch were obtained from the medical records. The analysis was restricted to the transfusion of packed RBCs and units. Differences between groups were assessed using non-parametric statistics (Kruskall-Wallis and Mann-Whitney U-test).

Results: There were 523 admissions of 256 different patients. Complete data for analysis could be obtained for 487 admissions of 237 patients (92.6% of patients, 93.1% of admissions), corresponding to 10,673 days of hospitalization. Total number of blood products transfused was 2284 packed RBC units, 13883 PLT units (apheresis platelets counted as 5 units). Values are reported as median (range), unless otherwise specified. In the BMTU, the type of transplant was correlated with transfusion needs; number of RBC units transfused per admission was 2 (1-5) for autologous transplanted (AUTO) patients, 4 (1-28) for allo-transplanted (ALLO) (no difference between sibling and matched unrelated donors), and 7 (1-14) for haplo-identical transplantations (HAPLO), p<0.001. Platelet units requirements were respectively 15 (5-45) for AUTO, 20 (5-205) for ALLO and 20 (30-130) for HAPLO, p<0.001. The number of admissions was 18 (13-23) days in AUTO, 22 (16-44) in ALLO, 30 (29-40) days in HAPLO transplantation, p<0.001, while the duration of aplasia in days was 9 (4-19) in AUTO, 13 (5-32) in ALLO and 25 (20-38) in HAPLO, p<0.001. The longer duration of aplasia and hospitalization was correlated with greater transfusion needs. In the PTU there was no statistically significant difference in transfused RBC or PLT units with regard to transplant type. Disease status (response versus active disease) was only correlated with RBC units transfused in PTU 2 (1-29) vs 6 (1-56) units respectively, p=0.006. Donor – patient blood group mismatch was correlated with increased transfusion demands in BMTU for RBCs [4 (1-28) vs 2 (1-5), p<0.001] and PLTs [25 vs 15, p<0.001]. In hematologic clinic, the underlying disease was correlated with transfusion needs in RBC and PLTs, as shown in table 1. Patients with AML had the higher needs in RBC and PLTs, whereas patients with lymphoma had the lowest needs in RBC transfusions. Disease status was not correlated with transfusion needs. The duration of aplasia was correlated with the number of RBC units (Pearson’s r=0.66, p<0.001, r2=0.435) and of PLTs transfused (Pearson’s r=0.78, p<0.001, r2=0.61).

Table 1. Units transfused in hematology clinic

<table>
<thead>

</tr>
</tbody>
</table>

Summary/Conclusions: The main determinants of transfusion requirements are the duration of aplasia, the type of transplant and the disease, with myeloid malignancies requiring more transfusions. The establishment of haplo-identical transplantations has increased the transfusion needs due to longer period of aplasia.
Acute lymphoblastic leukemia - Biology

**PB1611**

**BOTANICAL ALKYL HYDROQUINONE HQ17(3) EXERTS CYTOTOXICITY TO T(9;22) PHILADELPHIA CHROMOSOME SUP-B15 ALL CELLS THROUGH INDUCING ENDOPLASMIC RETICULUM STRESS, AUTOPHAGY, AND ANTIFLACHOLESTIC ACTIVATION.**

C.-W. Chen1, Y.-J. Chang1, Y.-Y. Kuo2, L.-L. Lin1, C.-Y. Hu1,2

1Department of Clinical Laboratory Sciences and Medical Biotechnology, 2Graduate Institute of Oncology, College of Medicine, National Taiwan University, Taiwan, Taiwan, Republic of China

**Background:** Patients suffering from Acute lymphoblastic leukemias (ALLs) harboring t(9;22) genetic abnormality are classified very high risk (VHR) ALLs displaying poor clinical outcome irrespective of intensive chemotherapies and tyrosine kinase inhibitor treatment. Development of new adjuvant therapeutics will provide great value. HQ17(3) [20, 21, 22] was isolated from the bark of Phellodendron amurense (amur cork tree) and is known for its cytotoxic and antiflacholestic activities.

**Methods:** HQ17(3) (30 µM) was tested against all 6 VHR ALL cell lines (PB1611, PB1612, PB1613, PB1615, PB1616, PB1617) to determine the antileukemic effect. Flow cytometry was used to examine cell death. Lysosomal protease inhibitors (AEBSF (serine protease inhibitor), pepstatin/CA074-Me (caspase D/B inh.)) or autophagy inhibitors (3-MA (3-(3-Chlorostyryl)indole), CQ (chloroquine) (lysosomal membrane permeabilization blocker) were used to elucidate the effect of HQ17(3) on autophagy.

**Results:** HQ17(3) (30 µM) showed the best antileukemic effect on PB1611 cells compared with other cell lines. HQ17(3) activated autophagy as revealed by aggregation of ectopically expressed GFP-LC3. Western blot analysis revealed phosphorylated eIF2a, ER chaperone Grp78, and spliced XBP-1 (markers for ER stress). Lenti-viral delivery of shRNAs was used to repress the expression of Beclin-1. Nuclear accumulation of apoptosis inducing factor (AIF) was revealed by fluorescence microscopy.

**Summary/Conclusions:** In conclusion, HQ17(3) induced multi-targeted effects in PB1611 cells. Further investigation is needed to elucidate the mechanism of action of HQ17(3) and its potential antileukemic activity.

**PB1612**

**TARGETED MUTATIONAL PROFILING OF CHILDHOOD AND ADULT ACUTE LYMPHOCYTIC LEUKAEMIA PATIENTS.**

J. Peric1, T. Karon Durasevic1, T. Kocic1, I. Marjanovic1, J. Lazic2, M. Virijevic3, N. Krstovski4, D. Dokmanovic5, D. Tomin3,4, A. Vidovic3,4, N. Suvajdzic5,6

1Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, 2University Children’s Hospital, 3Clinic of Hematology Clinical Centre of Serbia, 4School of Medicine, University of Belgrade, Serbia

**Background:** Acute lymphoblastic leukemia (ALL) is the most common cancer in children, representing about 80% of acute leukemias, whereas it is less common in adults (20%). Identification of cytogenetic aberrations and a small number of molecular abnormalities are still the most important risk and therapy stratification methods in clinical practice today.

**Aims:** The aim of the present study was to assess mutational profile of both childhood (cALL) and adult acute lymphoblastic leukemia (aALL) patients, by applying targeted next generation sequencing (NGS) on MiSeq System. We set out to comprehensively characterise the second ALL, including conventional G-banding and fluorescence in situ hybridisation (FISH).

**Methods:** We set out to comprehensively characterise the second ALL, including conventional G-banding and fluorescence in situ hybridisation (FISH). The
acquired results were compared with those derived from the first ALL diagnosis. Results: The median age was 36.2 years (range: 2-73). The diagnosis showed the presence of ,4q34,17q22, and t(9;22), with a loss of chromosomes 5p, 9p, 11q, and 14q. The absence of Philadelphia chromosome was confirmed by FISH analysis in all samples. The presence of the Ph+ ALL clone was confirmed in all cases. The ratio of CD4+ and CD8+ T cells in the leukemic marrow was elevated (21.0% [IQR 16.7-28.5] vs NL BM (9.6-18.7%), of CD8+ cells, p=0.0107). The ratio of OX40-positive T cells was not significant (p=0.36). Further analysis of the T cell phenotype showed that there are relatively more CD8+ T cells in the leukemic than in the non-leukemic marrow. The ratio of memory CD4+CD45RO+ T cells was significantly elevated (p=0.0044). The difference in memory CD8+CD45RO+ T cells was not significant (p=0.36). Further analysis of the T cell phenotype showed increased proportion of both PD1-positive helper T cells and PD1-positive suppressor T cells. The ratio of CD4+CD8+ and CD4+CD8- T cells in comparison with the non-leukemic controls. The proportion of PD1+expressing T cells is also elevated. However, the heterogeneity between patients is marked. The analysis of other marker panels is presently ongoing, as well as correlation to clinical and treatment outcome parameters.

PB1614
IMMUNOLOGICAL CHARACTERIZATION OF PH+ ALL BONE MARROW BY MULTIPLEX IMMUNOHISTOCHEMISTRY
H. Hohsti1, O. Brück1, S. Blom2, R. Turkj2, A. Ribeiro3, M. Sinisalo3, P. Kovanen4, O. Kallioniemi2, T. Pellinen2, K. Porkka5, S. Mustjoki1
1Hematology Research Unit, University of Helsinki and Helsinki University Central Hospital, Helsinki, 2Department of Pathology, HUSLAB and Haartman Institute, Helsinki, 3Division of Hematology, Tampere University Hospital, Tampere, 4Department of Pathology, HUSLAB and Haartman Institute, Helsinki University Central Hospital and University of Helsinki, 5Hematology Research Unit, University of Helsinki and Helsinki University Central Hospital Comprehensive Cancer Center, Department of Hematology, Helsinki, Finland

Background: The treatment results in Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph+ ALL) have improved significantly in the era of tyrosine kinase inhibitors (TKIs). However, many patients relapse despite having intensive treatments with initially favorable responses. TKI therapy is known to modulate the immune system, and it may play a critical role in keeping the leukemia under control. However, little is known about the status of the immune system in patients with Ph+ ALL. Especially with the emerging immunotherapies in sight, it is vital to chart the immunological landmarks that could help us direct the treatment towards a more personalized course.

Aims: To characterize the immunological microenvironment in Ph+ ALL bone marrow (BM) by multiplex immunohistochemistry (IHC).

Methods: Ph+ ALL BM biopsies from the diagnosis stage were collected from Helsinki University Hospital and Tampere University Hospital (N=31). BM biopsies from non-leukemic (NL) controls (N=14) were used as a reference. Samples were hematopathologically evaluated and a tissue microarray (TMA) was constructed by selecting two BM cores with high leukemic cell infiltration per patient. The TMA sections were stained with both fluorescent and chromogenic dyes for six markers and nuclei simultaneously enabling cytometric analysis at cell-resolution. Marker panels included T and B lymphoid cells, NK and dendritic cells, macrophages as well as myeloid derived suppressor cells. Furthermore, we analyzed immune checkpoint molecules (PD1, LA83, OX40, TIM3, CTLA4) and their ligands (PD-L1, PD-L2, HLA-G, HLA-ABC) alongside with various activation markers (granzyme B, CD45RO, CD25, CD69, CD27). After the staining, the cells were segmented and quantified with the image analysis software CellProfiler and the cell analysis software FlowJo.

Results: The CD4+/CD8+ ratio was lower in Ph+ ALL BM versus NL BM (1.3 [interquartile range (IQR) 1.0-1.9] vs 2.0 [IQR 1.7-2.4], p=0.0134) indicating that there are relatively more CD8+ T cells in the leukemic than in the non-leukemic marrow. The ratio of memory CD4+CD45RO+ T cells in Ph+ ALL BM versus NL BM was elevated (21.0% [IQR 16.7-28.5] vs 13.0% [IQR 8.7-15.9] of CD4+ T cells, p=0.0044). The difference in memory CD8+CD45RO+ T cells was not significant (p=0.36). Further analysis of the T cell phenotype showed increased proportion of both PD1+positive helper T cells and PD1-negative CD8+ T cells in Ph+ ALL BM vs NL BM (29.7% [IQR 17.5-30.1] vs 6.9% [IQR 5.7-8.9], of CD4+ cells, p=0.0001 and 28.8% [IQR 13.2-38.0] vs 14.9% [IQR 9.6-18.7], of CD8+ cells, p=0.0107). The ratio of OX40-positive helper T cells was also higher in Ph+ ALL BM (27.1% [IQR 21.6-33.25] vs 18.5% [IQR 14.8-21.9], of CD4+ cells, p=0.0001), but no difference was observed in the proportion of OX40+positive CD8+ T cells (p=0.49).

Summary/Conclusions: Multiplex IHC enables ample cytometric evaluation of different immune cell subtypes in their original microenvironmental context of the bone marrow. The TMA format not only allows analysis of tens of BM samples in parallel but also serves as a retrospective, easy-access archive for any follow-up studies. Ph+ ALL BM is characterized by a decrease in the CD4+/CD8+ ratio and an increase in the proportion of CD4+CD45RO+ T cells in comparison with the non-leukemic controls. The proportion of PD1+expressing T cells is also elevated. However, the heterogeneity between patients is marked. The analysis of other marker panels is presently ongoing, as well as correlation to clinical and treatment outcome parameters.

PB1615
CDKN2A/p16INK4A DELETION IS NOT A POOR PROGNOSIS PREDICTOR IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED ACCORDING TO PROTOCOL RALL-2009
P. Ingia, T. Olaitainia, P. Elena4, T. Vera1, G. Olga1, R. Michail1, K. Sergey1, A. Zalina1, S. Valery1
1National Research Center for Hematology, Moscow, Russian Federation
2Russian Cancer Research Center, Moscow, Russian Federation
3Institute of Molecular Medicine Finland (FIMM), Helsinki, 4Division of Hematology, Tampere University Hospital, Tampere, 5Department of Pathology, HUSLAB and Haartman Institute, Helsinki University Central Hospital and University of Helsinki, 6Hematology Research Unit, University of Helsinki and Helsinki University Central Hospital Comprehensive Cancer Center, Department of Hematology, Helsinki, Finland

Background: CDKN2A/p16INK4a deletion is a frequent cytogenetic abnormality in acute lymphoblastic leukemia (ALL), ranging from 16% to 45%. In pediatric groups, the p16INK4a deletion was associated with T-cell ALL phenotype and poor event-free survival. The prognostic impact of CDKN2A/p16INK4a deletion in adult ALL patients appear controversial.

Aims: To evaluate the prognostic impact of the CDKN2A/p16INK4a deletion in adult patients with acute lymphoblastic leukemia.

Methods: We present the acquired results were compared with those derived from the first ALL diagnosis. In order to further characterise the genetic diagnostics, FISH probes were used on archived diagnostic slides. Careful selection of probes demonstrated that the original leukemic sample contained two co-existing clones – one low hypodiploid clone (with an identical pattern of loss and gain of chromosomes as the second ALL) and one clone resembling a doubled uniparental triplod low hypodiploid clone.

Summary/Conclusions: This case report demonstrates the value of in-depth genetic analyses to guide management of patients with ALL. This patient proceeded with re-induction according to our current relapsed therapy guidelines (RALL-2009), for which she has shown partial response. She is considered for allogeneic bone marrow transplantation using an unrelated donor.

In hindsight, the treatment regimen used for the initial ALL was incorrect. If it had been established that she had low hypodiploid ALL the first time around, she would have been allocated the most intensive regimen within the trial. Nevertheless, she maintained remission status for 5 years with low intensity treatment and ironically relapsed when most patients are told they are cured.

Since the original diagnosis of ALL in 2007, research has vastly improved our understanding of the biology and genetic landscape of ALL. This has facilitated risk stratification, improved outcome after treatment and identified novel drug targets. Genomic profiling of low hypodiploid ALL has identified oncogenic activation of Ras and phosphoinositide 3-kinase (PI3K) signalling conferring sensitivity to PI3K inhibitors, thus providing therapeutic avenues if conventional treatment were to fail.

Figure 1.
Results: The prevalence of the CDKN2A deletion in all studied population was 24.5% (27 cases). The frequency of homozygous deletions was 70% (in 19 cases), heterozygous deletion was 30% (in 8 cases). CDKN2A deletion was detected in 14 (52%) patients with precursor-B phenotype, in 11 cases (41%) with T-ALL and in 2 (7%) cases with biphenotypical ALL. Our study demonstrated that CDKN2A deletion had no significant association with age, sex, WBC counts, BM blasts, risk stratification groups, complete remission (CR) and relapse rate in B-cell ALL. We didn’t reveal any significant differences in OS, clinical and laboratory dates between groups of patients with homozygous and heterozygous deletion of the CDKN2A deletion. The analysis for T-ALL has detected that CDKN2A deletion was strongly associated with high WBC count (the median is 86x10^9 /L, p=0.000), with high CSF (376x10^6) of blasts (the median is 306x10^6, p=0.0004) and no associating with CR and relapse incidence was found. We didn’t revealed relationship between CDKN2A deletion and MLL, TEL/AML1 rearrangement, MYC translocation, TP53 mutation and IAMP21. CDKN2A deletion didn’t have statistically significant impact on outcome of patients. The five-years OS of patients with and without deletion was 85% and 76% (p=0.00, 35); DFS was 92% and 65% (p=0.07), respectively. OS for T-CELL ALL patients with and without deletion was 90% and 80% (p=0.03, 63); DFS was 100% and 82% (p=0.24, respectively) (Figure 1).

Summary/Conclusions: We were unable to demonstrate prognostic value of the CDKN2A deletion in adult ALL patients and did not find significant association between deletion of the CDKN2A gene and with known cytogenetic prognostic factors. However patients with T-cell ALL and CDKN2A deletion had a more frequent incidence of other features (high level WBC and LDH) and it didn’t associate with poor outcomes including overall survival.

Deletion of CDKN2A is not adverse prognostic factor in adult ALL treated according to protocol RALL-2009.

PB1616 FREQUENCY AND CLINICAL IMPACT OF CDKN2A/B GENE LOCUS IN AN ADULT T-ALL COHORT OF PATIENTS ENROLLED IN THE SPANISH PETHEMA GROUP PROTOCOLS

1All Research Group, Josep Carreras Leukaemia Research Institute (UCIC), 2ICO-Germans Trias i Pujol Hospital, 2Pediatric Oncology, Nantes University Hospital, 3Josep Carreras Leukaemia Research Institute (UCIC), Badalona, 4ICO-Duran i Reynals Hospital, Hospital de la Llo- bregat, 5ICO-Josep Trueta Hospital, Girona, 6Donostia University Hospital, Donostia, 7Virgen de la Victoria Hospital, Málaga, 8102 October Hospital, Madrid, 9Vall de Hebron Hospital, Barcelona, 10Alzicante General Hospital, Alicante, 11Son Llàtzer Hospital, Mallorca, 12Barcelona Clinics Hospital, Barcelona, 13Virgen del Rocio Hospital, Sevilla, 14USAL-BNADN, Salamanca, 15La Fe Hospital-Biobanco de la Fe, 16La Fe Hospital, Valencia, Spain

Background: Recurrent 9p21 deletions involving CDKN2A/CDKN2B locus are frequent in ALL. The very few data regarding their prognostic significance in adult T-ALL have shown that homozygous deletions of the CDKN2A/CDKN2B locus are associated with improved overall survival (OS).

Aims: We precisely characterized the copy number status (CNA) of CDKN2A/CDKN2B locus by discriminating deletions in A or B gene in order to elucidate its clinical impact separately.

Methods: Samples from 30 adult T-ALL cases included in high-risk protocols of the PETHHEMA group were analyzed by CytoScan array (Affymetrix). Additionally, we set up a genomic qPCR to screen for homozygous deletions in both genes (normal karyotype). We corrected our CNA values for the normal cells (2N) contaminant present in the diagnosis and in 2 (7%) cases with biphenotypical ALL. We didn’t reveal any significant differences in OS, clinical and laboratory dates between groups of patients with homozygous and heterozygous deletion of the CDKN2A deletion. The analysis for T-ALL has detected that CDKN2A deletion was strongly associated with high WBC count (the median is 86x10^9 /L, p=0.000), with high CSF (376x10^6) of blasts (the median is 306x10^6, p=0.0004) and no associating with CR and relapse incidence was found. We didn’t revealed relationship between CDKN2A deletion and MLL, TEL/AML1 rearrangement, MYC translocation, TP53 mutation and IAMP21. CDKN2A deletion didn’t have statistically significant impact on outcome of patients. The five-years OS of patients with and without deletion was 85% and 76% (p=0.00, 35); DFS was 92% and 65% (p=0.07), respectively. OS for T-CELL ALL patients with and without deletion was 90% and 80% (p=0.03, 63); DFS was 100% and 82% (p=0.24, respectively) (Figure 1).

Summary/Conclusions: We were unable to demonstrate prognostic value of the CDKN2A deletion in adult ALL patients and did not find significant association between deletion of the CDKN2A gene and with known cytogenetic prognostic factors. However patients with T-cell ALL and CDKN2A deletion had a more frequent incidence of other features (high level WBC and LDH) and it didn’t associate with poor outcomes including overall survival.

Deletion of CDKN2A is not adverse prognostic factor in adult ALL treated according to protocol RALL-2009.

PB1617 BUTEIN KILLS ACUTE LYMPHOBLASTIC LEUKEMIC CELLS IN VITRO AND IN VIVO THROUGH FOFOX3A AND CASPASE-DEPENDENT APOPTOTIC PATHWAYS

Y.-L. Tang1, L.-B. Huang1

1Department of Pediatrics, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China

Background: Acute lymphoblastic leukemia (ALL) is a common hematological malignancy in children. Discovering and developing effective chemotherapeutic drugs are needed for ALL.

Aims: In this study, the anti-leukemic effect and the potential molecular mechanisms of butein on ALL were investigated.

Methods: We examined the rate of apoptosis of CEM-C7 (T-ALL), CEM-C1 (T-ALL), MOLT-4 (B-ALL), RS4-11 (B-ALL) cell lines and primary ALL blasts from 11 leukemic children for in vitro and in vivo experiments.

We tested the expression of the caspase-9, poly ADP-ribose polymerase (PARP), nuclear Forkhead class oxo3a (FOXO3A) and BCL-2 interacting mediator of cell death (BIM) using western blot assay. We established the xenograft model to examine the anti-leukemic effect of butein in vivo.

Results: Butein was found to significantly induce the cellular apoptosis of ALL cell lines and primary ALL blasts in a dose-dependent manner. It also activated the cleavage of caspase-9 and PARP. We also found that butein promoted FOXO3A localization, enhanced the binding of FOXO3A on the BIM gene promoter and then increased the expression of BIM. Moreover, we showed that FOXO3A knockout significantly decreased the apoptosis of butein, whereas overexpression of FOXO3A enhanced the butein-induced apoptosis. However, overexpression of FOXO3A mutation (C-terminally truncated FOXO3A DNA-binding domain) decreased the expression of btein through decreasing the expression of BIM. Furthermore, treatment with butein was highly efficacious in vivo, with enhanced reduction of tumor burden in a xenograft model of ALL.

Summary/Conclusions: Our results therefore demonstrate the therapeutic potential of butein for ALL via FOXO3A and caspase-dependent apoptotic pathways.

PB1618 GENOMIC LANDSCAPE AT DIAGNOSIS AND RELAPSE IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA.

O. Theisen1, C. Godon1, F. Riailland2, C. Thomas2, A. Grain2, Y. Le Bris1, N. Robillard1, M. C. Béné1, M. Eveillard1

1Hematology Laboratory, 2Pediatric Oncology, Nantes University Hospital, Nantes, France

Background: Childhood acute lymphoblastic leukemia (ALL) is the most common of pediatric malignancies, but intensive chemotherapy now allows to obtain complete remission in over 90% of the cases. Nevertheless, 1 out of 5 children will relapse.

Aims: In order to identify new markers prognostic of relapse, we analyzed SNP arrays of paired diagnosis and relapse samples from 8 B-ALL children.

Methods: The cohort included 3 males and 5 females, aged between 6 months and 21 years old (median age 4 years old). Bone marrow samples were obtained from 8 children. Diagnostic cytogenetics was performed by single karyotyping and SNP array analysis. The expression of the caspase-9, caspase-dependent apoptotic pathway were tested with CEM-C7 (T-ALL), CEM-C1 (T-ALL), MOLT-4 (B-ALL) cell lines and primary ALL blasts from 11 leukemic children for in vitro and in vivo experiments.

Results: qPCR results showed that most of the 9p21 losses corresponded to homozygous deletions in both genes (36%, 19/53), while heterozygous deletions corresponded to 5.7% (3/53) and different CNA status between CDKN2A/B locus in all the cases analyzed. With that, we ask for clinical implications of the CDKN2A/B locus abnormalities, mainly homozygous deletions, were found in 70% of adult T-ALL patients. Different CNA status was found for CDKN2A and CDKN2B. Although homozygous deletion in CDKN2A was associated with a trend for better OS, the level of MRD was the only prognostic factor for OS in these cases.

Background: In cells, while DNA bases can be protected by double helix forma-
and nucleosome packaging, deoxyribonucleotide triphosphates are unpro-
ected, thus, are vulnerable to damage. One of the enzymes which are respon-
sible for removing damaged nucleotides is Nudix hydrolase15 (NUDT15).

NUDT15 works as a negative regulator in thio
go protein expression. Nudix hydrolases are active metabolites of thiopurines. Mechanisms of action of thio

Background: In cells, while DNA bases can be protected by double helix forma-
and nucleosome packaging, deoxyribonucleotide triphosphates are unpro-
ected, thus, are vulnerable to damage. One of the enzymes which are respon-
sible for removing damaged nucleotides is Nudix hydrolase15 (NUDT15).

NUDT15 works as a negative regulator in thionucleoside metabolism. Thioguanines are active metabolites of thiopurines. Mechanisms of action of thioguanines are disruption of DNA synthesis and induction of apoptosis. NUDT15 inhibits incorrect base pairing and apoptosis through catalysis of thioguanine hydrolysis. Tanaka et al. claimed that, besides TPTM variants in Japanese patients, there might be possible additional factors that may influence thiopurine toxicity. They reported that NUDT15 variants are more specific to Asian population when compared to European population. As far as we know, this is the first study on screening of possible variants in the first exon of NUDT15 in Turkish children with precursor B-cell acute lymphoblastic leukemia (Pre-B ALL).

Aims: In this study, our aim was screening of gene variants in first exon of NUDT15 in pediatric group of patients diagnosed with Pre-B ALL.

Methods: Our study group was composed of 63 patients aged between 1-15 diagnosed with Pre B-ALL at Lösante Hospital. DNA samples were isolated by using MagNa Pure Pure system. First exon of NUDT15 was amplified by PCR reaction. After PCR purification, sequencing was performed. Results: After screening of first exon of NUDT15, we detected two variations. First variation was intronic insertion which was defined as rs3831098 (c.158+52_158+53insGGGGCGTGCGCAGAGGGACGATCTC). The other intronic variation was defined as rs79687000 (c.158+117C>T). rs3831098 was determined in one of the 83 patients and rs79687000 was found in three out of the 83 patients (Table 1).

Table 1.

Summary/Conclusions: The changes in NUDT15 that we found have not been previously reported in pediatric ALL patients. We do not know if these changes have an effect on pre-mRNA or "splice" regions and ALL. This issue needs further investigation, because in a large number of children with leukemia.

We are planning the screening of other exons of NUDT15 in order to evaluate for possible applications to clinical practice (e.g. cytopenia).

COMPREHENSIVE MOLECULAR CYTGENETIC ANALYSES OF BONE
MARROW CELLS IN 64 CHILDREN WITH T-ALL REVEALED
PROGNOSTICALLY RELEVANT RECURRENT FINDINGS
L. Lizzova1,*, Z. Zemanov1, E. Prihodova1, L. Pavlištova1, K. Svobodov1, E. Mejstrikov1, O. Hrusak2, P. Luknarov1, J. Janotov1, L. Sramkova1, J. Starý1, K. Michalov1
1Center of Oncogenetics, Institute of Medical Biochemistry and Laboratory Diagnostics, General University Hospital and 1st Faculty of Medicine, Charles University in Prague, 2CLIP - Childhood Leukaemia Investigation Prague, Department of Paediatric Haematology and Oncology, 3Department of Paediatric Haematology and Oncology, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic

Background: T-ALL represents 15% of newly diagnosed children with ALL and it is a clinically and genetically heterogeneous disease. Despite the use of intensive chemotherapy, relapse occurs in almost 25% of patients whose outcome remains dismal. Visible chromosomal aberrations are seen in approxi-

mately half of the cases, while cytogenetically cryptic aberrations are observed in almost all cases of T-ALL. However, prognostic implication of majority of them still remains unclear.

Aims: The aim of this study was to retrospectively and prospectively analyze bone marrow cells of children with T-ALL, to determine a frequency of recurrent cryptic chromosomal aberrations and to assess their impact on event free (EFS) and overall survival (OS).

Methods: Bone marrow cells of all patients were analyzed at the time of diag-

nosis by combination of conventional and molecular cytogenetic methods. For detection of the most frequent known chromosomal changes, i.e. rearrange-
mants of TCR loci (TRA-14q11, TRE-7q34, TRG-7p14) and TLX3 gene (5q35), deletion of CDKN2A (9p21) and amplification of ABL1 (9q34), interphase FISH with locus-specific probes (Dako, Abbott Molecular) was used. Complex chromo-

somal rearrangements were proved by multicolor FISH and multicolor band-
ing (24XCyte/XCyte Probe Kit; MetaSystems) or CGH-SNP array (SurePrint G3 Cancer CGH+SNP 4x180K, Agilent). For OS and EFS Kaplan-Maier analy-
sis with Mantel Cox test was done.

Results: During the years 1996-2016 we examined archived material of 64 children with T-ALL (19 girls and 45 boys, median age 8.25 years). In total, chromosomal aberrations were detected in 86% of patients. The most frequent aberration was deletion of CDKN2A gene, which was found in 35/64 patients (19x homozygous, 16x heterozygous). Rearrangement of TCR loci were detected in 17/64 children (11x TRA, 6x TRB). TLX3 gene rearrangement was established in 15/64 patients. No aboration of TRG gene and amplification of ABL1 were found. Complex chromosomal aberrations were proved in 12/64 children. In two cases, isochromosome of the long arm of chromosome 9 was found. 48 patients are living in the first/second complete remission. Relapse of the disease occurred in 17 patients, 16 children died. Best outcome (EFS and OS) was associated with TRA translocations (p<0.05). Patients with TLX3 rearrangement had significantly shorter OS and EFS (p<0.05).

Summary/Conclusions: Using molecular cytogenetic methods cryptic recurrent aberrations were proved in vast majority of patients. Rearrangement of TLX3 gene was related to poor outcome in contrast to TRA translocations associated with more favorable course of the disease. Our work attempts to clear up the significance of chromosomal aberrations related to childhood T- ALL in order to facilitate the patients’ stratification into cytogenetic prognostic groups and to identify patients at an increased risk of relapse similarly like it has been adopted in p-B-ALL.

Background: Acute leukemia (AL) is a severe disease of the hematopoietic sys-
tem and associated with a poor outcome for patients. Patient derived xenograft (PDX) mouse models provide an attractive tool to engraft and grow primary tumor cells. In contrast to culture growth, samples can be monitored in a consisting
microenvironment. This powerful tool provides the baseline for further experiments like preclinical treatment trials or biology studies. While good engraftment rates were published for primary pediatric ALL samples, engraftment rates of adult ALL samples might be inferior, but remain largely elusive.

**Aims:** This study aimed to determine engraftment and growing ability of primary adult AL samples in immunodeficient mice. Genetic engineering was performed to evaluate transduction efficiencies by lentiviruses in PDX AL cells.

**Methods:** Primary adult ALL and AML samples were transplanted into NSG mice in the absence of total body irradiation. Both frozen as well as fresh patient material was used. Human CD45 and human CD38 were stained in blood to monitor successful engraftment. Mice were sacrificed before coming down with leukemia. Isolated cells from bone marrow and spleen were analyzed by flow cytometry. Genetic engineering was performed using lentiviral vector systems and monitored by expression of fluorochrome markers and flow cytometry.

**Results:** Engraftment and growth was successful in NSG mice in 12 out of 15 primary adult ALL samples. Frozen samples showed a longer median engraftment time, but in contrast to the fresh samples there could already be visible engraftment with an average time of 75.29 days. Generally, the engraftment time varied from 47 days up to 166 days and was shortened for slow samples over several passages. Genetic engineering was successfully performed using lentiviral transduction to introduce expression of fluorescent colours for cell marking and monitoring in further experiments. Lentiviral transduction was performed in 8 ALL samples with BCR-ABL rearrangement and 2 ALL-F4 ALL samples. Adult AML PDX samples with chromosomal translocations showed very low transduction rates around 1%. Three AML samples with MLL-AF6, MLL-AF9, and MLL-AF10 translocation were analysed for this study. Interestingly and in contrast to ALL, transduction efficiency for AML rearranged samples was high with up to 60%. These values are similar to non-rearranged ALL samples having transduction rates between 30% up to 80%.

**Summary/Conclusions:** In summary, we observed a high engraftment rate of primary adult ALL samples in immunodeficient mice which was above what we anticipated for ALL. AML samples can be transduced more efficiently than lentiviruses with identical high transduction efficiency as pediatric samples, with an age independent exception of AL PDX cells with BCR-ABL or MLL translocations.

**SYNERGIC CHEMOTHERAPEUTIC EFFECT OF MENADIONE COMBINED WITH EPIGALLOCATECHINE-3-GALLATE OR DOXORUBICIN IN A HUMAN CELLULAR MODEL FOR ACUTE LYMPHOBLASTIC LEUKEMIA**

A. Garaiman1,2,*, I. T. Tofolean1, R. M. Babes1, C. Ganea1, I. Baran1
1Department of Biophysics, “Carol Davila” University of Medicine and Pharmacy, Bucharest, 2Department of Hematology, Coltea Clinical Hospital, Bucharest, Romania

**Background:** Epigallocatechin-3-gallate (EGCG) and menadione (vitamin K3; MD) are known as potent apoptogens in cellular models for acute lymphoblastic leukemia (ALL) – Jurkat T cells.

**Aims:** The goal of this study was to explore the chemotherapeutic potential of MD combined with EGCG or DOX, and to determine whether there is a synergic interaction between these agents that could significantly enhance their antitumor effect in a cellular model of ALL. We investigated the antiproliferative effect of EGCG and MD, applied alone or in combination EGCG:MD and DOX:MD on the human leukemia Jurkat lymphoblasts. Some underlying cellular mechanisms were also scrutinized.

**Methods:** Cell suspensions of Jurkat lymphoblasts were treated at various concentrations of EGCG, MD, and DOX. Clonogenic survival was evaluated as the colony forming capacity in 96-well plates. Cell cycle and apoptosis/necrosis were determined by flow cytometry using the fluorescent indicators propidium iodide and Annexin V-FITC/7-AAD, respectively. Determination of oxidative stress and mitochondrial polarization was performed by spectrofluorometry, using the fluorescent probes CM-H2DCFDA and JC-1, respectively.

**Results:** The clonogenic survival was 117 µM EGCG, 97 µM MD, and 97 µM DOX with Hill coefficient h = 3.17 and mitochondrial calcium in a dose-dependent manner (IC50 = 97 µM, h = 2.53). Furthermore, data show that there is no correlation between the level of mitochondrial calcium ([Ca2+]m) and mitochondrial membrane potential (ΔΨm) (Pearson correlation coefficient r = 0.100) or between [Ca2+]m and mitochondrial transcription factor A (mTRA) gene expression. Key results were as follows:

- There was a significant amount of DOX generated oxidative stress. MD augmented this effect, enhancing the antiproliferative effect of DOX most likely by increasing the affinity of DOX for nuclear DNA.

**Summary/Conclusions:** Our results support the notion that the combinations EGCG:MD and MD:DOX exert a strong synergic antiproliferative effect in human leukemia Jurkat cells and encourage further studies to test the clinical utility of this association in ALL therapy.

**FOCAL ERG DELETIONS AND DUX4 FUSIONS IN CELL LINES DERIVED FROM B CELL ACUTE LYMPHOBLASTIC LEUKEMIA**

H. Quentinmeier1,2,*, R. A. MacLeod1, C. Pommerenke1, H. G. Drexl1
1DSMZ, Braunschweig, Germany

**Background:** DUX4 has recently been presented as new oncogenic driver in B cell acute lymphoblastic leukemia (pre B-ALL) of adolescents and young adults [1]. Translocations of DUX4, especially those with the IGH locus led to high expression of the corresponding fusion gene. DUX4 then triggered the expression or a novel isoform of the ETS transcription factor ERG in pre-B ALL [2]. Focal deletions of exons 3-9 were a second cause for short ERG variants. Up to 7% of pre-B ALL showed deregulated expression of both genes, DUX4 and ERG [2].

**Aims:** We set out to find pre-B-ALL cell lines with DUX4 translocation and ERG deletion as potential model systems for this novel subtype of pre-B-ALL.

**Methods:** We screened a panel of ALL cell lines for aberrant expression of DUX4, using qRT-PCR (polymerase chain reaction). The existence of two binding sites for EGCG is suggested by the linear relationship between the level of mitochondrial calcium ([Ca2+]m) and mitochondrial membrane potential (ΔΨm) (Pearson correlation coefficient r= −0.304) or between [Ca2+]m and mitochondrial transcription factor A (mTRA) gene expression - which could only in part be explained by DUX4 being a one-exon gene. NALM-6 was the only cell line expressing the DUX4 protein. Likewise, the alternative ERG transcript with alternative exon 6 was observed in NALM-6 only.

**Summary/Conclusions:** In conclusion, focal ERG deletions in pre-B-ALL cell lines (2/6) occur at similar frequencies as in the primary tumor. Cell line NALM-6 carries the DUX4-IGH translocation, expresses the DUX4 protein and an ERG mRNA variant including the alternative exon 6. ERG deletions were present in cell lines NALM-4 and SUP-B15. However, cell line SUP-B15 did not express DUX4 protein and consequently also not alternative ERG exon 6 transcript. These results indicate that focal ERG deletions are not a safe indicator for aberrant expression of DUX4. Cell line NALM-6 is presented as model system for DUX4/ERG pre-B-ALL.

**HISTORICAL RURAL OF SECONDARY MULTILINEAGE PROLIFERATION WITH MYELOID 7 FOLLOWING TREATMENT OF RELAPSED ACUTE LYMPHOBLASTIC LEUKEMIA**

J. Buls1,*, A. Pobudejka-Pieniążek1, L. Śędek2, A. Łopeć2, M. Jara-Acevedo3, A. Kowalska-Pawlak4, A. Sonsala1, A. Orfao3, T. Szczepanek1
1Department of Pediatric Hematology and Oncology, Zabrze, Medical University of Silesia, Katowice, Poland; 2Department of Clinical Hematology, University of Silesia, Katowice, Poland; 3Department of Myeloid and Immunology, Medical University of Silesia, Katowice, Zabrze, Poland; 4Cancer Research Centre (IBMC, USAL-CSIC), Instituto for Biomedical Research of Salamanca (IBSAL), Department of Medicine and Cytometry Service (Nucleus Research Support Platform), University of Salamanca (USAL), Salamanca, Spain; 5Genetic Laboratory, 1st Independent Public Clinical Hospital of the Medical University of Silesia, Zabrze, Poland, Zabrze, Poland

**Background:** Approximately 90% of children with acute lymphoblastic leukemia (ALL) are cured with current treatment protocols. However, 15-20% of the patients still experience disease relapse. Overall, 5-10% of patients develop secondary therapy-related leukemia or myelodysplasia. Isolated ALL cell subpopulations have been identified in patients who develop therapy-related leukemia or myelodysplasia, which are closely related to patients who develop secondary therapy-related leukemia or myelodysplasia.

**Aims:** We present a case of a 11-year-old boy with the history of relapsed ALL followed by aberrant proliferation of several different subsets of precursor cells in both marrow (BM), which was associated with progressive ineffective hematopoiesis.

**Methods:** A boy diagnosed with standard risk B-cell Precursor (BCP) ALL in 2009 was treated until 12-2011 with frontline chemotherapy according to ALL-IC BFM 2002 protocol. In 12-2012, one year after treatment completion he relapsed with BM involvement. BM aspirate IHC and Cytogenetic Study was performed, while the biopsy of the second tests showed no leukemic infiltration. He received 2nd line chemotherapy according to InTReALL 2010 and local radiotherapy for the testicular area. Despite the borderline minimal residual metastasis, BM samples showed the expression of the myeloid-7 gene.
Results: AMI aspirate morphology showed at least 5% blasts. However, detailed 8-color flow cytometry according to the EuroFlow protocols revealed no cells with BCP-ALL-specific immunophenotype, but several subsets of BCP with aberrant immunophenotypes were observed. The frequency of these aberrant phenotypes was compared between children with ALL and healthy controls. The frequency of abnormal BCP (total 3.5%) and plasmacytoid dendritic cell precursors (2.1%) was significantly higher in children with ALL compared to controls. Future studies in larger populations are needed in order to specify the role of the above polymorphisms in genes that regulate inflammation and tumor suppression such as CXCL12 and CYP1A1. In conclusion, the study of single nucleotide polymorphisms in genes that regulate inflammation and tumor suppression such as CXCL12 and CYP1A1 is essential for the identification of potential biomarkers for early detection and risk stratification of childhood leukemia.

Summary/Conclusions: In conclusion, the study of single nucleotide polymorphisms in genes that regulate inflammation and tumor suppression such as CXCL12 and CYP1A1 is essential for the identification of potential biomarkers for early detection and risk stratification of childhood leukemia.

Methods: Bone marrow mononuclear cells (BMMCs) are collected from bone marrow samples of T-ALL patients, including at initial presentation (n=46), during first CR (n=23) and at relapse (n=6). The expression level of mRNA encoding L-cellular Fas-associated death domain-like interleukin-1β converting enzyme inhibitory protein (c-FLIP) was assessed by real-time PCR. Changes in the expression level of HDAC before and after chidamide treatment were also assessed by western blot. Necrosis and apoptosis after chidamide treatment were assessed by flow cytometry. Changes in expression level of c-FLIP, protein before and after treatment were assessed by western blot. Necrosis level of early apoptotic protein, key proteins of necroptosis were assessed by western blot. The effect of chidamide on NF-kB signaling pathway activity and expression of key molecules when inducing necrosis were assessed by western blot. The regulating effect of chidamide on downstream genes of NF-kB pathway including cyclin D1, TNFα, IL-2, IL-8 were assessed by RT-PCR.

Results: The expression level of c-FLIP, mRNA is significantly higher in patients at initial presentation and relapse, compared to those at complete remission and healthy control. The expression level of c-FLIP, mRNA is associated with patient risk stratification, white blood cell count at initial presentation, serum lactate dehydrogenase (LDH), serum level of hydroxybutyrate dehydrogenase (HBDH), CD45, HLA-DR, SIL-TAL1 fusion gene and complex karyotype, and is not associated with sex, plasma fibrinogen level, and the chromosomal aberration 6q-. Patients who did not achieve CR during first chemotherapy had a higher c-FLIP, mRNA level than those who did (p<0.05). A total of 10 patients (21.7%) of histone deacetylase inhibitor (HDAC inhibitor) were chosen for further studies. All these patients were with abnormal mononuclear cells of T-ALL patients, Jurkat and HUT-78 cell lines. After treatment with chidamide, the expression level of histone deacetylase was significantly decreased in both cell lines. Chidamide induced necrosis and apoptosis in Jurkat and HUT-78 cell lines. After apoptosis inhibitor was applied, chidamide almost completely exerted its effect of inducing cell death by inhibiting necroptosis. Chidamide inhibits the translation and translation to c-FLIP, gene. When apoptosis is inhibited, chidamide upregulates the expression level of receptor-interacting protein 3 (RIP3) and the phosphorylation level of mixed lineage kinase domain-like (MLKL). After treatment with chidamide, the phosphorylation level of RIP3 and RIP1 were both significantly decreased.

Summary/Conclusions: c-FLIP, mRNA expression level is abnormally high in T-ALL patients both at initial presentation and at relapse. The expression level of c-FLIP, is associated with risk stratification, white blood cell count, serum LDH level, serum HBHD level, CD45, SIL-TAL1 fusion gene, complex karyotype and disease outcome. c-FLIP, could be used as a prognostic marker in T-ALL. Chidamide suppresses histone deacetylation in Jurkat and HUT-78 cell lines. Chidamide induces necrosis in Jurkat and HUT-78 cell lines by down regulating the transcription and translation of c-FLIP, gene. Chidamide induces necrosis in Jurkat and HUT-78 cell lines by classical NF-κB signaling pathway.

CYP1A1 AND CXCL12 GENE POLYMORPHISMS IN CHILDHOOD ACUTE LYMPHOBlastic LEUKEMIA

E. Kampouraki1, M. Lourou1, E.-D. Ampazoglou 1, M. Karachaliou1, E. Stilakos1

1Pediatric Hematology - Oncology, University Hospital of Heraklion, University of Crete, Heraklion, Greece

Background: Acute lymphoblastic leukemia (ALL) is the most common type of childhood leukemia and represents one third of all pediatric malignancies. Despite high survival rates (total 80%), relapses and number of children relapse and for them the outcome remains poor. Epidemiological studies that examined possible risk factors of acute leukemias, proved that genetic factors play a crucial role in leukemogenesis. Recent genetic association studies on cancer risk, have focused on the effects of single nucleotide polymorphisms in genes that regulate inflammation and tumor suppression such as chemokines and P450 cytochrome. Chemokines induce the motility of endothelial and tumor cells. CXCL12, a chemokine expressed in various tumors, binds to chemokine receptor 4 (CXCR4) and is considered to play an important role in tumor growth and invasion. The polymorphism rs1801157 of the CXCL12 gene has been investigated concerning the disease pathogenesis. Moreover, CYP1A1 gene belongs to family 1, subfamily A1 of cytochrome P450. CYP1A1 protein is a phase I xenobiotic metabolizing enzyme that activates the conversion of environmental chemicals into carcinogens. The above gene contains two important single nucleotide polymorphisms, CYP1A1*2A (rs4646903) and CYP1A1*2C (rs1048943), which are associated with an increased risk of leukemia.

Aims: The study of single nucleotide polymorphisms rs1801157 of CXCL12 and CYP1A1*2C (rs1048943) in children with B-lineage ALL.

Methods: Thirty children with B-lineage ALL (19 boys, mean age 6.8 years) were included in this study. c-FLIP, was measured by RT-PCR. CXCL12 polymorphism was determined by polymerase chain reaction (PCR) in all patients. The PCR products were digested with the restriction enzymes MspI and BsiDl for CXCL12 and NoVI for CYP1A1. Descriptive statistics and logistic regression analysis were used to examine for differences between children with ALL and controls.

Results: In the CXCL12 loci, the frequencies of AA, AG, and GG genotype were 3.45%, 93.1% and 3.45% in children with ALL, 13.3%, 60.0%, 26.7% in children control group and 4.17%, 45.83% and 50.0% in adult control group respectively. In the CYP1A1 loci, the frequencies of AA, AG, and GG genotype were 13.3%, 86.7% and 0% in children with ALL, 90.0%, 10.0%, 0% in children control group and 81.6%, 16.4% and 2.0% in adult control group respectively. No statistical significant differences in CXCL12 polymorphism were revealed between children with ALL and healthy groups using logistic regression analysis. Regarding CYP1A1 loci, we detected a positive association for the AG polymorphism and ALL [OR: 37.7 (95% CI: 10.81, 131.37), p<0.001 and OR: 58.5 (95% CI: 9.66, 354.12), p<0.001 using only the children’s control group].

Summary/Conclusions: A higher frequency of CYP1A1 heterozygote allele was observed among children with ALL compared to controls, whereas no differences were observed regarding CXCL12 polymorphisms. Future studies in larger populations are needed in order to specify the role of the above polymorphism in childhood ALL.

INTRACHROMOSOMAL AMPLIFICATION OF CHROMOSOME 21 IN PEDIATRIC ACUTE LYMPHOBlastic LEUKEMIA: A RARE SUBTYPE

L. Vida1,2, B. Burjan1, B. Horváth1, L. Kereskai1, G. Oštěfő1, L. Tiszlavicz1, D. Alpár4, B. Kajtár1

1Pathology, 2Pediatrics, University of Pécs, Pécs, 3Pediatrics, University of Pécs, Pécs, 4Department of Internal Medicine, JUZK University Medical Centre, Pécs, Hungary

Background: The study of single nucleotide polymorphisms rs1801157 of CXCL12 and CYP1A1*2C (rs1048943) in children with B-lineage ALL.
Szeged, Szeged, Hungary, Research Center for Molecular Medicine of the Austrian Academy of Sciences, Vienna, Austria

Background: Intrachromosomal amplification of chromosome 21 (iAMP21) defines a rare subtype of pediatric acute lymphoblastic leukemia (pALL) occurring in approximately 2-3% of cases. The patients are older (median age is 9 years), usually have low white blood cell counts and show high relapse risk with standard therapy. Thus, it has been proposed to include ALL with iAMP21 as a distinct entity in the WHO classification of hematological malignancies.

Aims: To assess the frequency as well as the clinicopathological and genetic characteristics of ALL with iAMP21 in one of the three national diagnostic centers of pALL in Hungary. We sought to determine additional genetic aberrations associated with this rare entity.

Methods: Between 2008-2016, 175 samples of pALL patients were tested with FISH for BCR-ABL1, ETV6-RUNX1 and MLL translocations. When available, bone marrow karyotyping was used to verify the abnormal results. In one case with iAMP21, multiplex ligation-dependent probe amplification (MLPA) was used to verify the cytogenetic aberrations as well as to detect associated copy number alterations.

Results: Among the 175 samples screened with FISH, three showed evidence of iAMP21 (1.7%), Case 1 was a 16-year-old male who presented with thrombocytopenia and hepatosplenomegaly. Flow cytometry (FCM) showed common ALL phenotype with the expression of CD13 and CD33. FISH showed >10 RUNX1 signals in clusters in leukemic blasts, while karyotyping demonstrated r(21) with 7q deletion and +X. The lesions were verified by MLPA, which additionally revealed biallelic CDKN2B and RB1 deletions. The patient was treated with ALL-IC BFM 2002 standard risk protocol. Following remission, isolated meningeal relapse occurred, for which he received radiotherapy. The patient died with recurrent meningeal disease without bone marrow involvement after 52 months. Case 2 was an 11-year-old girl, who presented with symptoms suggesting osteomyelitis of the tibia with unremarkable blood count. MRI showed multiple lesions in vertebrae as well as meningeal involvement of the spinal cord. Bone marrow biopsy and biopsy of the left tibia showed diffuse infiltration of lymphoblasts with only 5% leukemic cells in bone marrow aspirates. FISH detected 6-8 copies of RUNX1 in leukemic blasts, while karyotyping yielded only normal bone marrow cells. She was commenced on ALL-IC BFM 2002 standard risk and was later switched to high risk protocol. She is in complete remission after 14 months. Case 3 was an 11-year-old boy who presented with anemia and thrombocytopenia. FCM showed ALL with common phenotype with two populations; one being strong CD19+/CD66c+ and one with dim CD19+/CD66c-. FISH showed >10 RUNX1 signals in clusters in 95% of cells, while 52% showed BCR-ABL1 positivity. Bone marrow karyotyping yielded metaphases of poor quality (Figure 1).

HIGH RESOLUTION TECHNOLOGIES IN B-CELL ACUTE LYMPHOBlastic LEUKE.MIA

A. Escudero1,*, P. Carrasco1, J. Nevado1, M. Palomares1, E. Vallespin1, P. Lapunzina1, L. Fernández2, M. Vela3, I. Gonzalo1, B. González4, D. Bueno4, Á. del Pozo1, A. Pérez-Martínez4

1INGE.M, Hospital Universitario la Paz, 2Clinical Research, CNIO, 3IdiPAZ, 4Pediatric Hemato-Oncology, Hospital Universitario la Paz, Madrid, Spain

Background: B-cell acute lymphoblastic leukemia (B-ALL), the most common pediatric malignancy and main case of childhood cancer death, resulting from accumulation of genetic aberrations. Advances in our understanding of these aberrations is useful to improve disease classification, prognosis, therapeutic purposes, and to provide an overall understanding of the pathogenesis of the B-ALL.

Aims: Genomic characterization of childhood B-ALL.

Methods: We retrospectively examined bone marrow samples from 29 pediatric B-ALL using high resolution technology. We study copy number alteration (CNAs) and copy neutral loss of heterozygosity (CN-LOH) using Illumina CytoSNP-850K BeadChip in the Illumina HiScan platform. Analysis of more than 90 genes related with pediatric cancer was done using Next Generation Sequencing (NGS).

Results: Except for one, all patients showed copy number alterations. Losses were more common than gains. Whole and partial CN-LOH were observed in 12 cases. Only four recurrent genetic alterations were found: hyperdiploidy (44% of the cases), deletion of CDKN2A/B genes (22%), deletion of PAX5 gene (16%) and deletion of ETV6 (9%) gene. Several possible target genes were identified, including SESN1, NME1 and BMPR1B, but additional studies are needed to confirm their implication in the disease. We identified high diversity of mutations 30 genes, 40% of all mutations are previously described in cancer patients. We found several mutations in Jak gene family in 5 patients that could have been the subject of therapeutic intervention with specific inhibitors of these kinases.

Summary/Conclusions: NGS and SNP arrays are powerful genetics tools capable of identifying a multitude of genetic alterations associated with B-ALL. The use of SNP arrays and NGS in clinical practice can help identify new prognostic alterations and develop individualized treatment plans for affected children.

Figure 1.

Summary/Conclusions: ALL with iAMP21 is a rare subtype with distinct clinicopathological characteristics. Presenting with only mildly elevated WBC in older children is typical, relapses are frequent if standard risk chemotherapy is administered. Association with BCR-ABL1 translocation is rare, having been reported in case only 4 cases. Observing BCR-ABL1 translocation in a subpopulation of leukemic cells is an intriguing phenomenon; it indicates that this translocation may occur as a secondary event even after leukemic transformation has commenced.
Acute lymphoblastic leukemia - Clinical

COMPLETE REMISSION WITH BLINATUMOMAB IN TWO PATIENTS WITH SKIN RELAPSED B-CELL ACUTE LEUKEMIA

H. Leroy1,*, M.-L. Jullie1, E. Forcade1, G. Laboure1, R. Tabrizi1, P.-Y. Dumas1, M. Robies1, A. Chauvel1, B. Vergier1, N. Milpied1, A. Pigneux1, T. Leguay1

1CHU Bordeaux Haut Lévêque, pessac, France

Background: Blinatumomab is a bispecific T-cell–engager (BiTE) antibody (CD19/CD3) indicated in relapsed/refractory B-cell Acute Lymphoid Leukemia (r/r ALL) (Topp et al.). Extra-medullary relapse is a rare event occurring in only 8% of the patients, of whom only 1.4% present a skin relapse which harbor a dismal prognosis (Gokbuget et al.).

Aims: Herein, we report the efficacy of Blinatumomab in two patients presenting with extra-medullary relapse of ALL.

Methods: The first patient (a 40-year-old man) was diagnosed a CD19+ Ph - B-ALL in 2009. He received a chemotherapy regimen according to the GRAALL protocol (Huguet et al.) until complete remission (CR). In 2015, he presented with a maculopapular rash of the right leg and the left flank, and two enlarged inguinal lymph nodes. Cutaneous relapse was attested by examination of skin biopsy specimen showing a blastic dermal infiltration harboring a CD10+, Tdt+ phenotype. The second patient was a 50-year-old male who presented, in 2016, a CD19+ B-ALL Ph- Ikaros- without central nervous system involvement. He obtained a first CR after GRAALL induction with negative MRD (IgH) but he relapsed 3 months later with a maculopapular rash of his chest. The skin biopsy revealed a blastic dermal infiltration. These two patients with skin relapse received frontline chemotherapy (COPRAALL 2007 regimen) (Domenisch et al.), with no efficacy (cutaneous blastic infiltrate). Both patients received one cycle of Blinatumomab from day 1 to day 28, at 28 μg per day, in an attempt to achieve CR before allogeneic stem cell transplantation, as previously described.

Results: At day 5 of Blinatumomab, an important non pruritic maculo-papular rash occurred in both patient, in the same area of the initial cutaneous involvement. Interestingly, it decreased after day 8. No new drug introduction or infection (bacterial, viral or parasitic) was documented in the days preceding or during Blinatumomab infusion. A skin biopsy performed at day 6 of Blinatumomab showed a blastic dermal infiltration harboring a CD3+ T-cell lymphocytic infiltrate with a perivascular, but also a peri-nervous distribution (on the first patient's specimen only). Few lymphocytes marginated at the basement membrane and rare basal necrotic keratinocytes were also noted but without blast for the first, although few residual blastic cells were observed on the second's. One month later, another skin biopsy showed a CR with a lymphocytic infiltrate. The medullar CR was confirmed at the molecular level (MRD negative). The first patient received allogeneic stem cell transplantation (SCT) from a matched related donor one month later. He presented an acute and chronic GVHD, and is now in complete remission with a follow-up of 7 months. The second is still waiting for a SCT.

Summary/Conclusions: These observations confirm the strong efficacy of Blinatumomab in r/r B-ALL. We observed a T-cell dermal recruitment 6 days after Blinatumomab initiation clinically mimicking skin GVHD. However, we couldn’t find specific histological features of GVHD, but only an “inflammatory dermatitis”. Blinatumomab in relapsed B-ALL with cutaneous infiltration suggests promising activity in extra-medullary relapse. Further studies are required to confirm a Blinatumomab-based strategy in extra medullary relapsed B-ALL. This may provide a better understanding of how cytolytic synapses between T lymphocytes and intradermal blasts happen and the underlying homing mechanisms involved.

PB1630

A NOVEL METHOD FOR MINIMAL RESIDUAL DISEASE ANALYSIS IN PHILADELPHIA-NEGATIVE ACUTE LYMPHOBLASTIC LEUKEMIA: MODIFIED BIOMED-2 POLYMERASE CHAIN REACTION FOR IMMUNOGLOBULIN HEAVY CHAIN REARRANGEMENT

D. Katoh1,*, M. Nakamura1, M. Morita1, H. Maruoka2, A. Fujimoto1, N. Yonetani1, A. Matsushita1, H. Hashimoto3, T. Ishikawa1

1Hematology, 2Clinical Laboratory, Kobe City Medical Center General Hospital, 3Cell Therapy, Institute of Biomedical Research and Innovation, Kobe, Japan

Background: Recent studies have demonstrated the clinical importance of minimal residual disease (MRD) monitoring in adult acute lymphoblastic leukemia (ALL) as well as pediatric ALL. However, patient-specific polymerase chain reaction (PCR)-based MRD assessment, one of the most commonly recognized methods, is not widely used in clinical practice because it is expensive, time consuming, and technically difficult. Therefore, we modified the BIOMED-2 protocol, PCR for immunoglobulin heavy chain (IgH) rearrangement, to assess MRD in ALL easily and readily in our hospital.

Aims: The aim of this study was to examine the clinical utility of monitoring MRD by the modified BIOMED-2 PCR for IgH rearrangement in patients with Philadelphia-negative (Ph -) ALL.

Methods: We enrolled 54 patients diagnosed with Ph (-) ALL between 2006 and 2016 in our hospital. IgH rearrangement was detected in 35 patients using the standard BIOMED-2 PCR protocol. Patients who received palliative chemotherapy, never achieved remission (blasts <5%), or had no follow-up MRD data were excluded. Finally, data from 27 patients with Ph (-) ALL were analyzed. We assessed MRD with the modified BIOMED-2 PCR for IgH using bone marrow samples collected after each chemotherapy session. Patients’ MRD statuses were classified as follows: Early MRDneg, achievement of MRD negativity within 6 weeks after chemotherapy initiation; Late MRDneg, achievement of MRD negativity more than 6 weeks after chemotherapy initiation; or MRDpos, persistent MRD detection during chemotherapy. The endpoint was disease-free survival (DFS), calculated from the date of achieving remission.

Results: The median age was 38 years (16–73), and the median follow-up time was 47 months (4–106). There were 8, 14, and 5 patients with early MRDneg, late MRDneg, and MRDpos, respectively. There were no differences in patient characteristics by bone marrow status, except for the duration to achieving remission (Table 1). There were significant differences in the 3-year DFS rates among patients with early MRDneg, late MRDneg, and MRDpos (100% vs 72.9% vs 20%; p=0.001) (Figure 1). Patients undergoing transplantation had better prognosis than those receiving chemotherapy alone in the late MRDneg group (100% vs 40%; p=0.028), whereas there was no difference in the early MRDneg group (100% vs 100%; p=0.48).

Table 1. Patient characteristics by MRD status as assessed with the modified BIOMED-2 PCR for IgH protocol.

<table>
<thead>
<tr>
<th>MRD Status</th>
<th>Number (%)</th>
<th>DFS (months)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Early MRDneg</td>
<td>8 (100%)</td>
<td>47 months (4–106)</td>
</tr>
<tr>
<td>Late MRDneg</td>
<td>14 (100%)</td>
<td>47 months (4–106)</td>
</tr>
<tr>
<td>MRDpos</td>
<td>5 (100%)</td>
<td>47 months (4–106)</td>
</tr>
</tbody>
</table>

Figure 1. The status of minimal residual disease was associated with prognosis.

Summary/Conclusions: The modified BIOMED-2 PCR protocol is a highly accurate and reliable method of MRD assessment in adult ALL. It predicted treatment outcomes in adult Ph (-) ALL, and patients with late MRDneg might derive a high survival benefit from allogeneic transplantation. Finally, the accuracy and reliability of the modified BIOMED-2 PCR for IgH were confirmed with a comparison to quantitative real-time PCR for BCR-ABL using samples from patients with Philadelphia-positive ALL (data not shown).

PB1631

SYSTEMATIC LITERATURE REVIEW OF PEGASPARGASE FOR THE TREATMENT OF NEWLY DIAGNOSED ADULTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

E. Hooper1,*, A. Wijatyk1, D. Bollag2

1Shire, Cambridge, United States, 2Shire, Zähringen, Switzerland

Background: Asparaginase is a component of a multi-agent chemotherapy regimen widely used in clinical practice for acute lymphoblastic leukemia (ALL). Since 2006, pegaspargase (PEG-ASP) has been the gold standard asparaginase for the treatment of pediatric ALL as it offers equivalent efficacy to native E. coli L-asparaginase (native ASP), with less frequent dosing,

Aims: The aim of this study was to review the efficacy and safety of asparaginase (native ASP and pegaspargase) for the treatment of acute lymphoblastic leukemia (ALL) in adults.
FACTORS AFFECTING THE TOXICITY OF PEGYLATED-ASPARAGINASE
FOR THE TREATMENT OF ADULT ACUTE LYMPHBLASTIC LEUKEMIA
P. Minetto1,*, N. Bisso1, F. Guolo1, M. Clavio1, E. Coviello1, D. Guardo1, N. Di Felice1, F. Canale1, L. Manconi1, F. Ballerini1, M. Miglino1, R. M. Lemoli1, M. Gobbi1
1Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genova, IRCSS AOU San Martino-IST, Genoa, Italy

Background: The application of pediatric regimens in the treatment of adult acute lymphoblastic leukemia (ALL) has led to a significant improvement in patients outcome. However, concerns about the feasibility of more intensive therapies and of the use of pegylated L-Asparaginase (PEG-ASP) in adult patients have emerged. Some patient-related risk factors as high BMI or hepatic steatosis have been already identified as risk factors, but few data are available on the synergic toxic effect from other concomitant drugs.

Aims: The aim of the present study was to evaluate the incidence of PEG-ASP related adverse events in a cohort of adult ALL patients in order to identify potential patient and therapy-related risk factors contributing to toxicity.

Methods: Since 2013, 21 adult ALL patients received PEG-ASP therapy in our institution. Median age was 44 (range 19-76); 12 patients were treated in front-line setting (7 according to a full pediatric protocol) whereas 9 patients received therapy for relapsed/refractory neoplasm. We retrospectively analyzed each single course which included PEG-ASP administration as an independent event, accounting 41 episodes. Patients’ features (age, BMI, disease status) and concomitant therapies were accurately analyzed as factors potentially affecting PEG-ASP toxicity. The incidence of major thrombotic/bleeding complications and grade III/IV hepatic or pancreatic toxicity was analyzed; toxicity grading and management of PEG-ASP related complications were performed according to guidelines recently published by Stock et al.

Results: No grade III/IV pancreatic, thrombotic or hemorrhagic adverse events were recorded. A total of 8 episodes of grade III/IV hepatic toxicities were observed. In 3 cases, grade IV toxicity was observed. Those patients experienced unexplained severe weight gain and painful epauchalgia, a common picture resembling sinusoidal occlusive disease, ultrasonography showed acute liver steatosis. All 3 patients concomitant therapy with idarubicin, vincristine, cytarabine. In univariate analysis, the incidence of grade III/IV hepatic toxicity was significantly higher when concomitant chemotherapy with at least 2 mg/sqm cumulative dose of vincristine (0.044, HR 4.75) or at least 16 mg/sqm cumulative dose of idarubicin (0.046, HR 1.45) were administered. Steroids therapy determined a borderline increase in toxicity risk (0.068, HR 2.33). The risk for increasing toxicity was observed with any dosing of daunorubicin, cyclophosphamide, cytarabine, methotrexate and 6-mercaptopurine (Table 1). Among concomitant antibiotic therapies, vancomycin administration seemed to increase the incidence of grade III/IV hepato-toxicity (0.02, HR 1.863). No significant increase was observed with carbenapenems and azoles (Table 2). Concomitant receipt of PEG-ASP and active leucovorin therapy with a high BMI (>25) were not related with an increased incidence of grade III/IV hepatotoxicity (Table 1). Notably, none of the patients undergoing full pediatic induction (who received the highest doses of PEG-ASP), regardless of age (ranging from 21 to 55) experienced grade III/IV hepatopathy. A multivariate logistic regression analysis disclosed that concomitant administration of idarubicin, vincristine or vancomycin were independent predictors of grade III/IV hepatotoxicity (p 0.004, 0.027 and 0.042, respectively, Table 1).

Table 1.

Summary/Conclusions: Our data show that the toxicity profile of PEG-ASP in adult patients is overall manageable. However, serious warnings emerge from our experience. Concomitant drugs and their timing of administration may play a crucial role in significantly contributing to PEG-ASP hepatic toxicity. In order to attempt to reduce toxicity, anthracyclines with shorter half-life, i.e. daunorubicin instead of idarubicin, should be used. A particular attention should be paid when administration of concomitant antibiotic therapy is required.

PB1633

COSt OF CARE FOR ADULT PATIENTS WITH RELAPSED ACUTE LYMPHBLASTIC LEUKEMIA WITH AND WITHOUT HEMATOPOIETIC STEM CELL TRANSPLANT IN GERMANY
Y. Su1,*, S. Schmitter2, A. Navarro3, L. Mayerhoff3, S. Pierre3, M. Lehne3, F.R. Lobez1
1Pfizer Inc., New York, United States, 2Pfizer Deutschland GmbH, 3Elsevier Health Analytics, Berlin, Germany

Background: Adult ALL is a rare but frequently fatal disease. Many patients who respond to initial therapy experience a relapse. For relapsed ALL (RALL), hematopoietic stem cell transplant (HSCT) is a potentially curative treatment option. HSCT is associated with added costs, however, which could impact overall healthcare budget.

Aims: This retrospective observational study aims to determine the cost of care and the impact of HSCT on total cost for adult RALL patients from a German payers’ perspective.

Methods: A German claims database with a representative sample of approximately 7 million individuals insured within the German statutory health insurance and continuously observable over a period of 6 years was used as data source. For these data, adult patients (18 years and older) with a new diagnosis of ALL (ICD-10-GM code: C91.0) between January 1, 2011 and December 31, 2015 and a relapse after remission to initial treatment were identified. Mean health care cost per patient per quarter, the smallest unit of time available in the database, was determined by whether or not patients had an HSCT after relapse. Costs were considered from the perspective of the German statutory health insurance and included costs for prescription medicine as well as outpatient and inpatient healthcare encounters.

Results: Of the total 116 incident adult ALL patients identified, 29 (25%) were determined to have had a relapse and 11 underwent HSCT after relapse (38%). Patients with an HSCT appear to incur higher cost than those without HSCT in each of the quarters after relapse was diagnosed (Table 1), with the highest in the first quarter after relapse, but decreasing in subsequent quarters. Inpatient cost accounted for the majority of the cost for the first three quarters for both HSCT and non-HSCT patients, but more for HSCT patients. The number of patients in the HSCT cohort remained relatively stable, while the non-HSCT cohort had only half the patients left by the third quarter post relapse.

Table 1. Costs in € per patient (with and without HSCT) by quarter after relapse

Summary/Conclusions: Our data show that the toxicity profile of PEG-ASP in adult patients is overall manageable. However, serious warnings emerge from our experience. Concomitant drugs and their timing of administration may play a crucial role in significantly contributing to PEG-ASP hepatic toxicity. In order to attempt to reduce toxicity, anthracyclines with shorter half-life, i.e. daunorubicin instead of idarubicin, should be used. A particular attention should be paid when administration of concomitant antibiotic therapy is required.
**Summary/Conclusions:** The results of this study inform the magnitude of cost in Germany associated with adult rALL patients who or without an HSCT after relapse. The cost estimates provide a benchmark against which new treatment options for rALL can be compared. For future studies, it would be important to determine the magnitude of benefit such as long-term survival and other health consequences associated with HSCT as well.

**PB1634**

RETROSPECTIVE STUDY OF ADULT ALL IN MEXICO CITY: FIRST REPORT OF THE WORKING GROUP ON ACUTE LEUKEMIA

**Background:** The prognosis of adult acute lymphoblastic leukemia (ALL) is dire, with a long-term survival of 40-50%. This disease entity is probably more frequent in the Latino population. Several studies have reported a worse prognosis in Hispanics with ALL as well as a greater incidence of the Ph-like genetic signature; however, the data is inconclusive in the Mexican population and there are no existing large multicenter series of ALL patients in Mexico that analyze survival.

**Aims:** The aim of this study was to describe the incidence, clinical and biologic characteristics as well as the survival of ALL patients in 5 referral hospitals in Mexico City.

**Methods:** A working group known as the Grupo de Trabajo de Leucemia Aguda (GTLA), was created as a result of an initiative of the Mexican Group for the Study of Hematology (Agrupación Mexicana para el Estudio de la Hematología) to promote acute leukemia research in Mexico. This is the first report of the GTLA which includes 5 referral hospitals in Mexico City. A retrospective, multicenter descriptive study of adult ALL patients treated between 2009 and 2015 was conducted.

**Results:** We included 559 adults in 5 centers in Mexico City. Their median age was 28 years (14-81): adolescents and young adults (AYA) 67.3%; adults 24.7% and elderly adults 8.1%. Tumor lysis syndrome was detected in 9.8% of patients. Cytogenetic information was unavailable in 45% of cases due to lack of access or growth in metaphase. Among cases that could be analyzed, a normal karyotype was the most frequent (70.5%), followed by Ph+ (16.7%). Patients were considered high-risk in 52.1% cases. The most frequently used drug protocol was Hyper-CVAD, in 47% of cases. Complete remission (CR) was achieved in 67.1% of patients, and 18% required a second cycle for CR, while 13% were primarily refractory. A mortality rate during induction was registered as 10.6%, and there were 11.4% deaths while in CR. Among patients in CR, 59.1% relapsed. At the time of analysis, 26.7% of patients were alive, with a median OS of 12.97 months and a DFS of 16 months. Only 5.7% were alive in complete remission at 2 years.

**Summary/Conclusions:** Survival for patients with refractory and relapsed ALL is lower than reported, which could be due to a real difference between populations or due to aspects related to cytogenetic techniques. Based on these results, the GTLA’s objectives will be: to standardize diagnostic testing and treatment options for refractory and relapsed ALL, including 19 cases in advanced stage (nonremission, NR) and 33 cases in more than or equal to second complete remission (≥CR2), received allo-HSCT after myeloablative conditioning regimen in our department.

**Background:** Patients with refractory or relapsed ALL are a challenging subgroup of patients. The overall survival (OS) is significantly worse compared to patients in first complete remission (CR). The choice of treatment options depends on several factors including disease status, fitness, and patient’s preferences. Therefore, it is essential to develop novel strategies for an effective treatment of these patients. The aim of this study was to identify the key factors affecting OS of patients with refractory or relapsed ALL in the institution.

**Methods:** We conducted a retrospective study of all patients with refractory or relapsed ALL treated in our institution from January 2000 to December 2015. A total of 51 patients were included in the analysis. Demographic, clinical, and treatment-related factors were collected. The main endpoints of the study were OS and progression-free survival (PFS).

**Results:** The median age of the patients was 41 years (range: 18-78). The most common WHO subtype was B-cell ALL (80%). The median follow-up time was 18 months (range: 1-120 months). The median number of treatment lines was 3 (range: 1-12). The most common initial treatment was Hyper-CVAD (64%). The most frequent chemotherapy regimens used as salvage therapy were Hyper-CVAD (42%), and Cytarabine, in 21% of cases. The median number of chemotherapy lines was 6 (range: 1-24). The median number of HSCT was 1 (range: 0-4). The most common conditioning regimens were Bu-Cy and Bu-ATG. The estimated 2 year OS and 2 year relapse-free survival (RFS) were 52.6% and 56.2% (P=0.730), including 42.1% vs 33.3% (P=0.527) with mild (grade I-II) and 10.5% vs 24.3% (P=0.399) with severe (grade III-IV) aGVHD. The incidence of cGVHD was similar also (41.6% vs 57.9%, P=0.860). With a median follow-up of 12(1.8-44.5) months, the cumulative relapse rate of NR and ≤CR2 was 47% vs 34.3% (P=0.425) respectively.

**Summary/Conclusions:** Allo-HSCT is an effective salvage treatment option for patients with refractory and relapsed ALL. Our retrospective analysis showed that R/F ALL with different status prior transplant had similar outcome post transplantation.

**PB1636**

THE FREQUENCY AND PROGNOSTIC SIGNIFICANCE OF IKZF1 DELETIONS IN ADULT PH-POSITIVE AND PH-NEGATIVE B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS TREATED IN RUSSIAN ACUTE LYMPHOBLASTIC LEUKEMIA STUDIES

**Aims:** To evaluate the frequency and prognostic impact of mutation status of IKZF1 in patients with de novo B-ACR-ABL1-negative and B-ACR-ABL1-positive B-cell acute lymphoblastic leukemia.

**Methods:** The study included 30 patients (median age 27, range 17-56; m:f=15:21) with newly diagnosed BCR-ABL1- neg B-cell ALL and 15 patients (median age 34 years, range 22–68; m:f=6:9) with BCR-ABL1- pos B-cell ALL, who were enrolled in Russian acute lymphoblastic leukemia (RALL) - 2009 [ClinicalTrials.gov public site; NCT01193933] and RALL-2012 protocols since Feb 2010 till Sep 2016 and Aug 2009 till Feb 2017, respectively.

**Results:** The IKZF1 deletions were detected in 7 (47%) of 15 patients with BCR-ABL1- pos ALL (3 cases with del 4-7 (43%), 2 - del 2-7 (28%), 1 - del 2a-8 and 1 – del 4-8 (14%)). The median follow-up time in 15 patients was 18 months (range: 4-79 month). Five patients died (33%) after relapse or progression of the disease, and 10 patients are alive. Overall survival (OS) in BCR-ABL1 - pos B-cell ALL patients with IKZF1 mutations and without was 37.5% and 57.1% (p=0.77), relapse - free survival (RFS) - 25% and 33.3% (p=0.88), respectively. In patients with BCR-ABL1- neg ALL the IKZF1 deletions were revealed in 8 (22%) of 36 patients (4 cases with del 4-7 (50%), 2 - del 2-7 (25%), 1 – del of 2-8 (12,5%) and 1 patient all types of deletions were determined (del 4-7, del 4-8, del 2-7, del 2-8)). The median follow-up time in 36 patients was 22 months (range: 0.5-84 month). 4 patients died of the disease (11%) and 2 of infections, 30 patients are alive. OS for patients with BCR-ABL1- neg ALL with IKZF1 mutations and without was 100% and 60.2% (p=0.77), RFS - 75% and 40.2% (p=0.74), respectively.

**Summary/Conclusions:** The frequency of IKZF1 gene deletions in patients with BCR-ABL1- pos and with BCR-ABL1- neg ALL was 47% and 22%, respectively. IKZF1 mutations seemed to be of poor prognosis for BCR-ABL1-
pos ALL and, on the contrary, more favorable for BCR-ABL1- neg ALL, though not statistically significant. Having or not IKZF1 mutations, all BCR-ABL1--pos ALL patients are candidates for allogeneic hematopoietic stem cell transplantation (allo-HSCT). Regarding BCR-ABL1-neg ALL: though the group of patients is small, we can suggest that IKZF1 mutation did not appear to influence survival due to different chemotherapy principal in RALL— 2009 – non-intensive but not-interruptive therapy with low numbers of HSCT.

Summary/Conclusions: Our results show that GMALL-based protocol yields good overall survival in adults ALL patients in a low income country, despite major adaptations. On the other hand, overall survival of AYA patients treated with BFM-based protocol was surprisingly poor, specially because of ineffective disease control may be related to several aspects: socioeconomic impairment, inadequate supportive care for more intensive therapies and ineffective cancer care network. Future prospective studies should focus on this issues.

Figure 1. Relapse-free survival.

**GMALL BASED PROTOCOL, USING NATIVE E. COLI L-ASPARAGINASE, IMPROVES SURVIVAL OF ADULTS WITH ACUTE LYMPHOBlastic LEUKEMIA IN BRAZIL**

I. Arcuri1,2, J. Ramires1, Y. Gonzaga1, R. Dal Bello1, B. Gomes1, J. Dobbin1, L. Arcuri1

1Instituto Nacional de Câncer, Rio de Janeiro, Brazil

**Background:** Despite being the most common childhood cancer, nearly one half of ALL cases occurs in adults. Recently, it has been suggested that more intensive protocols may improve survival in adolescents and young adults (AYA).

**Aims:** Compare results of patients treated with BFM-based protocol to those patients treated with GMALL-based protocol, in a developing country.

**Methods:** This is a single center retrospective study which included all newly diagnosed adult ALL patients admitted between May/2012 and October/2016. Initially, patients aged 18-39 years (AYA group) were treated with BFM ALL 2009-based protocol and those aged 40-59 years were treated with GMALL 2003-based protocol. Since September 2013, because of high toxicity, only patients under 30 years were eligible for BFM-based treatment. Major adaptations were: (1) native E. coli l-asparaginase was substituted for peg-asparaginase, and (2) GMALL irradiation therapy was postponed to maintenance phase. BCR/ABL1 positive patients received standard chemotherapy plus Imatinib. Negative MRD was defined as <0,01% by flow cytometry. Overall survival was estimated by Kaplan-Meier method. Competing risk analysis was carried out for cumulative incidence of death in CR1 or not in CR1. This study was approved by local Ethics Committee.

**Results:** Thirty five patients were included, 21 of them started BFM-based treatment and 14 started GMALL-based protocol. During the first three months, 7 patients migrated from BFM to GMALL-based treatment because of toxicity and were analyzed separately. Median age was 21 years (18-38) for BFM-based group, 44 years (30-57) for GMALL-based, and 33 years (21-38) for de-escalated. Male predominance was observed (71%), not different between groups. T-phenotype was more frequent than expected, representing 50% of BFM-based, 50% of GMALL-based and 29% of de-escalated groups. BCR/ABL1 was detected in 14% of BFM-based, 23% of GMALL-based and 14% of de-escalated groups (p=0,85). Seven patients (2 BFM and 5 GMALL) underwent allogeneic stem cell transplantation in first remission. Of all 35 patients, 31 achieved complete remission after first induction phase. With median follow-up of 18 months, 1-year overall survival (OS) was 60% for all patients (39% for BFM-based, 75% for GMALL-based and 86% for de-escalated groups – p=0,04; BFM-based versus other protocols). Cumulative incidence (CI) of death in first complete remission (CR1) at 12 months was 18%, not different between groups. CI of death at 12 months in non-CR1 (relapsed or refractory) patients was 39% for BFM-based, 7% for GMALL-based and 0% for de-escalated groups – BFM-based versus other CR 2.6; p 0.13. Among 31 patients who achieved CR1, MRD data was available for 26 (74%) of these at the end of first induction. OS at 18 months for CR1 patients with negative MDR after first induction was 74%, compared to 52% in MRO+ (Figure 1).

**Summary/Conclusions:** Our results show that GMALL-based protocol yields good overall survival in adults ALL patients in a low income country, despite major adaptations. On the other hand, overall survival of AYA patients treated with BFM-based protocol was surprisingly poor, specially because of ineffective disease control may be related to several aspects: socioeconomic impairment, inadequate supportive care for more intensive therapies and ineffective cancer care network. Future prospective studies should focus on this issues.

**THE INVESTIGATION OF RELATIONSHIP BETWEEN COL1A1 AND FOK1 GENE POLYMORPHISMS AND DEVELOPMENT OF TREATMENT-RELATED SKELETAL COMPLICATIONS IN CHILDREN WITH ACUTE LYMPHOBlastic LEUKEMIA**

M. Erdem1, Ö. Tüfekçi1, S. Kızıldağ2, S. Yılmaz Bengoa1,2, D. Kuzmaçoğlu1, B. Ergölu Filibeili3, H. Ören1

1Pediatric Hematology, 2Medical Biology and Medical Genetics, 3Pediatrics, Dokuz Eylül University, İzmir, Turkey

**Background:** Cure rates for childhood acute lymphoblastic leukemia (ALL) have approached 90% with therapeutic advances over the last several decades. Many treatment related long-term complications including impaired physical growth, neurocognitive dysfunction, emotional and occupational difficulties, cardiac abnormalities, hypertension, secondary neoplasms, decreased bone mineral density (BMD) and osteonecrosis have been observed as the number of survivors increased. Bone infiltration of leukemic cells, corticosteroid exposure, poor nutrition, low vitamin D levels, poor muscle mass, genetic predispositions contribute to the development or worsening of bone pathologies during therapy that may result in osteoporosis, fracture and osteonecrosis.

**Aims:** In this study, we aimed to investigate whether vitamin D receptor and collagen protein gene polymorphisms, which are important in bone mineral and matrix formation, have effects on bone turnover in patients with ALL.

**Methods:** Fifty children with ALL who were diagnosed and treated with BFM-95 protocol (25 girls, 25 boys) between 1998-2008 and 96 healthy children at Dokuz Eylül University Medical School were enrolled in this study. Polymorphisms of vitamin D receptor (VDR) Fok1 gene and the collagen Col1A1 gene were studied from peripheral blood samples of the patients that were collected before initiation of chemotherapy protocol. After genomic DNA extraction, VDR Fok1 gene and colloidal Col1A1 gene polymorphisms were analyzed by polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP). The data including age, sex, leukemia risk group, presence or absence of relapse were all noted. Bone marrow density and markers of bone metabolism including serum calcium, phosphorus, serum alkaline phosphatase, parathyroid hormone and 25-OH D vitamin levels were all screened before initiation of maintenance treatment.

**Results:** The distribution of Fok1 and Col1A1 gene polymorphisms was similar both in the patient group and healthy control group. The frequency of gene polymorphisms in the patient group were 8% FF, 46%FF and 46%FF for the Fok1 genotype and 62%GG, 26%GT and 12%TT for the Col1A1 genotype. Out of 50 patients, 16 (32%) patients were found to have skeletal diseases like osteopenia (16%), osteoporosis (12%) and osteonecrosis (8%). The Fok1 genotype and Col1A1 genotype polymorphisms were similar in both group of patients with or without skeletal diseases. The frequency of osteopenia was significantly higher in the male group (p=0.049) and the frequency of osteonecrosis was significantly higher in patients older than 10 years old (p=0.001). There was no significant association between Fok1 and Col1A1 gene polymorphisms and leukemia subtype, risk group or relapse rate.

**Summary/Conclusions:** It has recently become more important to prevent treatment-related complications that we see as a consequence of high cure rates in ALL. In this context we have investigated whether there is a relationship between gene polymorphisms and treatment related skeletal diseases like...
Background: Several retrospective studies have confirmed that adolescents and young adults (AYA) with acute lymphoblastic leukemia (ALL) treated with pediatric protocols have better outcomes than similarly aged patients treated with adult protocols.

Aims: We reported results and feasibility of a pediatric-based protocol (EORTC 58951) in adolescents and young adults.

Methods: From January 2000 to December 2015, 72 patients aged 16 to 30 years with newly diagnosed ALL were treated, in the department of clinical hematology of Hedi Chaker Hospital, according to the pediatric protocol EORTC 58951. Further leukemia characteristics (Sex, White Blood cell count, Blasts phenotype, Cytogenetic results), we studied the protocol results: response to induction, relapse, and survival, by using the Kaplan Meier analysis.

Results: Seventy-two AYA ALL were treated with the pediatric protocol. The patients were 45 males and 27 females (SRT=1:6). A WBC>100 G/l was noted in 32% of patients. T-ALL phenotype was noted in 53% of cases. Twenty-two of the 4 patients (30%) were PPR. Nine patients (13%) were treated according AR1 arm, 39 patients (54%) according AR2 arm and 24 patients (33%) according VHR arm induction. CR rate was 87% after one course and 94% after 2 courses. Induction death was noted in 3% and post-induction death was noted in 13%. Twenty-four patients belonging to the poor-risk protocol and 11 patients belonging to the intermediate risk protocol, were eligible for allogeneic stem-cell transplantation (SCT), among them 15 patients had a familial donor and 10 patients had a matched unrelated donor. The majority of the patients (8 patients, 6 at the Intermediate Risk group and 2 at the High Risk group) experienced disturbances during the reinduction phase, while treated with dexamethasone at 10 mg/m2 for 21 days. Two patients of the High Risk group presented with behavioral effects one during the second HR2 block. Patients who had symptoms of major depression were treated with either fluoxetine, or/and risperidone, or/ and escitalopram for a period of time ranging of 5 days to 6 months. One patient experienced a psychotic episode during reinduction (Prot.II,phase 2) with aggression and violence towards others and had to be treated immediately with intramuscularly haloperidol and diazepam. All of our patients are alive and in remission, 7 off therapy for a period of 3 years, and 2 receiving maintenance therapy. Statistical analysis showed that severe psychiatric disturbances were observed more frequently in older patients and they were more common with the administration of dexamethasone than with prednisolone.

Summary/Conclusions: Severe psychiatric disturbances are not infrequent in adolescents and young adults receiving treatment for ALL. Awareness of this complication, appropriate parental education for identifying early signs, and prompt therapeutic interventions are essential for optimal outcome. Further studies are required for identifying patients at risk and best use of chemotherapeutic agents and of dexamethasone.

Background: Leukemia is the most prevalent pediatric malignancy with acute lymphoblastic leukemia (ALL) being the most common accounting for 75% of leukemia cases with about 2400 newly diagnosed children each year worldwide. Treatment of ALL requires long course chemotherapy ranging up to 48 months with newly diagnosed children each year worldwide.

Aims: To evaluate incidence and severity of thrombotic or bleeding events in paediatric patients with ALL during chemotherapy.

Methods: We considered all patients hospitalized for ALL in the Pediatrics
Department of Clinical Institute Fundeni during 2010-2017 and received chemotherapy according to protocol ALL BFM 1995 and ALL BFM 2002, established after framing in the risk group. Results: Over a period of 8 years in our department 280 patients with ALL received L-asparaginase in the induction phase. Neurological manifestation suggestive for bleeding or thrombotic events occurred in 9/280 (3.21%) patients. 2 patients were treated according to protocol ALL BFM 1995 and 7 patients were treated according to protocol ALL BFM 2002. M/F ratio was 4/5. Patients had diagnosis between 3 and 15 years (median age 9 years). All patients had thrombotic events after starting administration of L-asparaginase during induction. Most had clinical symptoms after the fourth dose of L-asparaginase. Clinical manifestations were accompanied by hyperfibrinogenemia (<100 mg/dl) especially in patients who experienced bleeding. The patients who experienced thrombosis had decreased levels of antithrombin III, protein C and increased D dimer levels. The diagnosis of cerebral venous sinus thrombosis (CVST) is typically based on clinical suspicion and imaging confirmation. At 5 of these patients neuroimaging tests (computed tomography, magnetic resonance imaging) revealed CVST. After developing neurological symptoms, one of the patients suffered major complication (extended brain injury) and died. All patients with ALL and thrombotic events received low-molecular weight heparin (LMWH) for 3 to 6 months. A follow-up CT or MRI at 3 to 6 months after diagnosis was made to assess for recanalization of the occluded cortical veins/sinus. Survival in the patients with CVST was 84.6%. 1 patient with ALL and hemorrhosis alteration had intracerebral hemorrhage (ICH) with rapid progressive neurological deterioration to death. 1 patient had pulmonary embolism associated with clotting disorders and severe sepsis and he died. 2 patients had clinical manifestation (headache, confusion and seizures) and clotting disorders (decreased levels of antithrombin III, protein C, fibrinogen and increased D dimer levels), but with normal brain imaging. Survival in the cohort was 77.7%.

Summary/Conclusions: Thrombotic events have occurred in all patients during induction. Clinical manifestation were depending on, size and duration of thrombosis, from headaches, seizures or focal neurological deficits. Severe sepsis association was an additionally risk factor for thrombotic and bleeding events in patients with ALL. Screening for genetic prothrombotic defects diagnosis prior to initiating chemotherapy may represent a way to reduce thrombotic or bleeding events and appropriate management of hemostasis disorders that occur during the treatment.

Background: Leukaemia is the most common cancer in children. Childhood leukaemia incidence and survival vary globally, and this could be associated with the variations in the risk factors, genetics, and level of diagnosis and treatment. Armenia is considered to be a mono-ethnic nation. Aims: We aimed to quantify the incidence of and mortality from acute leukemias among children population in Armenia and their variation with gender, age, year of diagnosis.

Methods: In this work we included children diagnosed with de novo acute leukaemia, 0–18 years of age from 2006 to 2016. The initial data for this survey have been derived from ambulance/dispensary cards, hospitalization journals, and clinical data from the Registry of Blood Diseases at the R.Yeolyan Hematology Center, Yerevan, Armenia. The data has been supplemented by the data from the Registry of Oncological Diseases of the V. Fanarjyan NCO, as well as from death certificates. The demographic data has been obtained from the National Statistics Board of Republic of Armenia. The obtained data has been statistically analyzed using EPI INFO-2002 program.

Results: A total of 277 cases of childhood acute leukemia were identified, 174 (62%) were boys. The overall incidence of leukemia was 3.4 per 100 000 children-years. The higher incidence rates were noted in 2007, 2012, 2010 (accordingly 4.0, 4.0 and 3.9), and the lower rates in 2011, 2014, 2009 (accordingly 2.4, 2.4 and 2.9). There are three registered regions in Armenia-Lori, Vayots Dzor and Tavush with higher incidence rate (respectively 0.020, 0.019 and 0.024 per 100 000 children-years). 83.8% of patients were aged 0–17 years, 16.2% (n=46) were >= 18 years old and diagnosed with Ph+ ALL between 2002 and 2015 were included. Analysis was done by intent to treat for patients initiated with imatinib or dasatinib at the time of Ph+ diagnosis. The primary endpoints were 2-year LFS and OS and secondary endpoints were complete molecular response (CMR; BCR-ABL1/ABL1 ratio <0.01% by PCR) and major molecular response (MMR; BCR-ABL1/ABL1 ratio <0.1% by PCR).

Results: Among 46 patients with Ph+ ALL, 74% (n=34) were in imatinib group and 17% (n=8) in dasatinib group; 8% were treated with other or no TKI (1 ponatinib and 3 with no TKI). Thirty-eight percent (n=13) of patients in imatinib group and 13% (n=1) in dasatinib group switched to a different TKI due to adverse effects or failure to achieve remission. There was a trend towards increased 2-year LFS for patients on dasatinib (HR 0.40, 95% CI: 0.14-1.14, p=0.09) and no difference in 2-year mortality (HR 1.00 95%CI: 0.46-2.17, p=0.99). Molecular response data was available for 61% (n=28) of patients; 75% of imatinib group achieved CMR or MMR (65% CMR) compared to 76% of dasatinib group (63% CMR) (p=0.98) (Figure 1).

Aims: To characterize long-term survival outcomes including leukaemia-free survival (LFS) and overall survival (OS) for Ph+ adult ALL patients treated with imatinib versus dasatinib.

Methods: Retrospective chart review was conducted at our institution. Patients ≥18 years old and diagnosed with Ph+ ALL between 2002 and 2015 were included. Analysis was done by intent to treat for patients initiated with imatinib or dasatinib at the time of Ph+ diagnosis. The primary endpoints were 2-year LFS and OS and secondary endpoints were complete molecular response (CMR; BCR-ABL1/ABL1 ratio <0.01% by PCR) and major molecular response (MMR; BCR-ABL1/ABL1 ratio <0.1% by PCR).

Results: Among 46 patients with Ph+ ALL, 74% (n=34) were in imatinib group and 17% (n=8) in dasatinib group; 8% were treated with other or no TKI (1 ponatinib and 3 with no TKI). Thirty-eight percent (n=13) of patients in imatinib group and 13% (n=1) in dasatinib group switched to a different TKI due to adverse effects or failure to achieve remission. There was a trend towards increased 2-year LFS for patients on dasatinib (HR 0.40, 95% CI: 0.14-1.14, p=0.09) and no difference in 2-year mortality (HR 1.00 95%CI: 0.46-2.17, p=0.99). Molecular response data was available for 61% (n=28) of patients; 75% of imatinib group achieved CMR or MMR (65% CMR) compared to 76% of dasatinig group (63% CMR) (p=0.98) (Figure 1).

Aims: To characterize long-term survival outcomes including leukaemia-free survival (LFS) and overall survival (OS) for Ph+ adult ALL patients treated with imatinib versus dasatinib.

Methods: Retrospective chart review was conducted at our institution. Patients ≥18 years old and diagnosed with Ph+ ALL between 2002 and 2015 were included. Analysis was done by intent to treat for patients initiated with imatinib or dasatinib at the time of Ph+ diagnosis. The primary endpoints were 2-year LFS and OS and secondary endpoints were complete molecular response (CMR; BCR-ABL1/ABL1 ratio <0.01% by PCR) and major molecular response (MMR; BCR-ABL1/ABL1 ratio <0.1% by PCR).

Results: Among 46 patients with Ph+ ALL, 74% (n=34) were in imatinib group and 17% (n=8) in dasatinib group; 8% were treated with other or no TKI (1 ponatinib and 3 with no TKI). Thirty-eight percent (n=13) of patients in imatinib group and 13% (n=1) in dasatinib group switched to a different TKI due to adverse effects or failure to achieve remission. There was a trend towards increased 2-year LFS for patients on dasatinib (HR 0.40, 95% CI: 0.14-1.14, p=0.09) and no difference in 2-year mortality (HR 1.00 95%CI: 0.46-2.17, p=0.99). Molecular response data was available for 61% (n=28) of patients; 75% of imatinib group achieved CMR or MMR (65% CMR) compared to 76% of dasatinig group (63% CMR) (p=0.98) (Figure 1).

Figure 1.

Summary/Conclusions: In conclusion, dasatinib, compared to imatinib, in combination with chemotherapy, may prolong LFS in patients with Ph+ ALL and may be a suitable first-line agent. Large, randomized studies are needed to better define a detailed treatment protocol in this high-risk patient population.
RESULTS: Eight of 21 (38%) patients exhibited an isolated t(4;11) translocation. Additional chromosome abnormalities (ACA) were revealed in 11 (52%) patients, including 8 (42%) subjects with 3 and more chromosome aberrations. In univariate analysis, significance was shown for clinical stage at HSCT (1st remission vs other stages, 75% vs 0%; p<0.001 for OS; 58% vs 0%, p<0.001 for EFS), complex chromosomal aberrations (<3 abnormalities vs ≥3 abnormalities, 58% vs 13%, p=0.04 for OS; 46% vs 0%, p=0.04 for EFS). According to multivariate analysis, the clinical stage at HSCT (HR 26.8, 95% CI 3.28-218.80; p=0.002 for OS; HR 11.18, 95% CI 2.92-42.80 p=0.0004 for EFS) was the only independent prognostic factor for clinical outcome.

Summary/Conclusions: The study has shown the stage of disease at the moment of allo-HSCT to be a significant independent factor in a mixed cohort of KMT2A- AFF1 ALL patients treated with HSCT. The good results of allo-HSCT can be obtained using a haploidentical transplantation from parents that removes the problem of searching the HLA-matched donors in the Registers and, therefore, greatly simplifies the treatment.

DERMATOLOGIC COMPLICATIONS ASSOCIATED WITH TYROSINE KINASE INHIBITORS FOR THE TREATMENT OF ACUTE LEUKEMIA
K. Zarubina1,*, O. Gavrilina1, E. Parovichnikova1, V. Troitskaya1, A. Sokolov1, E. Chelysheva1, A. Türkina1, E. Usikova1, A. Abramova1, G. Baskhava1, I. Lukyanova1, V. Savchenko1
1Department of chemotherapy of hemoblastosis and depression of hemo-poiesis, National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Despite of targeted effects of tyrosine kinase inhibitors (TKIs), they are not absolutely selective in relation to their target. Hair pigmentation is regulated by factors including the interaction of the ligand stem cell factor (SCF) with its class III receptor tyrosine kinase, c-kit. Hair depigmentation involves inner and outer root hair matrixes. The CSF IL-6 dosing could clarify the pathogenesis of the event.

Methods: All patients treated by second-generation TKI (bosutinib), third-generation TKI (ponatinib) and multikinase inhibitor sorafenib developed dermatological side effects, temporarily discontinuation of TKI therapy led to complete resolution of skin lesions. Restoring TKI at full dose did not lead to dermatological adverse reactions reappearance. Moreover, the temporary cancellation did not reduce its effectiveness.

CYTOKINE RELEASE SYNDROME AFTER THE FIRST INTRATHecal CHEMOTHERAPY IN A PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA WITH AN EARLY MENINGEAL RELAPSE
F. Petruzziello1,*, M. Palma1, A. Varone2, M. Colonna1, D. Cicala3, N. Marra1, F. Giagnuolo1, G. Maisto1, G. Menna1, R. Parasole1
1Pediatric Hemato-Oncology, 2Neurosciences, 3Paediatric Neuroradiology Unit, Santobono-Pausilipon Hospital, Naples, Italy

Background: Central nervous system (CNS) is a frequent site of recurrence in childhood acute lymphoblastic leukemia (ALL) and it is a major cause of treatment failure, with long-term sequelae. The primary CNS infection (PIT) is the most important treatment-related CNS relapse. Severe neurotoxicity is well known TIT complication, usually related to repeated infusions and neurotoxic concomitant systemic drugs.

Aims: We describe a case of a massive acute leucenoecephalopathy after only one TIT, in a 5-year-old child with an early isolated CNS relapse of ALL (26 months after the first diagnosis), rapidly proceeding to coma status.

Methods: At admission for disease restaging at the end of first-line trial, the child showed physical and neurological examination completely negative, such as haematological, bioumoral and ultrasound findings. The cerebral spinal fluid (CSF) analysis showed eosinophilic pleocytosis with no signs of bacterial or fungal infection, macroglobulinemia, elevated concentrations of lactate dehydrogenase (LDH) and a low protein content. The MRI showed diffuse areas of hyperintensity of white matter, particularly cortical and subcortical areas, cerebellar region, optic chiasm and brainstem in T2-Flair sequences; spinal cord shower massive edema, especially in lobar region. The MRI pattern was interpreted as diffuse grade IV leucenoecephalopathy of probable toxic nature. The child, 30 h after TIT, was transferred to intensive care unit for progressive ascending paralysis and respiratory distress that required intubation. During the following days, other than diagnostic lumbar puncture were performed that showed significant reduction of blasts cells (20, 10 and 0 cells /µL, respectively).

Results: Patient persisted in deep coma for 5 days, until he restart a spontaneous breathing. After waking up, the child showed rapid neurological amelioration, absence of seizures and no neurologic sequelae. However, bilateral leucencephalopathy persisted, with persistence of altered signals in subcortical white matter. The visual evoked potentials were normal and the motor and sensory conduction velocity of peripheral nerves was normal, too.

At the moment, after three week from severe neurological complication, the child is fully awake, moving all four limbs, but requires motor and phoniatric rehabilitation. Systemic chemotherapy with high-dose MTX and IT ARA-C is restarted without any additional neurotoxicity. Dosage of CSF levels of interleukin 6 and its soluble receptor is ongoing.

Summary/Conclusions: Although leucenoecephalopathy following IT MTX or ARA-C administration are described, the severity and rapidity of event’s onset, associated with CSF remission after a single TIT administration, suggests us that neurotoxicity could be related to massive blast cytolysis with subsequent patient-induced release syndrome, which could be an inflammatory meningoencephalitis. This syndrome is a frequent complication of blinatumomab or chimeric antigen receptor T-cells administrations. The CSF IL-6 dosing could clarify the pathogenesis of the event.

Figure 1. Results: All of the 6 patients who had taken second-generation TKI (bosutinib), third-generation TKI (ponatinib) and multikinase inhibitor sorafenib developed dermatologic reactions (skin rash or grey hair). Generalized maculo-papular skin rash grade II evolved after 2 weeks of sorafenib treatment in pt1. Both patients on ponatinib therapy developed localized maculo-papular skin rash grade I in pt 2 after 8 weeks of therapy. In pt 3 after 6 weeks of ponatinib treatment gray hair observed. Skin rash with pigmentation grade I evolved in pt 3 after 12 weeks of therapy. Pt 4 had gray hair after 12 weeks second-generation TKI (bosutinib) treatment. Palmer-plantar erythrodysesthesia syndrome grade II and hair and total skin depigmentation were evolved after 2 weeks and after 4.5 months respectively observed during the sorafenib treatment in pt 5 (with psoriasis anamnesis). Pt 6 developed localized maculo-papular skin rash grade I after 5 weeks of sorafenib treatment. Despite of all patients developed dermatological side effects, temporarily discontinuation of TKI therapy was required in only three (50%) cases. In the other cases the treatment was continued. The therapy was restarted in all pts with temporarily discontinuation after skin lesions disappearing (Figure 1).

Summary/Conclusions: Dermatological adverse events in acute leukemia pts who have taken second-generation TKI (bosutinib), third-generation TKI (ponatinib) and multikinase inhibitor sorafenib they were not serious. Temporarly dose reduction or interrupting of TKI therapy led to complete resolution of TKI therapy led to complete regression of skin lesions. Restarting TKI at full dose did not lead to dermatological adverse reactions reappearance. Moreover, the temporary cancellation did not reduce its effectiveness.
PB1648
SEVERE HYPOFIBRINOGENEMIA ASSOCIATED WITH IMATINIB AND PREDNISONE THERAPY IN PHILADELPHIA CHROMOSOME–POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA
M. Sciumé1,*, N. S. Fracchiolla1, G. Reda1, R. Cassin1, V. Mattilello1, A. Cortelezzi1
1Oncohematology Division, IRCCS Ca’ Granda - Maggiore Policlinico Hospital Foundation and University of Milan, Milan, Italy

Background: Hypofibrinogenemia associated to acute lymphoblastic leukemia (ALL) is rare and usually due to L-asparaginase. Consumption coagulopathy or therapy-related hepatopathy are other possible explanations. Severe hypofibrinogenemia, not linked to the causes listed, was rarely reported and a role of steroid treatment on fibrinogen metabolism was suggested.

Aims: Our aim was to identify the incidence of severe hypofibrinogenemia during induction phase in a cohort of consecutive ALL patients and to assess its impact on clinical decision-making.

Methods: In order to avoid confounding factor due to L-asparaginase, we revised our cohort of Philadelphia chromosome–positive (Ph+) ALL that we treated according to pediatric-type therapy program (imatinib, intensive chemotherapy without L-asparaginase) for patients aged 18-65 years and through LAL0210-B protocol (imatinib, prednisone) for patients ≥65 years. We retrospectively analyzed coagulation tests on admission and during induction therapy of all Ph+ ALL patients diagnosed at our Institution from 2004.

Results: Twenty-one Ph+ ALL were identified: 17 patients were younger than 65 years, while the remaining 4 patients had a median age of 74 years (66-76). No alteration of plasma fibrinogen during induction was observed in younger patients. Severe hypofibrinogenemia (≤100 mg/dl) was detected in 3 out of 4 Ph+ ALL over 65 years. In these patients induction consisted of prednison 40 mg/d for 6 weeks and imatinib at the fixed dose of 800 mg/d. On admission hemoglobin levels were ≤10 g/dl in all patients, leucocytes counts were 2x10⁹/L (blasts 15%), 8x10⁹/L (blasts 30%) and 18x10⁹/L (blasts 61%), while platelet count was reduced in 2 cases (6x10⁹/L and 65x10⁹/L). Coagulation tests were normal (fibrinogen median level 380 mg/dl). Severe hypofibrinogenemia developed between 6 and 15 days after beginning treatment and lasted between 4 and 48 days. Fibrinogen nadir ranged from 47 to 100 mg/dL (median 61 mg/dL); reduced plasma fibrinogen levels at functional tests were also confirmed to immunological assays. During fibrinogen nadir, D-dimer was positive in all patients, but stable compared to the outset. Antithrombin, coagulation factors, activated partial thromboplastin and prothrombin time, common liver function tests remained in a normal range; platelet counts showed a trend to normalization. Early clearance of peripheral blood blasts was observed and when hypofibrinogenemia appeared no blast cells were detectable. At the end of induction bone-marrow evaluation demonstrated the absence of BCR-ABL transcript by qualitative RT-PCR. There were no bleeding events and only one patient received a prophylactic transfusion of fresh-frozen plasma (10 ml/kg) for fibrinogen <50 mg/dl on two occasions. Normal fibrinogen levels (≥165 mg/dl) were recovered at the end of steroid therapy.

Conclusions: We observed severe hypofibrinogenemia in Ph+ ALL patients older than 65 years treated with imatinib and high-doses steroid, while normal fibrinogen levels were detected in younger Ph+ ALL during intensive chemotherapy plus imatinib. In our experience, hypofibrinogenemia was not associated to major bleeding events, although its clinical significance should be investigated in larger series. Fibrinogen may recognize multiple metabolic pathways, also unrelated to in vivo coagulation and fibrinolysis; the correspondence between steroid treatment and hypofibrinogenemia seems to suggest that glucocorticoids may alter some steps in fibrinogen kinetics and could be considered as a cause of acquired hypofibrinogenemia.

LATE EFFECTS OF CHEMORADIOThERAPY ON THE ENDOCRINE SYSTEM IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA
G. Aydogan1,*, S. Etlan1, F. Akci1, Z. Salcioglu1, A. Akcay1, T. Akcay1, H. Sen1, N. Ozdemir1, C. Bayram1, A. Aycicek1
1Pediatric Hematology, KANUNI SULTAN SULEYMAN EDUCATION AND RESEARCH HOSPITAL, Istanbul, Turkey

Background: Over the past four decades treatment of childhood acute lymphoblastic leukemia has been modified with the aim of achieving high survival rate while reducing the risk of the life threatening late-effects and promoting risk-based follow-up care of survivors.

Aims: The aim of our study is evaluation of late effects of chemotherapy and cranial radiotherapy on the endocrine system in children with acute lymphoblastic leukemia.

Methods: Forty-eight patients, who were diagnosed and treated for ALL between 1997-2007 in Istanbul Kanuni Sultan Suleyman Education and Research Hospital Pediatric Hematology-Oncology Clinic and have disease-free for at least 5 years after cessation of treatment, were evaluated prospectively. The study form included each patients age, gender, weight, height, target height, parental height, treatment protocol, stage of puberty, bone age, TSH, free T4, LH, FSH, estradiol or testosterone, IGF-1 and IGFBP-3 levels. Annual rate of growth was evaluated for each patient. The patients with inadequate growth rate and delayed bone age were subjected to growth hormone stimulation test with clonidine.

Results: Mean age of the patients was 14.4±2.85 (10.5-22.4) years. Thirty-one of patients had prophylactic cranial radiotherapy; five of them 18 Gy and twenty-six had 12 Gy CRT. Fifteen of the 48 patients were diagnosed with at least one endocrinological disorder. Six patients had lower height (<-2 SD), three patients had a body mass index >30kg/m². Bone age delayed in two patients. Four patients had IGF-1 value below <-2SD and two patients had inadequate levels of growth hormone. Tanner stage of the patients were appropriate for their ages except for one patient with hypergonadotropic hipogonadism and one patient with pubertas precoex. Subclinical hypothyroidism was detected in two patients.

Summary/Conclusions: Significant late effects may develop over time in children treated for ALL. For this reason long-term follow-up of these children is necessary. Because of the awareness of the late effects the treatment modified to reduce the impact on clinical decision-making.

MUTATIONAL ANALYSIS OF 231 DE NOVO AML PATIENTS BELOW 60 YEARS WITH CURATIVE THERAPY

A. Foti1,*, I. Jezirowska1, D. Dvorakova1-2, N. Tomi2, M. Cule1-2, Z. Kesarova2, A. Durnikova2, P. Cetkovsky3-4, P. Jindra5-6, T. Szotkowska1, P. Zak7, J. Mayer1,2,4, Z. Racil1-2

1University Hospital Brno, 2Masaryk University, Brno, 3Institute of Hematology and Blood Transfusion, Prague, 4On behalf of CELL, Brno, 5University Hospital Pilsen, Pilsen, 6University Hospital Olomouc, Olomouc, 7University Hospital Hradec Kralove, Hradec Kralove, Czech Republic

Background: Acute myeloid leukemia (AML) is an aggressive cancer disease of the myeloid lineage of blood cells, characterized by rapid growth of undifferentiated myeloid precursors. Analysis of the spectrum of somatic mutations in leukemic cells may help to improve the identification of individual prognostic subgroups of patients as well as to observe clonal evolution in the course of AML treatment.

Aims: The aim of the project is to identify somatic alterations in genes related to AML using next generation sequencing (NGS) in large cohort of AML patients from Czech Republic and to determine their frequency and mutual coexistence.

Methods: The analyzed group consists of 231 de novo consecutively diagnosed AML patients with curative therapy below 60 years from five hematological centers. The NGS libraries are prepared from peripheral blood samples from diagnosis using ClearSeq AML panel (Agilent Technologies) and sequenced on MiSeq and NextSeq machines (Illumina). As positive are determined mutations with variant allele frequency (VAF) at least 2%.

Results: At least one somatic mutation (median 2; range 0-6) was identified in 204 (88.3%) patients with de novo AML. In total, 526 recurrent mutations in 19 genes were identified. The most frequently mutated genes were: FLT3 91/231 (39.4%), from this FLT3-ITD 69/231 [29.9%] and FLT3-ITD 22/231 [9.5%], NPM1 90/231 [39.0%; mutation type A 71/90 [78.9%], type B 11/90 [11.1%], other types 10/90 [10.0%], DNMT3A 68/231 [29.4%; mutations in codon R882 49/68 [72.1%], NRAS 51/231 [22.0%; the most frequent mutation G12D 17/51 [22.0%]; 1151 patients [21.6%] contain more than one mutation in NRAS gene), IDH2 35/231 (15.2%) and CEBPA 35/231 (15.2%). The analysis also identified mutations in rarely mutated genes U2AF1, SF3B1, EZH2 and SETBP1 in 4/231 (1.7%), 4/231 (1.7%), 1231 (0.4%) and 1/231 (0.4%) samples, respectively (Figure 1).

Summary/Conclusions: The results of mutational analysis of large cohort of AML patients show high heterogeneity of detected mutations. Surprisingly we have detected high percentage of patients with mutations in gene NRAS. Together with sequencing results from the time of remission/relapse/resistence of the disease, the data will enable to get more complex view on the development of AML in time.

INHIBITION OF LIN28B IMPAIRS LEUKEMIA CELL GROWTH AND METABOLISM IN ACUTE MYELOID LEUKEMIA

J. Zhou1,*, J.-Y. Chooi1, J.-Y. Quiah1, S.-H.-M. Toh1, T.Z. Tan1, P.S. Chong1, W.-J. Chng1

1Cancer Science Institute of Singapore, National University of Singapore, , Singapore, Singapore

Background: Current conventional chemotherapy for acute myeloid leukemia (AML) can achieve remission in over 70% of patients, but a majority of them will relapse within 5 years despite continued treatment. 2. The relapse is postulated to be due to leukemia stem cells (LSCs), which is different from normal hematopoietic stem cells (HSCs). LIN28B is microRNA regulator and stem cell reprogramming factor. 3. Overexpression of LIN28B has been associated with advanced human malignancies and cancer stem cells (CSCs), including AML. However, the molecular mechanism by which LIN28B contributes to the development of AML remains largely elusive.

Aims: 1. To study the function role of LIN28B in cell proliferation, cell cycle and colony formation ability of AML cells. 2. To systematically dissect transcriptional signaling mediated by LIN28B on whole genome level. 3. To determine the key targets of LIN28B in AML. 4. To explore the function of LIN28B in AML in vivo.

Methods: 1. We modulated LIN28B expression in AML and non-leukemic cells and investigated functional consequences in cell proliferation, cell cycle and colony forming assays. 2. We performed a microarray-based analysis for LIN28B expressing cells and interrogated gene expression data with different bioinformatic tools. 3. AML mouse xenograft model was used to examine the in vivo function of LIN28B.

Results: We first showed that increased LIN28B expression was associated with worse survival in AML patients. We demonstrated that targeting LIN28B in AML cells resulted in cell cycle arrest, inhibition of cell proliferation and colony formation, which was induced by de-repression of let-7a miRNA. On the other hand, overexpression of LIN28B promoted cell proliferation. Mechanistic studies revealed that inhibition of LIN28B induces metabolic changes in AML cells. IGFBP2 was confirmed to be a novel downstream target of LIN28B via let-7 miRNA. Notably, silencing LIN28B led to slow tumor growth in vivo.

Summary/Conclusions: In conclusion, these results uncover a novel mechanism of an important regulatory signaling, LIN28B/let-7a/miRNA, and provide a rationale to target this pathway as effective therapeutic strategy.

EVALUATION OF MINIMAL RESIDUAL DISEASE IN NPM1-MUTATED AML PATIENTS

C. Martínez-Laperche1,2,*, V. Pradillo1, G. Rodríguez-Macías1, M. Chicano1,2, D. Carbonell1,2, J. Suárez-Gónzalez2, J. L. Díez-Martín1,2, I. Buño1,2

1Hematology, H.G.U Gregorio Marañon, 2Instituto de Investigación Sanitaria Gregorio Marañon, Madrid, Spain

Background: Minimal residual disease (MRD) tests provide early identification of hematologic relapse and timely management of AML patients. About 60% of adult normal karyotype AML has a mutation in exon 12 of NPM1 gene. This mutation is specific for malignant clone and potentially is a good marker of MRD.

Aims: The aim of the study was to analyze the usefulness of NPM1 as a marker for MRD quantification in AML during follow-up.

Methods: Retrospective study included 34 patients with mutated-NPM1 and treated with intensive chemotherapy (2009-2015). Bone marrow (188) and peripheral blood (277) samples were analyzed from complete remission (MRD NPM1 negative). NPM1 detection was performed by quantitative RT-PCR (Gorello et al. Leukemia 2006). Patients were considered positive when presented >1 NPM1 sample positive or/and one sample NPM1 >0.02%. Cox regression was used for univariate analysis.

Results: Patients were segregated in 2 groups: Relapse patients (Group 1: 32.2%, 11/34) and no relapse patients (Group 2: 67.6%, 23/34). Group 1 presented MRD NPM1 positive in 9/11 (82%) of patients, the time from NPM1 to relapse was 4.6 months (1.6-24), NPM1 mean was 1.7 (0.03-9). Group 2 presented MRD NPM1 negative (<0.02%) or 1 determination in 21/23 (91%) patients. Univariate analysis was performed and our results show that age, leukocyte, LDH and MRD NPM1 are prognostic factors for cumulative incidence of relapse (Figure 1).

Summary/Conclusions: The results show that the usefulness of NPM1 as a marker for MRD quantification in AML is limited. Future studies should be focused on the development of more sensitive MRD methods.
Summary/Conclusions: NPM1 is a useful marker for MRD quantification in AML patients undergoing intensive therapy. NPM1 positive during follow-up is associated with a higher probability of relapse.

AT101 ELIMINATES AML STEM CELLS VIA ACTIVATION OF INTRINSIC apoptotic PATHWAY AND PARTICIPATION IN DNA DAMAGE RESPONSE

X. Bing1,2, Z. Lei3, Z. Yong1, C. kaia4, S. pengcheng4, L. yin2, D. manman1, J. zhuiwa5, W. xiangmeng5, L. peng6
1The First Affiliated Hospital of Xiamen University, Xiamen, 2Nanfang Hospital, Southern Medical University, Guangzhou, 3Nanfang Hospital, Southern Medical University, Xiamen, 4Southern China Institute for Stem Cell Biology and Regenerative Medicine, Guangzhou, China

Background: Leukemia stem cells (LSCs) are considered as the main reason for treatment failure and relapse in acute myeloid leukemia. Overexpression of Bcl-2 anti-apoptotic proteins is associated with the survival and self-renewal of LSCs.

Aims: To observe the effect for AT101 to eliminate AML stem cells and its underlying mechanism.

Methods: Use CD34⁺/CD38⁻/CD123⁺/KG1a and primary AML CD34⁺ cells as research object.

Results: In this study, we demonstrated that AT101, a BH3 mimetic pan-Bcl-2 inhibitor, was significantly and effectively cytotoxic towards CD34⁺/CD38⁻/CD123⁺/KG1a and primary AML CD34⁺ cells, with slight effect on CD34⁺ normal hematopoietic cells. And the mechanism was closely associated with activation of intrinsic apoptotic pathway, such as loss of mitochondrial membrane potential and caspase activation, along with disturbance of DNA damage response. Further analysis on AML patients’ clinical characteristics revealed that the ex vivo efficacy of AT101 in primary samples was significantly correlated to hyperleukocytosis or FLT3-ITD mutation. Besides, AT101 exhibited exciting effect on CD34⁺ blasts from patients who are old or cannot achieve CR after induction therapy.

Summary/Conclusions: In conclusion, Together, these findings provides potentially for the use of AT101 to treat relapse and refractory AML as alternative salvage regime in the future, including those clinically characterized by one or more adverse prognostic abnormalities.

PB1655

COOPERATIVE EFFECT OF CHIDAMIDE AND CHEMOTHERAPEUTIC DRUGS INDUCE APOPTOSIS BY DNA DAMAGE ACCUMULATION AND REPAIR DEFECTS IN ACUTE MYELOID LEUKEMIA STEM AND PROGENITOR CELLS

X. Bing1,2, L. Yin2, D. Manman1, C. Kail3, S. Pengcheng4, Z. Yong1
1The First Affiliated Hospital of Xiamen University, Xiamen, 2Huizhou Municipal Central Hospital, huizhou, 3Nanfang Hospital, Southern Medical University, Guangzhou, 4Nanfang Hospital, Southern Medical University, Xiamen, China

Background: Lots of conventional chemotherapeutic drugs are confirmed to take part in DNA damage generation and initiation of DNA damage response, ultimately leading to apoptosis. However, they fail to completely eliminate leukemia stem cells (LSCs) on account of higher DNA repair capacity of cancer stem cells than bulk cancer cells, which become the root of resistance and recurrence. Thus, new strategy to eliminate LSCs in AML is urgently needed.

Aims: To observe the effect of low dose chidamide in combination with chemotherapy agents on eliminating AML stem cells.

Methods: We used a novel benzamide-type HDAC inhibitor, chidamide in combination with DNA-damaging agents (daunorubicin, idarubicin and cytarabine) to treat CD34⁺/CD38⁻/KG1a cells and primary refractory or relapsed AML CD34⁺ cells.

Results: Here, we report that low dose chidamide, a novel benzamide-type HDAC inhibitor, which selectively targeted HDAC 1, 2, 3, 10, could enhances cytotoxicity of DNA-damaging agents (daunorubicin, idarubicin and cytarabine) in CD34⁺/CD38⁻/KG1a cells and primary refractory or relapsed AML CD34⁺ cells. Further analysis on AML patients’ clinical characteristics revealed that the ex vivo efficacy of chidamide in combination with IDA gave rise to production of γH2A.X, with DNA damage accumulation and repair defects. Co-treatment with chidamide and IDA could rapidly diminish tumor burden in a patient with R/R AML.

Summary/Conclusions: These findings provide preclinical evidence for low dose chidamide in combination with chemotherapeutic agents to treat recurrent/resistant AML as an alternative salvage regimen, especially those possessed stem and progenitor cells.

NEW CANDIDATE GENES USEFUL TO PREDICT THE RISK OF RELAPSE IN ACUTE PROMYELOCYTIC LEUKEMIA

J. Nando1,2, M.C. Fontana1, G. Marconi1, C. Papayannidis3, S. Lo Monaco1, G. Simonetti1, A. Padella1, E. Ottaviani1, S. Paoli1, M.C. Abbenante1, L. Bertamini1, G. Martinelli1
1University of Bologna, Bologna, Italy

Background: Nowadays, Acute Promyelocytic Leukemia (APL) is a disease entity with a very high rate of cure and an estimated 2-year overall survival of 97%. Early death, rather than resistant disease so common in all other subtypes of AML, has emerged as the major cause of treatment failure, and relapse is a very rare occurrence.

Aims: To present a new candidate for APL relapse is a very rare entity, and it is announced to become rarer with the advances in first line therapy. Molecular characteristics are hard to analyze without an effort to collect and bank samples together from multiple institutions. Since relapses, especially relapses out of follow-up period, represent a sudden life-treating condition for patients, to predict patients at higher risk of relapse we selected two candidate genes that could be involved in pathways favoring relapse.

Methods: We collected data of all the APL referred to our institution from 2014. Within 23 patients, we encountered 20 new diagnosis and 2 relapse of APL. We evaluated blasts in samples obtained from Bone Marrow with Single Nucleotide Polymorphisms Array Cytoscan HD.

Results: We compared copy number alterations in both relapsed patients with alterations detected in the pool of 20 newly diagnosed APL and we found specific signatures of CNVs for each patient. There were several copy number alterations related to each patient: the first patient presented gain of ROBO2, GRIP1, CTNNB1, SOX6, PBX1, GRIK2, CDKAL1 and loss FAP1, CREBBP, SBF1; the second patient present gain of ROBO1, MAPK10, CADPS2, APBA1 and loss of GRIP1 and MYB. Subsequently we focused our attention on ROBO and GRIP1 genes because they were altered in both relapsed patients: ROBO proteins are associated to K channels while GRIP1 is involved in various critical functions, for example in androgen receptor binding, beta-catenin binding, glucocorticoid receptor binding, and it is also a regulator of glutamate metabolism, a well-known pathway in Leukemic Stem Cells.

Summary/Conclusions: By the analysis of ROBO-1 and GRIP1 FISH at the diagnosis, we could establish a different and strict follow-up program for patients with these alterations.

THE EXPRESSION OF SALL4 AND BMI-1 GENES IN MYELOID LEUKEMIA

M. El-Nagdy1,2, H. Farawela1, H. Zawam2, H. Al-Wakeel3, F. El-Rafaei1, H. Abdel-Rahman1
1Clinical & Chemical Pathology, 2Medical Oncology, Cairo University, 3Clinical & Chemical Pathology, National Cancer Institute, Cairo, Egypt

Background: Sall-like protein 4 (SALL4) and B-cell specific moloney murine leukemia virus integration site-1 (BMI-1) genes are stem cell genes that modulate stem cell pluripotency and may play a role in leukemogenesis. Leukemic stem cells (LSCs) have been implicated in being the origin of the leukemic blast, therapy resistance and recurrence.

Aims: The current study aimed at characterizing the expression pattern of SALL4 and BMI-1 genes in acute myeloid leukemia (AML) and chronic myeloid leukemia (CML), in patients who have achieved complete remission (CR), and in CML disease progression.

Methods: Real-time polymerase chain reaction was used to assess the gene expression patterns in 106 myeloid leukemia patients; 54 de novo AML (43 at time of diagnosis, 11 in CR), and 52 CML (31 in chronic phase (CP), 11 in deep molecular response (MR) & 10 in accelerated/blastic phase (AP/BP), and in 21 non malignant bone marrow samples.

Results: SALL4 gene expression was increased in AML patients, AML-CR, & CML-CP (median= 5.180, 4.604 & 14.125 respectively). No significant difference was observed between de novo AML and AML in CR patients. CML-CP patients showed a significantly higher percentage of patients with a high SALL4 expression as compared to both CML- MR4 and CML-AP/BP (p=0.033). BMI-1 gene expression was not found to be increased in any of the patient groups.

Summary/Conclusions: Our data describe altered SALL4 gene expression in different phases of myeloid leukemia. The role of BMI-1 gene needs further delineation to determine its significance.

AN INVESTIGATION INTO THE ROLE OF S100A8 AND S100A9 IN ACUTE MYELOID LEUKAEMIA
S. Chaudry1, T. Chevassut1, H. Stewart1
1Brighton and Sussex Medical School, Brighton, United Kingdom

Background: Acute myeloid leukemia (AML) is the a haematological malignancy characterised by the over proliferation and block in differentiation of clonally abnormal leukaemia stem/progenitor cells such as S100A8 could assess the progression and remission of AML.

Aims: S100A8 and S100A9 (Ca2+ binding helix E-loop-helix-F hand), are inflammatory markers which are also suggested to promote chemoresistance by stimulation of autophagy. Microarray data from the Chevassut lab shows that both S100A8 and S100A9 transcripts are downregulated by the BET-bromodomain inhibitor JQ1 in AML cell lines. We aimed to investigate this response in AML patient bone marrow samples and cell lines.

Methods: We used AML cell line including OCI-AML2, OCI-AML3 and THP-1 in addition to AML patient bone marrow samples and healthy volunteer samples. We carried out RT-qPCR and immunocytochemistry and western blotting techniques to look at levels of S100A8 and S100A9 in samples.

Results: Here we show that levels of S100A8 and S100A9 mRNA levels are suppressed in response to JQ1 in the AML cells lines OCI-AML2, OCI-AML3 and THP-1. We find also that protein levels of S100A8 and S100A9 are downregulated in response to JQ1 in OCI-AML3. In bone marrow samples of 17 AML patients with different cytogenetic profiles, the relative expression of S100A8 and S100A9 was found to be variable amongst the samples but also in comparison to OCI-AML3 cell line. In further experiments using AML patient bone marrow samples, treatment with JQ1 showed suppression of S100A8 and S100A9 in some patient samples but enhanced expression in other bone marrows. In peripheral blood samples of healthy volunteers, we found that treatment with JQ1 showed notable suppression of both S100A8 and S100A9 with a greater suppression being observed in the monocyte fraction of the samples.

Summary/Conclusions: Our data suggests that JQ1 regulates the expression of S100A8 and S100A9 in AML. The variability of the response seen amongst AML patient samples and AML cell lines may be reflective of the genetic profile differences present in these samples. Further work may give more detailed insight into the mechanisms of action and potential use of S100A8 and S100A9 in AML prognostic markers.

PB1660
SUCCESSFUL COVERAGE OF DIFFICULT TO SEQUENCE GENES (CALR, CEBPA, and FLT3) ASSOCIATED WITH MYELOID DISORDERS USING A HYBRIDISATION-BASED ENRICHMENT APPROACH PRIOR TO NEXT-GENERATION SEQUENCING
G. Speight1, L. Georgiev1, E. Uddin1
1R&D, Oxford Gene Technology, Begbroke, United Kingdom

Background: The application of short read NGS for research into myeloid disorders such as myeloproliferative neoplasms (MPNs) and acute myeloid leukemia (AML) is hampered by the inability to precisely sequence certain genes as they harbour key mutations so it is desirable to ensure suitable sequencing coverage is obtained. These genes amongst others include: CALR exon 9 insertions and deletions (up to 52 bp), CEBPA single nucleotide variants (SNVs) and FLT3 Internal Tandem Duplications (ITDs) and SNVs. Each of these regions contain certain challenging DNA sequences that can impact the quality of the data generated, e.g. large indels and low complexity regions (CALR), high GC content (75% on average for the whole gene with specific regions at 100%) and repetitive regions (CEBPA), and complex repetitive elements (FLT3).

Aims: To determine whether a hybridisation-based enrichment approach overcomes the difficulties associated with these genes, and permits the generation of high quality (sufficient de-duplicated depth) data to allow these targets to be accurately interrogated.

Methods: We utilised a hybridisation-based enrichment approach for library preparation in combination with a SureSeq myPanel™ NGS Custom AML panel. The library was then sequenced using a 2x150 bp read length protocol on an Illumina MiSeq®.

Results: Here we present the coverage and variants generated from numerous research samples for each of these difficult to sequence genes. The results clearly show that this approach can reliably detect and accurately size (including low allele frequency) insertions and deletions of up to 52 bp in CALR (exon 9), SNVs and deletions in CEBPA with a de-duplicated depth in excess of 2000x as well as ITDs of between 24 and 201 bp in FLT3.

Summary/Conclusions: This approach is suitable for the analysis by NGS of these difficult genes and therefore removes the requirements for supplementary approaches to analyse these difficult genes, such as Sanger sequencing (CEBPA) and fragment analysis (CALR and FLT3).

PB1661
ASSOCIATION OF MRNA EXPRESSION PROFILES WITH FUNCTIONAL AND MOLECULAR ACUTE MYELOID LEUKAEMIA CATEGORIES
C. Sargas1, M. Llopol, C. Alonso3, R. Ayala4, M. E. Onecha4, M. Ibañez2
1Instituto de Investigación Sanitaria La Fe (IIS La Fe), 2Hospital Universitario y Politécnico La Fe, 3Hospital Arnau de Vilanova, Valencia, 4Hospital 12 de Octubre, Madrid, Spain

Background: Development of high-throughput technologies such as Next Generation Sequencing (NGS) allowed the identification of recurrent mutated genes in Acute Myeloid Leukemia (AML), and new molecular markers which help refine patients’ classification in different risk groups.

Genetic alterations such as aberrantly expressed microRNAs (miRNAs) also play an important role in the pathogenesis of AML. miRNAs control processes such as cell development, differentiation, proliferation and apoptosis. Therefore, aberrant miRNA expression can affect signaling and metabolic pathways, directing cancer cell biological behavior. Recently, several studies have classified AML according to different criteria. A new classification system has been proposed according to their biological function. Moreover, Papaemmanuil et al suggested in 2016 a new classification based on molecular markers with not overlapping categories.

Aims: Our aim is to explore the miRNA profile of NK-AML and to find expression profiles associated with the categories proposed by TCGA and Papaemmanuil et al. Associations of miRNA expression profiles with altered categories could help understand the molecular mechanisms that lead to leukaemogenesis.

Methods: CD34+ cord blood progenitor cells from 5 healthy donors and 7 CD34+ NK-AML samples with >70% blasts were obtained. Total RNA from primary NK-AML samples were hybridized onto an Array miRNA 3.0 chip (Affymetrix) in order to identify deregulated miRNAs. The most deregulated miRNAs were validated by qRT-PCR (miScript) in an independent cohort of 73 patients. Muta-

tional analysis was performed by Next Generation Sequencing using the AML Community Panel with the Ion Torrent System (Life Technologies). Mann-Whit-

test was used to determine which miRNAs were differentially expressed among categories.

Results: We found a profile of 6 miRNAs up-regulated and 61 miRNAs down-regulated in NK-AML vs CD34+ cells. Validation by qRT-PCR confirmed that miR-494 (p=0.028) and miR-499 (p=0.035) were up-regulated in miR-27b (p=0.022), miR-99a (p=0.001), miR-146b (p=0.031), miR-15b (p=0.006) and miR-20b (p=0.001) were down-regulated in NK-AML. Interestingly, some of the deregulated miRNAs were significantly associated to a functional category according to the TCGA classification. Therefore miR-146b was down-regulated in AML with mutations in myeloid transcription factors (p=0.025). Low expres-

sion of miRNAs can cause the activation of certain signaling pathways, which increases transcription. miR-4668 was down-regulated in AML with mutations in activation pathways genes (p=0.004), several target predictors propose RASGEF1A and BRAF as targets of this miRNA. Thus, under-expression of this miRNA could cooperate with mutations leading to the activation of signaling pathways. Regarding to Papaemmanuil’s molecular classification, miR-494 was up-regulated in IDH2-R172 category (p=0.009). High levels of this miRNA are associated with lower expression of TET, specially TET1. Therefore, high levels of miR-494 could contribute to the hypermethylation signature of IDH (Acute Myeloid Leukemia) cell lines.

Summary/Conclusions: In conclusion, the mutational landscape of significant functional and molecular groups in AML is accompanied by miRNA deregulation, which could cooperate in the development of this hematologic malignancy.

PROTEOMIC APPROACH TO IDENTIFY MOLECULAR TARGETS OF HALOFUGINONE IN ACUTE MYELOID LEUKEMIA
L. Cándido1, C. Silva2, D. Moreno1, C. Thomé3, A. Nagler4, E. Regó5
1Hematology Division of the Department of Internal Medicine, School of Medicine University of São Paulo, 2Laboratory of Experimental Animal Studies, Faculty of Medicine of Ribeirão Preto - University of São Paulo, 3Hematology Division of the Department of Internal Medicine, School of Medicine of Ribeirão Preto, Brazil, 4Hematology Division and Cord Blood Bank, Chaim Sheba Medical Center, Tel Aviv University, Tel Hashomer, Israel, 5National Institute of Science and Technology on Cell-Based Therapy, School of Medicine of Ribeirão Preto - University of São Paulo, Ribeirão Preto, Brazil

Background: Halofuginone (HF) is a halogenated derivative of Febrifugine, which is a molecule isolated from the plant Dichroa febrifuga. It has been demonstrated that Halofuginone exhibits anti-fibrotic, anti-cancerogenic, anti-inflammatory and pro-apoptotic effects. Previously, we have reported that HF has anti-leukemia properties in vitro and in vivo in acute promye-

locytic leukemia (APL), reducing tumor growth through the induction of apop-

tosis and by stimulating the synthesis of the TGF-B protein and activating its downstream targets. In addition, HF presented anti-angiogenic effects by modu-

ing the level of pro and anti-angiogenic factors including VEGF. However, it is not known whether HF could act on the genetic and epigenetic profiles of acute myeloid leukemia (AML) and HF targets were not determined yet.

Aims: Evaluate the anti-leukemic effect of HF on other AML subtypes by APL and investigate its targets using a proteomic approach.
Methods: AML cell lines Kasumi-1, THP-1, M4A-11, U937 and OCI-AML3 were treated in vitro with HF at concentrations ranging from 25 to 100 ng/ml. The % of apoptotic cells, the distribution of cells in different cell cycle phases, and the HF IC₅₀ was determined for each cell line. We used the Proteome Profiler™ Array – Human-Phospho-Kinase Array to verify the possible tyrosine kinases and signaling pathways that could be modulated by HF. To analyze the in-vitro effect of the drug, we treated with HF the cell lines Kasumi-1 and THP-1 cell lines treated with vehicle or HF (mean OS of 70.5 and 68 days, respectively; p=0.24). In contrast, the mean OS for NSG mice transplanted with Kasumi-1 cells treated with HF was significantly prolonged compared to the control group (144 versus 94.5 days; p=0.007). The proteomic analysis identified significant decrease upon treatment with HF of four phosphorylated-proteins in both cell lines: Phospholipase C gamma 1 (PLCγ1), Proline-rich tyrosine kinase 2 (PYK2), Endothelial nitro oxide synthate (eNos) and Signal transducer and activator of transcription 3 (STAT3 Y705), thus suggesting that these proteins are primary targets of HF. In addition, the protein target of rapamycin (TOR) was downregulated only in THP-1, while the levels of STAT3 S727 and STAT5α/b were significantly decreased by HF treatment only in Kasumi-1 cells. This comparative analysis suggests that the sensitivity to HF may be dependent on inhibition of STAT3/5 pathway.

Summary/Conclusions: In summary, our results suggest that HF may be effective against core binding factor leukemias and, that the methodology based on a Phospho-Kinase Array is useful to identify drug molecular targets.

DNA METHYLATION AND HYDROXYMETHYLATION PROFILING IS CAPABLE TO DISTINGUISH AML SAMPLES WITH DISTINCT MUTATIONS IN DNA METHYLATION REGULATORY GENES

H. Hájková1,*, Š. Voráčková1, Z. Krejčík1, E. Cerovská1, P. Cetkovský2, C. Šálek2
1Department of Genomics, 2Clinical Department, Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: Ablarent DNA methylation as well as hydroxymethylation is a hallmark of acute myeloid leukemia (AML). Mutations of DNA methylation regulatory genes (DNMT3A, IDH1, IDH2 and TET2) are present in approximately 40-50% of AML. These mutations are often present together with the exception of TET2 and IDH2 as well as IDH1 and IDH2, which are usually mutually exclusive.

Aims: We aimed to perform DNA methylation, hydroxymethylation and gene expression profiling in clearly defined subgroups of AML patients with distinct mutations in DNA methylation regulatory genes to see whether there is a clear epigenetic signature.

Methods: We accomplished DNA hydroxymethylation and methylation profiling in 12 AML samples at diagnosis and in CD34+ cells of 3 healthy controls by MethylationEPIC array (Illumina) covering aprox. 850 000 CpGs. AML samples were chosen based on their mutational status and divided into 4 groups: DNMT3A+ (n=3), IDH1+ (n=3), DNMT3A+IDH1+ (n=3) and IDH2+ (n=3). The remaining DNA methylation regulatory genes as well as CEBPA were unmethylated. 1 μg of genomic DNA was treated with TrueMethyl Seq kit (CEGX) to convert DNA through oxidative bisulfite (oxBS) and bisulfite (BS) treatment. This approach allows us to determine whether CpG is methylated or rather hydroxymethylated.

Results: We performed hierarchical clustering analysis of oxBS β-values (corresponding to DNA methylation levels) of 830 304 CpGs with detection P<0.05 and observed clear separation of 4 groups according to mutational status – DNA methylated, IDH1+IDH2+, CD34+ and CD34+na. Interestingly, only positive DNMT3A+IDH1+ (n=3) samples clustered each into different group (DNMT3A+, IDH1+, CD34+ normal) strongly suggesting that there is a cumulative effect of these two opposing mutations (Figure 1). We found out that genes hypermethylated in IDH1+ samples are enriched for genes from HOX gene family (P<0.0001), IDH1 and IDH2+ and CD34+na. Genes that are hypermethylated in IDH1+ are hypomethylated in DNMT3A+ and normally methylated in DNMT3A+IDH1+ samples relative to CD34+na. Clustering of DNA hydroxymethylation profiles, which is possible from subtraction of oxBS β-values from BS β-values) resulted into the same 4 main clusters as shown for DNA methylation data. DNMT3A+ patients displayed the lowest hydroxymethylation levels from all patients. Genes hydroxymethylated in IDH1+ patients were enriched for

Figure 1.

Summary/Conclusions: We explored that AML patients with clearly defined mutational background exhibit distinct DNA methylation as well as hydroxymethylation profiles. The presence of two mutations that have the opposite effect on DNA methylation pattern (DNMT3A and IDH1) is linked to mixed DNA methylation patterns, which prevents unambiguous assignment to one cluster. Further, our data support that IDH1+ and IDH2+ represent distinct biological entities. On the contrary, gene expression profile did not support separation of samples into different mutational subgroups. We plan to enlarge the patients’ cohort and validate the most promising genes involved in selected pathways. Supported by Ministry of Health of the Czech Republic, grant nr. 15-25809a, and by the project for conceptual development of research organization (00023796) from the Ministry of the Health of the Czech Republic.
existing hypomethylating-based protocols: a) high gene specificity b) lower cytotoxicity and c) absence of drug based off-target side-effects. In the short term, this research can lead to the identification of novel key regulators of leukemogenesis and new targets for therapeutic treatments; in the long term pave the way for development of RNA-based gene demethylating agents for cancer treatment.

JQ1 AND CURCUMIN COMBINED TREATMENT SHOWS SYNERGIC EFFECTS IN MLL-REARRANGED LEUKEMIA CELL LINES

P. Vitullo1,*, P. Leoncini1, V. Tocco1, M. Pigazzì2, K. D'Ovidio1, D. Montagna3, R. Rota1, A. Bertaina1

1Oncohaematology, Bambino Gesù Children Hospital, Roma, 2Pediatrics-Oncoematology, University of Padova, Padova, 3Pediatrics, Policlinico San Matteo, Pavia, Italy

Background: MLL-rearranged leukemia accounts for >70% of infant and >10% adult acute leukemias, featuring a particularly poor prognosis and high risk of relapse. Our main field of study is AML, in which nearly 50% of total cases accounts for t(9;11) translocation, the remaining 50% predominantly includes t(6;11)(q27;q23), t(10;11)(p12;q23), t(11;19)(q23;p13.1) and t(11;19)(q23;p13.3). A 2% of AML total cases, however, is characterized by t(4;11) translocation, which is a marker of bad prognosis and it's, so far, poorly characterized. A key feature of MLL-rearranged leukemia is cMyc overexpression, a well-known oncogene involved in several types of cancer. JQ1 is a novel molecule, which prevents cMyc expression binding an important repressor of differentiation and involved in drug-resistance, typically upregulated in pediatric AML and ALL.

Methods: Four human leukemia cell lines with MLL fusion protein have been employed in this study. RS4:11, MOLM13 expressing MLL-AF9 fusion genes, 5μM and 10μM Curcumin were employed in this study: RS4:11, MOLM13 expressing MLL-AF9 fusion genes. 5μM and 10μM Curcumin were used to treat all the cell lines, similarly cell cycle evaluation showed a significant accumulation of cells at SubG1 phase (2-8 fold) (Figure 1). XTT metabolic assay showed a reduction in proliferation percentage: 65±5% for curcumin and JQ1 single treatment and 59±5% for combination of drugs in both MLL-AF4 cell lines, meanwhile in MOLM13 cells it was 64±2 and 87±2% for curcumin and JQ1, respectively and 76±2% for their combination (P<0.005). The THP1 cell did not show any significant modulation in the proliferation. We decided to focus our study on t(4;11) translocated cells, considering the more intense effect of the combined drugs on previous analysis. qRT-PCR and western blot experiments revealed a synergic effect of the 2 experimental drugs on both apoptosis and proliferation gene related (bcl2, caspase3, Parp, cdkn1a) as well as on direct targets of the drugs (cMyc, AcH3K14). Finally, in MLL-AF4 cell lines, curcumin and JQ1 together induced a significant decrease in mir-99a expression.

Summary/Conclusions: Our data demonstrated that curcumin and JQ1, inhibiting HATs and BRD4 respectively, exert a more intense synergic effect on MLL-AF4 than in MLL-AF9 cells. Increased apoptosis together with a reduced proliferation rate, prompted us to investigate on molecular pathway in which targets of these drugs are involved. Intriguingly, we found a significant decrease in cMyc, bcl2 and AcH3K14 expression, confirming that both curcumin and JQ1 have a synergic effect. Additionally, we revealed a significant reduced expression of mir-99a, a well known oncomiR reported to act as negative regulator of differentiation and involved in drug-resistance, typically upregulated in pediatric AML and ALL.

PB1666

TP33B AND TP33F EXPRESSION LEVELS IN RELATION TO NPM1 AND CEBPA MUTATIONS

K. Matiakowska1,*, A. Bartoszewska-Kubiak1, E. Bielinska1, M. Morgut-Klimkowska1, O. Haus1

1Department of Clinical Genetics, Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University in Torun, Bydgoszcz, Poland

Background: Acute myeloid leukemia (AML) is a heterogeneous clonal disorder with the presence of diverse genetic abnormalities in hematopoietic stem cells. The most frequent alterations in normal karyotype AML (NK AML) are mutations in exon 12 of nucleophosmin gene (NPM1). Until now 56 different mutations of NPM1 exon 12 have been described, mostly insertions. The NPM protein plays an important role in cell cycle and apoptosis control. It cooperates with several proteins, among them with p53 and ARF. The median levels of functional nuclear p53 protein are reduced in NPM1 and FLT3 ITD mutant samples. TP53 encodes a tumor suppressor protein which consists of transactivation, DNA-binding and oligomerization domains. Due to alternative splicing it may exist in 13 different isoforms. Alternative splicing of intron 9 leads to production of 2 different proteins, p53β and p53γ, without oligomerization domain (stop codon is localized in exon 9b). These isoforms can be present in acute myeloid leukemia (AML) cells. p53β binds to BAX promoter and can induce apoptosis independent from p53 wt. p53 has influence on activation of CEBPA which is associated with cell cycle regulation, especially cell cycle arrest and plays also role in cell differentiation. Generally, it is a transcription factor expressed during myeloid lineage development, from progenitor cells to mature granulocytes. Various mutations of CEBPA gene are described. Among them N-terminal and C-terminal mutations, mostly insertions and deletions, are often present. Alms: The goal of the study was to assess mutational status of NPM1, CEBPA and FLT3 in association with TP33beta and TP33gamma expression levels.

Methods: 75 NK AML patients were included in the study. NPM1, CEBPA and FLT3 gene mutations were analyzed by direct sequencing. TP33B and TP33F expression levels were assessed using real-time PCR. Expression levels were analyzed with ΔΔCt method, with ABL as a control gene and K562 cell line as a calibrator.

Results: In all 75 cases, TP33B and TP33F transcripts were detected. 36 patients had NPM1 mutations, 25 had CEBPA mutations or known polymorphisms, and 25 had FLT3 ITD mutation. Assessed median expression level of TP33B was much higher (ΔΔCt 43.11) than TP33F (ΔΔCt 10.85; p<0.05). Furthermore, expression level of TP33F in CEBPA mutated group (ΔΔCt 11.4) was significantly lower than in CEBPA wt group (ΔΔCt 17.7) (p=0.03). We have not found any other important correlation between mutations of studied genes and TP33F or TP33B expression. We also classified patients according to median expression value of TP33F, to two groups: with overexpression or with low expression. Haematological and clinical features, such as white blood cells count (WBC), blasts count in bone marrow or patient age did not depend on TP33F isoform expression. However, statistical analysis showed important difference between WBC count in NPM1mutated and NPM1wt groups.

Summary/Conclusions: Obtained results may suggest a clinical importance of simultaneous analysis of TP33F isoform expression and mutations in CEBPA gene. It may be hypothesized that a changed sequence of the latter gene might influence TP33F isoform expression and in consequence regulate the cell cycle.

PB1667

EXPRESSION PROFILE OF EPIGENETIC MODULATORS IN ACUTE MYELOID LEUKEMIA OF INTERMEDIATE RISK

C. Bilbao Sieyro1,*, Y. Florida Ortega1, C. Rodriguez Medina1, S. Gamrani1

Background: Acute myeloid leukemia (AML) is the heterogeneous clonal disorder with the presence of diverse genetic abnormalities in hematopoietic stem cells. The most frequent alterations in normal karyotype AML (NK AML) are mutations in exon 12 of nucleophosmin gene (NPM1). Until now 56 different mutations of NPM1 exon 12 have been described, mostly insertions. The NPM protein plays an important role in cell cycle and apoptosis control. It cooperates with several proteins, among them with p53 and ARF. The median levels of functional nuclear p53 protein are reduced in NPM1 and FLT3 ITD mutant samples. TP53 encodes a tumor suppressor protein which consists of transactivation, DNA-binding and oligomerization domains. Due to alternative splicing it may exist in 13 different isoforms. Alternative splicing of intron 9 leads to production of 2 different proteins, p53β and p53γ, without oligomerization domain (stop codon is localized in exon 9b). These isoforms can be present in acute myeloid leukemia (AML) cells. p53β binds to BAX promoter and can induce apoptosis independent from p53 wt. p53 has influence on activation of CEBPA which is associated with cell cycle regulation, especially cell cycle arrest and plays also role in cell differentiation. Generally, it is a transcription factor expressed during myeloid lineage development, from progenitor cells to mature granulocytes. Various mutations of CEBPA gene are described. Among them N-terminal and C-terminal mutations, mostly insertions and deletions, are often present. Alms: The goal of the study was to assess mutational status of NPM1, CEBPA and FLT3 in association with TP33beta and TP33gamma expression levels.

Methods: 75 NK AML patients were included in the study. NPM1, CEBPA and FLT3 gene mutations were analyzed by direct sequencing. TP33B and TP33F expression levels were assessed using real-time PCR. Expression levels were analyzed with ΔΔCt method, with ABL as a control gene and K562 cell line as a calibrator.

Results: In all 75 cases, TP33B and TP33F transcripts were detected. 36 patients had NPM1 mutations, 25 had CEBPA mutations or known polymorphisms, and 25 had FLT3 ITD mutation. Assessed median expression level of TP33B was much higher (ΔΔCt 43.11) than TP33F (ΔΔCt 10.85; p<0.05). We have not found any other important correlation between mutations of studied genes and TP33F or TP33B expression. We also classified patients according to median expression value of TP33F, to two groups: with overexpression or with low expression. Haematological and clinical features, such as white blood cells count (WBC), blasts count in bone marrow or patient age did not depend on TP33F isoform expression. However, statistical analysis showed important difference between WBC count in NPM1mutated and NPM1wt groups.

Summary/Conclusions: Obtained results may suggest a clinical importance of simultaneous analysis of TP33F isoform expression and mutations in CEBPA gene. It may be hypothesized that a changed sequence of the latter gene might influence TP33F isoform expression and in consequence regulate the cell cycle.
Background: Whole-genome sequencing has revealed acute myeloid leukemia (AML) as a very complex and dynamic disease. Epigenetic modulation is among the functional categories of the mutational landscape in AML. According to recent reports, suppression of the epigenetic reader BRD4 with small-molecule inhibitors (BET-i) results in antileukemic activity. Clinical trials are being developed, however, so far, identification of those patients that may benefit from this therapy is not possible as changes in mRNA BRD4 levels seem to be very subtle. It has been recently suggested that antileukemic effect of BET-i could be due to c-myc suppression and that also high Bcl-2 levels may target those patients that would benefit of BET-i. We believe that establishing the expression profile of epigenetic modulators in AML may help in the identification of patients that could benefit from BET-i.

Aims: We wanted to get a better insight regarding the expression profile of epigenetic modulator in AML of intermediate risk by studying: 1) expression levels of EZH2, ASXL1, BRD4, c-myc and Bcl2 in a consecutive series of AML patients; 2) correlation between mRNA and protein levels; 3) Determining BRD4 binding to the c-myc promoter through chromatin immunoprecipitation (ChIP).

Methods: Our series consisted of 104 consecutive patients with a mean age of 55.8 years (range 15-79 years) diagnosed and treated between 2005-2016 at the Hospital Universitario de Gran Canaria Dr. Negrín with a median follow up of 12 months. Gene expression analysis was carried out through real time PCR in a LightCycler 480 Instrument II (Roche) using GUS a control gene. Results were normalized with a cDNA pool from bone marrow of 10 healthy donors which was introduced as internal control in each experiment. Western blot were performed to determine protein levels for BRD4, c-myc and Bcl2. CHIP studies for BRD4 were carried out in HL60 cell line. For statistical analysis the SPSS (v.15.0) software was used.

Results: ASXL1 levels were positively associated with EZH2 (Pearson’s r=0.285, p=0.021) and BRD4 with c-myc (Pearson’s coefficient=0.420, p<0.001). Bcl2 (Pearson’s r=0.471, p<0.001) EZH2 (Pearson’s r=0.4565, p=0.008) and ASXL1 (Pearson’s r=0.949, p<0.001). Survival analysis considering 50th percentile as a cut-off value for BRD4 expression indicated that patients with higher levels of BRD4 had better overall survival (median OS 27 months, 95% CI 15.1-38.9) compared to those with low expression (median OS 12 months, 95% CI 0.4-23.7), although the association was not statistically significant (p=0.196) probably due to the limited series size. Protein levels of Bcl2 and c-myc correlated with those of mRNA, but not for BRD4, although other antibodies should be tested in order to confirm these results. CHIP analysis in HL60 cell lines confirmed the binding of BRD4 to c-myc promoter.

Summary/Conclusions: The positive association observed between EZH2 and ASXL1 agrees with the fact that both cooperate in the epigenetic repressive complex PRC2. The immunoprecipitation of BRD4 and c-myc mRNA in Bcl2 is in accordance to the reported binding of BRD4 to the c-myc enhancer regions and our CHIP analysis also supports so. Further studies in a larger series are necessary to confirm the relationship between higher BRD4 levels and better overall survival. Finally, future analysis should be done to determine whether patients with higher BRD4 expression levels determine a subgroup with better response to BET-i.

Figure 1. Summary/Conclusions: CEBPAdm cases showed an homogeneous immunophenotype with positivity for CD45, CD7, CD34, CD123, CD117, HLA-DR, CD71, CD33, CD13 and CD15. CD36 and/or CD56 overexpression was detected in a subgroup of cases (9/39, 23%) with an adverse outcome. The current findings suggest that CD36 and CD56 reactivity should be investigated in larger series of CEBPAdm AML cases. Small leukemic populations with B-cell markers are not uncommon in CEBPAdm AML (3/39, 7%).

PB1669
PROTEOME CHANGES IN ACUTE MYELOID LEUKAEMIA PATIENTS BEFORE AND AFTER INDUCTION TREATMENT
L.F. Restrepo Rodriguez1,*, S. Rothlisberger1
1Biomedical Engineering, Instituto Tecnologico Metropolitano, Medellin, Colombia

Background: Acute myeloid leukemia (AML) is a malignant disorder of hematopoietic stem and progenitor cells (HSPCs), characterized by the accumulation of immature blasts in the bone marrow and peripheral blood (PB) of affected patients. Standard induction therapy, based on cytarabine and an anthracycline, leads to complete remission in approximately 50% to 75% of patients, depending on prognostic factors, such as age or the presence of certain gene or chromosomal changes. In spite of favorable primary response rates, only approximately 20% to 30% of the patients enjoy long-term disease survival.

Aims: Our aim was to compare the protein expression profile of peripheral blood mononuclear cells (PBMCs) of AML patients at time of diagnosis and after induction therapy.

Methods: PB samples were taken from seven AML patients in Medellin-Colombia before and after concluding the induction therapy. Informed consent was obtained prior to sample collection. PBMCs were isolated from the 14 blood samples using a Histopaque-1077 solution. Cells were resuspended in lysis buffer (0.5% Triton x-100, 50 mM Tris-HCL pH 8.0, 150 mM NaCl, 1 mM EDTA, protease inhibitor) and proteins precipitated with trichloroacetic acid. Protein and RNA were separated by 2D SDS-PAGE (pL 3–10 NL), and stained with SYPRO®Ruby. The proteomes were compared using PDQuest™ Advanced 8.0.1 Software. Protein spots of interest were those with a fold change of +/- 1.5 and p <0.05.

FLOW CYTOMETRY IMMUNOPHENOTYPING IN CEBPA-DM DE NOVO AML. BIOLOGIC AND PROGNOSTIC RELEVANCE.
M. Fernandez1,*, M. Pratcrónica1, A. Gambó1, C. Estivill1, J. Esteve2, O. Balmaseda3, A. Tormo4, M. Armán5, B. Bellosancristóbal6, L. Zamora6, S. Vives7, R. Guardia7, S. Brunet1,*, S. Sierra1,*, J. Nomdedeu1
1Hematology, Hospital de la Santa Creu i Sant Pau, 2Hematology, Hospital Clinic, 3Hematology, Hospital de la Vall d’Hebron, Barcelona, 4Hematology, Hospital Clínic, Valencia, 5Hematology, ICO Hospitalet L’Hospitalet de Llobregat, Barcelona, 6Hematology, ICO Badalona, Badalona, 7Hematology, ICO Girona, Girona, Spain

Background: CEBPA is a transcriptional co-factor of RUNX1 which play a major role in the fate decisions associated with physiologic myelopoesis. Biallelic CEBPA mutations (dc) define an homogeneous molecular subgroup which is associated with a favorable outcome. CEBPA mutations may be transmitted in the germline giving rise to clusters of familial leukemias.

Aims: To analyze the immunophenotypic findings assessed by multiparametric flow cytometry in a consecutive series of de novo CEBPA-AML.

Methods: Thirty patients with de novo AML and CEBPA-DCM who have been enrolled on the AML-03 and AML-12 protocols of the Spanish CETLAM cooperative group were included in this study. The immunophenotypic analysis was performed on erythrocyte-lysed bone marrow (BM) samples obtained at diagnosis. Antigenic expression of leukemic cells was systematically analyzed by multiparametric flow cytometry using four-color staining. The antigens studied were: CD45, CD34, HLA-DR, CD10, CD20, CD19, CD2, CD33, CD7, CD117, CD66, CD13, CD64, CD36, CD56, CD14, CD123, CD61, CD42b, glycophorin, CD71, CD11b, myeloperoxidase, CD79a, TdT, lysozyme and lactoferrin. At least 10.000 events/tube were measured. Analytical gates were established according to CD45 reactivity and to FSC/SSC pattern. Positive threshold was established at 20%. The FACS-DIVA, Paint-a-Gate and InfiFlow software programs were employed for analysis. Amplification of overlapping PCR covers the whole CEBPA coding sequence followed by Sanger sequencing were used to investigate CEBPAdm mutations. FLT3-ITD, NPM1, MLL, PTDL, WT1 and GATA2 mutations were also investigated by conventional PCR-based molecular methods.

Results: Antigen reactivity was as follows: CD45 (39/39,100%), CD15 (35/39, 90%), CD34 (36/39,92%), HLA-DR (39/39,100%), CD33/39,100%), CD2 (2/39,5%), CD7 (36/39,92%),CD117(39/39,100%), CD13/37/39,95%), CD56 (39,15%), CD36 (6/39, 15%), CD123/39,100%), CD14 (1/39,0.02%), CD71 (37/39,97%), myeloperoxidase (38/39, 97%). In nine cases CD36 and/or CD56 expression on leukemic blasts was greater than 20% Those CD36/CDS6+ cases had a shorter overall survival and leukemia free survival (see graph). Four out five tested CD36/CD56+ cases also showed GATA 2 mutations. An additional CD36/CD56+ case had a FLT3-ITD. In three out 39 cases (7%) a population showing cytoplasmic CD79a reactivity was detected (8%, 11%,14% of the neoplastic population, respectively). Two of those cases had also a FLT3-ITD.
Results: Image analysis revealed an average of 464 protein spots in PB samples taken at time of diagnosis, and an average of 346 spots in PB taken after induction therapy, reflecting changes in protein expression due to treatment. Comparing the proteomes, we found 11 spots that differed significantly (fold change of +/-1.5 and p <0.05). Of these, seven proteins were up-regulated and four were down-regulated at time of diagnosis (before treatment) compared to after induction treatment. Nine of these spots corresponded to low molecular weight proteins (<40 kDa) and 2 spots have a molecular weight between 40-60 kDa. Based on the molecular weight and isoelectric point information of these spots we were able to search for proteins reportedly involved in leukemia, in order to propose possible identities (see Table 1). In terms of biological processes, four proteins (e.g.,B3, HSP27, 14-3-3 protein zeta/delta, and GST-P) are involved in the regulation of apoptosis. The F-actin-capping protein subunit beta could also be of interest, as reorganization of F-actin reflects unique characteristics of the differentiation process in promyelocytic leukemia cells. RuvB-like 2 is a positive regulator of histone acetylation and DNA repair. GBP2 is a positive regulator of histone acetylation and DNA repair. Our results demonstrate that quercetin has anti-leukemia activity. It is mediated by regulating telomere-binding protein expression to inhibit proliferation and induce apoptosis in acute myeloid leukemia (AML) THP-1 cells.

Methods: 1. In vitro: (1) We cultured human AML THP-1 cells. (2) The cells were treated with different concentration of quercetin for 24/48 h, and the cell viability was measured by cell counting kit-8 (CKC-8) to determine the IC50 of quercetin. (3) The cell cycle distribution and apoptotic rate were measured by Annexin V-FITC/PI double staining flow cytometry (FCM). (4) The protein expression levels of POT1, TRF1, TRF2 were measured by western-blotting. (5) The mRNA expression levels of POT1, TRF1, TRF2 were measured by real-time fluorescence quantitative polymerase chain reaction (RT-qPCR). 2 In vivo: (1) Established AML-NOD/SCID model based on THP-1 cell line in NOD/SCID mice, and treated with optimal quercetin concentration (40 mg/kg/d) for 4 weeks by tail vein injection. (2) We observed the changes of mice survival status, peripheral blood and bone marrow cell morphology and organ histophatology by microscopy before and after treatment with quercetin. (3) The cell cycle distribution and apoptotic rate of spleen cells were measured by Annexin V-FITC/PI double staining FCM. (4) The protein expression levels of POT1, TRF1, TRF2 were measured by immunohistochemistry (IHC) staining.

Results: In this study, we found that quercetin significantly suppressed THP-1 cells proliferation in dose- and time-dependent manner. Treatment with quercetin significantly increased the cell G0/G1 phase arrest rate. Furthermore, the protein expression levels of POT1 and TRF1 increased and the protein expression level of TRF2 decreased. The mRNA expression levels of POT1, TRF1, TRF2 were consistent with their protein expression levels, respectively.

Summary/Conclusions: Our results demonstrate that quercetin has anti-leukemia activity. It is mediated by regulating telomere-binding proteins expression to inhibit proliferation and induce apoptosis in AML cells.

PB1670 AMP-ACTIVATED PROTEIN KINASE ACTIVITY INTERFERS WITH OVEREXPRESSION OF NUCLEOPHOSMIN IN CYTARABINE-INDUCED CHEMORESISTANT AML CELLS

D. Kim1,2,*, K.N. Kim1,2, J. Kang1,2, C.S. Park1,2, H.G. Yi3
1Hypoxia-related Disease Research Center, 2Pharmacology, 3Internal Medicine, Inha University School of Medicine, Incheon, Korea, Republic Of

Background: Cytarabine is a chemotherapeutic drug used alone or in combination with other anticancer drugs to treat acute myeloid leukemia (AML). New treatment strategies are emerging to enhance the anti-cancer effect and decrease the toxicities. Nucleophosmin (NPM1 or B23) is a ribosomal protein localized in nucleolus, and multifunctional enzyme in cancer cell growth and proliferation. AMP-activated protein kinase (AMPK) is a critical energy sensor to regulate homeostasis and plays a potential role for anti-cell proliferating activity.

Aims: We investigated the effects of AMPK activation on the cell death (apoptosis) and cell cycle distribution in HL-60 AML cells treated with cytarabine, an anti-leukemic drug, to predict the mechanisms responsible for AML cells chemoresistance.

Methods: The HL-60 (FAB M2) cells were exposed to the different drug combinations including cytarabine and AMPK activators. The molecular mechanisms of apoptosis induced by cytarabine and AMPK activators were investigated by measuring the expression of cell cycle regulators, cell viability and apoptosis using cell counting kit-8 assay and flow cytometry.

Results: We found that cell apoptosis (36.27~42.11%) showed low dependence on cytarabine concentrations (10, 100, and 1000 mM), while the overexpression of NPM1 overexpression of NPM1 overexpression of NPM1 overexpression of NPM1 increased proportionally with drug dependence, indicating the drug-induced cell resistance. In the same point, cytarabine also inhibited the phosphor-activity (Thr172) and expression level of AMPK, which has mTOR-p70S6K pathway-repressor activity. As expected, single cytarabine treatment increased the ratio of p-mTOR/mTOR and p-p70S6K/p70S6K. Co-treatment of AMPK activator (phenformin or AICAR) with HL-60 AML cells inhibited significantly the induction of NPM1 overexpression level with the decrease of phosphor-activities of mTOR and its substrate p70S6K, resulting in the accelerated cell apoptosis.

Background: Leukemia cells are limitless cell sources for initiation and maintenance of leukemia. Telomere-binding proteins are key regulators for various diseases, including leukemia. Therefore, targeting telomere-binding proteins is considered as a promising therapeutic strategy for treatment of leukemia.

Aims: We aimed to explore whether quercetin, a natural flavonoids, could regulate telomere-binding proteins expression to inhibit proliferation and induce apoptosis in acute myeloid leukemia (AML) THP-1 cells.

Methods: 1. In vitro: (1) We cultured human AML THP-1 cells. (2) The cells were treated with different concentration of quercetin for 24/48 h, and the cell viability was measured by cell counting kit-8 (CKC-8) to determine the IC50 of quercetin. (3) The cell cycle distribution and apoptotic rate were determined by Annexin V-FITC/PI double staining flow cytometry (FCM). (4) The protein expression levels of POT1, TRF1, TRF2 were measured by western-blotting. (5) The mRNA expression levels of POT1, TRF1, TRF2 were measured by real-time fluorescent quantitative polymerase chain reaction (RT-qPCR). 2 In vivo: (1) Established AML-NOD/SCID model based on THP-1 cell line in NOD/SCID mice, and treated with optimal quercetin concentration (40 mg/kg/d) for 4 weeks by tail vein injection. (2) We observed the changes of mice survival status, peripheral blood and bone marrow cell morphology and organ histophatology by microscopy before and after treatment with quercetin. (3) The cell cycle distribution and apoptotic rate of spleen cells were measured by Annexin V-FITC/PI double staining FCM. The protein expression levels of POT1, TRF1, TRF2 were measured by immunohistochemistry (IHC) staining.

Results: In this study, we found that quercetin significantly suppressed THP-1 cells proliferation in dose- and time-dependent manner. Treatment with quercetin significantly increased the cell G0/G1 phase arrest rate. Furthermore, the protein expression levels of POT1 and TRF1 increased and the protein expression level of TRF2 decreased. The mRNA expression levels of POT1, TRF1, TRF2 were consistent with their protein expression levels, respectively.

Summary/Conclusions: Our results demonstrate that quercetin has anti-leukemia activity. It is mediated by regulating telomere-binding proteins expression to inhibit proliferation and induce apoptosis in AML cells.

PB1672 PPARY AGONISTS INHIBIT ADHESION SIGNAL TO ENDOTHelial CELLS IN THE DIFFERENTIATION INDUCTION OF 15D-ACETate PROMOlycytic LEUKEMIA CELLS

J. Park1,2, J.B. Koh3, J.W. Yoon4, O.Y. Hong5, J.-S. Kim2
1Division of Hematology/Oncology, Department of Internal Medicine, Gachon University Gil Hospital, Incheon, 2Biochemistry, Institute for Medical Sciences, Chonnam National University, Jeonju, Korea, Republic Of, 3Psychology, Fullerton College, Fullerton, United States

Background: All-trans retinoic acid (ATRA) has successfully been used in the treatment of acute promyelocytic leukemia (APL) patients, with a remission rate of greater than 90%. Despite the high cure rates, induction mortality is still a problem in APL. One of the most common causes of death was the differentiation syndrome (DS) . The early administration of high-dose dexmethasone at the onset of the first
signs or symptoms of DS is crucial, however specific biological therapies to counteract the syndrome are still not available. Peroxisome proliferator activated receptor gamma (PPARγ) is a ligand-dependent transcription factor and a member of the nuclear receptor superfamily, which is expressed in normal monocytes, various leukemias, and epithelial malignancies. PPARγ is highly induced in differentiating myeloid cells and subsequently contributes to their differentiation. Differentiation induction of APL cells is associated with increased expression of specific adhesion molecules and inflammatory cytokines, which may promote activation, migration, and adhesion of these cells.

Aims: Here, we studied the effect of PPARγ agonists on the adhesion of a human leukemia cell line (HL-60) to endothelial cells.

Methods: Differentiation was determined by an increase in reactivity with the CD11b antibody. For the adhesion assay, the Matrigel transwell system was used. Results: HL-60 cells were differentiated into macrophage-like cells by a PKC activator, 12-O-Tetradecanoylphorbol-13-acetate (TPA). During the differentiation of HL-60 cells, PPARγ agonists activate TPA-induced CD11b expression. However, PPARγ agonists completely blocked TPA-induced ICAM-1 expression of endothelial cells, which resulted in the inhibition of adhesion of HL-60 cells to endothelial cells. These responses also were reversed by PPARγ antagonist (GW9662), indicating that PPARγ agonists inhibit the adhesion of the HL-60 cells to endothelial cells through a PPARγ dependent mechanism.

Summary/Conclusions: These results suggest that PPARγ agonists inhibit TPA-induced adhesion signal in the between HL-60 cells and endothelial cells, and may control differentiation syndrome in APL patients.
Aims: Expression of p53 assessed by immunohistochemistry is a fast, objective and promptly available tool for prognostic evaluation of AML. A high expression of p53 (H-score >60) was related to a lower overall survival in de novo AML.

LONG-TERM FOLLOW-UP OF SALVAGE TREATMENT FOR RELAPSED AML WITH CLADRIBINE, HIGH DOSE CYTARABINE AND IDAURIBIN K. Mayer1,*, C. Hahn-Ast1, K. Schweb1, A. Glasmacher1, I. Schmidt-Wolf2, P. Brossart1, M. von Lilienfeld-Toal1
1Medical Clinic III, 2University Hospital Bonn, Bonn, Germany

Background: Despite improving response rates in induction treatment for AML during the last years the outcome for relapsed or refractory AML is still poor. Currently, no standard therapy exists for patients with relapsed AML. Furthermore, CR rates are lower than in newly diagnosed patients and range between 15% and 50%. There is evidence that cladribine (2CdA) has a single drug activity in AML as well as an enhancing effect on other cytostatic drugs such as cytarabine (AraC) and thus may help to overcome resistance mechanisms.

Aims: Therefore, testing the combination of 2CdA, AraC and idarubicin (CAI) seems reasonable. Here we present the final analysis from our single-center phase II trial evaluating the safety and efficacy of CAI in relapsed AML patients after a follow-up of 5 years.

Methods: Patients with relapsed AML after at least 6 months of remission and ECOG 0-2 were included. Chemotherapy regimen consisted of two courses of 2CdA 5 mg/m²/12 h, d-1, t3; AraC 1000 mg/m²/12 h, d-1 and 3-day idarubicin 8 mg/m²/d, d-3. After 8 patients, the prolonged duration of neutropenia especially in course 2 prompted us to change the protocol by 1) application of growth factors from day 15 onwards, and 2) omission of idarubicin from the 2nd course. The primary endpoint was the overall remission rate and safety of CAI.

Results: Because of slow recruitment the study was stopped after 20 patients. The median age was 63 years, 40% were female. 19/20 (95%) patients were included in the first relapse after at least 6 months of CR following 1st line therapy for AML. 1/20 (5%) patient was included with a second relapse. In 14/20 patients cytogenetic data at the time of relapse were available, according to the ELN risk classification (64%) intermediate and 2/14 (14%) belonged to the adverse cytogenetic group. The performance status was good in most patients (ECOG 0 in 10%, ECOG 1 in 80%), but reduced (ECOG 2 in 20%) patients. After the first course, CR/CRi was achieved in 60% and PR in 10% of patients. Median duration of neutropenia was 19-42d. The median grade 3 or 4 non-hematological toxicity was infection seen in 85% of courses. Nausea occurred in 30%, hepatotoxicity, mucositis and diarrhea in 11% of courses. Cardiac or renal toxicities grade 3/4 were not observed. Two patients (10%) died due to infection. Six patients received a second course of CAI/CA. Altogether, 6 patients were refractory. Nine patients (48%) proceeded to allogeneic stem cell transplantation after induction therapy with CAI. Of those, 4 patients are still alive and free of leukemia and one patient died in CR 88 months after salvage-therapy accounting for a 5-year survival rate of 55%.

Summary/Conclusions: Combination therapy with CAI in relapsed AML patients is feasible and induces good response rates. Combined with allogeneic stem cell transplantation, long-term survival can be achieved. However, infection rates are a serious complication warranting intensive supportive care.

HIGH EVIDENCE PREDICTS POOR OUTCOMES IN ADULT ACUTE MYELOID LEUKAEMIA PATIENTS WITH INTERMEDIATE CYTOGENETIC RISK RECEIVING CHEMOTHERAPY ONLY
Y.-Z. Qin1, T. Zhao1, H.-H. Zhu1, J. Wang1, J.-S. Jia1, Y.-Y. Lai1, X.-Z. Zhao1, H.-X. Shi1, Y.-R. Liu1, H. Jiang1, X.-J. Huang1, Q. Jiang1
1Peking University People’s Hospital, Peking University Institute of Hematology, Beijing, China

Background: Nearly half of acute myeloid leukemia (AML) patients are defined as an intermediate cytogenetic risk, however the patients in this group have greatly varied outcomes and need to be stratified. Apart from gene mutation, abnormal gene expression might also be prognostic, and ecotropic viral integration site 1 (EVII) expression is a representative. To date, the poor prognostic impact of EVII expression in AML has been reported, but almost all studies have been undertaken by European researchers. EVII prognostic significance in AML remains to be confirmed in other populations. Furthermore, because the selection protocol and cutoff values selection methodologies differed among studies, the threshold for defining EVII high expression remains obscure, which hinders its clinical routine application.

Aims: We investigated the prognostic impact of EVII transcript levels in Chinese adult intermediate cytogenetic risk AML (iCR-AML) patients who received chemotherapy only in a single center. The appropriate cutoff values for grouping EVII expression were also evaluated.

Methods: A total of 191 adult patients receiving chemotherapy only were included in this study. They were diagnosed as iCR-AML according to morphology, immunophenotyping, cytogenetics and molecular biology. Their bone marrow samples were collected at diagnosis. Real-time quantitative PCR was performed to test EVII, MLL partial tandem duplicate (MLL-PTD) and WT1 transcripts, and their transcript levels were calculated as the percentage of target transcript copies/ABL copies. NPM1 mutations and FLT3 internal tandem duplication (FLT3-ITD) were individually screened by real-time quantitative PCR and qualitative PCR, respectively. All patients were simultaneously tested EVII, MLL-PTD and WT1 transcripts. All participants provided written informed consent in accordance with the Declaration of Helsinki.

Results: The upper limit of EVII transcript levels in 27 NBM samples was 8.0%. Receiver operating characteristic curve analysis showed that 1.0% (a 0.9-log reduction from the normal limit) was the EVII optimal diagnostic cutoff value for significantly differentiating relapse (P=0.049). A total of 23 patients (12%) had EVII levels ≤1.0%. EVII≤1.0% had no impact on complete remission achievement, EVII≤1.0% was significantly associated with lower 2-year relapse-free survival (RFS), disease-free survival (DFS) and overall survival (OS) rates in the entire cohort (P=0.0003, 0.0017 and 0.0009), patients with normal karyotypes (n=148, P=0.0032, 0.0047 and 0.0007) and FLT3-ITD (-) patients (n=150, all P<0.0001). Multivariate analysis showed that EVII≤1.0% and FLT3-ITD (+) were independent adverse prognostic factors for RFS (Table 1), DFS and OS in the entire cohort. In addition, patients with EVII between 1.0% and 8.0% had 2-year RFS rates similar to those with EVII≤1.0%. (P=0.16), and both patient groups had significantly higher RFS rates than those with EVII>1.0%.

Table 1.

Summary/Conclusions: EVII transcript levels at diagnosis could further stratify adult iCR-AML, and high EVII expression predicts poor outcomes in patients receiving chemotherapy only. The optimal cutoff value which best differentiates patients is different from the normal upper limit.

EFFICACY AND SAFETY OF DECITABINE IN ELDERLY AML PATIENTS: A REAL LIFE MULTICENTER EXPERIENCE OF THE NETWORK RETE EMATOLOGICA LOMBARDIA
E. Borlingh1,*, C. Cattaneo1, M. Bernardi2, C. Basilio3, N. Fracchiolla2, M. Fumagalli3, M. Rossii, E. Sala2, M. Sciumé3, E. Todisco2, M. Petullá1, G. Rossi1
1Hematology, Spedali Civili, Brescia, 2Hematology and BMT Unit, San Raffaele Scientific Institute, Milano, 3Medicina Specialistica-Ematologia, ASST Sette Laghi, Varese, 4Hematology and BMT Unit, IRCS Ca Granda Ospedale Maggiore Policlinico, Milano, 5Hematology, ASST Monza - San Gerardo Hospital, Monza, 6Hematology, Humanitas Cancer Center , Milano, Italy

Background: The optimal treatment decision in older patients (pts) with AML remains controversial, especially in patients pts with comorbidities, non-fit to intensive therapy or with AML adverse biologic features. Recently decitabine was approved in Italy in AML pts unfit to chemotherapy aged >65 years (y) and could be adopted in a population based setting.

Aims: To evaluate efficacy and toxicity of decitabine in a consecutive series of elderly AML pts (no M3), considered unfit to chemotherapy (CT) according to Ferrara et al (Leukemia, 2013) and treated at 6 centers of the Hematological Lombardy Network (REL).

Methods: Between Dec 2015 and Dec 2016, 46 (F/M: 22/24) newly diagnosed AML treatment-naive elderly patients were selected for AML decitabine therapy in 6 centers of the Lombardy Network (REL). Median age was 76 y (69-85), ECOG performance status (PS) was ≥3 in 10.8%. According to “fitness”, 41 pts (89.1%) were defined unfit to intensive CT, 1 frail and 4 fit. Unfitness causes were age >75y (58.5%), PS ECOG≥3 unrelated to leukemia (12.2%), and comorbidities (29.3%). AML was “de novo” in 25 pts (54.3%), therapy-related in 3 and secondary to antecedent hematological disorders in 18 pts. WBC count at diagnosis was 4.4 ± 3.9 x10³/mL (0.46 to 63), marrow blasts were 51% (<30% in 19.5% of pts). Karyotype (K) was normal (NK) in 43%, t(8;21) in 4.5%, intermediate in 20.5%, adverse (adv) in 32% of
Results: The total number of cycles administered was 231 (median 3.5; range 1-20). In 37/46 evaluable pts (2 ongoing, 1 early and 6 aplastic deaths), overall response rate (ORR) and complete remission (CR) rate were 51.5% and 32%, respectively. Partial response (PR) and hematological improvement were achieved in 5.5% and in 13.6%, stable disease in 29.9% and failure in 19% of pts, respectively. Median time to best response was 3.5 months (range 1-8.5). Median response duration was 5.3 months (1-18+ ms). Relapse/disease progression was observed in 42% of responders. ORR was 21.4%, 47.3% and 77% in adv, NK and intermediate-9, respectively (P<0.0289). After a median follow-up of 6.5 months, median survival was 8.4 months and projected OS at 1 y and 2 y was 43%+/-9 (SEM) and 30%+/-12% (SEM). Treatment was fairly well tolerated except for a high incidence of infections (46 episodes in 231 cycles) particularly during the first 3 cycles (29% vs 11%) (p=0.0072). Pneumonia was the most frequent infection (46%), followed by sepsis (28%). It was more frequent during the first 3 cycles (14% vs 4%; p=0.012) when 44% of cases were of suspected fungal origin (3 probable aspergillosis and 4 possible IFI). Death occurred in 24 pts (52.2%): 12 (50%) of disease progression, 1 of early CNS hemorrhage and 11 (45.8%) of infection. In the first 3 months, infections were responsible for 46.7% of deaths. Pulmonary IFI were fatal in 57% of cases. These figures are higher than those reported by Cashen (JCO 2010) where the frequency of pneumonia was 11%.

Summary/Conclusions: These preliminary data confirm, in a population based setting, the high efficacy of decitabine and its longer time to response (more than 4 cycles) compared to CT. However infections complications were more frequent than expected and often fatal, particularly during treatment. Since pneumonia, especially IFI, was the major cause of death, the adoption of routine antimicrobial prophylaxis may be considered in order to reduce early mortality and further improve the results.

CLOFARABINE, CYTARABINE AND MITOXANTRONE FOR RELAPSED OR REFRACTORY ACUTE MYELOID LEUKAEMIA – INTERIM RESULTS OF A PROSPECTIVE PHASE II STUDY

H. Gill1, H. W. Ip2, S. F. Yip3, B. Kho4, H. Lee5, V. Ma6, J. Lau7, C. K. Lau8, S. Y. Lin9, R. Wong2, W. Li10, Y. L. Kwong1
1Medicine, The University of Hong Kong, 2Pathology, Queen Mary Hospital, 3Medicine, Tuen Mun Hospital, 4Medicine, Pamela Youde Nethersole Eastern Hospital, 5Medicine, Princess Margaret Hospital, 6Medicine, Queen Elizabeth Hospital, 7Medicine, Tseung Kwan O Hospital, 8Medicine, United Christian Hospital, 9Medicine and Therapeutics, 10Climical Oncology, Prince of Wales Hospital, Hong Kong, Hong Kong

Background: In unselected patients with acute myeloid leukaemia (AML) in first relapse or refractory to primary daunorubicin / cytarabine therapy, complete response (CR) rate is merely 20 - 30%. In patients <60-years old, CR rates of about 55% may be achieved.

Aims: We tested in a multicenter prospective phase 2 study the efficacy and safety of clofarabine, cytarabine and mitoxantrone (CLAM) in AML patients in first relapse or refractory to first-line daunorubicin / cytarabine induction therapy.

Methods: Consenting patients aged 18 to 65 years in first relapse or refractory to first-line dose-intensified daunorubicin / cytarabine were recruited. Bone marrow pathology and karyotype at diagnosis and relapse were centrally reviewed. Next-generation sequencing of a myeloid panel of 67 genes was performed. Re-induction CLAM comprised clofarabine (40mg/m²/day, days 1-5) and mitoxantrone (12mg/m²/day, days 1-5). Bone marrow assessment was done on day 28 using standard criteria. Treatment toxicity was evaluated using the Eastern Cooperative Oncology Group Common Toxicity Criteria (ECOG-CTC). Survivals were determined using Kaplan Meier method. The primary outcome was the response on day 28. Secondary outcomes were: treatment toxicity, leukaemia-free and overall survivals.

Results: In this interim analysis, 24 patients (14 men, 10 women) with a median age of 44.5 (19-66) years were treated. Karyotypic and genetic profiles were: normal karyotype (N=8) (NPM1 mutant, N=1); FLT3-ITD, N=3; K; respectively. (P<0.0289). After a median follow-up of 6.5 months, median survival was 8.4 months and projected OS at 1 y and 2 y was 43%+/-9 (SEM) and 30%+/-12% (SEM). Treatment was fairly well tolerated except for a high incidence of infections (46 episodes in 231 cycles) particularly during the first 3 cycles (29% vs 11%) (p=0.0072). Pneumonia was the most frequent infection (46%), followed by sepsis (28%). It was more frequent during the first 3 cycles (14% vs 4%; p=0.012) when 44% of cases were of suspected fungal origin (3 probable aspergillosis and 4 possible IFI). Death occurred in 24 pts (52.2%): 12 (50%) of disease progression, 1 of early CNS hemorrhage and 11 (45.8%) of infection. In the first 3 months, infections were responsible for 46.7% of deaths. Pulmonary IFI were fatal in 57% of cases. These figures are higher than those reported by Cashen (JCO 2010) where the frequency of pneumonia was 11%.

Summary/Conclusions: These preliminary data confirm, in a population based setting, the high efficacy of decitabine and its longer time to response (more than 4 cycles) compared to CT. However infections complications were more frequent than expected and often fatal, particularly during treatment. Since pneumonia, especially IFI, was the major cause of death, the adoption of routine antimicrobial prophylaxis may be considered in order to reduce early mortality and further improve the results.

FATAL EVOLUTION IN THE FIRST 96 HOURS OF PATIENTS DIAGNOSED WITH ACUTE LEUKAEMIA: ANALYSIS OF A SERIES OF 346 CONSECUTIVE CASES OF ACUTE LEUKAEMIA FROM A SINGLE CENTER

S. Martin-Batista1, J. M. Rayal2, T. Martín-Santos3, B. Soria1, R. Arcas1, M. Moreno1, S. Lakhwani1, B.-J. González-González1, M.-T. Hernández-García1
1Hematology and Hemotherapy, Hospital Universitario de Canarias, La Laguna, Spain

Background: The very early death of a newly diagnosed acute leukemia (AL) patient is very frustrating, and there are very few published works (except for the case of acute promyelocytic leukemia, APL) analyzing this circumstance and the features of these patients.

Aims: Our objective was to study the main characteristics of patients with acute leukemia who died within the first 96 hours after diagnosis in our centre in the last 15 years.

Methods: We studied all cases of acute leukemia diagnosed in our institution between April 2002 and January 2017, focusing on the analysis of those who died within the first 96 hours after diagnosis. In this subset of patients, we collected data concerning clinical presentation, hemogram, biochemical parameters, coagulation status, performance of a bone marrow aspirate, acute leukemia subtype, started therapy, initiation or not of induction chemotherapy, time elapsed from diagnosis to death (hours), and cause of death, among others.

Results: A total of 346 consecutive cases of acute leukemia were recorded in this time period: 222 of acute myeloid leukemia (AML, 64%) and 124 of acute lymphoblastic leukemia (ALL, 36%). Thirty-three patients were diagnosed of acute promyelocytic leukemia (15% of all AML). Those patients who died in the first four days after the diagnosis were only seven (2%), with a median of 45 hours of life (range 21-96). Main clinical and analytic findings are shown in the Table 1. They were 5 men and 2 women with a median of 57 years (range 22-91). Two of the seven patients had an APL (6% of all diagnosed APL). All patients showed leukocytosis, but hyperleukocytosis was only recorded in 27 patients, and severe thrombocytopenia (TP < 20 x 10⁹/L) in 3/7. There was possibility of bone marrow aspiration only in 4/7 cases. Coagulopathy was detected in four of six patients, including criteria for disseminated intravascular coagulation (DIC) in three cases. The exitus took place in the Intensive Care Unit in 5 cases, while it occurred in the Hematology facility in two.

Summary/Conclusions: In our experience, about 2% of patients with acute leukemia die within the first 96 hours after diagnosis (including 6% of APL). Clinical and analytical features of this subset of patients are very heterogeneous, although AML clearly predominate on ALL. More extensive and multicenter studies are needed to deepen into the circumstances conditioning this early fatal course of the disease.

PRIMARY POSACONAZOLE PROPHYLAXIS IN ACUTE MYELOID LEUKAEMIA - A SINGLE CENTER REAL LIFE EXPERIENCE

T. Firatlı Tuğular1, T. Özgümüş2, T. Etilbol3, F. Pedepi Tannkuål1,2, F. Geçgelı3, A. Sezgin1, Y. İpek1, B. Ertert Süngel3, A. Tekin1, B. Kömürçü1,2, H. Bilginer1, C. Mutlu1,2, T. Topaş1, I. Atağündüz1, Z. Odabaşi3
1Hematology, Marmara University, Istanbul, 2Hematology, Dr Ersin Arslan Research & Training Hospital, Gaziantep, 3Infectious Diseases and Clinical Microbiology, Marmara University, Istanbul, Turkey

Background: Invasive fungal infections (IFI) are a major cause of mortality and morbidity in acute myeloid leukemia (AML) patients receiving remission induction therapy, and relapsed/refractory AML patients. Posaconazole prophylaxis has shown the greatest benefit in preventing IFI in AML. Aims: We present our data of the real-life experience in AML patients under PP. Methods: We have retrospectively reviewed the data from 82 AML patients
receiving 105 cycles of chemotherapy between June 2012 and December 2016 in Marmara University Pendik Research and Training Hospital. Median patient age was 50 years (18-73); and there was no significant gender difference (38 female vs 44 male (46% vs 54%). All patients had active disease, 78 (74.3%) of them received 3+7 (idarubicine - ara-c), 25 (23.8%) of them FLAG-Ida, 1 patient received EMA and 1 patient received CLARA chemotherapy protocol. Acute promyelocytic leukemia was excluded from the analysis. All patients received posaconazole as oral suspension at the dose of 200 milligrams three times daily starting on the first day of chemotherapy. Prophylaxis was continued until marrow regeneration, or occurrence of IFI, or onset of adverse events, or discontinuation due to other reasons. All fungal infections were classified as possible, probable, or proven according to European Organization for the Research and Treatment of Cancer (EORTC) and the Mycoses Study Group (MSG) consensus criteria.

Results: Mean posaconazole prophylaxis duration was 20±3.1 (16-88) days. This duration was 29.7 days (16-50) in patients receiving prophylaxis until marrow regeneration, and 19.9 (9-34) days if IFI under prophylaxis. In 12.7 days (1-68) in prophylaxis discontinuations due to adverse events and other reasons. Posaconazole prophylaxis was administered until marrow recovery without IFI (clinical success rate) in 42 of 105 (40%) chemotherapy cycles. In 18 cycles prophylaxis was stopped after diagnosis of IFI (17.1%). Discontinuation was due to adverse events in 6 cycles (5.7%), and due to other reasons (diarrhea, intolerance of oral medication, recurrent high grade fever, death) in 39 cycles (37.1%). IFI incidence under effective posaconazole prophylaxis was 28.1% (18/64). Total clinical failure rate was 60% (63/105). IFI was diagnosed with pulmonary nodules in 12 of 18 patients (66.6%), EORTC-MSG: proven in 8 patients (44.4%), EORTC-MSG: probable in 3 patients (16.6%), EORTC-MSG: possible in 3 patients (16.6%; EORTC-MSG: proven). Data from 70 patients were available for mortality analysis. In patients receiving effective posaconazole prophylaxis, all-cause mortality rate at day 100 was (8/44; 20.4%) significantly lower than patients unable to continue posaconazole prophylaxis (12/26; 46.1%) [p=0.023]. In the subset of patients receiving prophylaxis as planned; there was no statistically significant difference in IFI incidence between previously untreated AML (13/46; 28.2%) and relapsed/refractory AML (5/18; 27.7%).

Summary/Conclusions: In our real-life experience, we have demonstrated effective protective benefit in patients receiving posaconazole prophylaxis. Although our IFI rate was comparable to other real-life data, our clinical failure rate was slightly higher. This is probably due to compliance issues, since in many chemotherapy cycles (37.1%) posaconazole was discontinued due to “other reasons” such as drug intolerance. Although not as effective as in the clinical trials; our data still supports the use of posaconazole prophylaxis in high risk AML patients.

PB1682

CLINICAL AND PROGNOSTIC VALUE OF FLT3 MUTATIONS IN ACUTE MYELOID LEUKEMIA PATIENTS IN ROUTINE CLINICAL PRACTICE – SINGLE CENTER EXPERIENCE

A. Radzhabova1,*, S. Voloshin1, I. Martynekievich1, V. Shuvav1, M. Ivanova1, E. Motyko1, N. Cybakova1, L. Polushkina1, D. Shikhbabaeva1, N. Potikhonova1, S. Tyranova1, M. Zenina1, S. Kudryashova1, A. Chechetkin1
1Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Detection of FLT3 gene mutations in acute myeloid leukemia (AML) now recognized as an unfavorable factor that affects the disease course, emerging the risk of relapses and overall survival (OS) shortening. Although about 30% of AML patients harbor one of the FLT3 gene lesion, at present there are no internationally standardized assays to quantify FLT3 mutation burden and no results of randomized clinical trials intended to individualize AML treatment based on FLT3 status. Some hematologists advocate to allo-SCT as consolidation in FLT3+ITD+ patients, but this way could be hard in frail and old patient groups with low access to transplant techniques. On the other hand, the development of target drug therapy – FLT3-kinase inhibitors gives us a new hope for improvement in the treatment results of such poor-prognosis subset of AML patients.

Aims: To assess the frequency of FLT3 gene mutations and its impact on clinical and survival of the patients with acute myeloid leukemia (AML) in routine clinical practice.

Methods: We have analyzed FLT3 gene mutation frequencies, complete blood count (CBC) parameters, karyotype and survival outcomes per FLT3-mutation status in 199 patients with AML (83 male / 116 female). The median age at diagnosis was 62 years (20-88 years). To determine FLT3 gene mutations we used the method of polymerase chain reaction (PCR) with subsequent restriction. FLT3 gene mutations were classified as internal tandem duplication (FLT3-ITD) and point mutation in the “A-loop” (FLT3-TKD). Statistical analysis was included Kruskall-Wallis ANOVA and Kaplan-Meyer curves.

Results: We observed next FLT3 gene mutations rates: FLT3-ITD - 22.6% (45/199), FLT3-TKD 5.5% (11/199), FLT3-ITD and FLT3-TKD in combination 1.0% (2/199), other 70.8% (141/199) patients had no mutations (FLT3-). CBC data at the time of diagnosis were as follows (median [max-min]): - FLT3-TKD: Hb 9.7 (3.7-13.0) g/dl, WBC 40.3 (0.6-400.0) x 109/l, blasts 80% (21-100), platelets 60 (2-140) x 109/l; - FLT3-TKD: Hb 10.2 (5.6-12.8) g/dl, WBC 62.4 (1.7-362.0) x 109/l, blasts 68% (23-100), platelets 55 (12-115) x 109/l; - FLT3-ITD+TKD: Hb 5.8, 8.4 g/dl, WBC 37.0, 157.0 x 109/l, blasts 65%, 86%, platelets 38, 186 x 109/l; - FLT3-: Hb 9.0 (2.8-14.0) g/dl, WBC 12.9 (1.0-260.0) x 109/l, blasts 64% (20-103), platelets 63 (1-334) x 109/l; Significant differences across the groups were seen only in W5.6 and blasts. Chromosomal aberrations were revealed in 38% of FLT3-ITD, 64% of FLT3-TKD, none of FLT3-ITD+TKD and 51% of FLT3- patients. All patients received chemotherapy (7.3; 5+2, HAM). Transplantation of hematopoietic stem cells (SCT) was performed in 28 (allo/aut 17/11) (14%) patients: FLT3-ITD allo-3; FLT3-TKD allo-1, auto-1; FLT3-ITD allo-2, auto-10. We found significant (p=0.00024) differences regarding to OS between FLT3-ITD, FLT3-TKD and FLT3- patients (Figure 1). Median survival times were: 5.1 months for FLT3-ITD, 7.1 months for FLT3-TKD and 13.0 months for FLT3- patients.

Figure 1.

Summary/Conclusions: We confirmed the role of FLT3 gene mutations as an unfavorable factor for AML patients in routine clinical practice by own experience. The investigation of qualitative assessment potential and target therapy value especially in SCT ineligible FLT3 gene mutations positive patients has of great value for AML management.

PB1683

TARGETING ENDOTHELIAL DYSFUNCTION FOR PROTECTION FROM ANTHRACYLINE-INDUCED CARDIOTOXICITY IN PATIENTS WITH ACUTE LEUKEMIA AND CO-MORBID ISCHEMIC HEART DISEASE

T. Lymanets1,*, I. Skrypnyk1, G. Maslova1
1Chair of Internal Medicine #1, Ukrainian Medical Stomatological Academy, Poltava, Ukraine

Background: Cardiotoxicity of chemotherapeutic drugs, in particular anthracycline antibiotics (AA), is one of the biggest problems in treatment of patients with acute leukemia (AL). Chemotherapy with AA is accompanied by systemic endothelial dysfunction, increasing cardiovascular toxicity and promoting vascular complications. Patients with co-morbid ischemic heart disease (IHD) are at extremely high risk of myocardial injury and in need of anthracycline cardiotoxicity (AC) prevention.

Aims: To assess the effectiveness of L-arginine in the prevention of endothelial dysfunction as a predictor of acute AC in patients with AL and co-morbid ischemic heart disease.

Methods: A total of 66 patients with newly diagnosed acute leukemia (acute lymphoid leukemia – 7 patients, acute myeloid leukemia – 59 patients) and co-morbid ischemic heart disease were included in the study. The cohort consisted of 46 (69.7%) males and 20 (30.3%) females. Age was 38-72 years, ECOG I-II. The duration of IHD ranged from 3 to 15 years. Chemotherapy (CT) schemes included AA (doxorubicin). The evaluation of endothelial dysfunction was performed by determining the stable metabolites of nitric oxide – nitrite anions [NO2−] and activity of total NO-synthase in serum of patients before the CT and year after the CT. To determine effective dose of AA from 100 to 200 mg/m2 by doxorubicin. The mean total cumulative dose of AA reached 162,04±24,65 mg/m2 and 166,49±27,34 mg/m2 in groups I and II respectively. The study was approved by the local ethical committee and all patients gave a written consent before they were included in the study. Patients were divided into two groups: (n=36) AL patients treated with CT; II (n=30) – AL patients, whom during the CT in order for prevention of acute AC were given L-arginine hydrochloride 4.2% 100 ml IV the day before and during administration of AA, followed by oral L-arginine aspartate for a month.
Results: In the debut of AL prior to the CT in all 66 (100%) patients the increased activity of total NOS in 3.8 times compared with the norm (p<0.001) was noted, with simultaneously reduced concentration of [NO2\(^-\)] in 1.5 times relatively normal values (p<0.05) (Table 1). As a result of two CT courses of remission induction in patients of group I the tendency to reduce the total NOS activity compared with its level before treatment was observed. At the same time the significant increase of [NO2\(^-\)] in 1.8 times relatively normal values (p<0.01) and a trend to lower their content in 1.2 times compared with the data before treatment (p>0.05) was noted. These changes constitute the violation of NO-dependent vasodilation mechanism and endothelial dysfunction intensification. Provided achieving low cumulative dose of AA in patients of group II on the background of AC prevention with L-arginine showed a significant decrease in 1.9 times the total NOS activity (p<0.001) with a simultaneous tendency to increase concentration of [NO2\(^-\)] in 1.3 times (p>0.05) compared to that before treatment.

Table 1.

Summary/Conclusions: Thus, during the CT with the inclusion of AA without L-arginine in patients with AL and co-morbid IHD we observed the depletion of NO synthesis and NO2\(^-\) production, accompanied by endothelial dysfunction impairment. The additional appointment of L-arginine on the background of CT can restore synthesis of NO and, respectively, the mechanism of NO-dependent vasodilation, thus reducing the risk of early anthracycline cardiotoxicity development.

CLINICAL CHARACTERISTICS AND SURVIVAL OUTCOMES IN ACUTE ERYTHROID LEUKEMIA (AML-M6): AML/MDS WORKING PARTY STUDY OF KOREAN SOCIETY OF HEMATOLOGY

1Internal Medicine, Kyung-Hee University Medical Center, 2Internal Medicine, Seoul St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, 3Internal Medicine, Seoul National University College of Medicine, Seoul, 4Internal Medicine, Chonnam National University Hwasun Hospital, Hwasun, 5Internal Medicine, Korea University School of Medicine, Anam Hospital, Seoul, 6Internal Medicine, Pusan National University Hospital, Busan, 7Internal Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, 8Internal Medicine, Yonsei University College of Medicine, 9Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, 10Internal Medicine, Gachon University Gil Medical Center, Incheon, 11Internal Medicine, Inje University Busan Paik Hospital, Busan, 12Internal Medicine, Kyung Hee University School of Medicine, Seoul, Korea, Republic Of

Background: Acute erythroid leukemia is a morphologically distinct and rare entity designated as M6 in FAB classification. In Korea, patients with AML-M6 have been treated as acute myeloid leukemia with intensive chemotherapy whenever possible rather than as myelodysplastic syndrome. The 2016 revision of the WHO reclassified erythroid/myeloid subtype (a case with ≥50% BM erythroid precursors and ≥20% myeloblasts among non-erythroid cells) to MDS category based on the close biological and genetic relationships between them. The aims of this multi-center study were to characterize clinical characteristics and treatment outcomes in patients with newly diagnosed acute erythroid leukemia.

Methods: Clinical data from newly diagnosed M6-AML patients between 2002 and 2012 at 11 academic centers were retrieved from the electronic registry data of AML/MDS working party of Korean Society of Hematology. Conventional cytogenetic analysis was performed on metaphase cells prepared from bone marrow aspirate by G-banding technique. Patients were classified according to the UK MRC cytogenetic risk criteria and the International Prognostic Scoring System (IPSS) risk groups for MDS based on karyotypes. Survival curves were analyzed using the Kaplan-Meier method and compared with a log-rank test. A p-value <0.05 was considered statistically significant.

Results: A total of 84 patients with AEL (M6-AML) as defined by 2008 WHO classification criteria were included in this study. The median age at diagnosis was 55 years with following distribution: age ≤49, 34 patients (40.5%); age 50–59, 17 (20.2%) patients; 60–69, 19 (22.6%) patients; age ≥70, 14 (16.7%) patients. There were 50 (59.5%) males and 34 (40.5%) females. Median hemoglobin, white blood cell count, and platelet count were 8 g/dL, 3.69 × 10^9/L, and 58 × 10^11/L, respectively. Peripheral blood blasts were observed in 55 (65.5%) patients. Cytogenetic risk was defined by UKMG criteria were intermediate in 63 (78.8%) patients, and poor in 17 (21.2%) patients. Seventy-two (85.7%) patients received induction chemotherapy and 55 patients (76.4%) achieved complete remission. Nineteen patients received two or three cycles of induction chemotherapy. Thirty-eight patients (45.2%) underwent allogetic hematopoietic stem cell transplantation (HSCT): 8 patients, matched-sibling donor; 15 patients, matched-unrelated donor; 5 patients, alternative donor were used. Treatment-related mortality of HSCT was observed in five (17.9%) patients. Fourteen (16.7%) among the study patients relapsed. The median overall survival (OS) of total 84 study patients was 21 months. Patients with intermediate risk karyotype showed better median OS than those with poor risk karyotype (22 months vs 7 months, P=0.020). The median OS was similar in patients with good and intermediate IPSS, but significantly worse in patients with poor IPSS (21 months, 7 months, respectively, P=0.026) (Figure 1).

PREGNANCY ACCUMULATES UNFAVORABLE MOLECULAR GENETIC AML AND SHOULD BE CONSIDERED AS A POOR PROGNOSTIC FACTOR

V. Tregubshchikova1, E. Parovnikova1, A. Sokolov1, A. Kokhno1, Z. Fidova1, A. Sidorova1, O. Gavrilina1, G. Galstian1, A. Bazhenov1, L. Kuzmina1, M. Drokov1, S. Makhinya1, O. Latishkevich2, A. Zvereva2, A. Olenev3, O. Korobitsyna4, A. Korobkin4, V. Savchenko1

1National Research Center for Hematology, 2Centre of Family Planning and Reproduction, 3City Clinical Hospital №24, Moscow, 4Chelyabinsk regional hospital, Chelyabinsk, Russian Federation

Background: Acute myeloid leukemia (AML) during pregnancy – is a rare clin-
ical condition that limits the possibility to conduct large prospective clinical studies. All publications present small retrospective data and case reports. Most of them conclude that pregnancy doesn’t affect the prognosis of acute leukemia.

Aims: To assess the pregnancy, as independent prognostic factor, in non APL AML-patients (pts), prospectively treated within Russian AML multicenter studies. Methods: From 1990 to 2017 the Russian Acute Leukemia study group has treated 382 pts. A total of 147 patients delivered at the gestation age of 34-40 weeks before chemotherapy (CT). 21 pregnant women received CT, that was started at 23 (14-32) weeks of gestation. 20/67 patients achieved a complete remission (29,9%), 4/67 a partial remission. CR rate - 73,3% (22/30); 42% (22/52) of the patients remained in CR for > 12 months. 1 pt died before CT due to septic shock, 2 pts – in induction CT now. 2 pregnant women died due to severe infections (p=0,006) [Blood 2016,128;22,p.5171]. One patient died before CT due to septic shock, 2 pts – in induction CT now. 2 pregnant women died due to sepsis during induction (5,7%). So, induction results were evaluated in 30/33 pts: CR rate - 73,3% (22/30): after the 1st course CT - in 16 and after the 2nd- in 6 pts. In pts, with available cytogenetic data, CR was received in 100% (9/9) from the intermediate and in 80,0% (8/10) from the poor prognostic group. Primary resistance was registered in 6/30 pts (20%). Antenatal fetal mortality was registered in 2 cases at the 21st and 32nd weeks during induction. 29 children were born. Allogeneic bone marrow transplantation (allo-BMT) was done in 10 of 28 (35,7%) AML-pts who had survived induction therapy at a median of 6 months after CR. 4 pts relapsed after allo-BMT and 1 woman remained with refractory AML after allo-BMT. Our results demonstrated rather low 10-y OS and DFS (10,48% and 10,46%) in women, whom AML was diagnosed during pregnancy. In order to evaluated the role of allo-BMT, we performed a landmark analysis (landmark=6 months of CR), that has shown better OS and DFS only in pts after allo-BMT (Pic). The results indicate that pregnancy does not affect the prognosis of acute leukemia.

Summary/Conclusions: Our results demonstrate: almost half of women, who were AML diagnosed during pregnancy, are referred to the poor molecular prognostic group; they demonstrated very low OS and DFS with their improvement after alo-BMT.

PB1686
CLOFARABINE IN RELAPSED-REFRACTORY ACUTE MYELOGENOUS LEUKEMIA: A SINGLE CENTRE EXPERIENCE
B. Scappini1,2,*, G. Gianfaldoni1, M. Armenio2, F. Mannelli1, I. Cutini1, M. Piccioni2, C. Bisagotti2, F. Fanci2, M. Di Gioia2, A. Bossi2
1Department of Haematology, AOUMC Careggi Florence, 2Institute of Haematology, University of Florence, Florence, Italy

Background: Clofarabine has been shown to be effective in AML patients, mainly in the induction treatment with high dose cytarabine.

Aims: On the basis of these reports, we tested clofarabine in association with high dose cytarabine in relapsed/refractory AML patients, selecting cases of primary refractoriness to at least two induction treatments, relapsed but refractory to a standard re-induction treatment, or very early relapse.

Methods: Data from the Adelphi AML Disease Specific Programme, a real-world, cross-sectional survey conducted between February–May 2015, was analysed. A total of 61 hematologists/oncologists provided their actual information about their management and treatment choices for AML patients via survey. Each physician was provided a pre-specified list of 16 patient characteristics. Via two separate questions, they were asked to select those considered important when choosing high and low intensity chemotherapy for their AML patients. Characteristics were analysed descriptively and ranked based on the frequency of mention from highest to lowest.

Results: The top three drivers for decision making when selecting high and low intensity treatment were: patient age, performance status and presence of comorbidities. More than 60% of physicians would prescribe high-intensity treatment for two patients aged < 65, with a good performance status or with no comorbid conditions. Over half of physicians would consider those who are eligible for a stem cell transplant or have a mutation in the CEBPA gene to be eligible for high-intensity chemotherapy (Table 1). Low-intensity chemotherapy was considered by more than 60% of physicians as being the most appropriate treatment for patients aged ≥ 65, with a poor performance status or increased number of comorbid conditions. A total of 38% of physicians would likely consider low-intensity chemotherapy if the patient was ineligible for a stem cell transplant or had had previous cancers or exposure to radiation/chemotherapy in the past.

Table 1. Top 5 patient characteristics considered by physicians when choosing high- or low-intensity treatment in AML.

</table>

Summary/Conclusions: Irrespective of treatment intensity, patient age, performance status and the presence of comorbidities are the top three drivers of treatment selection for physicians. In addition to patient age, identification of the other key drivers for therapy selection and the physician awareness of them is critical to ensure patients receive the most appropriate therapy. This improved awareness could also lead to better communication tools for patients and improve shared decision-making.

IRAIN LONG NON CODING RNA ARE DOWN-REGULATED IN POOR PROGNOSIS AML PATIENTS
M. Ghasemifard1, M. Yaghmaie1, M. Ghasemifard1, M. Ghasemifard1, M. Ghasemifard1, M. Ghasemifard1
1Hematology, Oncology and Stem cell Transplantation Research Center, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic Of
Background: IRAIN which is produced from the insulin-like growth factor type 1 receptor (IGF1R) imprinted locus is a newly identified IncRNA. There are very little knowledge about the specific role of this IncRNA in tumorigenesis presses. Recent studies have revealed that IRAIN is down-regulated in leukemia cell lines and viral expression of the IRAIN IncRNA inhibits tumor cell migration, suggesting a tumor suppressor function for this transcript.

Aims: In this study, we attempted to examine the expression level of IRAIN in different cytogenetic subtypes of AML patients.

Methods: Using quantitative polymerase chain reaction (qPCR) the expression level of IRAIN were analyzed in bone marrow specimen of AML patients (n=76) and healthy individuals (n=18).

Results: The expression level of IRAIN was found to be remarkably decreased in AML patients compared with healthy individuals (p= 0.02). Significant IRAIN down-regulation was observed in all FAB types except for the M3 (p= 0.11). When we analyzed the expression level of IRAIN in different cytogenetic subtypes of AML patients the statistically down-regulation of IRAIN was observed only in poor prognosis AML patients (p< 0.001).

Summary/Conclusions: Our results suggest that down-regulation of IRAIN IncRNA might play a role in the AML development and hence may be a potential prognostic factor and serve as therapeutic target for AML treatment.

PB1689

PERFORMANCE OF THE LEUKOSTRAT® CDX FLT3 MUTATION SIGNAL RATIO ASSAY TO DETECT INTERNAL TANDEM DUPLICATION AND TYROSINE KINASE DOMAIN MUTATIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

A. Osgood 1,*, E. Shakeri 2, V. Atkinson 1, N. Kha 3, J. Thomas 3,4,5, T. Schriever 1, M. Kelly 1, M. Miller 1

1Invivoscribe Technologies, San Diego, United States, 2Product Development, Invivoscribe Technologies, 3Laboratory for Personalized Molecular Medicine (LabPMM), San Diego, United States, 4Laboratory for Personalized Molecular Medicine (LabPMM), Kawasaki, Japan, 5Laboratory for Personalized Molecular Medicine (LabPMM), Martinsried, Germany

Background: Acute myeloid leukemia (AML) in general has a poor prognosis. Assessment of the mutation status of the FLT3 (fms related tyrosine kinase 3) receptor gene in AML is the most important prognostic indicator of disease outcome, which is often substantial, as many studies in AML have shown that the presence of FLT3 activating mutations portends a poor prognosis. The LeukoS- trat® CDX FLT3 Mutation Assay targets regions of the FLT3 gene to identify internal tandem duplication (ITD) mutations and tyrosine kinase domain (TKD) mutations. Since this assay is a signal ratio (SR) assay with a validated cutoff of 0.05, demonstration of international harmonization of results is paramount. FLT3 ITD mutations are caused by duplication and insertion of a portion of the FLT3 gene that includes the region in and around the juxtamembrane region of the FLT3 gene. These mutations vary in both the location and the length of the inserted duplicated DNA sequence. ITD mutations result in constitutive autophosphorylation and activation of FLT3. FLT3 TKD mutations are mediated by nucleic acid substitutions and/or deletions that result in a change in the amino acid sequence in this highly-conserved catalytic center. TKD mutations, such as D835 and I836 substitutions and deletions, result in constitutive autophosphorylation and activation of FLT3.

Aims: To assess the performance of the Invivoscribe® LeukoStrat® CDX FLT3 Mutation Assay.

Methods: White blood cells were removed from peripheral blood after 30 minutes of centrifugation at 2000 xg to create leukocyte depleted blood (LDB). Various fractions of four ITD positive cell lines, with insert sizes from 21 bp to 279 bp, and one TKD positive cell line, with a D835 substitution mutation, were created over a wide range of signal ratios (0.02 to 1.83) and added to the LDB. Mononuclear cells were isolated from the contrived LDB samples. DNA was extracted and amplified via PCR. The amplicons were analyzed via capillary electrophoresis. The assay measured the ratio of signals from mutation against a background wild type (WT) cell line. A FLT3 mutation was detected (and reported as positive) if the mutant:WT type SR met or exceeded the clinical cut-off of 0.05. Proprietary software calculated the SR and reported positive or negative. Clinical specimens were de-identified by LabPMM in San Diego. DNA from 2016 specimens was tested by three laboratories: LabPMM LLC in San Diego, LabPMM GmbH in Germany and LabPMM Gk in Japan.

Results: The analytical performance of the LeukoStrat® CDX FLT3 Mutation Assay was evaluated using contrived LDB samples, with known FLT3 mutations. For limit of blank (LoB), the SR was 0.00 in the ITD assay and 0.00 to 0.01 in the TKD assay, which is well below the clinical cutoft SR of 0.05. The limit of detection in the ITD assay detected allelic ratios of 0.03, 0.05, and 0.53 above the LoB SR in more than 95% of samples for insertions sized at 30 bp, 126 bp and 279 bp, respectively. The limit of detection in the TKD assay detected an allelic ratio of 0.05 above the LoB. For precision and reproducibility, the SR%CV was within 3-14% across ITD and TKD mutation types regardless of repeat number and operator. There was 100% agreement between all three clinical LabPMM laboratory sites.

Summary/Conclusions: This robust assay produced a SR%CV less than 15% regardless of reagent lot, equipment or operator. The high reproducibility between the three laboratories on three different continents provides evidence that the Invivoscribe® LeukoStrat® CDX FLT3 Mutation Assay is an internationally standardized assay.
the mouse or keypad. The software utilises the latest strides made in web technologies to respond to the varying screen sizes of devices, and display suitably sized graphs and gating information accordingly. Collaboration between parties is facilitated - a lab technician running the sample can upload the sample and instantly share with other parties with the required permissions. Analysis, such as gating, can take place immediately and can then be instantly shared via a web URL. No sensitive file data is displayed within the platform. All data transfer happens via SSL encryption.

A. Al-Seraihy 1

1Hematology, Hospital La Paz, Madrid, Spain

Background: A variety of different treatment regimens have been studied in an effort to improve outcomes of patients with relapsed or refractory acute myeloid leukemia (RR-AML), there appears to be no single superior approach. Spanish groups usually use the FLAG-IDA protocol (Fludarabine 30 mg/m2 days 1-4, Idarubicine 12 mg/m2 days 1-3, ara-C 2 mg/m2 days 1-5) in these patients. Usually use the FLAG-IDA protocol (Fludarabine 30 mg/m2 days 1-4, Idarubicine 12 mg/m2 days 1-3, ara-C 2 mg/m2 days 1-5) in these patients.

Aims: To evaluate our response rates and the survival with FLAG-IDA protocol.

Methods: Descriptive study of a case series of patients with acute leukemia that received intensive induction chemotherapy with FLAG-IDA protocol at our hospital between January 2007 and December 2016. Biodemographic, histopathological, cytogenetic and molecular results and previous treatment were recorded. We analyzed the response rate, the 30-day mortality rate and the overall survival.

Results: 65 patients received treatment with FLAG-IDA protocol between 2007-2016, 35 of them female, with an average age of 53.4 years (SD±23.3). We treated this protocol mostly patients with relapsed or refractory acute myeloid leukemia (RR-AML) (primary refractory or resistant AML as defined by not achieving complete remission after 1 cycle of intense induction therapy); 60% (n=38) of patients had a RR-AML, 37% (n=23) of them were relapsed AML and 23% (n=15) refractory AML. Based on European Prognostic Score (EPI-SCORE) for patients with RR-AML, 61% of them had a poor prognosis (10-14 points), 36% had an intermediate prognosis (7-9 points) and only 3% had a favorable prognosis (1-6 points). The next important group, 25% (n=17) were MDS patients transformed to AML. We had 9% (n=6) patients with treatment-related AML and 6% with other acute leukemia (3 cases of refractory ALL and 1 case of biphenotypic leukemia). We observed a global response rate of 63%; 51% (n=33) of patients had a complete response (CR) and 12% (n=8) partial response, 17% (n=11) did not have a response and 20% of patients were not evaluated after to receive the treatment because they had a early death. The 30-days mortality rate was 21.5% (n=14), similar to the 65%-86% of patients developed acute leukemia. We can see in the overall survival curve (picture 1) that most patients died first months after treatment, after that patients remain alive and we achieve a plateau. The median overall survival was 82 days (standard deviation: 25 days). 10 patients were alive when we analyzed the data (Figure 1).

Summary/Conclusions: Most AML patients ultimately die from their disease. In our case serie none died by any other cause. We had a similar response rate, mortality and overall survival that other groups in our country. Despite a variety of salvage therapy options, like FLAG-IDA protocol, prognosis in patients with RR-AML is generally poor and treatment is very complex.

PB1693

BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASMS - UNUSUAL PRESENTATIONS AND UNFAVOURABLE OUTCOMES

M. Guenova1,2, M. Vlachova1, T. Dikov1, Y. Georgieva1, B. Spassov1, K. Prisadashka2, M. Balabanova2, V. Kaleva3, G. Balatzenko3

1National Specialised Hospital for Active Treatment of Hematological Diseases, 2Alexandrovska University Hospital, Sofia, 3University Hospital St.Martina, Varna, Bulgaria

Background: Blastic plasmacytoid dendritic cell neoplasm (BPDCN) is a rare hematological malignancy with an aggressive clinical course. Most patients (pts) with BPDCN have skin lesions and involvement of the skin, peripheral blood, bone marrow, and lymph nodes. Very few cases have been described with lack of skin and/or bone marrow manifestations at the time of diagnosis.

Aims: To characterise the clinical presentation and clinical outcomes of a cohort of consecutive patients with a rare blastic plasmacytoid dendritic cell neoplasm in a single institution.

Methods: Patients diagnosed with BPDCN at the National Hematology Hospital between 2010 and 2016 were retrieved from the database. The diagnosis was confirmed by morphology and immunophenotyping by flow cytometry and/or immunohistochemistry, according to 2008 WHO Classification of Hematopoietic Neoplasms. The relevant clinicopathologic features were reviewed.

Results: We identified 8 adult patients at a median age of 70 years (range: 37-84 years) with a male:female ratio of 6:2 (75%:25%) and only 1 child. Mean values of blood cell counts were as follows: WBC 5.109/L; hemoglobin 99 g/L; platelets 116.109/L. LDH was generally elevated with a mean of 962.8 U/L. At diagnosis, 54% of pts had a leukaemic presentation with 40-95% of bone marrow infiltration. Interestingly, in 4 pts (50% of adult pts) the initial presentation affected other tissues and organs such as testis, bronchial wall, stomach and periorbital soft tissues, however, only the latter one case presented with a leukemic picture. Biopsies revealed diffuse, monomorphous infiltrate of medium-sized blast cells with irregular nuclei, fine chromatin with ≥1 nucleoli, scant and agranular cytoplasm, without angioinvasion or coagulation necrosis. Immunophenotype generally demonstrated CD45+, CD4+, CD56+, CD123+. No standard therapies were applied. Patients received CHOP or HyperCVAD or AML-induction therapy. However, response rates in adult patients were low and the mean OS was 2.6 months (ranging from early deaths before any treatment could be initiated to 10 months).

Summary/Conclusions: BPDCN is a rare aggressive disease that typically affects elderly patients. The most commonly affected non-hematopoietic organ is the skin, however any other organ or tissues can also be involved. Response to therapy if any is relatively short and long-term prognosis is poor despite of the site of presentation. Larger scale studies are warranted to understand the pathophysiology of the disease and to find optimal management.

Acknowledgements: Partial support by the National Science Fund.

PREDICTIVE RELEVANCE OF CLINICAL CHARACTERISTICS IN PEDIATRIC PATIENTS WITH RELAPSED ACUTE MYELOID LEUKEMIA TREATED AT SINGLE INSTITUTION—REPORT OF AN OUTCOME ANALYSIS

S. Al-Sweedan1,2, K. Siddiqui1, R. Jafri1, I. Ghemlas1, A. Al-Ahmari1, A. Al-Seraihy1

1Hematology, Hospital La Paz, Madrid, Spain

Background: The latest web technologies can be effectively harnessed to enhance flow cytometry analysis and allow for faster, more accessible and more collaborative analysis. Within the field of haematology in particular, this opens up the option of remote diagnosis - a haematologist need not be in the lab, or even in the same country, to deliver a diagnosis.

The latest web technologies can be effectively harnessed to enhance flow cytometry analysis and allow for faster, more accessible and more collaborative analysis. Within the field of haematology in particular, this opens up the option of remote diagnosis - a haematologist need not be in the lab, or even in the same country, to deliver a diagnosis.

Methods: Our platform is a web app that facilitates the delivery of a virtual laboratory. This is a modular system that allows the user to upload sample files, upload results of histopathological, cytogenetic and molecular studies and previous treatment. The software utilises the latest strides made in web technology, such as HTML5 and JavaScript, to provide a user-friendly experience.

The software utilises the latest strides made in web technology, such as HTML5 and JavaScript, to provide a user-friendly experience.

Figure 1. Web app is available at https://www.redmatterapp.com
Background: Western hospitals have achieved First Complete Remission (CR-1) and Overall Survival (OS) rates of 90% and 60% for children with Acute Myeloid Leukemia (AML). Intensified regimen (SR) chemotherapy along with precise risk classification and improvements in supportive care are mainly attributed to this achievement.

Aims: We analyzed clinical data of our pediatric AML patients treated at KFSH&RC from 2005 to 2015 in order to assess the outcome of our treatment efforts including Hematopoietic Stem Cell Transplantation (HSCT).

Methods: A total of 155 pediatric patients with AML were registered at our institution from 2005 to 2015. 55.5% (86) were boys with a F/M ratio 1.12; and median age at diagnosis 5.5 years (Min: 1.3months, Max: 13.8 years). 12 patients were excluded from further analysis for not being able to complete induction therapy. Cytogenetic analysis (Caucasian, 77% (11 of 143) had concomitant malignancies. 85.7% (120) of CNS-1, 27.4% (20 of 73) had MLL Gene rearrangement. 21.2% (14 of 66) were positive for TELAML/RUNX1/RUNX1T1 and 22% (13 of 59) had PML/RARA (+). Trisomy 4, 10 or 17 was not seen among any of 13 patients tested. Most commonly observed FAB classification was M5 (23.5%, 24 of 102) followed by M2 (18.6%). 27.3% (39) were Low Risk, 43.4% (62) Intermediate and 29.4% (42) High Risk. 43.3% (58 of 134) received HSCT.

Results: Our CR-1 rate was 93.7% (143 of 143) with 100% in Low Risk, 95.2% Intermediate Risk and 85.7% in High Risk patients (P = 0.023), requiring 13-3 cycles of chemotherapy with a median time of 1.3 months. Treatment Failure was observed in 6.3% (9 of 143). Relapse rates was 38.8% (52 of 134). Most common site of relapse was bone marrow (75%, 39 of 52), PML/RARA (P = 0.044), Post-Induction BM Classification M-3 (P = 0.034) and AML High Risk (P = 0.003) were found to be significantly associated with Relapse. Age at diagnosis, or Time to CR-1 were not found to have any association with relapse. 51.9% (27 of 52) who relapsed, went for HSCT. With a median follow-up of 68.8 months, five year overall survival for our cohort of patients was (0.567±0.046); significantly poor (P=0.001) in relapsed (n=52, 0.17±0.051) compared to non-relapsed (n=82, 0.86±0.041); resulting in a five year disease-free survival of 0.47±0.044. Among relapsed group (n=52), five year overall survival was significantly better (0.16±0.073) for those who received HSCT (27) than who did not (n=25, 0.11±0.073, P-Value: 0.029). Five year overall survival was also significantly better for Non-Relapse group (n=31, 0.82±0.070) compared to relapsed patients (n=27, 0.16±0.073, P-Value: 0.000). OS was administered (n=58)

Summary/Conclusions: The results of our treatment efforts are in conformity with the western literature. Precise risk classification can be a vital predictor in planning for first line and salvage therapies including HSCT for pediatric patients with AML.

PB1695
IS HIF-2 ALPHA A POOR PROGNOSIS FACTOR IN HUMAN ACUTE MYELOID LEUKEMIA? A SINGLE CENTER ANALYSIS - PRELIMINARY RESULTS
J. Dybko1, D. Urbaniai-Kujda1, D. Szmyczak1, O. Haus1, B. Jazwiec1, M. Kulczykowski1, 1Hematology and Bone Marrow Transplantation, Wrocław Medical University, Wrocław, 2Department of Clinical Genetics, Collegium Medicum , Nicolaus Copernicus University, Bydgoszcz, Poland

Background: Hypoxia-inducible transcription factors (HIF) are well known regulators of cellular response to hypoxia. HIFs control functional, metabolic and vascular adaptation to hypoxia on transcriptional level. HIF-1 alpha has been described in mouse model as increasing vascular permeability and promoting angiogenesis. HIF-2 alpha has been described in mouse model as increasing hypoxia-inducible factor (HIF) transcriptional activity.

Aims: The aim of the study was to determine the role of HIF-2 alpha in human AML.

Methods: We analyzed a 26 primary AML patients group (median age 54.5 (21-77), F/M = 13/13). The group consisted of 21 AML-NOS cases, 2 AML with inv(16), one case with t(6;9) and one with t(9;11) according WHO classification. ELN cytogenetic risk stratification divided the group into intermediate-1, intermediate-2 and adverse cases in 10, 12 and 4 patients respectively. All patients were treated with Daunorubicin, Cytarabine and Cladribine based first line chemotherapy. We collect bone marrow and blood samples before chemotherapy and blood samples alone 48 hours after chemotherapy start. In all samples leukemic blasts were counted and determined by flow cytometry. Western blot for HIF-2 alpha expression and HIF-2 alpha subunit - HIF-2 alpha was performed. The results of our treatment efforts are in conformity with the western literature.

Results: In all samples leukemic blasts were counted and determined by flow cytometry and the subpopulation of HIF-2 alpha positive blasts was estimated as well. Volunteer bone marrow donors were the control group in this study and the CD34+HIF-2α+ subpopulation was assessed in their bone marrow samples during the routine harvest procedure. The study was approved by the local Ethics Committee.

Results: After the first line chemotherapy 15 patients achieved complete remission (CR-1) and 11 did not (NR group). We did not find significant differences between the groups regarding patients age, the mean percentage of blasts in bone marrow and blood before the treatment, the percentage of HIF-2 alpha positive blasts in BM and blood before and 48 hours after the treatment start (data not shown). But the analysis of the percentage of HIF-2 alpha positive blasts in blood before and 48 hours separately in CR and NR groups revealed quite different dynamics. In CR group the mean percentage of HIF-2 alpha positive blasts was 14.65 (+33.32) and 8.48 (+11.63) before and after chemotherapy respectively (p=NS); in NR group the values were 11.74 (±22.6) and 24.01 (±33.68) respectively (p=0.007) (Figure 1). The Cox analysis revealed HIF-2 alpha positive blasts in blood after chemotherapy to be proportional to death probability (p=0.0036) (Figure 2).

Figure and 2.

Summary/Conclusions: We are aware our results are preliminary. But if they are confirmed it will be very interesting to determine the role of HIF-2 alpha inhibitors in improving the prognosis and survival in human AML.

RARE BCR/ABL FUSION PROTEINS AND THEIR CLINICAL SIGNIFICANCE INTO PH+ ACUTE MYELOID LEUKEMIAS
M. Piedimonte1, T. Ottone2, A. Ferrari1, E. Conte1, M. Divona2, M. P. Bianchi1, M. R. Ricciardi1, S. Mirabili1, R. Licchetta1, F. Falco1, A. Campagna1, L. Cicioni2, G. Galassi1, S. Pelliccia1, A. Leporace1, F. Lo Coco2, A. Tafuri3
1Department of Clinical and Molecular Medicine & Sant’Andrea AOU, Sapienza University of Rome, 2Department of Biomedicine and Prevention, University of Tor Vergata, Rome, Italy

Background: The Philadelphia (Ph) translocation t(9;22)(q34;q11) results in an oncogenic BCR/ABL gene fusion, representing the hallmark of chronic myeloid leukemia (CML), although it has been also described in acute lymphoblastic (ALL) and myeloid (AML) leukemia. Three main different transcripts have been described (p210, p190 and p230), but rare atypical BCR breakpoints outside the cluster regions have been also reported and their clinical significance is under investigation. Atypical transcript p190 e6a2 is a rare fusion protein associated with aggressive phenotype and dismal prognosis. The breakpoint in BCR intron 6 is responsible for increased kinase activity and greater transforming potential because of the partial loss of the Guanine Exchange Factor (GEF)/dbl-like domain, completely absent in p190 proteins. This truncation could increase the BCR/ABL oncogenic activity.

Aims: In this report we describe 2 rare cases of Ph+ AML patients with the atypical p190 e6a2 isoform.

Methods: Routine morphologic, immunophenotypic and genetic analyses were carried out in all samples at diagnosis. cDNA extracted from bone marrow was synthesized from 1 μg of total RNA. Most common AML genetic alterations were investigated and a quantitative RT-PCR (qRT-PCR) for p190 transcripts was performed. qRT-PCR assay for FLT3-ITD and p190 e6a2 transcript were used for CML fluorescence in situ hybridization (FISH). AML molecular biology analysis revealed the simultaneous presence of the common p190 e1a2 and the rare e6a2 isoforms (Figure 1A). Because of persisted pan cytopenia and presence of blasts, according to the molecular data, he was then switched to TKIs treatment. Nevertheless, after 2 months, the patient was still refractory to second line treatment dying because of a pulmonary infection. Case 2. A 61-years old male was admitted at our hospital with clinical and laboratory features allowing to make the diagnosis of AML. No evidence of a preceding CML (splenomegaly or basophilia) was found. The karyotype analysis performed. qRT-PCR assay for FLT3-ITD and p190 e6a2 transcript were used for CML fluorescence in situ hybridization (FISH). AML molecular biology analysis revealed the simultaneous presence of the common p190 e1a2 and the rare e6a2 isoforms (Figure 1A). Because of persisted pan cytopenia and presence of blasts, according to the molecular data, he was then switched to TKIs treatment. Nevertheless, after 2 months, the patient was still refractory to second line treatment dying because of a pulmonary infection.

Results: Case 1. A 78-years old male was admitted at our hospital with clinical and laboratory features allowing to make the diagnosis of AML. No evidence of a preceding CML (splenomegaly or basophilia) was found. The karyotype analysis performed.
consolidation chemotherapy was postponed, relapsing without reach the already planned transplantation. At the bone marrow transplantation. At the bone marrow transplantation, the patient died 5 months later for transplant complications. gqF-PCR assays performed in diagnosis sample showed the main clone FLT3-ITD accompanied by subclones with p190 e1a2 and e6a2 isoforms. These data indicate a clonal selection process and the expansion of a resistant clone with p190 e6a2.

Summary/Conclusions: The atypical p190 e6a2 transcript seems to be associated in AML with aggressive disease. TKI therapy alone does not seem to control the disease. Prompt observations on these patients carrying rare BCR/ABL transcripts may allow help to establish optimal treatment approaches on these aggressive BCR/ABL phenotypes.

HYPOMETILATING AGENTS AS SALVAGE THERAPY IN RELAPSED OR REFRACTORY AML: A 2-CENTERS RETROSPECTIVE STUDY
F. Lessi1,*, A. Branca1, M. Laurino1, D. Lazzarotto2, C. Filì2, A. Candoni2, G. Semenzato2
1Department of Medicine, University of Padua, Hematology and Clinical Immunology Unit, Padova, 2Division of Hematology and Bone Marrow Transplantation, Azienda Sanitaria-Universitaria Integrazione, University of Udine, Udine, Italy

Background: 5-azacytidine and decitabine have been widely studied as first line chemotherapy in acute myeloid leukemia (AML) patients not eligible for allogeneic stem cell transplantation, but data on their use as salvage chemotherapy is limited.

Aims: To define efficacy and feasibility of hypomethylating agents (HMA) as salvage chemotherapy in patients without previous allogeneic stem cell transplantation.

Methods: We retrospectively reviewed clinical records of 15 patients treated with HMA as salvage therapy in our institutions since their introduction in clinical practice for AML patients.

Results: Median age was 66 years. Six patients were men and 9 women. One patient was AML (t(15;17)), 7 were AML MRC, 1 was therapy-related AML, 6 were AML NOS. Two patients were favorable risk sec ELN 2008, 11 were intermediate I and II and 2 were adverse risk. 67% of patients received HMA as second line therapy for their disease, 27% as third line and 6% were beyond the third line. Seven patients were treated with decitabine and 8 with azacitidine. Five patients reached CR or CRi after HMA. All patients underwent intensive chemotherapy (i.e. FLA like or 3+7 like) as first line induction, and we excluded patients who had a HMA as first line chemotherapy and another one as second line. Median number of hospitalization days during HMA therapy was 16; median number of HMA cycles was 2 (range 1-31). 26% of patients underwent allogenic bone marrow transplantation, in whom the prognosis is generally extremely poor. Further studies are needed to determine which are the cytogenetic subsets of patients who could benefit from such a salvage chemotherapy.

PB1698
OMITTING CYTARABINE FROM CHEMOTHERAPY FOR ACUTE PROMYELOCYTIC LEUKEMIA REDUCES TOXICITY AND NOT EFFICACY
C. Laiyannì1, G. Karavaliakìs1,*, E. Gavriliaki1, A. Lazaridou1, M. Iskas1, A. Syrigou1, M. Papathanasioni1, G. Papaioannu1, A. Athanasiadou1, A. Papalexandri1, C. Vadikoliou1, N. Stavroyianni1, R. Saloum1, A. Anagnostopoulos1
1Hematology Department - BMT Unit, G. Papanicolaou Hospital, Thessaloniki, Greece

Background: The introduction of retinoic acid (ATRA) has changed the treatment paradigm in Acute Promyelocytic Leukemia (APL). Combination of ATRA without cytarabine (AIDA) has shown high efficacy in Spanish and Italian studies. However, early mortality resulting from coagulation disorders remains high. Furthermore, ARAc administration during consolidation is questioned and often limited to high-risk patients.

Aims: We aim to compare the efficacy, tolerance and toxicity between 2 consecutive treatment protocols that differed in ARAc administration during consolidation.

Methods: We studied clinical characteristics, prognostic factors, response to treatment, toxicity, and outcomes in APL patients treated in our Department during the last decade. All patients received induction with AIDA (Idarubicin x4, ATRA until remission) and 2-year maintenance therapy. Protocol 1 included 2 cycles of consolidation with anthracyclines/AraC. Protocol 2 was implemented the last 5 years and included 3 cycles of anthracyclines and AraC only in high-risk patients (PETHEMA LPA2005).

Results: APL was diagnosed in 35 patients, of whom 2 patients older than 80 years did not receive treatment and were not included in the analysis. The rest 18 male: 15 female patients aged 37 (10-75) years old presented at diagnosis with: thrombocytopenia (32), leukopenia (22), leukocytosis (6), impaired performance status/PS ≥3(10), lactate dehydrogenase >400 IU (17), increased d-dimers (33), low fibrinogen (11), fibrinogen <1 mg/dl (5). Five patients died during induction from severe differentiation syndrome (2), bleeding (2) and infection (1). In the multivariate analysis, these patients had significantly impaired PS (3, p=0.005), older age (median of 59 years, p=0.014) and lower fibrinogen (median of 0.9 mg/dl, p=0.05). Among 28 patients eligible for the comparison, all patients achieved complete remission (CRF ≥80%). PB1699
DISEASE CHARACTERISTICS AND TREATMENT PATTERNS OF AML PATIENTS <60 YEARS OLD VERSUS ≥60 YEARS OLD
1Stanford University, Stanford, 2Astellas Pharma Inc., Northbrook, United States, 3Adelphi Real World, Cheshire, United Kingdom

Background: There is limited real-world data in patients with acute myeloid leukemia (AML) that looks at presenting disease characteristics and subsequent treatment decisions made for patients <60 and ≥60 years of age in the United States (US).

Aims: This analysis examined the characteristics of patients <60 years of age and ≥60 years of age at the point of AML diagnosis and further investigated subsequent treatments.

Methods: Data from the Adelphi AML Disease Specific Programme, a real-world, cross-sectional survey conducted between February–May 2015, were analyzed. A total of 61 hematologist/oncologists provided data on their 457 AML patients treated at various stages of AML. Disease characteristics upon presentation were compared between patients <60 years old and ≥60 years old. The following characteristics were compared: gender, age, risk category, and treatment patterns.
initial AML diagnosis including symptoms, performance status, and physician-
determined prognostic category were taken from physician-completed patient-
record forms. Details about subsequently prescribed AML treatment were also
taken from this data source. Treatments for n=15 (3.3%) patients were reas-
signed as high or low intensity following evaluation of physician treatment selec-
tion. Post-hoc T-tests and Chi-Squared/Fisher’s exact tests were used to deter-
mine differences between groups.

Results: Table 1 shows key presenting characteristics of AML patients <60 and ≥60 years old. According to physicians, those patients <60 years of age were significantly more likely than those ≥60 years of age to have de novo AML, a performance score of 0 versus ≤1 at diagnosis, more tests conducted to establish the diagnosis and a more favorable prognosis at baseline, accord-
ing to physician perception. Following initial diagnosis, patients <60 years of age were 1.65 times more likely than those ≥60 years of age to be initiated on high-intensity induction treatment: 67% (n=143) of patients <60 years of age versus 50% (n=98) of patients ≥60 years of age versus those ≥60 years of age (p < 0.001). There were the

Summary/Conclusions: The age of an AML patient at initial diagnosis appeared to play a significant role in the diagnostic, prognostic and treatment intensity decisions made by AML-treating physicians in the US. The estimated performance and prognostic status tend to be considerably better for younger patients and consequently, they were more likely to receive the most aggressive yet more effective high intensity treatments currently available to treat AML.

PB1701

A UNIQUE PRESENTATION OF ACUTE PROMYELOCYTIC LEUKEMIA: AORTOILIAC OCCLUSIVE DISEASE (LERICHESYNDROME)

S. Berk1, M. Gümaltılı2, S. Sadrı1, A. E. Eşkanazı1, Z. Başlar1, T. Soysal1

1Haematology, 2Internal Medicine, Istanbul University Cerrahpaşa Medical Fac-
culty, Istanbul, Turkey

Background: Acute promyelocytic leukemia (APL), FAB M3 subgroup of acute
myeloid leukemia is known for its association with haemostatic disorders. Com-
pared to bleeding thrombosis is a less commonly encountered complication of
APL. Thrombosis of major arteries is a rare form of presentation.

Aims: A case, who applied with acute lower limb ischemia and diagnosed with
APL and aortoiliac occlusive disease (Leriche syndrome), is presented.

Methods: A 53-year-old female patient presented with weakness, loss of
appetite and pain in the lower extremities. She had diabetes mellitus (DM) reg-
metered with metformin, hyperlipidemia (HL), and smoking history. Physical exam-
ination revealed general paleness and ischemia around big toe of the right
foot. Laboratory studies revealed leukopenia, neutropenia, anemia, thrombo-
cytopenia, elevated D-Dimer. A bone marrow aspiration and biopsy was done to
enlighten the etiology of pancytopenia. The pathological examination of the
bone marrow revealed abundant granular blasts (78%) and Auer rods. The
patient was diagnosed with APL, hypergranular classical form. t(15;17) was
positive with fluorescence in situ hybridization. All-trans retinoic acid (ATRA)
plus idarubicin treatment was started. In few days findings of ischemia pro-
gressed and encompassed 2nd, 4th and 5th toes together with the big toe (Fig-
ure 1 on the left). Monophasic flow pattern (proximal stenosis?) was detected
in bilateral common femoral arteries in lower extremity venous doppler ultra-
sonography. On CT angiography, abdominal aorta and bilateral common iliac
arteries were observed to be occluded from L3 vertebra level till 1.5 cm after
aortic bifurcution (Figure 1 on the right). Low-molecular-weight heparin therapy
was started. According to rheumatological tests and tests for lupus anticoagu-
lant, anticardiolipin and antiphospholipid antibodies, anti-beta-2 glycoprotein-
1, protein C-S, Antithrombin III and homocysteine levels, methylene tetrahydra-
folate reductase, Factor V Leiden and prothrombin gene mutations no cause
of tendency to thrombophilia could be determined. Echocardiography was nor-
mal. The patient was transferred to Cardiovascular Surgery Department for
axillofemoral bypass operation.

PB1700

FLT3, NPM1, CEBPA AND TP53 MUTATIONS AT ACUTE PROMYELOCYTIC LEUKEMIA: PROGNOSTIC FACTORS AND CORRELATION WITH OTHER MARKERS WITHIN THE PATIENTS OF GOMEL REGION IN BELARUS

Z. Kozich1,*, V. Martinkov2, A. Silin2, I. Tropashko2

1Hematology, 2Molecular Genetics, The Republican Research Center for Radi-
ation Medicine and Human Ecology, Gomel, Belarus

Background: Acute Promyelocytic Leukemia (APL) is one of the favourable
variants of acute myeloid leukemias due to the usage of ATRA in the treatment
simultaneously with chemotherapy. But relapses occur in 13-33% cases after
achievement the remission and there are cases of early death from the bleed-
ing. High leukocytosis, the presence of lymphoid immunophenotypic markers
and gene mutations are important prognostic factors.

Aims: To examine prognostic factors in APL

Methods: The materials for research were the samples of whole venous blood
and bone marrow of 40 patients with APL treated in the period of 2009-2016
in Hematology department for adults, Gomel. The diagnosis was proved by the
presence of t(15;17) or PML/RARA. Induction therapy was carried out according
to the protocol <7+3> using ATRA. Immunophenotypic analysis was carried
out by standard immunofluorescence methods. The method of polymerase
chain reaction (PCR) with specific primer and following electrophoretic detection
was used for recognition of gene mutations.

Results: Out of 40 examined patients (mean age 48.5), 80%(32) achieved
remission and 15.6%(5) subsequently relapsed after the first course of chemotherapy.
Clinical, laboratory, molecular genetic and immunophenotypic data which could affect remission results and general survival rate were ana-
yzed within all the patients. As a result, mutations were detected in 55% of
cases. FLT3-ITD mutations were detected in 32.5%(13); NPM1 mutations in 12.5%(5); TP53 and CEBPA mutations were detected in 5%(2) and 12.5%(5) of cases respectively. After achievement of remission after the first course of chemotherapy NPM1 mutation remained at 6.2%(2). Mutations were identified more frequently within the patients with the absence of response to the therapy or with the developed relapse. To examine prognosis had the patients with the combination of
FLT3-ITD and NPM1 mutations. There were the patients with high leukocy-
tosis, presence of CD56 and CD2 immunophenotypic markers, who didn’t achieve remission or had the recurrence when the treatment was dropped. The

Figure 1. Results: In APL 80% of thrombotic events occur before treatment or during induction. Acute lower limb ischemia as an initial feature of APL is very rare

haematologica | 2017; 102(s2) | 685
which makes our case unique. Thrombotic risk factors in APL include high leukocyte count, presence of coagulation disorder, ATRA+chemotherapy+ antifibrinolytic therapy and ATRA syndrome. None of these were seen in the presented case. The effects of known predisposing risk factors to thrombosis meaning DM, HL and smoking cannot be ruled out. But development of acute thrombosis concomitant with APL diagnosis points out to the relationship between these two entities.

Summary/Conclusions: Current literature knowledge is based on case reports and 9 patients with APL who presented with acute lower limb ischemia were reported yet. As far as we know our case is the first APL case presenting with aortoiliac occlusive disease (Leriche syndrome).

Background: Although therapy-related acute leukemia (tAL) is a well-recognized clinical syndrome and is increasing owing to the prolonged survival of patients treated with chemoradiotherapy, tAL with mixed phenotype is extremely rare.

Aims: Here, we report a rare case of tAL with mixed phenotype with BCR-ABL1 after achieving complete remission (CR) of Diffuse Large B-Cell Lymphoma (DLBCL).

Methods: A 57-year-old woman was diagnosed as DLBCL. The patient received six cycles of R-CHOP regimen with G-CSF injected after each cycle and achieved CR. The patient was readmitted to the hospital after a follow-up examination revealed the presence of immature cells in the blood.

Results: Her complete blood count findings were as follows: hematocrit, 35.1%; hemoglobin, 116 g/L; platelet count, 129×10^9/L; and white blood cell count, 2.41×10^9/L, with 4% blasts, 26% segmented neutrophils, 3% band neutrophils, 39% lymphocytes, and 26% monocytes. Bone marrow aspirations revealed the presence of blastemic blasts with medium cell size, oval-round shape, vesicular nuclei, fine chromatin patterns, and basophilic cytoplasm. On cytological staining, these blast cells were not positive on PAS and NSE staining, but were weakly positive for MPO staining. Flow cytometric analysis showed that the blasts were positive for both T-lymphoid and myeloid markers (cytoplasmic CD20, CD25, CD4; membrane CD13, CD33, and CD117) and negative for CD2, CD10, CD11b, CD14, CD15, CD19, CD20, CD61, CD117, and CD14. Immunophenotyping, using RT-PCR, was positive for ATRA syndrome. RT-PCR also revealed the presence of a minor BCR-ABL1 (e1a2) fusion transcript. Chromosome analysis of bone marrow cells failed because of insufficient mitotic cells. Immunoglobulin heavy chain rearrangement and TCR gene rearrangement were not detected on bone marrow aspiration.

Summary/Conclusions: Mixed phenotype acute leukemia is an uncommon subtype that comprises 0.5-1% of leukemia. The T/myeloid phenotype is rarer and represents 35% of all MPAL cases. The risk of secondary malignancies after lymphoma treatment is relatively increased for leukemia. AML, ALL, MDS, CML and chronic myelomonocytic leukemia are reported secondary hematologic malignancies. Until now, only one case of tAL with mixed phenotype after lymphoma has been reported worldwide. To the best of our knowledge, this is the second case of tAL with mixed phenotype after DLBCL. This case is also unique because the BCR-ABL1 has not been described in the literature for patients with tAL with mixed phenotype, after hematologic malignancy. According to the WHO classification, tAL can be attributed to radiation, alkylating agents, or topoisomerase II inhibitors. Our patient did not receive radiation therapy but previously received cyclophosphamide and doxorubicin. Therefore, this is the first case of tAL with mixed phenotype and BCR-ABL1 after alkylating agent and topoisomerase II inhibitor therapy for DLBCL.

PB1703

CROSS-SECTIONAL ANALYSIS OF CONCORDANCE RATES BETWEEN KARYOTYPING AND RT-PCR IN ACUTE MYELOID LEUKEMIA; REAL WORLD CHALLENGES

D. Kauch et al.

Background: Translocation and chromosomal anomalies have prognostic implications in acute myeloid leukemia (AML). Cyto genetic analysis assumes great importance in their diagnosis and treatment stratification which are assessed by karyotyping and/or reverse transcriptase polymerase chain reaction (RT-PCR). Given the decreasing trend of karyotyping on sample quality, more and more centers are now relying on RT-PCR to detect specific translocations. Varying rates of concordance between Karyotyping and RT-PCR have been reported and no consensus has prevailed. Given the resource constraint, it is economically non-viable to perform both for prognosis in real world scenarios. Therefore, the cost of the extra tests also adds to the burden of healthcare economy.

Aims: In 132 patients of AML, we aimed at determining the incidence of cytogenetic abnormalities and molecular anomalies detected by Karyotyping and RT-PCR respectively. Concordance rates between conventional cytogenetic tests and RT-PCR were also calculated.

Methods: We conducted a retrospective analysis on the medical records of 132 patients of AML at a tertiary health care facility in India, treated during 2010-2017. Results from commercially available molecular assays for detection of specific translocations by RT-PCR and of adequate samples of karyotype analysis were compared.

Results: In AML patients, out of those tested 50.6% had chromosomal aberrations detected by karyotyping while 30% had a positive detection with RT-PCR. The concordance rate in AML was found to be 56.3%. In a large number (31 in AML) karyotyping provided additional information in the form of detection of deletions, additions and hyper diplody (Table 1).

Table 1.

Summary/Conclusions: RT-PCR cannot substitute conventional cytogenetic analysis due to the absence of a broad based application for detection of aberrations other than translocations. However, given its efficiency and reliability it can have a complimentary role in prognosis assessment.
Results: Four pts were treated with 3+7 chemotherapy. Complete remission (CR) was achieved in 3 pts, and treatment was continued according to the HIDAC and IDAC protocol. The duration of remission was 3, 8 and 11 months respectively, followed with relapse and lethal outcome. One of the pts died within first 0.5 months after BPDCN was diagnosed. Three pts, treated with Hyper-CVAD, are alive and in CR with duration of 1, 3 and 10 months respectively. The continuation of the treatment within the programme of allogeneic stem cell transplantation is planned in 2 pts.

Summary/Conclusions: BPDCN diagnostics is difficult due to the heterogeneity of immunological characteristics of disease. Aggressive course of disease with median survival of 12-18 months, in the view of the unique treatment recommendations indicates necessity of further clinical investigations on larger patients groups.

Background: DLBCL is the most common histologic subtype of non-Hodgkin lymphoma (NHL), accounting for about 33% of all NHL cases. However, the healthcare burden associated with DLBCL has not been extensively studied in a US population.

Aims: We evaluated the costs of care and healthcare utilization (HCU) of DLBCL patients treated during routine care in the US.

Methods: The Optum claims database was used to identify adult patients (≥18 years old) with newly diagnosed DLBCL between 01/01/08 and 10/31/15. DLBCL diagnosis was based on ≥1 inpatient claim or ≥2 outpatient claims with DLBCL diagnosis codes, with the index date being the first DLBCL claim. Patients were followed from index date until end of continuous enrollment, death, or end of study period (12/31/15) for the assessment of HCU and costs. DLBCL-related and non-DLBCL-related HCU and costs incurred during follow-up were evaluated. DLBCL-related HCU and costs were medical claims with a primary diagnosis of DLBCL or DLBCL-related treatment (chemotherapy, radiation, stem cell transplant [SCT], supportive care) and pharmacy claims for DLBCL treatment. Proportions of patients with HCU were reported. Costs were calculated as per-patient-per-month (PPPM) costs and reported as mean and standard deviation (SD). Patients with a capitated payment plan were excluded from the cost analysis.

Results: 1,267 treated DLBCL patients were identified. Over the follow-up period, 66.0% of patients had ≥1 inpatient admission, with more patients having a non-DLBCL-related than DLBCL-related admission (Table 1). 60.0% of patients had ≥1 emergency room visit over the follow-up period; visits were predominately for non-DLBCL-related reasons. Nearly all patients had ≥1 physician office visit (92.4%) and other outpatient visits (99.6%). The mean PPPM costs incurred during the follow-up period was $11,890 (SD: $11,515) (Table 1), and costs were higher in Year 1 ($14,402, SD: $10,951) than in Year 2 ($4,190, SD: $8,076). About 55% of costs overall were related to DLBCL medical services ($6,532 PPPM, SD: $6,457). DLBCL-related medical PPPM costs decreased substantially from Year 1 ($8,327, SD: $5,925) to Year 2 ($1,443, SD: $4,349). This decrease was driven by the decreases in chemotherapy and supportive care medical services from Year 1 to Year 2. Non-DLBCL-related medical costs accounted for about 42% of the overall PPPM costs ($4,955, SD: $7,210); and a decrease was observed from Year 1 ($5,840, SD: $7,468) to Year 2 ($2,447, SD: $5,456). Inpatient admission was the main component of non-DLBCL-related costs, and associated costs decreased from Year 1 to 2.

Table 1.
Summary/Conclusions: The economic burden associated with the treated DLBCL population is high, with the majority of costs incurred during the first year of diagnosis. Between the first and second year of diagnosis, costs decrease mainly because of the decrease in the DLBCL-related treatment costs. In addition, HCU for DLBCL-related services decreased in Year 1 vs Year 2.

PB1706
PHARMACOKINETICS OF RITUXIMAB IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA
S. Rožman1, I. Grabnar2, S. Novaković3,4, A. Mrhar2, B. Jezersek Novakovic4,*, 1Pharmacy Department, Institute Of Oncology Ljubljana, 2Department of Bio-pharmaceutics and Pharmacokinetics, Faculty of Pharmacy, University of Ljubljana, 3Department of Molecular Diagnostics, 4Department of Medical Oncology, Institute Of Oncology Ljubljana, Ljubljana, Slovenia

Background: Rituximab dosing is based on evidence from clinical practice rather than from consideration of pharmacokinetics and factors influencing individual exposure. Clinical use of rituximab can be improved through a more individualized treatment.

Aims: The objective of this investigation was to typify rituximab pharmaco-kinetics in 29 newly diagnosed patients with the diffuse large B-cell lymphoma who received rituximab in combination with cyclophosphamide, doxorubicin, vincristine and methylprednisolone every three weeks. The association of rituximab pharmokinetics with clinical outcome was also investigated.

Methods: Rituximab serum levels were defined by enzyme-linked immunosor- bent assay and assessed by a population pharmacokinetic analysis applying the non-linear mixed effects modelling.

Results: A 2-compartment model comprising linear non-specific clearance of 0.206 wk-1 (CI 0.207 – 0.279) L/day and time-varying Deficit clearance of 0.278 (95% CI: 0.181 – 0.390) L/day, corresponding to targeted-medicated drug disposition of rituximab was recognised to best describe the data. The nonspecific clearance was found to be lower in older patients and those with lower body weight. Addi- tionally, the central compartment volume was higher in males. An unambiguous association of clinical response with rituximab pharmacokinetics has been detect- ed. The rate constant of specific clearance decay was 0.143 day−1 (95% CI: 0.0478 – 0.418) in patients with no disease progression, while in patients with disease progression it was 82.2% lower (95% CI: 33.4 – 95.0).

Summary/Conclusions: These results imply that time-changes in clearance could serve as a predictive marker of response to rituximab. Our findings prove the rationale for studies evaluating higher doses of rituximab in selected patients.

PB1707
HOW 18FDG PET/CT CAN IDENTIFY BONE MARROW INFLTRATION IN PATIENTS WITH NON-HODGKIN'S LYMPHOMA
C. Mainolfi1,*, T. Mannarino1, L. Marano2, F. Trastulli2, L. Simeone2, C. Mainolfi1,*, T. Mannarino1, L. Marano2, F. Trastulli2, L. Simeone2

Background: Bone marrow infiltration (BMI) occurs in 40% of newly diagnosed NHL and has an important impact on the clinical management of patients with NHL. However, BMI remains underdiagnosed in clinical practice and is not commonly included in the International Prognostic Index (IPI), other clinical and laboratory parameters being used to evaluate BMI.

Aims: To compare real-world treatment patterns of patients with newly diagnosed DLBCL in the United States – a claims database study

Methods: A total of 393 patients (188 females/205 males) with the median age of 57 years (range 19-91 years). All patients were initially treated with rituximab plus CHOP (Cyclophosphamide, Doxorubicin, Vincristine, Prednisone) or CHOP-like protocols.

Results: Ann Arbor stage I, II, III and IV had 56 patients (14.2%), 142 (36.1%), 71 (18.1%) and 124 (31.6%), respectively. Bulky disease had 99 patients (25.2%), B symptoms 263 patients (66.9%), and poor performance status according to the European Cooperative Oncology Group (ECOG) at 2 had 82 (20.9%). Bone marrow involvement was present in 68 patients (17.3%). Low IPI risk was present in 194 patients (49.4%), low intermediate in 86 (21.9%), high intermediate in 77 (19.6%), and high in 36 (9.2%). Median absolute lymphoma cell count (ALC) at diagnosis was 1.35×10⁹/L (range 0.07-60.7×10⁹/L), absolute monocyte count (AMC) was 0.64×10³/L (range 0.06-5.8×10³/L), AMC/LC was 2.3 (range 0.07-37.0×10⁹/L), hemoglobin level was 125g/l (range 57-421g/l), platelet level was 274x10⁹/L (range 50-584x10⁹/L), C-reactive protein level was 10.2mg/l (range 0.10-436mg/l), erythrocyte sedimentation rate (ESR) was 30mm/h (range 2-636mm/h), and albumin level was 38g/l (range 20-51g/l). Complete remission (CR) was achieved in 288 patients (73.3%), partial remis- sion (PR) in 58 (14.8%), stable disease (SD) in 5 (1.3%) and progressive disease in 42 (10.7%). Disease relapse was confirmed in 59/346 patients (17.0%). OS was influenced by the presence of B symptoms (p=0.004, 95% CI 1.263-10.278), ECOG 2 (p=0.001, 95% CI 1.827-4.290), Ann Arbor clinical stage (p<0.0001, 95% CI 1.601-3.883), and albumin level (p<0.0001, 95% CI 0.905-0.953). Optimal cut off point for albumin level was 34g/l, and was determined by Receiver operating characteristic (ROC) curve (AUC 0.699, 95% CI, 0.629-0.770, p<0.0001). The prognostic value of IPI was highly statistically significant for OS (p<0.0001, 95% CI, 1.545-2.236). However, other analyzed parameters did not influence OS. Multivariate analysis among significant parameters (pres- ence of B symptoms, IPI, and albumin), has pointed to IPI (HR 1.81, p<0.0001, 95% CI, 1.489-2.222), and albumin level (HR 1.77, 95% CI, 1.164-2.69, p=0.008) as the most important parameters that influenced survival.

Summary/Conclusions: Although IPI is widely used as a prognostic index in DLBCL, it cannot fully recognize high-risk patients. Pretreatment albumin level may represent a useful tool in order to discriminate high-risk patients and is likely to add significant information to the IPI.
Methods: The Optum claims database was used to identify adult patients (≥18 years old) with newly diagnosed DLBCL between 01/01/08 and 10/31/11. DLBCL diagnosis was based on ≥1 inpatient claim or ≥2 outpatient claims with DLBCL diagnosis codes, with the index date being the first DLBCL claim. Patients were followed from index date until end of continuous enrollment, death, or end of study period (12/31/15). Treatment patterns and response to treatment were defined according to the study group. Possible remission was defined as no additional chemotherapy and no supportive care use or receipt of supportive care <30 days after end of line of therapy (LOT) for <30 days. Lack of remission was defined as receipt of supportive care <30 days after end of LOT for >30 days. Progression was defined as initiation of another LOT or evidence of supportive care ≥30 days after end of a LOT.

Results: Of the 2,216 patients selected into the study, 1,267 (57.2%) initiated 1LOT, and median (inter quartile range [IQR]) time to therapy was 0.7 (0.4–1.1) months. The majority of patients received combination (87.7%) vs single-agent (12.3%) chemotherapy. R-CHOP (60.5%) was the most frequently used combination chemotherapy, while rituximab monotherapy comprised 46% (8.2%) of single-agent use in 1LOT. Median (IQR) duration of 1LOT was 4.2 (2.3–4.5) months. At the end of 1LOT, 64.0% (n=881) had evidence of remission, 15.0% (n=190) progressed, and 1.2% (n=15) had no evidence of remission. Second-line therapy (2LOT) was initiated by 159 patients who progressed after 1LOT; 29.6% received a single agent, and 70.4% received combination chemotherapy. In 2LOT, rituximab (12.6%) remained the top single agent used, while bendamustine+rituximab (15.7%) and R-CHOP (8.2%) were the most common combinations; 82% of patients received stem cell transplant. Median (IQR) duration of 2LOT was 2.1 (1.2–3.8) months. Of the 2LOT patients, 44.0% (n=70) had evidence of remission, 26.4% (n=42) progressed, and 3.1% (n=5) had no evidence of remission. 34 patients who progressed after 2LOT received third-line therapy (3LOT); 29.4% received a single agent, while 70.6% received combination chemotherapy. In 3LOT, rituximab (5.9%), etoposide (5.9%), and carboplatin (5.9%) were the most common single agents, while bendamustine+rituximab (20.8%) and etoposide+carboplatin+rituximab (17.6%) were the most common combinations; 8.8% of patients received stem cell transplant. Median (IQR) duration of 3LOT was 3.5 (0.9–5.2) months. Following 3LOT, 32.4% (n=111) had evidence of remission, 29.4% (n=10) progressed, and 5.9% (n=2) had no evidence of remission.

Summary/Conclusions: DLBCL treatment in routine clinical care aligns with guiding therapeutic principles and most patients receiving rituximab in combination with chemotherapy. A small proportion of patients received single-agent chemotherapy in 1LOT. As expected, remission rates decreased with subsequent lines of therapy. Some patients were untreated; therefore, subsequent studies should explore reasons for lack of treatment.

PB1710
TP53 GENE MUTATIONS IS A PREDICTOR OF HIGH GRADE B-CELL LYMPHOMA PROGRESSION
A. Misiryuni1,*, V. Misiryuni2, S. Kravchenko1, A. Kovrigina1, A. Misyurin2, E. Baryakh3, A. Magomedova1, E. Nesterova1, E. Pushkova4, J. Finashutina2, A. Vorobiev1
1National Research Center for Hematology, 2Federal State Institution “Russian Cancer Research Center. NN Blokhin” Russian Ministry of Health, 3State budget health care institution “City Clinical Hospital №52 Moscow Health Department.”, 4LLC “Genotechnologiya”, Moscow, Russian Federation

Background: High grade B-cell lymphoma (HGBL) is subdivided on poor prognosis double-hit (DH) and not otherwise specified (NOS) variant, which appears sometimes with primary refractory behavior. Mutations in TP53 gene (MUT-TP53) lead to blockage of apoptosis in cells and appearance of additional oncogenic events contributing to tumor progression. Correlation between presence of MUT-TP53 and anti-tumor response in patients with HGBL is unclear.

Aims: To evaluate an effect of MUT-TP53 on survival parameters of patients with high grade B-cell lymphoma.

Methods: Since 2005 to 2017 years in FGBU National Research Center for Hematology Ministry of Health Russian Federation diagnosis of high grade B-cell lymphoma were established in 47 patients: 13 – double hit, 34 – not other.

Results: The presence of TP53 mutations were found in 9 patients’ samples (29.4% (n=10) progressed, and 5.9% (n=2) had no evidence of remission. Among 203 patients (median age 62 years: range 19 to 86 years), 43% was carrier and 57% was diagnosed with ATL. According to clinical subtype, 5% was chronic, 38% was smoldering, 28% was acute, 29% was lymphoma type. Median overall survival was 30 months in carrier, 10 months in acute, 8 months in lymphoma, and smoldering was not available. In all ATL seropositive patients, the occurrence of primary malignant neoplasm was 32%, they were all carrier or smoldering. Among them, 53% was hematology malignancy (T cell lymphoma; 41%, B cell lymphoma; 29%, MPN; 16%, MDS; 12%), Soid tumor was 47% (lung cancer; 33%, prostate cancer 13%, colon cancer; 13%, renal cell cancer; 13%). Four patients with HTLV-1 carrier who developed primary malignant neoplasm received standard chemotherapy for the neoplasm, and after the chemotherapy they developed 3 acute type and 1 smoldering type ATL.
Background: CNSL represent 4% of primary central nervous system (PCNSL) and secondary CNS lymphoma (SCNSL) occur in 7% of systemic lymphoma. Overall survival (OS) and progression-free survival (PFS) have dramatically increased in PSNL since the introduction of Methotrexate high doses and ASCT usually conditioning with TBC (Thiotepa, Busulfan and Cyclophosphamide). The studies usually tend to recommend TBC/ASCT in front line for patients under 65 years with CNSL with very few prospective data about this strategy. Aim of our study is to present our experience concerning TBC/ASCT and its main toxicities.

Methods: All patients treated with TBC/ASCT for PCNSL or SCNSL from August 2010 to November 2016 in our centers were researched by using CHIMIO® software. TBC combined Thiotepa (250mg/m²/d from d-9 to d-7), Busulfan (3.2mg/kg/d from d-6 to d-5 and 1.6mg/kg/d on d-4) and Cyclophosphamide (60mg/kg/d on d-3 and d-2) followed by ASCT (transplantation at d0). Clinical data were extracted from the medical records. We measured OS and PFS from the date of ASCT and transplant related mortality (TRM) (defined by death occurred 3 months after ASCT).

Results: 24 patients, without any major comorbidity, were included. Median age at ASCT was 58 years (23-66). 22 of 24 were DLBCL and 2 follicular lymphoma and there were 15 PCNSL and 9 SCNSL. All but one, received 1 or 2 lines of chemotherapy (with high doses Methotrexate in first or second line) before ASCT. 15 were in complete response (CR) and 9 in partial response (PR) before TBC/ASCT. Median duration of hospitalisation was 33 days (15-78 d) and of aplasia was 14 days (7-37 d). Median follow-up was 10 months (0-73). At the end of follow up 5 patients have died. Among the 3 patients older than 60 years in the 1st group before A.C.T, patients treated with R-CHOP and FAPE were respectively 78% and 73%. Surprisingly (Table 1), we noted an important rate of toxicity (100% with 66% grade 3) with a TRM=21%. Neurological adverse events (37%; 9 patients with 4 comas) and infections (100% with 41% grade 3) were predominant. We documented 2 CMV reactivations and 5 funga
gal infections (3 candida, 1 aspergillus and 1 cryptococcus).

Table 1.

We observed 5 deaths (4/5 older than 60 years) in first 3 months due to a septic choc, 4 associated with a persistent coma and 2 with an acute respiratory distress syndrome.

Summary/Conclusions: To our knowledge, here is one of the biggest retrospective cohort concerning TBC/ASCT in CNSL. If TBC seems to give interesting response rates (72% CR), we noted an unacceptable toxicity compared to other used conditionings (for example TRM with Thiotepa Carmustine is 1%). Our high toxicity rates (86%/grade 3), especially in elderly patients, with neurological adverse events and infections (with unusual microbiological agents) lead us to disavise the use of TBC before ASCT.

PB1714 TREATMENT RESULTS IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA FROM HIGH RISK AND HIGH-INTERMEDIATE RISK GROUPS I. Kriačok1, K. Filipenko2, A. Martynchik2, I. Titenenko2, I. Stepanishyna2, O. Aleksey2, I. Dyagi3, E. Kushchevy2, Z. Martina3, V. Kozlov3
1Radiation therapy, National Cancer Institute, 2Radiology, Odessa, Ukraine

Background: Using of Rituximab-containing regimens, as the «gold standard» of survival (OS) and progression free survival (PFS), showed significant improvement in the treatment results throughout all prognostic groups. The “real-life” treatment approaches vary depending on financial support of health-care system in different countries. Unfortunately, treatment results in patients with DLBCL from high and high-intermediate risk groups are still unsatisfying.

Aim of our study was to compare efficacy and toxicity of different treatment approaches in patients with DLBCL from high risk and high-intermediate risk groups.

Methods: Prospective cohort study was initiated in 2014 in three Ukrainian centers. Patients with newly diagnosed DLBCL and ≥3 risk factors according to International Prognostic Index (IPI) were treated according to “investigators decision” (85%). Patients with newly diagnosed DLBCL and ≥3 risk factors according to International Prognostic Index (IPI) were treated according to “investigators decision” (85%). Patients with newly diagnosed DLBCL and ≥3 risk factors according to Inter-

PB1716 HIGH LEVELS OF SOLUBLE INTERLEUKIN-2 RECEPTOR ARE ASSOCIATED WITH A POOR PROGNOSIS IN CASES OF RELAPSED/REFRACTORY PERIPHERAL T CELL LYMPHOMA, NOT OTHERWISE SPECIFIED M. Morita1, D. Kato1, A. PB1715 PROGNOSTIC MODEL WITH NEUTROPHIL-LYMPHOCYTE RATIO AND PERFORMANCE STATUS IN DIFFUSE LARGE B CELL LYMPHOMA TREATED WITH R-CHOP S.-I. Goi1, G.-W. Lee2
1Internal Medicine, Gyeongsang National University School of Medicine, Jinju, Korea, Republic Of

Background: Growing evidences suggest the close relationship between inflammation, host immune, and tumor cells. The neutrophil to lymphocyte ratio (NLR) has been known to predict the prognosis in patients with diffuse large B-cell lymphoma (DLBCL).

Aims: This study was planned to confirm the prognostic and predictive value of NLR and to make a model to predict the prognosis more precisely in patients with DLBCL.

Methods: Data of 192 DLBCL patients treated with R-CHOP from 2004 to 2016 were retrospectively assessed. Patients with NLR ≥4 and <4 were determined as the high and low NLR groups, respectively. Treatment response and survival were compared according to the NLR status and using the model including NLR and other variable interacting with NLR.

Results: High NLR group was associated with old age, poor performance status (PS), elevated lactate dehydrogenase, and more advanced prognostic indices than low NLR group. High NLR group had a low complete response (CR) rate compared to low NLR group (57.5% vs 81.4%, p=0.004). However, the NLR ≥4 as prognostic factor was not prognostic in univariate analysis, which showed strong interaction between NLR and PS. The model composed of NLR and PS could stratify the patients into low-, intermediate-, and high-risk groups for overall survival (OS). On multivariate analysis, compared to low risk group, the hazard ratios of intermediate and high risk groups were respectively 2.49 (p=0.004) and 4.49 (p=0.002). The model containing NLR and PS could stratify the patients into low-, intermediate-, and high-risk groups for overall survival (OS). The model containing NLR and PS could stratify the patients into low-, intermediate-, and high-risk groups for overall survival (OS). The model containing NLR and PS could stratify the patients into low-, intermediate-, and high-risk groups for overall survival (OS). The model containing NLR and PS could stratify the patients into low-, intermediate-, and high-risk groups for overall survival (OS). The model containing NLR and PS could stratify the patients into low-, intermediate-, and high-risk groups for overall survival (OS). The model containing NLR and PS could stratify the patients into low-, intermediate-, and high-risk groups for overall survival (OS).
are no established predictors of prognosis. Although serum soluble interleukin-2 receptor (sIL-2R) levels are associated with clinical outcomes in newly diagnosed patients with PTCL-NOS, it remains unclear whether sIL-2R levels can predict prognosis in patients with relapsed/refractory PTCL-NOS.

Aims: This study evaluated whether sIL-2R levels at the time of salvage chemotherapy were associated with prognosis in cases of relapsed/refractory PTCL-NOS.

Methods: We retrospectively analyzed 45 patients with relapsed/refractory PTCL-NOS who received salvage chemotherapy at our institutions (1996–2016). All patients received CHOP or CHOP-like therapy as their initial treatment. The primary outcome was defined as overall survival (OS), which was calculated from the date of the salvage chemotherapy to the date of death from any cause or the last follow-up.

Results: The median age at salvage chemotherapy was 68 years (range: 37–86 years). The median serum sIL-2R level was 3,476 U/mL (range: 280–24,400 U/mL). Receiver operating characteristic curve analysis revealed that the optimal sIL-2R cut-off value for predicting OS was 2,283 U/mL (area under the curve: 0.672, 95% confidence interval [CI]: 0.421–0.923). Thus, we defined patients with serum sIL-2R levels of ≥2,283 U/mL as the high sIL-2R group and the other patients as the low sIL-2R group. The two groups had similar clinical characteristics at the salvage chemotherapy, with the exception of their international prognostic index (secondary IPI) and performance status (PS). The high sIL-2R group had significantly higher secondary IPI (≥0 and lower PS (≥2). Eight patients were alive at the time of the analysis, with a median follow-up of 55 months (range: 2–136 months). The 2-year OS among all patients was 25.1% (95% CI: 13.6–38.5), and the high sIL-2R group had significantly poorer 2-year OS (10.9%, 95% CI: 2.8–25.4 vs 50.0%, 95% CI: 24.5–71.0, P < 0.001). A multivariable analysis was performed using the following factors: serum sIL-2R levels (high vs low), secondary IPI (≥0 vs ???? ?????) (Figure 1).

Summary/Conclusions: Serum sIL-2R levels are a useful predictor of prognosis in cases of relapsed/refractory PTCL-NOS, especially among patients with low secondary IPI risk.

AUTOIMMUNE DISEASES ARE NOT ASSOCIATED WITH INFERIOR PROGNOSIS IN PTCL-NOS PATIENTS

Y.-H. Shih1, N. Elhalawani1, A. Nazir1, N. Mashali2, M. H. Nafea1, A. Sorour3

1Hematology, 2Pathology, 3Clinical Pathology, Alexandria Main University Hospital, Faculty of Medicine, Alexandria University, Egypt, Alexandria, Egypt

Background: Previous epidemiological studies have shown that autoimmune diseases increase the risk of lymphoma development. Immune dysregulation could be the possible underlying pathogenesis. Whether autoimmune diseases deteriorate outcome of lymphoma patients, however, remains unclear.

Aims: The objective of this study is to compare the clinical outcome among lymphoma patients with and without autoimmune diseases.

Methods: From January 2008 to November 2016, we retrospectively reviewed medical records of 913 newly diagnosed lymphoma patients. From these 913 lymphoma patients, 34 (3.71%) patients were diagnosed to have autoimmune diseases before their lymphoma identification. Among these 34 patients, six patients lost their follow-up. A total of 28 lymphoma patients with pre-existing autoimmune diseases were finally analyzed. For the further comparison, 56 lymphoma patients without pre-existing autoimmune diseases who were adjusted for age and gender were considered to be the control group. Response rate, progression-free survival (PFS), and overall survival (OS) were compared between these two groups of patients.

Results: Rheumatoid arthritis was the most common autoimmune disease in lymphoma patients (11/34; 32.3%). The complete remission rate for lymphoma patients with and without autoimmune diseases were 72.0% and 83.3%, respectively (p=0.178). The PFS for patients with and without autoimmune diseases were 44.3±32.1 months and 50.9±28.6 months, respectively (mean±standard deviation; p=0.334). These two groups of patients had similar OS time as well (46.4±31.5 months vs 52.9±28.0; mean±standard deviation; p=0.337). Univariate analysis did not show autoimmune diseases were associated with inferior OS in lymphoma patients (crude hazard ratio: 1.32; 95% confidence interval: 0.672–2.58; p=0.272).

Summary/Conclusions: The results of this case-control study showed the autoimmune disease was not a poor prognostic factor for lymphoma patients.

THE DIAGNOSTIC AND PROGNOSTIC IMPLICATIONS OF CIRCULATING MiRNA-21 IN A SAMPLE OF HEPATITIS C/NONE HEPATITIS DIFFUSE LARGE B-CELL LYMPHOMA EGYPTIAN PATIENTS

M. Moussa1, N. Elhalawani1, A. Nazir1, N. Mashali2, M. H. Nafea1, A. Sorour3

1Hematology, 2Pathology, 3Clinical Pathology, Alexandria Main University Hospital, Faculty of Medicine, Alexandria University, Egypt, Alexandria, Egypt

Background: MicroRNAs (miRNAs) are small RNA molecules which control the expression of many target messenger RNAs involved in cell differentiation, proliferation and apoptosis. Circulating microRNAs are potential biomarkers of diagnostic and prognostic impact in various inflammatory and malignant diseases. Unlike other malignancies, studies of the prognostic impact of miRNA-21 expression in diffuse large B-cell lymphoma (DLBCL) patients have been a matter of debate. To our knowledge, there are no existing data up to date on the expression of miRNA-21 in hepatitis C virus (HCV) associated DLBCL.

Aims: Linking inflammation with malignancy, we studied the expression of miRNA-21 in sera of hepatitis-C-virus and none hepatitis DLBCL patients, aiming to identify its differential expression and prognosis in DLBCL with its subtypes; germinal center B-cell (GCB) and activated B-cell-like (ABC) and to evaluate its relation with HCV.

Methods: MiRNA-21 expression was measured using Taq-Man quantitative RT-PCR in sera of 30 newly diagnosed DLBCL patients (HCV positive (n=10), HCV negative (n=20)) and 20 controls (HCV positive (n=10), HCV negative (n=10)). The diagnosis of DLBCL and its sub-classification in GCB and ABC subtypes were done by applying the criteria of the WHO classification of tumors of the hematopoietic and lymphoid tissues 2008 and revised in 2016. These criteria were confirmed by Immunohistochemistry using antibodies to CD10, BCL-6, MUM-1 and BCL-2. HCV was diagnosed by detection of anti-HCV antibodies in sera of patients and controls by Enzyme-Linked Immunosorbent Assay (ELISA) technique and HCV genetic detection and quantification by polymerase chain reaction (PCR). All the patients received CHOP chemotherapy and were followed up for an average of 24 months.

Results: MiRNA-21 expression was significantly higher in DLBCL patients than in controls (p<0.00). Significant positive correlations between miRNA-21 and LDH, IPI and disease stage were detected (p<0.05). Significantly higher miRNA-21 were detected in ABC subtype compared to GCB subtype (p=0.00). Significantly higher miRNA-21 expression levels were detected in BCL6 negative, CD10 negative, MUM1 positive DLBCL cases compared to its levels in BCL6 positive, CD10 positive and MUM1 negative cases, (p=0.018, 0.002 and 0.001 respectively). Higher miRNA-21 was associated with worse response (p=0.016), 2-year progression-free survival (p=0.017) and 2-year progression-free survival with statistical significance (p=0.003). Significantly higher miRNA-21 levels were detected in HCV positive DLBCL patients compared to HCV-negative patients (p<0.00). Higher miRNA-21 levels were detected in HCV positive ABC subtype than GCB subtype (p=0.05). Significantly higher levels were also detected in HCV positive controls compared to HCV-negative controls.

Summary/Conclusions: Our study showed that miRNA-21 was overexpressed in DLBCL patients, displaying higher levels in ABC than in GCB subtypes. MiRNA-21 was associated with poor response to treatment and survival in DLBCL. According to our results, miRNA-21 is a potential marker of necro-inflammation independent of its role in tumorigenesis, showing higher expression in HCV positive DLBCL patients compared to none hepatitis patients.

A NEW SCORING SYSTEM FOR PRIMARY CENTRAL NERVOUS SYSTEM LYMPHOMA – A RETROSPECTIVE MULTI-CENTER ANALYSIS IN TAIWAN

Y.-C. Su1,2,*, S.-W. Lai3, C.-C. Lin1, W.-L. Hwang1

1Division of Hematology/Oncology, Department of Internal medicine, Taichung Veterans General Hospital, Taichung, Taiwan, Republic of China

Background: There has been much debate about the classification of primary central nervous system lymphoma (PCNSL) in Taiwan. According to our results, miRNA-21 was associated with worse response and outcome in ABC subtype than GCB subtype (p=0.05). Significantly higher levels were also detected in HCV positive controls compared to HCV-negative controls.

Summary/Conclusions: Our study showed that miRNA-21 was overexpressed in DLBCL patients, displaying higher levels in ABC than in GCB subtypes. MiRNA-21 was associated with poor response to treatment and survival in DLBCL. According to our results, miRNA-21 is a potential marker of necro-inflammation independent of its role in tumorigenesis, showing higher expression in HCV positive DLBCL patients compared to none hepatitis patients.

Aims: The objective of this study is to compare the clinical outcome among lymphoma patients with and without autoimmune diseases.

Methods: From January 2008 to November 2016, we retrospectively reviewed medical records of 913 newly diagnosed lymphoma patients. From these 913 lymphoma patients, 34 (3.71%) patients were diagnosed to have autoimmune diseases before their lymphoma identification. Among these 34 patients, six patients lost their follow-up. A total of 28 lymphoma patients with pre-existing autoimmune diseases were finally analyzed. For the further comparison, 56 lymphoma patients without pre-existing autoimmune diseases who were adjusted for age and gender were considered to be the control group. Response rate, progression-free survival (PFS), and overall survival (OS) were compared between these two groups of patients.

Results: Rheumatoid arthritis was the most common autoimmune disease in lymphoma patients (11/34; 32.3%). The complete remission rate for lymphoma patients with and without autoimmune diseases were 72.0% and 83.3%, respectively.
Background: Primary central nervous system lymphoma (PCNSL) is a rare type of non-Hodgkin’s lymphoma. Two independent prognostic scoring systems have been developed at the Memorial Sloan-Kettering Cancer Center (MSKCC) and the International Extranodal Lymphoma Study Group (IELSG). The former considers age and Karnofsky’s performance status (PS) as prognostic parameters (JCO. 2006;24:5711). The latter includes age, Eastern Cooperative Oncology Group (ECOG) PS, the presence of deep lesions, serum lactate dehydrogenase (LDH) and total protein levels in the cerebrospinal fluid (CSF) (JCO 2006;24:571). Neither of the two systems has been verified in the Asian population, leading to concerns regarding applicability in this region.

Aims: This study was conducted to test the prognostic power of the 2 systems in PCNSL patients in Taiwan. In addition, we analyzed the parameters of the IELSG system to figure out the most powerful prognostic factors and then established a new scoring system.

Methods: The medical records of patients with tissue-proven PCNSL were retrieved from 15 academic hospitals in Taiwan through January 2002 to December 2011. They were stratified into different groups according to the MSKCC or the IELSG system and the overall survivals (OS) were evaluated. All parameters in the IELSG system were checked by multi-variable analysis to establish a new scoring system.

Results: When the IELSG scoring system was applied, the 2-year OS in low, intermediate and high-risk groups were 78.3%, 43.9% and 37.5% respectively with a crossover in the latter 2 groups (Figure 1A). When the patients were stratified by the MSKCC scoring system, the 2-year OS of class I, II and III were 65%, 68% and 20% (Figure 1B), respectively. We conducted single-variable analysis of the 5 parameters included in the IELSG scoring system and only age and ECOG PS were statistically significant. In the multi-variable analysis, these 2 factors were almost equally weighted. Based on these findings, we re-stratified the patients into 3 groups. Group 1 comprised patients with both age <60 and ECOG PS <2 and Group 3 with both age ≥60 and ECOG PS ≥2. The patients not fulfilling criteria of either Group 1 or Group 3 were categorized as Group 2. According to this new scoring system, the median OS of Groups 1, 2 and 3 were 1,573, 548 and 304 days (Figure 1C), respectively, and their OS curves could be nicely distinguished.

Background: The incidence of lymphomas is increasing with age. Many aggressive lymphomas are now considered to be curable. All fit patients, even elders, are candidates for optimal treatment with a curative intent. Diffuse Large B Cell Lymphoma (DLBCL) is the most common non-Hodgkin Lymphoma, with 60% of curative rates after standard R-CHOP regimen. Patients that relapse can be rescued with salvage treatment in 20-30%. The elders are not considered for full standard treatment in many centers. Geriatric scales are starting to being used to stratify patients and offer them individualized treatments. The use of GCSF for neutropenia prophylaxis is not a standard of care in this population.

Aims: The objectives of this study were: 1) Validate CIRS score in a DLBCL cohort; 2) Analyse the impact of CIRS score in OS; 3) Analyse the impact of GSCF prophylaxis on neutropenic fever.

Methods: Between November 2008 and November 2015, 41 DLBCL patients with ≥60 years at diagnosis from a single institution and homogeneously treated with R-CHOP were analyzed. Patients were evaluated for comorbidities with Cumulative Illness Rating Scale (CIRS). CIRS score was used to detect the most impact on OS. The CIRS scale was also used to discriminate two OS groups; the low risk showed a median OS not reached vs 29 mo. The high-risk group, with CIRS <6 (n=17), 7 (41%) patients were admitted with a mean of stay of 6,2 days (range 1-62), p=0,035. The CIRS scale was also used to discriminate two OS groups; the low risk showed a median OS not reached vs 29 mo. The high-risk group, with a Hazard ratio of 2.68 (CI95%: 1,031-5,882, p= 0,042). NF was the most common ER visit, n=18 (36%). Of the 18 patients with NF, 10 (55%) were prescribed with GCSF prophylaxis mid cycles. Of all patients with GCSF (n=43) only 10 (24%) NF were reported. 11/17 patients (65%) who didn’t use GCSF prophylactic had an NF episode. The Odds ratio (OR) for the patients under prophylaxis was 0,232 (CI 95%: 0,085-0,634, p=0,004) (Figure 1).

Summary/Conclusions: The OS and the PFS in our sample is similar as described in larger studies. The days of admissions adjusted to the CIRS scale give us a tool to help physicians to discriminate patients who will have prolonged admissions when treated with the standard of care. The CIRS scale also help separate two distinct OS curves, giving physicians a new tool to help discriminate worse prognostic patients, making them good candidates for adapted therapies. The use of GCSF prophylactic can protect the elderly patients from NF, and should be used in all patients in this category.
6/10 evaluated patients. Computed tomography scans showed slight to moderate contrast enhancement of adrenal masses in 4/5 patients (80%), and magnetic resonance imaging identified a normal T1 and longer T2 phase. Diffuse large B cell lymphoma (DLBCL) was the most common immunophenotype (82.6%). Two patients died due to rapid disease progression before treatment. Three patients were treated with chemotherapy + external beam radiotherapy. Two patients received autologous stem cell transplantation as consolidation therapy. Five-year overall survival and progression-free survival were 54.2% and 51.0%, respectively.

Summary/Conclusions: These findings suggest that PAL should always be considered in differential diagnosis of adenral mass with AI. Moreover, DLBCL was observed as one of the most common histological subtype of PAL despite the above, contrasting previous reports. Longer-term prognosis of PAL is not necessarily inferior to that of non-Hodgkin lymphoma in general.

PB1721

EFFICACY AND SAFETY OF IBRUTINIB TREATMENT IN RELAPSED/REFRACTORY MANTLE CELL LYMPHOMA IN REAL-LIFE – A MULTICENTRIC STUDY (R.E.P. - APULIAN HEMATOLOGY NETWORK)

V.P. Gagliardi1, N. Cascavilla2, N. Di Renzo3, A. Melpignano4, G. Leo5, V. Pavone6, F. Gaudino7, G. Specchia1, T. Perrone8

Background: Mantle cell lymphoma (MCL) is a rare subtype of non-Hodgkin lymphoma that has an aggressive clinical course and poor prognosis. Although current front-line combination chemo-immunotherapies followed by autologous stem-cell transplantation (ASCT) have improved the outcomes of affected patients (pts), there is a need to develop new strategies. We herein report on an oral covalent inhibitor of Bruton tyrosine kinase that showed significant activity in relapsed/refractory MCL in clinical trials, but in real-life routine, the efficacy and safety may not always mirror those seen in clinical trials.

Aims: We investigated the clinical use of ibritinib as a single-agent in 31 pts with relapsed or refractory MCL to obtain additional information about predictive factors, outcomes and toxicity in a real-life context.

Methods: We studied a group of 31 pts treated (or still in treatment) with ibritinib to assess effectiveness in terms of overall response rate, complete response rate, progression free survival and adverse events (AEs) in a real-life context. Data were collected also with reference to clinical and biological characteristics of the disease (MIPI, MIPIb, bone marrow involvement, stage, history, presence of bulky mass and/or extranodal disease) both at the time of diagnosis and at the time of the start of ibritinib therapy, and to the type and number of previous therapies.

Results: 100% of pts treated with ibritinib for MCL, the median age was 70 years (range, 45-82), 100% of pts had high risk MCL according to the MIPI score, 83.9% of pts had disease stage III or higher, 41.9% of pts had bone marrow involvement, and 45.2% of pts presented extranodal involvement of MCL. 26 pts were treated for relapsed MCL, 5 for refractory disease. They had received a median of 2 (range, 1-5) prior regimens including different chemo-immunotherapy schemes. ASCT and newer agents such as bortezomib, lenalidomide, thalidomide. We observed 6 complete responses, 1 after only 2 months of therapy, the others within 6 months of therapy. After 15 months, we observed 4 relapses, characterized by leukemic dissemination, 3 pts presented central nervous system involvement, and 8 progression. 80% of pts treated for refractory disease presented progression within 6 months. The most common AEs were fatigue (13% of pts) and weight increase (13% of pts), followed by diarrhea and bleeding (grade ≥ 2) (6.4% of pts). The most common hematologic event observed was neutropenia (9.7% of pts, grade ≤ 2). With an estimated median follow-up of 6 months (range, 4-29), 19 pts are still receiving treatment, 12 have discontinued therapy for relapse or progression of disease. Follow-up is still ongoing.

Summary/Conclusions: Single-agent oral ibritinib shows a high response rate and produces rapid responses regardless of the number and quality of prior regimens. However, the quality and time of response does not seem to be predictive of a better PFS or longer duration of response. Furthermore, resistance to ibritinib in pts with MCL is associated with fulminant, severe progression. Ibritinib is well tolerated also in real-life experience. The weight increase in 13% of pts suggests that ibritinib may have an anabolic effect, including alterations in body fat, pressure and lipid profile. Large cohorts of pts and longer follow-up are warranted to confirm these preliminary data.

HEMATOLOGICAL MALIGNANCIES IN SOLID ORGAN TRANSPLANT RECIPIENTS: RETROSPECTIVE SINGLE-CENTER ANALYSIS IN JAPAN

K. Hozawa1, K. Ninomiya2,1, I. Daki1, R. Goto1, K. Mortiz3, T. Ookaz2, K. Hatanka2, H. Goto1, J. Sugita1, M. Onozawa1, D. Hashimoto1, K. Kato1, T. Kondo1, Y. Matsumoto1, T. Shimamura1, T. Teshima1
1Department of Hematology, 2Department of Urology, 3Department of Surgery, 4Department of Cardiovascular and Thoracic Surgery, Hokkaido University Graduate School of Medicine, 5Department of Surgical Pathology, 6Division of Organ Transplantation, Hokkaido University Hospital, Sapporo, Japan

Background: Solid organ transplant recipients have elevated onset risks of hematological malignancies (HMs) due to long-term administration of immunosuppressive drugs. However, few studies about the incidence and impact on survival of HMs following solid organ transplantation have been conducted in Asian countries.

Aims: The aim of this study was to identify the incidence, characteristics, risk factors and prognosis of HMs in solid organ transplant recipients at our institution.

Methods: Clinical data of patients undergoing kidney, liver and heart transplantation in Hokkaido University hospital between January 1986 and December 2016 were retrospectively. Kaplan-Meier analysis was performed for the cumulative incidence rates (CI) of HMs, graft survival and patient survival. Patient’s characteristics were compared between groups by the student t-test or K‐square test.

Results: A total of 16 cases of HMs were identified, 9 post-transplant lymphoproliferative disorders (PTLDs), 2 acute myeloid leukemia (AML), 1 myelodysplastic syndrome (MDS), 1 myeloproliferative neoplasm (MPN) and 1 recurrent non-Hodgkin lymphoma. The CI of PTLD were 1.1%, 1.5% at 10 years in kidney transplant recipients (n=352), 0.92%, 2.6% at 5 years in liver transplant recipients (n=287) and 29% at 1 year heart transplant recipients (n=5), respectively (P<0.001). AML/MDS and MPN were both more frequent in kidney transplant recipients, and CI were 2.3% at 5 and 10 years (P<0.01). There was no difference in background factors other than transplanted organ type between recipients with HMs and without HMs. Patients with EBV-positive PTLD were younger (P<0.05) and had less extranodal diseases (P<0.05) compared with EBV-negative PTLD (n=4). All patients with monomorphotic PTLD (n=4) were treated with chemotherapy combined with rituximab and had been in remission. In patients with other PTLD, reduction or withdrawal of immunosuppressant or rituximab alone resulted in stable disease or remission. All AML/MDS but 2 acute promyelocytic leukemia in pediatric patients were chemo-refractory and lethal. 10-year OS were 92% and 100% in kidney and heart transplant recipients. In liver transplant recipients, 10-year OS were 74%, 100% and 50% in patients without disease, with PTLD and with myeloid neoplasm, respectively. Survival in adult liver transplant recipients with myeloid neoplasms was inferior to that without disease (P<0.05), 10-year graft survival rates were 72% and 75% in patients with and without transplant recipients with HMs.

Summary/Conclusions: The incidence of PTLD in solid organ transplant recipients in Japan is comparable to that in Western countries, whereas the incidence of myeloid neoplasm is higher in liver transplant recipients. PTLD does not have a negative impact on the prognosis of solid organ transplant recipients under appropriate management, while heightened awareness and a better clinical approach for myeloid neoplasms following solid organ transplantation are needed.

PB1724

MYC REARRANGEMENT HAS A STRONG PROGNOSTIC IMPACT IN THE FEMALE PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

H. Nitta1, M. Tanaka2, Y. Otani1, A. Goto1, N. Komatsu3
1Hematology, Juntendo University School of Medicine, 2Pathology, Teikyo University School of Medicine, Tokyo, Japan

Background: Cytogenetic abnormalities of MYC are associated with poor prognosis of patients with diffuse large B-cell lymphoma (DLBCL). However, the incidence of MYC rearrangement of MYC reportedly occurs in approximately 10% of DLBCL cases. In addition, in various clinical trials of rituximab with standard dosing, female receiving rituximab have had better outcomes than male. However, gender-segregated outcomes of patients with MYC rearrangement have not been reported. In addition, the gender segregation of known prognostic factors, such as high international prognostic index (IPI) score, elevated lactate dehydrogenase (LDH) level, poor Eastern Cooperative Oncology Group performance status (PS), advanced stage, and ≥2 extranodal sites, not as yet been fully elucidated.

Aims: The aim of this study was to determine the gender segregation of clinical and genetic prognostic factors, including MYC (fluorescence-in-situ hybridization: FISH) in patients with DLBCL by analyzing data from consecutive DLBCL patients.

Methods: In order to identify prognostic factors, we analyzed gender segregation from the medical records of patients with DLBCL, including newly diagnosed and relapsed not yet treated. The inclusion criteria for this study were: 1) newly diagnosed B-cell lymphoma with DLBCL; and 2) relapsed between 2010 and 2016. We retrospectively analyzed the data of 161 consecutive DLBCL patients (male: 91 patients, female: 70 patients). Patients in this study were treated with R-CHOP or R-CHOP-based regimens with minor modifications. The relationships between overall survival (OS), progression free survival (PFS) and age, LDH level, stage, ≥2 extranodal sites, FISH: MYC (fluorescence in-situ hybridization: FISH) expression, IHC: BCL6 (IHC), MYC (IHC), double expression (MYC and BCL2 expression on IHC), and MYC (FISH) were investigated. Univariate and multivariate analyses of estimated risk factors for OS and PFS were performed using the log-rank test and Cox proportional hazard regression analysis.

Results: Median age was 62 (range, 27–82 years). The median follow-up was 17 months (range: 1–81 months). To adjust the impact of age, LDH level, PS, stage, ≥2 extranodal sites, IPI, COO, BCL2 (IHC), BCL6 (IHC), MYC (IHC), double expressor (IHC), MYC (FISH), and other significant factors, uni-
PB1725

ASSESSING THE RISK FOR PERFORATION IN DIFFUSE LARGE B-CELL LYMPHOMA INVOLVING THE INTESTINES USING COMPUTED TOMOGRAPHY CHARACTERISTICS.

N. Sardí1, A. Sherban1, U. Bendet1, E. Luttwak1, Y. Herishanu1, C. Perry1, I. Avivi1
Tel-Aviv Sourasky Medical Center, Tel-Aviv, Israel

Background: Around 40% of all Diffuse Large B-Cell Lymphoma (DLBCL) cases involve extra-nodal sites, the most common being the gastro-intestinal (GI) tract. DLBCL patients with intestinal involvement are particularly prone to developing GI perforation, which might be life threatening and entail significant morbidity. Identification of patients at risk for perforation may promote the performance of pre-emptive surgical resection of the involved segment. Although computed tomography (CT) scan is widely used at diagnosis, incorporation of CT evidence into the risk stratification of perforation has not yet been performed.

Aims: To determine risk factors for perforation in patients with DLBCL and intestinal involvement, with an emphasis on CT findings.

Methods: A retrospective single center study, including all consecutive DLBCL patients that presented with intestinal involvement between 2005 and 2016. The analysis included clinical, laboratory, pathological and radiological parameters. Cases with DLBCL of the stomach were excluded.

Results: Forty-nine cases (30 men, 19 women) were included. Median age of the entire cohort was 64 years (54.7-77 IQR). Early stage (1, 2) according to the Lugano system was reported in 35% of cases. Small intestine involvement was reported more often than large intestine (67% vs. 23% and 16%, respectively). Forty-three (88%) patients underwent CT scan at diagnosis. Most lesions were defined radiology as concentric (n=27, 63%) (as opposed to eccentric), and transmural (n=31, 74%) (as opposed to non-transmural). Of note, 96.3% of the 27 concentric lesions were also transmural, compared with 96% in the eccentric lesions (P=0.005). Of the 27 concentric lesions, 6 of the perforations (60%) occurred within the first 21 days post therapy. All perforated lesions were eccentric and transmural, with a median length of 11.2 cm. Eight (80%) patients underwent an urgent operation due to GI perforation, including 3 that resulted in an ostomy. Perforation led directly to 2 (20%) deaths. Perforation resulted in delayed administration of chemotherapy in 50% of cases (n=5). A univariate regression analysis found a higher risk of perforation in patients presenting with a concentric lesion (P=0.001, HR=34.6, CI 25.9-53.3) and a transmural lesion (P=0.008, HR=1.06, CI 1.017-1.166). Each extra centimeter to the length of the GI segment involved was associated with a 6% increase in the risk for perforation. There was no association between sex, age, performance status, hemoglobin, LDH, albumin, iron, ferritin, KI67, disease stage, anatomical location nor the involved site wall thickness and risk of perforation.

Summary/Conclusions: DLBCL patients presenting with an involvement of a long intestinal segment, especially with a concentric, transmural lesion, are at higher risk for perforation. These patients should be considered for a preemptive surgical resection, dependent on lesion site and operative risk.

DOUBLE-HIT AND TRIPLE-HIT LYMPHOMAS: TREATMENT AND CLINICAL OUTCOME IN A SINGLE INSTITUTION

L. Martínez Serra1, E. Gimeno2, F. García Pallarós2, J. Vázquez3, B. Sánchez-González2, E. Abella1, A. Pedro3, A. Fener2, M. Ferraro2, I. Parraga1, B. Espinel2, C. Bassols1, L. Colomo2, A. Salas2

1Hematology department, Hospital del Mar, 2Hematology department, Hospital del mar, Barcelona. Grup de recerca aplicada en Hematologia PSMAR, 3Hematopathology United, 4Laboratori de citologia hematològica, Servei de Patologia, 5Laboratori de citogenètica, Servei de Patologia, Hospital del mar, Barcelona. Grup de recerca en Neoplasies Médiques (IMIM), 6Laboratori de Citogenètica. Servei de Patologia, Hospital del mar, Barcelona, Spain

Background: Five to 15% of patients with diffuse large B cell lymphoma (DLBCL) present MYC and BCL2 and/or BCL6 rearrangements which are detected by fluorescence in situ hybridization (FISH) or standard cytogenetic. This rearrangement defines a subgroup of DLBCL so-called double hit or triple hit lymphomas (DHL/THL) which are included in the 2016 WHO classification revision of lymphoid neoplasm in a new category “High-grade B-cell lymphoma with rearrangements of MYC and BCL2 and/or BCL6”. DHL/THL have an aggressive clinical course and poor response to standard chemotherapy and a median overall survival of 0.2-1.5 years. The best therapeutic option in these patients is not yet well established.

Aims: To evaluate retrospectively the incidence, clinical-biological characteristics, type of treatment, overall survival (OS) and progression-free survival (PFS) of patients diagnosed with DHL/THL and to compare them with patients with DLBCL without double/triple-hit genotype (DLBCL-noDHTH) in a single institution.

Methods: From January 2000 to April 2016, we analyzed 18 patients with DHL/THL and 312 patients with DLBCL-noDHTH. DHL/THL cases were identified using FISH for MYC, BCL2 and BCL6 rearrangements which are detected by fluorescence in situ hybridization (FISH) or standard cytogenetic. This rearrangement defines a subgroup of DLBCL so-called double hit or triple hit lymphomas (DHL/THL) which are included in the 2016 WHO classification revision of lymphoid neoplasm in a new category “High-grade B-cell lymphoma with rearrangements of MYC and BCL2 and/or BCL6”. DHL/THL have an aggressive clinical course and poor response to standard chemotherapy and a median overall survival of 0.2-1.5 years. The best therapeutic option in these patients is not yet well established.

Results: The incidence of DHL/THL was 5.5%. The median age was 70 years (range 53-93). The patients included in DHL/THL group had a higher prevalence of advanced disease and higher IPI (P=0.002). Thirteen patients received anthracyclines containing chemotherapy, 3 cidofovir reductive treatment and 2 palliative care. No stem cell transplantation was performed in any patient as a consolidation therapy. Four out of 13 patients achieved complete remission, 3 patients partial response and 6 patients were refractory. At last follow up, 13/18 patients were dead (11 lymphoma progression; 2 infectious complications). Median follow-up 63 months. OS in DHL/THL was 9 months and in DLBCL-noDHTH was not reached (P=0.001). The PFS in DHL/TH and in DLBCL-noDHTH was 5.4 and 63 months, respectively (P=0.001) (Figure 1).

Figure 1. Overall survival.
Summary/Conclusions:  1) The incidence of double or triple hit lymphomas in our institution is consistent with the literature.  2) The most common regimen used in double or triple hit patients was anthracycline-containing chemotherapy achieving more than 50% of overall responses in our series. Nevertheless, the majority of patients relapse, showing a short PFS and worse outcome than DLBCL without double or triple hit, as reported previously.

PB1727  EFFECTIVE TREATMENTS ARE REQUIRED FOR PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA WITH PRIMARY FRAYCTORARY DISEASE  M.Q. Salas1,2, D.D. Eva2, M. Santiago1, O. Ana1, C. Aguilera3, E. De la Banda4, F. Cimient3, N. Garcia Muñóz1, L. Anna1, F.D.S. Alberto1, S.B. Anna2, G.B. Eva2 1Hematology, ICO-Duran i Reynals, 2Hematology, ICO Duran i Reynals, 3Hematology, ICO-Duran i Reinals, 4Hematology, 5Pathological anatomy, Hospital Universitario de Bellvitge, 6Oncology Radiation Therapy, ICO-Duran i Reynals, Barcelona, Spain

Background:  DLBCL is a heterogeneous disease; it has been described that around 30% of patients present a refractory/relapsing disease following R-CHOP treatment. Rituximab-containing salvage chemotherapy followed by high-dose therapy and autologous stem cell transplant (ASCT) in chemoresistant patients remains the standard of care for these patients.  Aims:  We aimed to study the clinical features and outcome of patients diagnosed of DLBCL, homogeneously treated with R-CHOP/R-CHOP-like first line regimen, who have primary refractory disease (PRD).

Methods:  Three hundred and sixty-seven patients were diagnosed of DLBCL between January 2004 to August 2016 in our center: 317/367 (86.3%) were treated with R-CHOP or R-CHOP-like in first line. Forty-four (13.9%) patients had PRD and 39 (12.3%) progressed during the follow up. Survival curves were estimated using the Kaplan-Meier method and compared using the Log-Rank test. Univariate analyses were performed by Chi square test and multivariate analyses by Cox proportional hazard regression model.

Results:  Among the 44 primary refractory patients, 15 (34%), with a median age of 76 years (range 53-91), were considered unfit, 11 received supportive care and 4 were treated with palliative chemotherapy (cyclophosphamide and prednisone). Twenty nine (66%) were eligible for salvage therapy and consolidation with ASCT. Characteristics of those 29 patients at the time of salvage therapy were: median age 50 years (range 21-71), males 19 (65.5%), ECOG 2-4 16 (55.2%), Ann Arbor stage III-IV 23 (79.3%), B-symptoms 9 (31%), bulky disease (20.7%), extranodal involvement 20 (69%), leptomeningeal infiltration 4 (13.8%), high LDH 19 (65.5%), MIPI score was high in one patient (10%), intermediate in 5 patients (50%) and low in 4 patients (40%). Stem cell harvest was performed after 2 cycles. Survival follow up of 4 cycles. Successful mobilization was defined as achieving a CD34+ cell density of 2x10^6/kg. The G-CSF (Lenograstim) infusion started per protocol at day 6 at the dose of 5 μg/kg.

Results:  All patients completed the scheduled treatment (4 cycles). The ORR was 80%. CR 90% and PD 10% (1 patient). Overall, the rates of successful mobilization and the proportion of patients achieving a total PBSC yield of ≥2x10^6/kg were 100%, and the median PBSC yield was 10 x 10^6/kg (range 3-20x10^6/kg). The median time to stem cell harvest was 17 days (range 14-19). The median number of apheresis to achieve the PBSC target was 1 and only 1 patient (10%) required a second collection procedure. Plexiforax was not used. 80% of patients underwent high dose chemotherapy according to BEAM protocol (Fotemustine 150 mg/m² on days -7, -6, -4, 150 mg/m² on days 1-3, Cytarabine 70 mg/m² day 1, 2, 3, Etoposide 75 mg/m² day 1, Bendamustine 70 mg/m² day 2, 3, 4, Cytarabine 500 mg/m² day 2, 3, 4). 90% had a stage IV disease; MIPI score was high in one patient (1%), intermediate in 5 patients (50%) and low in 4 patients (40%). Stem cell harvest was performed after 2 cycles. Successful mobilization was defined as achieving a CD34+ cell density of 2x10^6/kg. The G-CSF (Lenograstim) infusion started per protocol at day 6 at the dose of 5 μg/kg.

Summary/Conclusions:  As in the relapsed/refractory setting and in MCL patients ineligible for high dose chemotherapy, RBAC has been proven to be an efficacious induction and mobilization regimen also in transplant eligible MCL patients with an encouraging safety profile. Further investigations are needed to assess the optimal role of RBAC within the standard first line treatments.
Aims: The objective of this retrospective, observational study is to evaluate the efficacy and safety of liposomal cytarabine in patients with CNS infiltration by haematological malignancies.

Methods: 36 consecutive patients with haematological disease and risk of CNS infiltration underwent flow cytometry (FC) analysis of CSF in a single center from December 2014 to December 2016. CNS involvement was assessed by standard CT/MRI examination, 8-color flow cytometry or MRI imaging. Along with systemic therapy, all patients considered positive were treated 50 mg of IT Liposomal cytarabine administered by lumbar puncture every 2 weeks for 4 doses and every 4 weeks thereafter. Concomitant dexamethasone for arachnoiditis prophylaxis was added both i.v. and IT. We analysed the rate of adverse events (AE) and the time for CSF clearance. Short follow up precluded assessment of cumulative incidence of CNS relapse/progression.

Results: Data from 36 patients were analysed. A total of nine patients were considered to have CSF involvement, all of them detected by FC. Of note, all of them were considered negative for CSF infiltration by standard cytology. Three additional patients received IT therapy as second line therapy after MRI positive brain involvement by the malignancy. The median age of this 12 patients was 52 years (range 16-69). 58.3% were female. Diagnosis were B-cell lymphoproliferative disorder 41.7% (CLL, Burkitt, DLBCL), ALL 25%, AML 25% and multiple myeloma 8.3%. The median number of doses per patient was 6.5 (SD 1.7). CSF clearance was achieved after a median of 1 dose (range 1-3) or 20 days (range 16-86). Overall rate of CNS response was 100%. Two patients (16.7%) had leptomeningeal reactivation during the IT treatment. The overall AE incidence was 66.7%. The most common AE include: headache, peripheral sensory neuropathy, back pain and nausea. Severe neurotoxicity has been encountered in four patients: caudal equina syndrome and peripheral neuropathy (3 patients) and arachnoiditis (1). Treatment had to be discontinued in 3 patients because of side effects but this did not lead to relapse. The median time to AE occurrence was 6 cycles (range 4-7) or 110 days (range 33-227). The incidence and severity of AE seemed to increase with the cumulative number of cycles administered. In most patients neurological complications were associated with initiation of IT therapy.

Summary/Conclusions: use of liposomal formulation of cytarabine for IT administration has become an effective option for the treatment of leptomeningeal involvement by haematological malignancies. Neurological AE are reversible; however, they accumulate and worsen with time, thus precluding long-term use.

PB1730
RETRORSPETIVE ANALYSIS OF OUTCOMES FOR ELDERLY PATIENTS WITH STAGE 3 AND 4 DISEASE HIGH-GRANDE DLBCL WITH REDUCED CYCLES OF R-CHOP OR R-GCVP: A 7 YEARS SINGLE-INSTITUTE EXPERIENCE

K. Joshi1, K. Leung2, C. Page2, A. Rajic3, F. Masiern4, N. Gill5, J. Morgan2, A. Hodson1, M. Prahalad1
1Haematology, Ipswich Hospital/ Addenbrookes Hospital, Cambridge, 2Haematology, Ipswich Hospital, 3Molecular Biotechnology Unit., University of Suffolk, Cambridge, United Kingdom

Background: The most common high-grade lymphoid malignancy in adults is Diffuse Large B-Cell Lymphoma (DLBCL), which has an increasing incidence with age (1). Over 40% of patients with DLBCL are above the age of 70, and the co-morbidities in this age-group present significant challenges and complexities with regards to selecting and implementing treatment regimens (2).

Aims: We present a retrospective analysis of outcomes for patients with high-grade DLBCL (stage 3 or 4 disease) who have received fewer than 6 cycles of full-dose R-CHOP or R-GCVP because of poor tolerability or disease progression with treatment.

Patients and Methods: Retrospective data were collected from the cancer registry for all newly-diagnosed DLBCL patients who received R-CHOP or R-GCVP chemotherapy, with data collected from Jan 2010 to Feb 2017 from Ipswich Hospital NHS Trust, United Kingdom. Patients who completed 6 cycles of chemotherapy were excluded. Interim PET-CT scan/staging CT scan was done to assess the disease response to therapy after 2 cycles of chemotherapy. The main baseline characteristics collected were age, sex, ECOG Performance Status, Ann-Arbor Stage and IPI risk stratification. The primary end point was progression free survival (PFS) and the secondary endpoints were overall survival (OS) and the reasons for premature ceasing of treatment based on graded toxicity according to NCI-CTCAE 4.0.

Results: Out of 87 patients, 12 patients were identified that fulfilled the inclusion criteria. The median age of patients was 72 years (range: 64-88 years), sex distribution was 7 male: 5 female, ECOG PS was 0-2 in 10 (83%) and ≤3 in 2 (17%) of the patients, Ann-Arbor Stage was 3 in 6 patients (50%) and 4 in 6 patients (50%), and IPI score was 3 in 12 all patients. 11 patients received R-CHOP and 1 patient received R-GCVP. The median length of treatment was 3.5 years (range: 2-8 years). The overall survival rate was 50% at 12 months assessment and 75% at end of treatment assessment scan. The complete and partial response rates at the end of the treatment were 58% and 17% respectively. Progression free survival was 73% at 2 years (8 out of 11 patients) and 50% at 3 years (4 out of 8 patients). The median overall survival of deceased patients (out of 12) was 9.5 months (range: 2-42 months) and the median overall survival of living patients (8 out of 12) is at 40.5 months (range: 27-84 months). The most common reasons for stopping the treatment were intolerance of side-effects (4 out of 12) or neutropenic sepsis (3 out of 12). 2 out of 12 patients received an incomplete course of chemotherapy due to non-responsive progression of disease with treatment.

Conclusions: DLBCL treated with less than 6 cycles of full dose R-CHOP or R-GCVP chemotherapy may achieve sustained long-term remission in selected patients with high IPI and significant co-morbidity. Further research on disease characteristics including molecular profile is needed to elucidate selected populations who may achieve long-term remission with shorter cycles of chemotherapy. Further insights may derive, for example, from analysis of polymorphism of folate pathway genes and/or of NF-kb, which have been previously suggested as pharmaco-genomic targets in lymphoid neoplasm. A risk stratification model needs to be developed to reduce drug toxicity and other short and long term treatment related complications so as to improve patient experience, and pharma-economic benefits.

PB1731
MULTIPLE NEOPLASMS CONSIST OF SOLID CANCER AND NON-HODGKIN LYMPHOMA

K. Natori1,*, D. Nagase1, S. Ishihara1, A. Shibuya1, Y. Mitsui1, Y. Kuraishi1, H. Izumi1
1hematology and Oncology, Toho University Medical Center, Oota city, Japan

Background: Malignant lymphoma is a ninth cause of death in Japan. And non-Hodgkin lymphoma(NHL) occupied more than 90%. We experienced cases and will report that we reviewed multiple neoplasms consisting non-Hodgkin lymphoma. We experienced 176 cases.

Aims: We aimed for epidemiology and prognosis improvement of malignant neoplasms including NHL. We want to look for a hint of the early detection.

Methods: We intended for multiple neoplasms 340 cases including hematological malignancy. We reviewed 190 cases of multiple neoplasms including malignant lymphoma. In 190 cases, NHL case were 176 cases. The examination factors are type of the hematological malignancy, gender, the age at onset of the first cancer, interval with the second cancer, treatment strategy. The definition of multiple neoplasms followed Warren & Gates theory. And as for the definition of synchronous cancer, synchronous was defined as an interval less than 6 months, metachronous type interval is more than 6 months. About statistical examination, we used SPSS statistics ver21.

Results: All cases are 176 cases, consist of male 108 cases, female 68 cases, synchronous type 45 cases, metachronous type 131 cases. Double neoplasms 149 cases, triple neoplasms 25 cases, quadsple neoplasms 2 cases. The median age was 7yrs (ranged51-93yrs), the synchronous type 70yrs(ranged 51-88yrs), the metachronous type was 73yrs(ranged 57-93yrs). The counterpart of malignancies, Hodgkin’s lymphoma 1 case, myelodysplastic syndrome 3 cases, acute myeloid leukemia 8 cases, multiple myeloma 4 cases, gastric cancer 36 cases, colon cancer 32 cases, lung cancer 26 cases, renal cell carcinoma 6 cases, prostate cancer 12 cases, breast cancer 14 cases, urinal bladder cancer 5 cases, uterin cancer 7 cases, esophageal cancer 9 cases, hepato-tellar carcinoma 12 cases. In double neoplasms was 149 cases, metachronous type was 112 cases. The median age of first diagnosis, 68yrs(ranged43-85yrs), the second cancer were 74yrs(ranged57-89yrs). About interval between solid cancer and NHL, median interval time was 58M, solid cancer precede case was 53 cases, interval was 81M (ranged 7-564M), hematological malignancy precede case was 59 cases interval was 55M (ranged 8-364M). The cause of death was that 15 cases were solid cancer, 72 cases were hematological malignancy and 6 cases were accident. The median overall survival was 18M (ranged 1-121M), synchronous type 14M(range 2-132M), metachronous type 22M (ranged1-116M).

Summary/Conclusions: In the case of a double cancer including solid cancer and NHL, the first cancer occurs in elderly. Diagnosis of malignant neoplasms and NHL are 149 cases(32.2%). The important point is that 3 years are required for careful observation at the time of malignancy diagnosis. It is necessary to discover at the early stage. So it could be a lot of treatment options formalneoplasm. We think that a prognosis is improved.
phomas (DHL) and double or triple-protein-expression lymphomas (DPLs, TPLs) display a worse outcome. R-CHOP, which is the frontline treatment for DLBCL, showed a poor outcome in high risk IPI patients and DHLs or DPLs. From January 2011 in our centre (IRCCS AOU San Martino Hospital–IST, Genoa, Italy) R-CODOX-M/IVAC regimen has been adopted as first line in patients with aggressive DLBCL, defined by at least one among these features: higher tumor burden, DPLs, IPI score >3 or by the presence of at least 1 extra nodal site.

**Aims:** Our aim was to define the efficacy and feasibility of this frontline strategy and eventually identify the subgroups of patients who may benefit from this approach.

**Methods:** We retrospectively analyzed 20 patients affected by aggressive DLBCL treated with R-CODOX-M/IVAC. R-CODOX-M consists of rituximab 375 mg/m2 day 1, cyclophosphamide 800 mg/m2 day 1, 200 mg day 2-5, doxorubicin 40 mg/m2 day 1, vincristine 1.4 mg/m2, methotrexate 6700 mg/m2. IVAC-R contains rituximab 375 mg/m2, ifosfamide 1500 mg/m2 day 1, etoposide 1000 mg/m2 day 1-3, cytarabine 2000 mg/m2 bid day 1-2. In both cycles CNS prophylaxis was administered. According to Ann Arbor classification, 11 patients were on stage IV, 1 on stage III, 3 in stage I I and 5 in stage I. Twelve patients had B symptoms. Median IPI score was 3. Eleven patients had DPLs and 4 of them had TPLs. Overall survival (OS) was calculated from the time of diagnosis to the time of death or last follow-up.

**Results:** After a median follow-up of 28 months, 5 patients died (25%). OS at six and twelve months was 89.4 and 70.4%, respectively, median not reached (NR). Complete remission was achieved in 11 patients (55%), partial remission in 2 patients (10%). The overall response rate was 82%. Three patients (18%) went on to receive involved field radiation therapy. OS 12 months was 88.9 and 64.8%, respectively, not significantly lower than non DPLs patients (p=n.s., median NR). In patients with Ann Arbor stage III or IV, OS at six and twelve months was 90.9 and 80.6% (median NR). In patients with IPI score >3, OS at six and twelve months was 78.6 and 45% (median 12 months). The main toxicity during CODOX-M was grade >2 mucositis, 63% of patients. Infections occurred in 71% of patients. Renal and liver toxicity was mainly of low grade and was observed respectively in 38% and 50% of patients. Median severe neutropenia was 4.5 days (range 0-16) and median severe thrombocytopenia was only 1 day (range 0-21). Most patients (56%) needed transfusion support. In IVAC regimen the main toxicity was the hemorrhagic colitis with 7 days of median duration of severe neutropenia (range 3-10), and 7 days (range 6-23) of thrombocytopenia. Seventy-five patients required transfusion support. Infections occurred in 42% of patients. We observed few case of grade >2 mucositis (17%), renal toxicity (8%) and liver toxicity (17%).

**Summary/Conclusions:** R-CODOX-M/IVAC is a generally well tolerated regimen, with acceptable toxicity profile in the setting of aggressive DLBCL. Results in our cohort support a potential benefit for DPLs, whereas higher IPI scores retain a negative prognostic impact. The next step of the study will be retrospective FISH evaluation of C-MYC, BCL2 and BCL6 translocations, for lacking patients in our cohort, in order to disclose a potential benefit for double or triple hit lymphomas.

**PB1734**

**STOMACH DIFFUSE LARGE B-CELL LYMPHOMA: A SINGLE CENTER EXPERIENCE**

M.-T. Sung1,*, L.-W. Chiou1, S.-N. Huang2, A.-C. Feng2, M.-C. Wu1, P.-Y. Chen1, C. Hsiao-Hsiang 1, T.-D. Tan1
1Department of Hematology and Medical Oncology, 2Office of Epidemiology and Biostatistics, Koo Foundation Sun Yat-Sen Cancer Center, Taipei City, Taiwan, Republic of China

**Background:** Primary gastric diffuse large B cell lymphoma is a relative rare type of diffuse large B cell lymphoma. Immunohistochemistry followed by consolidation radiation is the standard of care. However, the cycles of chemotherapy and the role of consolidation radiation are still under debate.

**Aims:** To review and analyze the treatment experience of newly diagnosed primary gastric diffuse large B cell lymphoma. We presented the treatment outcome of our institution.

**Methods:** We retrospectively reviewed medical records from Jan 2005 to Dec 2014 from our institution. 30 patients with primary gastric diffuse large B cell lymphoma were included. Clinical characteristics, treatment regimes, treatment response, treatment modality, and survival were analyzed.

**Results:** From Jan 2005 to Dec 2014, there were 30 patients with primary gastric diffuse large B cell lymphoma. Median age was 65 years of age. 53% (n=16) of patients were male. All 30 patients (100%) have received chemotherpay. 13 of them (43%) have received involved field radiation therapy (IFRT), RCHOP or RCEOP was administered in 86% (n=26) of patients. Complete response (CR) rate was 80% (46/58), 5-year survival was 69%. In patients who achieved complete remission (CR), 6 cycles of consolidation chemotherapy were recommended in 86% (46/58), 5-year survival was 69%. In patients who received consolidation chemotherapy, 6 cycles of chemotherapy were recommended in 86% (46/58), 5-year survival was 69%. In patients who achieved complete remission (CR), 7 cycles of consolidation chemotherapy were recommended in 86% (46/58), 5-year survival was 69%. In patients who received consolidation chemotherapy, 7 cycles of chemotherapy were recommended in 86% (46/58), 5-year survival was 69%.

**Summary/Conclusions:** In our series, the 5-year survival was good. In patients who achieved CR, cycles of chemotherapy and consolidation radiation did not make significant difference to the survival. Prevention of early mortality may improve the outcome of this disease. Gastrointestinal bleeding in treatment is rare but with high mortality.

**PB1735**

**IMMUNOHISTOCHEMISTRY BIOMARKERS IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA: A RETROSPECTIVE STUDY**

T. Mendes1,*, F. Mousinho1, P. Sousa E Santos1, E. Viegas2, A. P. Gomes1, F. Falcão2, F. Lima1
1Clinical Hematology, 2Pharmacy Department, Faculty of Pharmacy, University of Lisbon, Hospital de São Francisco Xavier, Centro Hospitalar de Lisboa Ocidental, Lisbon, Portugal

**Background:** Diffuse Large B-cell Lymphoma (DLBCL) is a heterogeneous hematological disease characterized by genetic and immunohistological features. The International Prognostic Index (IPI) is the most important tool to identify subgroups with different survival, however, certain biological markers seem to have a prognostic value relevant and independent of IPI.
Aims: To analyze the evolution of patients diagnosed with DLBCL and the expression of BCL2, BCL6 and MYC.

Methods: We conducted a retrospective study that included hospitalized patients with *de novo* CD20+ DLBCL, with expression of BCL2+, BCL6+, BCL2/BCL6, MYC/BCL2, MYC/BCL6 treated with regimens containing rituximab, from February 2012 to November 2016. Samples were analyzed by immunohistochemistry. Statistical analysis with the SPSS V17.0 program.

Results: We included 43 patients with a median age of 65 years (22-97), 59.5% male, 45.2% had IPI 0-2, 54.8% had IPI 3-6, 26.2% stage I, 73.8% stage III-IV, 61.9% had extranodal disease and 23.8% bulky disease. Ki-67 was elevated in all patients who did this examination (n=28). In 13 patients was identified BCL2+, BCL6+ in 6, and 21 patients had co-expression of BCL2/BCL6. 1 patient had MYC/BCL2 and 1 had MYC/BCL6. The R-CHOP regimen was first-line treatment in 92.8% of patients. The ORR was 82.5%, with 65% of CR, 15% PR and 17.5% PD. Of those patients who received second-line treatment, 8 expressed BCL2/BCL6, 4 BCL2, 2 BCL6, 1 MYC/BCL2, and 1 MYC/BCL6. Of those patients who received surgery, 8 patients with lymph nodes had complete remission. In 2 patients the disease progressed (one with BCL2+ BCL6+, 1 and 1 MYC/BCL6. The average time to next treatment (TNT) was 5.2 months (0.5-19) for second-line and 4.9 for third-line. Mortality rate was 45.2%. With a median follow up of 18.6 months (3-58.6), the overall survival was 24.6 months (3-62).

Summary/Conclusions: The identification of biomarkers by immunohistochemistry is a relatively inexpensive process, which, when well elaborated and interpreted, allows to find in a safe way, subgroups of patients at high risk, who benefit from more aggressive 1st line therapy and, whenever possible, from the Inclusion in clinical trials with new drugs.

**PB1736**

**INVESTIGATION ON TREATMENT STRATEGY, PROGNOSTIC FACTORS, AND RISK FACTORS FOR EARLY DEATH IN ELDERLY TAIWANESE PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA**

S.-F. Cho1,*, Y.-C. Liu1, H.-H. Hsiao1, Y.-F. Tsai1, H.-C. Wang1, T.-C. Liu1

1Division of Hematology and Oncology, Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung City, Taiwan, Kaohsiung City, Taiwan, Republic of China

Background: Given that the population of elderly cancer patients, including those with diffuse large B-cell lymphoma(DLBCL), is increasing, the management of cancer in the elderly has emerged as an increasingly common problem. Aims: This study aimed to investigate the treatment strategy, prognostic factors, and risk factors of early death in elderly patients (age ≥65 years) with DLBCL in the rituximab era.

Methods: Elderly patients diagnosed with DLBCL between 2008 and 2014 were enrolled for analysis.

Results: There were 145 elderly patients with DLBCL diagnosed between 2008 and 2014. After excluding patients with primary central nervous system DLBCL (n=9) and incomplete data (n=3), a total of 133 patients (64 male and 69 female) with a median age of 74 years (range 65 to 94 years) were enrolled in the present study. Patients at a younger age and with better performance status were more likely to receive intensive frontline treatment. The median progression-free survival (PFS) and overall survival were 15 and 21 months, respectively. Anthracycline-containing chemotherapy achieved a higher remission rate and showed a trend toward better overall survival at the expense of a higher risk of severe neutropenia. Multivariate analysis revealed that very old age (≥81 years), a high-risk age-adjusted international prognostic index (aIPI) score, and bone marrow involvement were associated with poorer PFS and overall survival. Progression of lymphoma was the major cause of death in the study population. In addition, approximately 25% of patients died within 120 days of their diagnosis. The risk factors for early mortality included very old age, a high-risk aIPI score, and bone marrow involvement. The appearance of symptoms or signs of tumor lysis syndrome at diagnosis was associated with a trend toward early death.

Summary/Conclusions: Treatment of elderly patients with DLBCL remains a challenging task. As the understanding and comprehension of the disease have increased, early diagnosis and the tailored therapeutic interventions and offer the best supportive care may reduce complications and improve the clinical outcome of these patients.

**PB1737**

**TREATMENT OUTCOME OF MONOMORPHIC EPITHELIOPTHROPIC INTESTINAL T-CELL LYMPHOMA: EXPERIENCE FROM AN ASIAN CANCER CENTER**

M.-T. Sung1,*, M.-Y. Lee2, M.-C. Wu1, T.-D. Tan1

1Department of Hematology and Medical Oncology, 2Department of Pathology and Laboratory Medicine, Koo Foundation Sun Yat-Sen Cancer Center, Taipei City, Taiwan, Republic of China

Background: Monomorphic epitheliotropic intestinal T-cell lymphoma (MEITL), previously type II enteropathy-associated T-cell lymphoma(ENTERAL), primarily occurred in Asian countries. It is refractory to chemotherapy and the prognosis is poor. Intensive chemotherapy has been proposed to improve treatment outcomes.

Aims: We examined the treatment outcome of MEITL in our institution.

Methods: We retrospectively searched our institutional database from 1996 to 2014 for intestinal T-cell lymphoma. Medical records were reviewed and the patients were classified on the basis of WHO-2016 classification. Patient’s characteristics, treatment modalities, response and survival were collected and analyzed.

Results: Ten patients with intestinal T-cell lymphoma were identified. One patient had enteropathy-associated T-cell lymphoma (EATL) presenting with celiac sprue. Five patients had intestinal T-cell lymphoma, NOS. Four patients were diagnosed (pathologically epitheliotropic intestinal T-cell lymphoma (MEITL). For patients with MEITL, median overall survival was 7.9 months (4.2-15.0 months). Median age was 46 years of age. Bowel perforation was the initial presentation in 3 patients (3/4, 75%). One patient was treated with chemotherapy with CHOP regimen, while another patient underwent surgery alone. The remaining two patients of MEITL received surgery followed by chemotherapy (one with CHOP, the other with BFM-90 protocol). Only one patient (1/4, 25%) entered complete response. Of concern, the unique patient achieved complete response received surgery followed by chemotherapy with Berlin-Frankfurt-Munster(BFM)-90 protocol. Remission duration was 10.3 months. He passed away 15.0 months after remission because of relapsed lymphoma.

Summary/Conclusions: Though the prognosis of MEITL is poor, operation followed by high dose chemotherapy such as BFM-90 protocol may have better treatment response, response duration and survival. It deserves further investigation.
7 (28%) in group 1 and 2 in group 2 (15.4%) (p=0.39). Overall response rate was 9 (36%) in group 1 and 8 (61.5%) in group 2 (p=0.13). A Kaplan Meier curve of all 3 groups is illustrated in Figure 1 below.
gress. We believe that the determination of vitamin D levels should be routinely included in the diagnosis in patients with NHL-B because it could be a modifiable factor. At this time, the monitoring period is not completed, so the data related to those patients in whom the vitamin deficit persisted despite the treatment is still not available. It would be interesting to see if further work with larger numbers of patients would support this. Since this audit was completed, the ePrescribing system has been altered to improve practice and a re-audit is planned.

PB1741

IMPLICATION OF BASIC VALUES OF VITAMIN D IN THE CLINICAL COMPLICATIONS OF PATIENTS WITH NON-HODGKIN LYMPHOMA IN ACTIVE CHEMOTHERAPY TREATMENT

R. Martos1,2, D. Villalba1, M. Yuste1, L. Bermejo2, A. Pascual2, P. Belmonte2, N. Patrignani2, P. Llamas3
1Hematology, Hospital General VilaReal, Collado VilaReal, 2Hematology, Hospital Universitario “Infanta Elena”, Valdemoro, 3Hematology, Hospital Universitario “Fundación Jimenez Diaz”, Madrid, Spain

Background: The incidence and prevalence of Non-Hodgkin’s Lymphoma B (NHL-B) has increased in recent years, reaching approximately 3-7 cases / 100,000 habitants for this reason, the number of patients who receive chemotherapy treatment is also considerably higher; this implies a greater presence of adverse events. In many of these patients, baseline vitamin D levels at the time of diagnosis are decreased, and may be related to the development of the tumor pathology, also to the severity of the adverse events.

Aims: To assess the implication of vitamin D values in the development of relevant clinical complications in patients diagnosed with NHL-B receiving chemotherapy. To determine its clinical evolution after correcting the vitamin D deficit.

Methods: Retrospective study (January 2013-June 2017), which includes patients diagnosed with NHL-B with histological confirmation. We analyze demographic parameters (age, sex), histological subtype of NHL-B according to WHO classification, laboratory values of vitamin D (cut-off values: optimal 25-66 pg/mL; low 25-18 pg/mL or very low <18 pg/mL), adverse effects: hematological toxicity, infection, gastrointestinal toxicity, hospital admissions and exitus. A subanalysis of complications was performed in patients with vitamin D deficiency.

Results: 68 patients were analyzed, and 57 cases (84%) were valid because they had vitamin D determination in the 8 weeks near the diagnosis. The distribution was: 58% (n=39) vs 42% (n=24), with median age 59 years (range: 29-91 years). The subtypes of LNHB-B: Follicular (n=23(40%)), Diffuse large cell (n=21(37%)), Mantle n=16(11%), Marginal n=4(7%) and others n=3(5%). Patients were included in 3 groups according to serum vitamin D levels: patients with optimal levels (n=23;40%), low levels (n=27; 48%) and very low levels (n=7;12%). Hematological toxicities were higher for the subgroup with decreased vitamin D levels vs subgroup with level in range (28% vs 72%) (p<0.01). Neutropenia was more severe (grade>2) in patients with very low levels of vitamin D (p<0.01). No patient with optimal vitamin D levels had severe anemia (Hb<8 g/dl) or thrombocytopenia (<70,000/mm3), in relation to 28 cases of severe toxicity diagnosed in vitamin D deficient groups. In this group were documented the two infections of the study (both pneumonias), a gastrointestinal toxicity, hospitalizations for complications (60%) and only one exitus. After treatment, it was found that 74% (n=25 patients) corrected levels, presenting a lower incidence of toxicity to the treatment vs. 26% (n=9) who did not correct levels and presented more complications (especially hematological toxicity) more complex and durable.

Summary/Conclusions: Vitamin D deficiency in the diagnosis of patients with NHL-B has been correlated with a higher incidence of medical complications due to the treatment of chemotherapy. In our series, patients had greater hematological toxicity and greater severity (p<0.01), more infectious episodes and a higher hospital admission rate. These adverse effects are even more pronounced in the lower vitamin D levels (18 pg/mL). A study conducted by Drake et al. (JCO, 2010) on 980 patients presents similar data, with a significantly higher incidence of complications in vitamin D deficient patients. After treatment with vitamin D, patients who corrected levels had a more favorable evolution with fewer hematological and infectious complications (p<0.01) in relation to those patients in whom the vitamin deficit persisted despite the treatment. At this time, the monitoring period is not completed, so the data related to OS and SLE still have to be updated and will be presented at the next congress. We believe that the determination of vitamin D levels should be routinely included in the diagnosis in patients with NHL-B because it could be a modifiable risk factor in the complications of this patients.
GLOBAL HEMOSTATIC ASSAY AT DIFFERENT TARGET ACTIVITY OF FACTOR VIII AND FACTOR IX
K. Yoo
Korea Hemophilia Foundation, Seoul, Korea, Republic Of

Background: Based on reports addressing hemophilia B patients bleed less common and less intensively than hemophilia A, it has been expected that the hemostatic level of factor IX (FIX) activity can be lowered than that of factor VIII (FVIII) activity.

Aims: We compared the hemostatic efficacy of the different hemostatic level of FIX and FVIII activity using global hemostatic assay.

Methods: A total of 17 severe hemophilia patients without inhibitor, aged more than 15 years were subject; 12 hemophilia A patients and 7 hemophilia B patients. Factor concentrates were injected to reach the target activity of 80% in hemophilia A and 40% in hemophilia B which is given by Korean health insurance guideline. All patients were in non-bleeding state and kept the wash-out period of 3 days for hemophilia A and 5 days of hemophilia B. Before and on 15 minutes after injections, we conducted one-stage factor assay, thrombin generation assay (TGA), thromboelastography (TEG) and clot-wave form analysis (CWA).

Results: Median ages of hemophilia A and hemophilia B patients were 28 and 33 years old. Baseline FVIII:C and FIX:C were 0.6% and 1.8% and they rose after injection rose to 70.8% and 49.8%. The dosage of FVIII concentrates and recombinant FIX concentrates were 28.4 IU/kg and 50.7 IU/kg. In vivo recovery (IVR) in hemophilia A and hemophilia B patients recorded 2.43% IU/kg and 0.91% IU/kg. Peak thrombin of FVIII and FIX were 451.3 nM and 376.6 nM (P=0.108, normal range, 458 nM±60). TEG index of FVIII and FIX were -1.60 and -3.77 (P=0.004, normal range, -2.2±2). MIN2 of CWA of FVIII and FIX were 0.62 and 0.59 (P=1.000).

Summary/Conclusions: Global hemostatic assay indicates even though IVR of FVIII and FIX are normal, less amount of FIX is insufficient to normalize hemostatic parameters in comparison with FVIII.

THE RATE OF SUCCESSFUL IMMUNOTOLERANCE INDUCTION IN HAEMOPHILIA A BOYS TREATED WITH OCTOCOG ALFA - THE EXPERIENCE OF POLISH PAEDIATRIC HAEMOPHILIA CARE CENTRES
K. Koltan1,2, A. Klukowska3, P. Laguna3, W. Badowska5, W. Balwierz5, G. Karolczyk5, D. Pietrys1, H. Bobrowska1, M. Kozstrzewski5, T. Ociepa8, T. Urasinski5, I. Woznica-Karzonczak1,11

Background: Development of neutralizing anti-factor VIII alloantibodies (inhibitor; INH) is the most challenging complication of haemophilia replacement therapy (HRT). It occurs in up to 30% of severe haemophilia A (HA) patients. Data published recently indicate that immunotolerance induction (ITI) is effective in 62–75% of cases.

Aims: To assess the rate of successful ITI in boys with severe HA treated with full length recombinant FVIII (octocog α) in all Polish Paediatric Haemophilia Care Centres between 2011-2016.

Methods: From 2011 to 2016 in all Polish Paediatric Haemophilia Care Centres between 2011-2016. In the period 2011-2016 the number of treated patients aged below 16 years old: 155 boys with severe HA on prophylaxis or on demand treatment with octocog α developed INH after 3 - 489 (median 20) exposure days (EDs). Twelve of them (85.7%) were high responders with the peak inhibitor titre (PIT) 5.88 - 716.8 (median 20.1) BU/ml. Two patients were low responders (14.3%) and had PIT 2.8 and 3.02BU/ml. All except one boys were Caucasians and had normal platelet counts. One patient who didn’t start prophylaxis with activated prothrombin complex concentrate (APCC). The remaining 3 patients are still on ITI. All 7 patients after successful ITI were started prophylaxis with activated prothrombin complex concentrate (APCC).

Results: Median ages of hemophilia A and hemophilia B patients was 28 and 33 years old. Baseline FVIII:C and FIX:C were 0.6% and 1.8% and they rose after injection to 70.8% and 49.8%. The dosage of FVIII concentrates and recombinant FIX concentrates were 28.4 IU/kg and 50.7 IU/kg. In vivo recovery (IVR) in hemophilia A and hemophilia B patients recorded 2.43% IU/kg and 0.91% IU/kg. Peak thrombin of FVIII and FIX were 451.3 nM and 376.6 nM (P=0.108, normal range, 458 nM±60). TEG index of FVIII and FIX were -1.60 and -3.77 (P=0.004, normal range, -2.2±2). MIN2 of CWA of FVIII and FIX were 0.62 and 0.59 (P=1.000).

Summary/Conclusions: Global hemostatic assay indicates even though IVR of FVIII and FIX are normal, less amount of FIX is insufficient to normalize hemostatic parameters in comparison with FVIII.
PB1746
SINGLE CENTRE FX DEFICIENCY EXPERIENCE
Z. Basilar1,*, S. Sadri1, I. Erdogan1, M.G. Ar1
1Internal medicine- Hematology, Istanbul University, Cerrahpasa Medical Fac-
ulty, Istanbul, Turkey

Background: Factor X is a vitamin K-dependent serine protease that works at the crossroads of the extrinsic and intrinsic pathways to cleave prothrombin into thrombin. Inheritance pattern of factor X deficiency is autosomal recessive, with heterozygote patients most often remaining asymptomatic or having only a mild bleeding phenotype. 1) Homozygous individuals may experience haemorrhagic symptoms, including easy bruising, haematuria, soft-tissue haemor-
rhages, haemarthroses, recurrent epistaxis, and menorrhagia (2) Congenital factor X deficiency is among the most rare factor disorders. We present here our experience with patients having congenital factor X deficiency.

Aims: We aimed to present our experience with rare FX deficiency in our centre.

Methods: There are currently 4 patients with factor X deficiency (F/X: 3/1) that are followed at our centre.

Results: First patient is 40 years old man who got his diagnosis at the age of 31 years following a gastrointestinal bleeding. He was treated with fresh frozen plasma (FFP) at that time. His FX was found: 5.0. Two years later underwent a planned tooth operation under the coverage of prothrombin complex concentrate (PCC) (Table 1). Three years after the tooth extraction he underwent an intraocular lens operation under PCC prophylaxis. No complication was observed while on PCC treatmet.

Our second patient is a woman who was diagnosed at the age of 3 because of recurring gum bleeding. She has been treated with FFP replacement throughout her childhood and adolescence due to recurring nose and soft tissue bleeds as well as menorrhagia. She was first referred to our hospital at the age of 42 due to soft tissue bleeding. Given the lack of health insurance she mainly received FFP and tranexamic acid tablets during most of her bleed-
ing attacks. However, PCC of 1000 unit for two days had to be used for her excessive vaginal bleeding irrespective to FFP. Her number of annual bleeding is 15-20 times in a year and most of them are gum bleeding and rarely vaginal bleeding. Third and 4th patients were referred to our centre because of pro-
longed the prothrombin time (PT) and the activated partial thromboplastin time (aPTT) and received the diagnosis of FX deficiency.

Summary/Conclusions: Bleeding phenotype differs in a wide range in patients with congenital FX deficiency. Secondary causes including amyloidosis should be excluded especially in patients receiving diagnosis at advanced ages. Usually the factor level does not correspond to the severity of the bleeding ph-
notype. Therefore bleeding pattern of the patients with FX deficiency should be carefully observed and considered while planning a prophylactic treatment with PCCs to prevent the risk for thrombosis and unnecessary utilisation of PCCs. FFP and PCCs replacement continue to be the source for FX in bleeding patients or in individuals requiring prophyllaxis. Recently, a FX concentrate has entered the market in the USA and the European Community.

PB1747
IMPROVEMENT OF THE SURVIVAL FOR LIFE-THREATENING HEMORRHAGE WITH HEMOPHILIA PATIENT
K.S. Lee1,*, J.Y. Kim2, J.K. Seo2, S.Y. Hyun3
1Division of Pediatric Hematology, 2Department of Pediatrics , Dr. Behçet Uz Children’s Hospital, Daegu, 3Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Korea, Republic Of

Background: In life threatening hemorrhage such as brain and abdomen, sev-
eral important factors are affect for improving the survival. One tenth (223) of hemophilia patients in Korea lived in Daegu city and Kuyngpook province and have been treated in one treatment center.

Aims: We reviewed the result of life threatening hemorrhage and our unique care of hemophilia patients for 34 years.

Methods: Korea Hemophilia Foundation was established in 1991. After that all factor concentrates were free to all hemophilia patients. Home treatment were available for rapid administration of factor concentrate of full required amount. Rapid transportation to emergency room are available for immediate operation. Hot line of mobile phone between patient and doctor for 24 hours are available for emergency care. Monthly group education has done. Prophyl-
lytic treatment was started to all who had a life threatening hemorrhage history in 1996. But HIRA permitted officially since 2011.

And then recovery rate test was done for the optimal blood level for life threat-
ening hemorrhage patient. Continuous infusion with every 2 to 4 hours recon-
stitution dilution fluid has been done for preserve in vitro factor activity to all surgery cases.

Results: Thirty five events were intracranial hemorrhage in 17, general surgery in 9 and orthopedic surgery in 9. Age distribution was 0-32 yr (mean; 24.8 yr). Severity was severe (16), moderate (7) and mild (5). Time interval between first symptom and arrival at ER were 15 min to 10 days (mean; 1.7days). We confirmed in vivo factor activity within permissible level in all patients. All recov-
ery from hemorrhage or surgery and are healthy, but one had limping gate and one had mild neurologic sequelae for more than 10 years follow-up period.

Summary/Conclusions: Education, financial support, home and prophylactic treatment, hot-line, individual pharmacokinetics with effective blood level and fresh concentrate during continuous infusion are important factors to improve the survival of surgery case.

PB1748
CAN BLEEDING SCORE AND FACTOR LEVELS DETERMINE HEMOPHILIA CARRIERS?
Y. Ay1,*, A. Çakıl2, S. Okur Acar1, E. Töret3, T. Hilkey Karapınar1, Y. Oymak1, S. Güzen1, C. Vergin3
1Division of Pediatric Hematology, 2Department of Pediatrics , Dr. Behçet Uz Children’s Hospital and Surgery Training and Research Hospital, Izmir, 3Division of Pediatric Hematology, Balikesir Atatürk State Hospital, Balikesir, Turkey

Background: Hemophilia A and B are X-linked recessive hemorrhagic disease. Due to this type of inheritance, males are usually affected, but girls are carriers. Factor levels are usually detected around 50% because only one chromosome is affected in carriers. Inconsistently, it has been reported that factor activity can be detected in a wide range of 22%-116% as a result of random inactiva-
tion (lyonization) of one of two X chromosomes. It is specified that factor levels may be very low due to excessive inactivation in a significant part of the hemop-
ilha carriers, which creates a risk of bleeding in carriers.

Aims: In this study, we aimed to investigate the role of bleeding score and factor levels in detecting hemophilia carriers.

Methods: Bleeding Assessment Tool (BAT) for hereditary factor deficiencies of the International Society on Thrombosis and Haemostasis (ISTH/SSC) were applied to the mother and sisters of 32 hemophilia patients who were follow-

Results: Thirty-two mothers and 13 sisters of hemophilia patients were includ-
ed in this study. The mean age was 31.6 (4-57) years. Three of the patients were male, 3 were moderate, 23 were severe hemophilia A; 2 were severe and 1 had moderate hemophilia B. Twelve were obligate and 33 were probable carriers. Only seven in 45 (15.5%) probable and obligate hemophilia carriers had high bleeding scores (≥4). Those with high bleeding scores, three were obligate carriers and four were probable carriers. The mean factor activity of 12 obligate and 18 probable carriers were 78.9% (20.8%>189%). Factor activ-
ities of the three obligate carriers with high bleeding scores were 77%, 80% and 98%, respectively. Factor activities of the three probable carriers with high bleeding scores were 58.8%, 69.3% and 112%, respectively. The median bleeding scores of four probable and one obligate carriers with low factor activity (<60%) were 2.8 (1-4).

Summary/Conclusions: Measurement of factor activity seems to be insuffi-
cient to detect hemophilia carriers. ISTH/SSC-BAT may help to determine the carriers. However, a larger study is needed to understand the diagnostic value of the BAT.

PB1749
FETAL INTRACRANIAL HEMORRHAGE AS A PRESENTING FEATURE OF SEVERE CONGENITAL FACTOR VII DEFICIENCY: THE NEED FOR EARLY PROPHYLAXIS
M. Elshinawy1,*, A. Alrawas2, Y. Wali2
1Pediatric Hematology, SQUH, University of Alexandria, Oman, Egypt, 2Pedi-
atric Hematology, Sultan Qaboos University Hospital, Muscat, Oman

Background: Congenital factor VII (FVII) deficiency is a rare autosomal reces-

sive bleeding disorder, with an estimated prevalence of 1:300,000. Compared to western countries, rare bleeding disorders (RBDs) are relatively commoner in Oman, owing to high rate of consanguineous marriage.

Aims: To discuss an interesting case fo severe congenital factor VII deficiency and to explore the need for early prophylaxis.

Methods: Case report and retrospective data analysis of all children diagnosed with inherited coagulation factor deficiencies in Pediatric Hematology Unit, Sultan Qaboos University Hospital, Muscat, Oman from January 2009 till December 2016.

Results: We report a male full term baby, delivered by cesarean section. His older sister is a known case of severe congenital factor VII deficiency. Antenatal scans of this baby revealed two intracerebral hematomas and dilated cerebral ventricles. Postnatally, the diagnosis of severe congenital FVII deficiency was confirmed. CT scan revealed obstructive hydrocephalus at the level of aqueduct of Sylvius (Figure 1). At day 10 of life, ventriculo-peritoneal shunt has been done successfully under cover of recombinant activated factor VII replacement therapy. Afterwards, the patient has been initiated on rFVIIa prophylaxis at a dose of 30 ug/kg three times weekly. In our center, deficiencies of fibrinogen, FV, FVII, FX and FXIII were diagnosed in 22 pediatric patients (10 males and 12 females), accounting for 11.1% (22/198) of all children with inherited coagulation factor deficiencies. The age range from 1 day to 6 years and consanguinity is found in 19/22 cases (86.4%). Hypofibrinogenemia, FV and FVII deficiency are the commonest RBDs, diagnosed in 8, 6 and 5 patients respectively. As an initial presentation, intracranial hemorrhage occurred in 7/22 cases (31.8%). Three patients with FV, FVII and FXIII deficiencies suffered from global developmental delay due to severe intracranial hemorrhage. As regards management, 14 patients with severe FV deficiency and one with severe FXIII deficiency are on fresh frozen plasma (FFP) and recombinant FXIII prophylaxis respectively. Other patients receive on-demand therapy.

Figure 1.

Summary/Conclusions: Children with RBDs constitute more than one tenth of cases of hereditary coagulation factor deficiencies in our center. They have some unique features in terms of severity, clinical profile and the need for prophylaxis early in life. We recommend establishing a national/regional registry of RBDs to identify the magnitude and the peculiar genotype-phenotype correlations of such rare, yet significant disorders.

PB1750

THE ASSOCIATION OF BLOOD TYPE WITH THE NEED FOR TRANSFUSIONS IN PATIENTS WITH VENTRICULAR ASSISTIVE DEVICES

T. Kanellopoulo1, M. Aliberti1, A. Apostolou1, M. Fidirikou1, S. Georogantis1, E. Kabana1, M. Kataflogioti1, P. Litras1, A. Makrianni1, N. Matoula1, E. Papadaki1, G. Souflia1, E. Zalachori1, T. Kostelidou1

1Department of Haematology and Blood Transfusion, Onassiss Cardiac Surgery Centre, Athens, Greece

Background: Patients who have implantation of continuous flow ventricular assistive devices (VAD) as a bridge to heart transplantation are subjected to complications secondary to pump support. The use of antiplatelets either alone or in combination with anticoagulation is necessary to avoid clot formation and pump thrombosis. However, a proportion of patients reveal an increasing risk of bleeding episodes. A possible reason of this situation could be that high shear forces lead to devastation of high molecular weight von Willebrand factor (vWF) making it functionally inactive and resulting in acquired von Willebrand disease (vWD). People with blood type O have lower baseline vWF levels and this abnormality could exacerbate the bleeding risk of patients with blood type O with VAD, resulting in more frequent bleeding episodes and need for transfusions.

Aim: The aim of current study was to investigate the possible association of blood type with acquired VWD induced by VAD, with the need for transfusions.

Methods: In this retrospective study, 17 patients who had a VAD implant in our hospital in a six-month period were included for analysis. The investigation of underlying VWD was estimated by ristocetin-induced platelet aggregation (RIPA) using classical light transmission aggregometer.

Results: Six patients (35.3%) had left-VAD (L-VAD) implantation while the others had biventricular VAD implantation (BiVAD). The mean age was 42.41 years (SD±15.33) and 9 patients (52.9%) were male. Female patients had VAD implantation at younger age than male (p<0.001). The mean follow-up after VAD implantation was 15 months (SD±11.88). At the time of analysis, 13 patients (76.5%) were alive, 2 patients (11.8%) had died while 2 patients (11.8%) had been heart-transplanted. Eight patients (47.1%) had blood type O, 8 patients (47.1%) had blood type A and a patient (5.9%) had AB. Mean RIPA before VAD implantation was 59.3% (SD±14.76) while after VAD implantation was 47.29% (SD±15.47), whereas the decrease was no statistically related. No statistical correlation was found between RIPA among different blood types. Among patients with blood type O, the need for blood transfusions was associated with the duration of having the VAD implantation in months (p=0.001) while the need for fresh frozen plasma (FFP) transfusions was associated with RIPA before VAD implantation (p=0.016). In non-blood O type patients no statistical correlation was found with the need for transfusions with RIPA percentage or median follow-up of patients.

Summary/Conclusions: It has been shown by several studies that patients with VAD show a decrease in vWF increasing the bleeding risk. Thus the best antiplatelet treatment and/or anticoagulation that those patient needs, remains challenging. In our study, there was a decrease in mean RIPA percentage after VAD implantation and patients with blood type O had lower RIPA before implantation. However, none of these measurements was statistically significant. The blood type O patients showed an increased need for transfusions in correlation with the duration of VAD implants and an increased need for FFP in correlation with RIPA baseline. Our study has limitations due to the small population and the fact that vWF was not estimated within the different blood groups at baseline and after VAD implantation.

ACQUIRED PURE RED CELL APLASIA ASSOCIATED WITH LYMPHOPROLIFERATIVE DISEASES IN ERYTHROPOIETIN-REFRACTORY ANEMIA PATIENTS ON DIALYSIS

K. Yoshinaga1,*, N. Mori2, M. Ohwash2, M. Ishii3, M. Shiseki1, J. Tanaka1
1Department of Hematology, Tokyo Women’s Medical University, Tokyo, Japan

Background: Erythropoietin-refractory anemia is a serious problem and complicated cases should be ruled out in patients on dialysis. Acquired pure red cell aplasia (PRCA) may be hidden behind anemia of chronic kidney disease. Recently it was reported that PRCA patients with large granular lymphocyte frequently had STAT3 mutations (Oie ZY et al. Hematol Oncol 2013, Ishida F et al. Cancer sci 2014). Molecular or flow-cytometric analysis is useful for detecting a small amount of abnormal lymphocytes.

Aims: We conducted this study to determine the clinical characteristics and STAT3 mutations of patients with acquired PRCA on dialysis with lymphoproliferative diseases.

Methods: In our hospital, 4 patients were diagnosed as having acquired PRCA on dialysis with lymphoproliferative diseases after 2005. Patients were retrospectively studied for presenting feature, laboratory data, and clinical course. Surface markers of lymphocytes were examined by flow cytometric analysis, and T-cell receptor (TCR) rearrangements were examined by Southern blot analysis. Mononuclear cells were separated after obtaining written informed consent. STAT3 (Y640F and D661Y) mutations were examined by allele-specific PCR. Current study was conducted within the guidelines and with the approval of the institutional ethics committee.

Results: In spite of adequate administration of erythroid colony-stimulating factor, all 4 patients required blood transfusion due to erythropoietin-refractory anemia. Median leukocyte and lymphocyte counts at diagnosis were 4650/mL (range, 3180-4850) and 1794 mL (range, 1183-2859), respectively. Two patients (Cases 1 and 2) had low percentage of CD4+ CD8+ by flow-cytometry, and TCR C beta1 and gamma rearrangements by Southern blot analysis. Another patient (Case 3) had high percentage of gamma-delta T cell component (66.2%) with TCR delta rearrangement. The other patient (Case 4) had high CD16+CD56+ NK cell percentage without TCR receptor rearrangement. The surface markers of the patients were different from the majority of PRCA patients (range, 5-19 years). Of the 4 patients, only one patient (Case 3) had the mutations of the STAT3 gene (Y640F). This patient first received cyclophosphamide but he did not respond to the therapy. He subsequently received cyclosporine (CyA). The other three patients received CyA as an initial therapy, and it was effective in all 4 patients. Median follow-up were 7 years from diagnosis, and two patients died during follow-up period. One patient (Case 4) died of cardiac failure 7 years from the diagnosis. Another patient (Case 2) developed diffuse large B-cell lymphoma 5 years after the administration of CyA. He was treated with R-CHOP chemotherapy and complete remission (CR) was achieved. Although he had been in CR, he died of refractory pancytopenia with infection, 2 years after the lymphoma onset. The other two patients are still alive without blood transfusion for 6 and 7 years.

Summary/Conclusions: A proportion of erythropoietin-refractory anemia patients on dialysis have acquired PRCA associated with lymphoproliferative diseases. Surface markers of patients were useful for diagnosis of acquired PRCA associated with lymphoproliferative diseases. Further accumulations of patients were required for understanding the pathogenesis of lymphoproliferative diseases causing acquired PRCA on dialysis.

PB1752

ADULT PATIENTS WITH ACQUIRED PURE RED CELL APLASIA: TREATED BY CYCLOSPORINE A OR CORTICOSTEROIDS: SIMILAR EFFICIENCY

X. Wu1,*, S. Wang1, W. Shen1, G. He1, J. Li1
1Hematological Department, The First Affiliate Hospital, Nanjing Medical University, Jiangsu Province Hospital, Nanjing, China

Background: Adult pure red cell aplasia (PRCA) is a syndrome characterized by a severe normocytic anemia, reticulocytopenia, and absence of erythroblasts from an otherwise normal bone marrow. Immunosuppressive therapy has been used as the initial treatment for acquired chronic PRCA. Aims: This study evaluated the efficacy of cyclosporine A and/or corticosteroids, and possible factors influencing it.

Methods: 34 cases of PRCA were retrospectively analyzed at our institution. Clinical data of 23 inpatient cases and 11 outpatient cases since 2009 October were collected. These patients were treated by cyclosporine A (CsA), and/or corticosteroids (CS), or other immunosuppressive agents if become refractory and relapsed. Results: 31 patients were evaluated in our institution (one patient lost to follow-up and two patients with short observation period). The remission induction therapy included CsA (n=13), CS (n=13), or a simultaneous combination of CsA and CS (n=5). The initial response rate of CsA alone, CS alone, combination of CS and CsA were 69.2%, 46.2%, 80%, respectively (P=0.422). There was no statistical difference in response rate and CR rate between CsA-containing group and CS group, although the patients treated with CsA had a better response than those treated with CS (response rate 72.2% vs 46.2%, P=0.262; CR rate 33.3% vs 23.1%, P=0.596). Including patients who had crossed over from other treatment groups, the cumulative response rate of CsA, CR, combination of CsA and CsA was 73.7% (14/19), 46.7% (7/15), 83.3% (5/6), respectively (P=0.193); the cumulative rate of CR was 26.3% (5/19), 26.7% (4/15), 66.7% (4/6), respectively (P=0.202). In 23 refractory and relapsed PRCA patients, 8 out of 12 (66.7%) refractory patients and 4 out of 11 (36.4%) relapsed patients achieved remission. The response rate of treatment with traditional immunosuppressive agents (CS and/or CsA) was higher than other immunosuppressive agents (65.0% vs 20%, P=0.014).

Summary/Conclusions: CsA and/or CS are effective similarly in treating PRCA. Patients with relapse or refractory PRCA, there were no satisfactory treatment measures if CsA and/or CS were not be administered or un-effective. It was still needed to explore a more effective therapy for them.

PB1753

REACTIVATION OF HEPATITIS B VIRUS INFECTION IN APLASTIC ANEMIA PATIENTS

S. Wang1,*, X. Wu1, G. He1, W. Shen1, J. Li1
1Hematological Department, The First Affiliate Hospital, Nanjing Medical University, Jiangsu Province Hospital, Nanjing, China

Background: There is little data about the influence of infection of HBV on the therapy of aplastic anemia.

Aims: This article is aimed at assessment the HBV reactivation risk in HBSAg-positive or HBSAg-negative, antithetapies B core antigen antibody (anti-HBc) -positive patients with AA receiving CsA and/or ATG.

Methods: We analysis the clinical data of 60 AA patients with HBV infection out of 201 cases of AA from our center at AA diagnosis during the recent 3 years, and laboratory test data such as levels of liver enzyme, HBV DNA in serum, HBSAg anti-HBs and anti-HBc were monitored. Entecavir (ETV) or lamivudine (LAM): was started when HBV reactivation (defined as detectable HBV DNA) was encountered or as a anti-viral prophylaxis regimen for some patients with high risk of HBV reactivation. All patients were treated with IST.

Results: Among 60 (29.8%) AA patients, 12 were chronically infected (HBSAg positive) and 48 were previously exposed (HBSAg negative/anti-HBc positive). 5 patients (8.33%) who were HBSAg positive and not given any prophylactic antiviral therapy suffered HBV reactivation. 7 patients who were HBSAg positive but given antiviral prophylaxis, 4 patients who were exposed to HBV before AA diagnosis and 48 patients with negative HBsAg and positive anti-HBc were found no HBV reactivation during the follow-up.

Summary/Conclusions: Antiviral prophylaxis should be recommended for HBSAg-positive patients who will receive IST with AA as they had high rate (41.6%) of HBV reactivation. HBV infection were found no influence to the clinic course in AA and antiviral therapy had no influence to the effect of IST.

MULTICENTER RESULTS OF SCHWACHMAN-DIAMOND SYNDROME PATIENTS

S. Unal1,*, N. Kalkan1, T. Celnak2, G. N. Ozdemir2, N. Ozbek3, N. Yarali4, S. Wang1,*, N. Guleray5, M. Cetin6, F. Gumruk1, N. Akarsu1,6
1Hacettepe University, Division Of Pediatric Hematology, Ankara, 2Cerrahpasa University, Department of Pediatric Hematology, Istanbul, 3Ankara Çocuk Sagligi ve Hastalıkları Hastanesi ve Araştırma Hastanesi, Ankara, 4Ankara Çocuk Sagligi ve Hastalıkları Hastanesi ve Araştırma Hastanesi, 5Gazi University, Department of Pediatric Hematology, 6Hacettepe University, Medical Faculty, Ankara, 7Istanbul Saglik Bilimleri University, Department of Pediatric Hematology, Istanbul, 8Hacettepe University, Department of Medical Genetics, Ankara, Turkey

Background: Schwachman-Diamond syndrome (SDS) is an autosomal recessively inherited disease characterized with neutropenia, exocrine pancreas insufficiency, failure to thrive and skeletal abnormalities. In approximately 90% of the patients, the molecular defect is related to SBDS gene mutations. The classical triad is present in one-fourth of the patients and a high degree of suspicion is required in order to make the diagnosis. In this study, molecular work-up to patients with suspected SDS were made and the clinical and laboratory findings that predict the SDS diagnosis were investigated.

Aims: Aim of the study was to find out the predictive clinical and laboratory characteristics of SDS patients.

Methods: The patients were sent to Hacettepe Inherited Bone Marrow Failure Center for molecular work-up between June 2015 and August 2016 were evaluated with clinical and laboratory data obtained from a standardized patient registry form.

704 | haematologica | 2017; 102(2)
Results: Molecular work-up was performed in 20 patients referred to our center with a suspected diagnosis of SDS. Of these 20 patients (12 girls), 4 (20%) (3 boys) were found to have mutation in SBDS gene. The median age of these patients was 3.2 years (1-18). Of the 4 patients with genetically verified SDS, 1 (25%) had history of chronic diarrhea and pancreas atrophy was detected in ultrasonography of that patient. Another patient (25%) with SDS had had acute renal failure (5%) of the patient who had failure to thrive. Three patients (75%) had anemia associated to neutropenia, and 1 patient (25%) had pancytopenia at presentation. On the other hand of the patients who were referred with a suspicion of SDS but was found to have no mutation, 43% had neutropenia, 25% had hicytopenia, 10% had pancytopenia. The patients with PNH clone had failure to thrive in 25% of the patients and chronic or persistent diarrhea was present in 25% of this group. There was no statistically significant difference in the clinical and laboratory parameters of the genetically verified SDS patients and patients without SDS but was referred with SDS suspicion.

Summary/Conclusion: Although, there was no statistically significant difference in the clinical and laboratory parameters of the genetically verified SDS patients and patients without SDS but was referred with SDS suspicion, this might be attributed to the small sample sizes. Compatible with the previous literature data, SDS is a cryptic disorder and the classical triad is not commonly fulfilled in most of the patients. On the other hand, failure to thrive/growth retardation was three times more common in patients with SDS. Thus, in patients neutropenia, accompanying failure to thrive/growth retardation might be an indicative to make molecular work-up for SDS. Additionally, not only neutropenia, but bicytopenia or pancytopenia might be the hematological presentational findings of SDS.

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA AND APLASTIC ANAEMIA – DATA FROM THE SPANISH PNH REGISTRY

1Hematology, H. Universitario de Gran Canaria Doctor Negrín, Las Palmas de Gran Canaria, 2Hematology, H. Universitario La Paz, Madrid, Spain, 3Hematology, Hospital de Jerez, 4Hematology, Hospital Carlos III, Madrid, 5Hematology, H. Universitario Vall d’Hebron, Barcelona, 6Hematology, H. Universitario Príncipe de Asturias, Madrid, 7Hematology, H. Universitario Miguel Servet, Zaragoza, 8Hematology, H. Clínico Universitario Virgen de la Arrixaca, Murcia, 9Hematology, H. Universitario Donostia, Bilbao, 10Hematology, H. Universitario Germans Trias i Pujol, 11Hematology, H. Parc Taulí, 12Hematology, SEHH, Madrid, Spain

Background: Aplastic anaemia (AA) and Paroxysmal Nocturnal Hemoglobinuria (PNH) are included, together with other pathologies, within the bone marrow failure syndromes (BMFS). In the present study, these clinical entities were considered to be understood as independent pathologies, due to the extremely frequent evolution to PNH clone at the time of diagnosis, throughout the pathologic evolution of each pathology.

Aims: The aims of this study were analyzing and comparing the behaviour of patients who suffered from PNH with pancytopenia with respect to that of patients who were initially diagnosed of AA and who later developed a PNH clone.

Methods: A clinical form was elaborated and distributed among the investigators of the PNH Spanish Registry. Clinicial, laboratory and treatment data of the patient were asked. Soon after, a descriptive analysis of the data was performed.

Results: 34 patients were recruited and analyzed (12 women and 22 men). Their age interval ranged from 2 to 87 years, and all of the patients suffered from either PNH with pancytopenia and/or AA with a developing PNH clone. The average age at the time of initial diagnosis was 28.5 years old (4-72y). The initial presentation of the patients with pancytopenia was in 1994 (1), moderate AA (16), severe AA (10), very severe AA (7). 15 patients presented a PNH clone in their granulocytes and/or monocytes at the time of diagnosis, being 24% the average of such clone (0-55%) and less than 2% in 7 patients. All of the patients that showed hemolitic signs at diagnosis presented clones >20%. The time of the diagnosis was determined in 10 cases (56%). In 2 patients the diagnosis was three times more common in patients with SDS. On the other hand, failure to thrive/growth retardation might be an indicative to make molecular work-up for SDS. Additionally, not only neutropenia, but bicytopenia or pancytopenia might be the hematological presentational findings of SDS.

Summary/Conclusions: Clonal evolution in AA is frequently associated with the development of a PNH clone at the time of diagnosis, throughout the pathologic natural course or even after disease's resolution. The development of such clone has been related to better prognosis in AA right after the immunosuppressive therapy (IST). Our experience demonstrated the presence of hemolisis in at least half of the cases, making it necessary in these patients treatment with eculizumab, generally obtaining a very good response.

PB1756
AUTOIMMUNE CYTOPENIAS IN PRIMARY IMMUNODEFICIENCY DISEASES: SINGLE CENTER EXPERIENCE
T. Patrorgu1,*, M. Canserè2, F. Bektas2
1Pediatric Hematology, 2Pediatric Immunology, Erciyes University Medical Faculty, Kayser, Turkey

Aims: Primary immunodeficiency diseases (PIDD) are associated with hematologic complications such autoimmune hemolytic anemia (AIHA) and thrombocytopenia (ITP). The most common autoimmune cytopenia is ITP. Although ITP is observed in 7.6% of patients with PID, AIHA is seen at 4.5%. Also, we aimed to present the patients who had autoimmune cytopenias and PID.

Methods: Fifty six PID patients who were followed at the Pediatric Immunology Department of Erciyes University Medical Faculty (they were analyzed genetically) were evaluated retrospectively. Autoimmune cytopenias such as ITP and AIHA were detected in 9 (15.1%) of the patients (combined immunodeficiency:4 patients, common variable immunodeficiency: 2 patients, hyper immunoglobulin E syndrome:1 patient, X-linked lymphoproliferative :1 patient, chronic granulomatous disease:1 patient). ITP was detected in 8 of 9 patients and AIHA was also detected in 6 patients. In 4 patients (LRBA deficiency:2 patients, hyper IgE syndrome:1 patient and OSD:1 patient), both ITP and AIHA were observed. Immunosuppressive therapy with steroid, cyclosporine, mycophenolate mofetyl and intravenous immunoglobulin were given to all patients. Bone marrow transplantation was performed to the four patients. However, five patients died because of immunodeficiency.

Results: There was a paradoxical situation between PID and autoimmunity. The reduction of central and peripheral tolerance is held responsible for autoimmunity in PID.

Summary/Conclusions: As a conclusion, we wanted to point out autoimmune cytopenias in patients with PID and the requirement of multidisciplinary approach for treatment.

HEAVY METAL LEVELS IN PATIENTS WITH FANCONI APLASTIC ANEMIA
T. Bayhan1,*, O. Erdem2, S. Uнал1, F. Gunrük3, S. Çetinkaya4, E. Cirak4, I. Eker4
1Division of Pediatric Hematology, Hacettepe University, 2Department of Pharmaceutical Toxicology, University of Health Sciences, 3Pharmacologist, Retired, Ankara, 4Division of Pediatric Hematology, University of Aфyon, Afyon, Turkey

Background: Fanconi aplastic anemia (FAA) is a rare, autosomal recessively inherited bone marrow failure syndrome. Familial or congenital anomalies may accompany disease and various complications including malignancy and endocrinopathies may develop during the course.

Aims: Heavy metal levels in patients with different chronic disorders have been investigated, however, up to our knowledge there is no literature data on the heavy metal levels in patients with FAA. Heavy metal levels in patients with different chronic disorders have been investigated, however, up to our knowledge there is no literature data on the heavy metal levels in patients with FAA.

Methods: Study was performed between July 2015 and April 2016 among patients with FAA and the results were compared with age and gender matched healthy group (16 volunteers).

Results: Total of 17 patients with FAA were included in the study. Median age was 9 years (1-30), female to male ratio was 8/9. One patient had undergone stem cell transplantation, four patients were transfusion dependent. When we compared patients with FAA and age/sex matched healthy group (16 volunteers), Cr, cobalt (Co), selenium (Se) levels were measured in patients with FAA.

Summary: Total of 17 patients with FAA were included in the study. Median age was 9 years (1-30), female to male ratio was 8/9. One patient had undergone stem cell transplantation, four patients were transfusion dependent. When we compared patients with FAA and age/sex matched healthy group (16 volunteers), Cr, cobalt (Co), selenium (Se) levels were measured in patients with FAA.

FAA: Fanconi aplastic anemia.

Summary/Conclusions: In our study we found chromium and cobalt levels higher in patients with FAA than control group. In vitro studies have revealed that FAA cells are more sensitive to chromium toxicity. With larger number of patients, chromium level and clinical association should be investigated in further studies. Lower Se level in patients with FAA may be related with oxidative stress in these patients.

CLINICAL IMPACT OF AGE AND COMORBIDITY IN PNH PATIENTS

E. Salido Fírez1, S. de la Iglesia Iñigo2,3, P.A. Urquía Plazaola2,10, I. Jarque Ramos2,11, A. Urbano Ispizua2,4, A.M. Villegas Martínez2,12

1Hematología, Hospital Universitario Central de Asturias, Oviedo, 2Grupo Español de Hemoglobinuria Nocturna, Sociedad Española de Hematología y Hemoterapia, 3Hematología, Hospital Universitario La Paz, Madrid, 4Hematología, Hospital Clinic, Barcelona, 5Hematología, Hospital Universitario Príncipe de Asturias, Madrid, 6Hospital Universitario Cruces, Bilbao, 7Hospital Universitario Lucus Augusto, Lugo, 8Hospital Clinico Universitario Virgen de la Arrixaca, Murcia, 9Hospital Universitario de Gran Canaria, Las Palmas, 10Hospital Universitario Donostia, San Sebastián, 11Hospital Universitario La Fé, Valencia, 12Hospital San Carlos, Madrid, Spain

Background: PNH is an ultra-rare disorder affecting mainly young adults, but can be diagnosed in geriatric population. Comorbidity is more prevalent in geriatric population and can either hamper diagnostic evaluation or increase the complexity of PNH patient care.

Aims: To identify geriatric-age PNH in Spanish PNH registry. To study the clinical characteristics at diagnosis and evolution of geriatric-age PNH and compare them to non-geriatric PNH population. To analyse the impact of both age and comorbidity in the PNH setting. To evaluate the use of eculizumab in geriatric age patients.

Methods: In a multicentric retrospective study, Cumulative Illness Rating Scale for Geriatric (CIRS-G) and clinical and biological variables have been collected from a Spanish PNH Group patient cohort. Statistical analysis was performed using GraphPad Prism v5 (La Jolla, CA).

Results: 44 patients from 11 centres in Spain have been included up to date. 8 patients (17.8%) were diagnosed in geriatric age (equal or older than 65 years) (Age range for the complete cohort: 17-83 years) and 9 patients presented with high comorbidity, arbitrary defined as CIRS-G score >10. (Range for the geriatric cohort: 3-13) Age and comorbidity were poorly correlated (p = 0.0187, R-square 0.15). No differences in clinical presentation (Classic, PNH in the setting of another bone marrow failure syndrome or Subclinical PNH or high disease activity) when stratifying by age or comorbidity were observed. 4 patients had a concomitant myeloid clonal disorder (3 myelodysplastic syndrome and 1 myeloproliferative neoplasm, 3 of them (75%) in geriatric age. Median follow up was 7.2 years. Both age equal or older than 65 years and CIRS-G >10 were associated to poorer overall survival (HR: 0.134 and 0.045 & p = 0.0015 and 0.103 respectively). Regarding PNH with high disease activity, 18 patients were identified, 4 of them in geriatric age. In 2 of them (50%), Eculizumab was used, which contrasts with eculizumab use in younger patients (78.6% in the same indication) Regarding comorbidity impact on eculizumab therapy outcome, 2 patients had CIRS-G score >10 and had similar overall survival as patients with lower comorbidity in this cohort.

Summary/Conclusions: Age and comorbidity are associated with poorer overall survival in PNH. Older age and comorbidity may not preclude the use of effective treatment in PNH patients, including those with high disease activity. Prospective evaluation of comorbidity in PNH patients, regardless of age is warranted.

PB1759

A RARE ASSOCIATION: EBSTEIN-BARR VIRUS ASSOCIATED LYMPHOPROLIFERATIVE DISORDER AND PURE RED CELL APLASIA

S. Berk1, M. Günahit2, S. Sadri1, M. C. Ar1, T. Soysal1

1Haematology, 2Internal Medicine, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Lymphoproliferative disorders (LPD) constitute a heterogeneous group of diseases related to expanding polyclonal or monoclonal lymphoid cells in the setting of immune dysfunction. Ebstein-Barr virus (EBV) has been implicated in the development of a wide range of B-cell LPD spectrum. EBV associated LPDs (EBV-LPD) are more commonly encountered after stem cell and organ transplantations. Pure red cell aplasia (PRCA) is an uncommon disorder characterized by a severe normocytic anemia due to erythroblastopenia in an otherwise normal bone marrow. PRCA may be primary or develop secondary to viruses, autoimmune diseases, hematological malignancies, thyromegaly, solid tumors and drugs.

Aims: A case, who was diagnosed with EBV-LPD and developed PRCA during follow-up, is presented.

Methods: A 75-year-old woman with pain in upper and lower extremities applied to our center in February 2016. Her past medical history was unremarkable except for rheumatoid arthritis. On physical examination bilateral cervical, submandibular, axillary lymphadenopathies (LAP) and splenomegaly were detected. Laboratory tests revealed normochromic normocytic anemia, elevated serum lactate dehydrogenase and acute phase reactants. Positron emission tomography (PET) showed supra- and infradiaphragmatic malignant lymph nodes and splenic involvement. An excisional biopsy of cervical LAP was performed. Pathological examination showed CD20 (+) and CD30 (+) large B cells in the interfollicular area. EBV early RNA signals were checked by in-situ hybridization and viral transcripts were detected. Diagnosis of EBV-LPD was made. During diagnostic work-up deepening of anemia with reticulocytopenia, increased transfusion requirement and inadequate response to transfusion necessitated a bone marrow aspiration and biopsy. Pathological examination of the bone marrow was compatible with PRCA. Parvovirus IgM and DNA was negative; IgG was found to be positive. Because of the lack of response to steroids, Rituximab was given (375 mg/m2, weekly). Anemia and patient’s clinical condition improved after 8 weeks of treatment.

Results: In the pathogenesis of LPD polyclonal lymphoid response to an antigenic trigger is thought to be followed by development of monoclonal neoplastic diseases. In our case, this trigger was thought to be EBV as it is known as one of the main causative agents for LPD in the literature. Clinical complaints and physical examination findings are common among all patients and frequently not leading to a definitive diagnosis in most of them as it is the case in our patient. Compared to the strong association of secondary PRCA with parvovirus B19 its association with EBV is rare. PRCA can develop before the diagnosis, during the course and after the remission of LPD. In our case we observed PRCA in the follow-up period of EBV-LPD.

Summary/Conclusions: On the basis of EBV-LPD being more common in transplant setting our case was thought to be unique due to the absence of transplantation or immunosuppression history. This case report points out to the possibility of existence of two rare diseases, EBV-LPD and PRCA.
Chronic lymphocytic leukemia and related disorders - Biology

Businco, Cagliari, Italy, 16Azienda Ospedaliera Bianchi-Melarino-Morelli, Reggio Calabria, Italy, 17Ospedale C. G. Mazzoni, Ascoli Piceno, Italy

Background: Patients affected by chronic lymphocytic leukemia (CLL) that have trisomy 12 (+12) on FISH analysis have unique clinical and biological features. In a prior analysis (Autore F, ASH 2016) of 487 patients with +12 compared to 816 patients with negative FISH, patients with +12 had a significantly higher prevalence of elevated LDH, β-2-microglobulin, ZAP70 positivity, CD38 positivity, CD49d positivity and unmutated IGHV as compared to patients with negative FISH. They also showed shorter progression free survival (PFS), treatment free survival (TFS) and overall survival (OS).

Aims: To identify clinical and laboratory features that predict disease progression, time to treatment and survival in treatment-naïve patients with +12 CLL.

Methods: This study included 487 treatment-naïve patients with +12 CLL from 16 academic centres, diagnosed between January 2000 and July 2016. A cohort of 250 patients with +12 CLL followed at a single US institution was used as external validation. Data were summarized as medians and 25th and 75th percentiles. Chi-square test or Fisher’s exact test were used to compare categorical variables, while Wilcoxon-Mann-Whitney-Test was applied for continuous variables. The survival analysis was based on the Kaplan-Meier method and the log-rank test was used to compare survival curves. A Cox model was used for multivariate analysis of the impact of different factors on survival. P-values lower than 0.05 were considered statistically significant (STATA 12.0) and reported as two-sided. We analysed also CLL-specific survival considering events deaths due to the haematological disease.

Results: Parameters associated with shorter PFS, TFS, OS and CLL-specific survival on univariate analysis were IGHV, LDH, β-2-microglobulin and Rai stage; age, ZAP70 and CD38 associated with shorter OS. Considering interestingly the association of β-2-microglobulin with shorter OS. Considering interestingly the association of β-2-microglobulin with shorter OS.

Summary/Conclusions: Our study on 487 patients with +12 CLL and the analysis on 250 patients of the validation cohort showed that patients with +12 and elevated LDH have shorter PFS, TFS, OS and CLL-specific survival.

PB1761
THE PERCENTAGE OF CELLS WITH ABNORMALITIES IN FISH STUDIES CONFERS PROGNOSTIC INFORMATION IN CLL PATIENTS

1Hospital Universitario Infanta Leonor, MADRID, 2IBSAL, IBMCC, Centro de Investigación del Cáncer, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: Genomic aberrations detected by FISH have become one of the most important and widely used prognostic factor for chronic lymphocytic leukemia (CLL) patients. In addition several publications have described that patients with a higher percentage of abnormal nuclei have a worse outcome.

Aims: To analyze the effect of the percentage of abnormal nuclei detected by FISH (13q deletion (13q-), 11q deletion (11q-), 17p deletion (17p-)) and trisomy (12 (+12)) in overall survival (OS) and time to first treatment (TTFT).

Methods: We studied a non-selected cohort of 650 consecutive CLL cases from a local database with a median follow up time of 50 months (0-346). The cut-off point for the percentage of abnormal nuclei for each alteration was determined by dividing the variable into deciles, and selecting the most efficient cut-point, and based on previous publications.

Results: FISH detected aberrations in 85% of the cases (442/650). The most frequent abnormality was 13q-, observed in 302 patients (47%), but as a sole alteration in 212 cases, followed by +12 (106 patients, 16%), 11q- (83 patients, 13%), and 17p- (33 patients, 5%). As expected, the group of patients with 13q- as a sole abnormality was the one with the better OS (195 months) followed by the group of patients with normal FISH (160 months), +12 (124 months), 11q- (56 months) and 17p- (46 months), consistent with the Döhner hierarchical classification (Döhner H et al. NEJM 2000). Similar results were observed in TTFT: 13q- as sole abnormality (106 months), normal FISH (112 months), +12 (29 months), 11q- (10 months), 17p- (10 months). The best predictive cut-off point that divided patients according to its prognosis was different for each alteration. We confirmed that a high percentage of cells carrying the deletion is associated with a significantly worse TTFT in cases with 17p, 13q, and 11q deletions, and a significantly shorter OS in cases with 17p deletion. We observed a similar trend for OS in cases with 13q and 11q deletions, probably not significant because of the low number of patients included, compared to previous studies. We observed the same trend in patients with +12. The Table 1 summarizes these findings. Probably with a higher number of cases and a longer follow up, it could have also been possible to reach statistically significant differences in the subgroups in which it was not objectified.

Table 1

Summary/Conclusions: Not only the type of cytogenetic abnormality but also the percentage of abnormal nuclei detected by FISH are important factors in the prognosis of CLL patients.
Background: Chronic lymphocytic leukemia (CLL) pathogenic mechanisms have not been fully elucidated yet. However, genetic and epigenetic alterations seem to be involved in the pathogenesis and extensive clinical heterogeneity of the disease. DNA methylation in CpG sites of a gene promoter, which may affect the chromatin structure as well as gene transcriptional activity, is a crucial epigenetic modification in CLL. RAD21 gene is involved in DNA repair and its encoded product acts as basic subunit of the Cohesin protein complex that regulates the cohesion and proper separation of sister chromatids during mitosis or meiosis. Aims: We investigated the methylation status of RAD21 gene promoter and its possible implication in CLL pathogenesis and the formation of CLL cytogenetic aberrations. Methods: The study included 105 CLL patients and 17 healthy donors (controls). Total genomic DNA extraction was performed from bone marrow or peripheral blood samples of all patients and controls. Methylation analysis of RAD21 gene promoter was carried out using the new technology of MethylScreen™ in the FXC96Biorad Real-Time PCR system. For this purpose, we used EpTect Methyl II PCR Assay which enables us to calculate the methylated and unmethylated fraction after simultaneous digestions with specific restriction enzymes. Methylation analysis was performed on unstimulated and stimulated with CpG-oligonucleotide DSP-30 bone marrow cells of CLL patients. FISH analysis was carried out using the commercial CLL sets probes for detection of the most common abnormalities of the disease including deletions of 17p13 (TP53), 11q22.3 (ATM) and 13q14.3/13q34 (D13S319/13q34) regions and trisomy 12 (CEP12). Results: Among the 105 CLL patients, 21 patients exhibited a normal karyotype also confirmed by FISH and 84 patients showed chromosome aberrations detected by karyotypic or/and FISH analysis. Methylation study was successful in all healthy donors and in 101 out of 105 CLL patients. All healthy donors had non-methylated RAD21 gene promoter. On the contrary, 25.74% (26/101) of CLL patients carried >10% cells with methylated CpG islands in RAD21 promoter, which was significantly increased compared to controls (p=0.039, χ²=4.25, df=1). RAD21 methylated cell fraction varied among patients. More specifically, 9% of patients (10/101) showed 11-50% methylation rate, 10.89% (11/101) for 51-75% and 1.23% (1/84) for >75%. The RAD21 promoter methylation was significantly associated with karyotypic complexity (p=0.0001, Cramers’s V=0.23). Methylation rate seems to be implicated in CLL pathogenesis and the formation of specific chromosome aberrations. Summary/Conclusions: Methylation of RAD21 gene promoter, which leads to transcriptional inactivation and consequent inhibition of RAD21 expression, seems to be implicated in CLL pathogenesis and the formation of specific chromosome aberrations. Confirmation of the epigenetic landscape of CLL may help in the design of new targeted therapeutic agents.
Results: An increased number of CAs, including chromatin breaks and denticles, in CLL patients (6.59±5.3) compared to controls (0.25±0.04) (p=0.021) was observed. A tendency to increased CA frequency in cases with abnormal (8.18±6.1%) compared to normal karyotypes (5.67±4.4%) (p=0.08) was also found. The analysis taking into account FISH risk groups showed a higher frequency of CA in patients with deletions 11q22 and/or 17p13 associated to poor outcome (8.54±4.9%), than those with no alterations or 13q14 deletion related to a better outcome (5.64±3.9%) and cases with +12 with an intermediate prognosis (5.45±3.5%). By MN analysis, an increased frequency in CLL patients (2.81±1.5%) compared to controls (0.67±0.3%) (p=0.0001) was found. Patients with +12 presented the highest percentage of MN compared to the other two groups (+13-fold), indicating the aneugenic effect of this alteration. The evaluation according to the IGHV mutational status showed similar frequencies for CAs and MN in M-CLL (6.2±5.2% and 2.8±2.4%, respectively) and UM-CLL (6.2±5.8% and 2.7±1.3%, respectively).

No association between CA and MN frequencies and clinical parameters was found.

Summary/Conclusions: Our results confirm the presence of basal genomic instability in untreated CLL patients as measured by both CA and MN techniques. To our knowledge, this is the first analysis of these parameters taking into account prognostic factors of the disease. Cases with deletions 11q22 and/or 17p13 had the highest value of CA and those with +12 showed the highest frequency of MN, reflecting different mechanism of DNA damage.

B CELLS RESISTANT TO CD20 MONOCLONAL ANTIBODIES DISPLAY SPECIFIC ALTERATIONS IN GENE EXPRESSION PROFILE

A. Lefercèrová1, V. Komárek2, V. Vakulová2, M. Douplek1,2, M. Mayer1,2, Š. Pospíšilová1,2, M. Šmída1,2
1Central European Institute of Technology (CEITEC), Masaryk University, 2Department of Internal Medicine - Hematology and Oncology, Medical Faculty of Masaryk University and University Hospital Brno, Brno, Czech Republic

Background: CD20 monoclonal antibodies (mAb) are a standard of care for B-lymphoid malignancies. Yet, their clinical efficacy is quite variable and many patients relapse, while their malignant cells express very low density of CD20 on the cell surface. In spite of being used for 20 years as a therapy target, little is known about the biology and regulation of CD20 inside the cell.

Aims: The aim of this proposal was to investigate the intracellular mechanisms regulating expression of CD20 antigen.

Methods: Diverse cell and molecular biology techniques were used, including flow cytometry analysis, real-time PCR and RNA sequencing.

Results: We show that treatment of B cells with different CD20 mAbs initiates a signaling cascade within the cells that is partially distinct from classical B-cell receptor signaling machinery and does not involve BCR proximal proteins. Importantly, it results in a prompt downregulation of CD20 expression. Through chromatin regulation to gradually increasing doses of monoclonal antibodies, we have generated cell lines that are resistant to additional treatment with mAb. Notably, these cells are resistant also to any of the available anti-CD20 antibodies even at very high concentrations as shown by dose-response experiments. This resistance is sustained for long period and maintained even upon multiple rounds of cell passages. We could discover that these cells have regulated CD20 protein from the cell surface and that this effect was not just due to its internalization. Instead, we detected a defect in CD20 transcription as measured by quantitative real-time PCR. Flow cytometry analysis of other surface markers showed a strong upregulation of CD55 and CD59, known inhibitors of complement activation. The combination of CD20 loss together with the increase of CD55 and CD59 is responsible for the complete resistance to the mAbs. We have then analyzed changes in overall gene expressions by performing RNA sequencing and quantitative real-time PCR. We have identified several interesting genes whose expression was altered in our resistant cells when compared to the other two groups (+13-fold), indicating the aneugenic effect of this alteration. The evaluation according to the IGHV mutational status showed similar frequencies for CAs and MN in M-CLL (6.2±5.2% and 2.8±2.4%, respectively) and UM-CLL (6.2±5.8% and 2.7±1.3%, respectively).

Summary/Conclusions: Our results confirm the presence of basal genomic instability in untreated CLL patients as measured by both CA and MN techniques. To our knowledge, this is the first analysis of these parameters taking into account prognostic factors of the disease. Cases with deletions 11q22 and/or 17p13 had the highest value of CA and those with +12 showed the highest frequency of MN, reflecting different mechanism of DNA damage.

DIFFERENTIAL EXPRESSION PATTERNS OF CHEMOKINE RECEPTORS IN CHRONIC LYMPHOCYTIC LEUKEMIA

A. Petrackova1, G. Manukyan1,2, T. Papajik3, V. Kraiczová1, R. Fillerová1, Z. Mikulíková1, G. Gabbova1, R. Urbarová3, P. Turscany3, P. Ryznerová3, L. Kružová3, E. Kriegová1, 1Department of Immunology, Palacky University Olomouc, Olomouc, Czech Republic, 2Laboratory of Molecular and Cellular Immunology, Institute of Molecular Biology NAS RA, Yerevan, Armenia, 3Department of Hemato-Oncology, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, Czech Republic

Background: Chemokines and their receptors are involved in the regulation of cell recruitment, survival, proliferation, and trafficking, all these processes crucial in the pathogenesis of chronic lymphocytic leukemia (CLL). Comprehensive profiling of chemokine receptors in CLL and its subgroups according to prognostic relevance is missing.

Aims: To characterize the chemokine expression pattern in CLL patients and subgroups according to clinical course and cytogenetic aberrations.

Methods: We studied the gene expression pattern of 16 canonical and 4 atypical chemokine receptors in peripheral blood mononuclear cells (PBMC) of CLL patients (n=88) and healthy subjects (n=34) by using SmartChip quantitative RT-PCR (WaferGen Bio-systems). The expression of CXCR3, CXCR4, CXCR5, CXCR7, and CCR7 was confirmed by flow cytometry.

Results: Among deregulated receptors, 5 receptors (CCR7, CCR10, CXCR3, CXCR4, CXCR5) were up-regulated and 9 receptors (CCR2-CR6, CCR8, CXCR1, CXCR2, CXCL12) were down-regulated in CLL; these values did not differ between CLL and controls (P>0.05). In patients with del(17p) associated with a poor prognosis, we observed higher mRNA levels of CXCR6, CXCR7 and CCR10 comparing to del(13q). On protein level, the percentage of neoplastic B cells positive for CXCR4, CXCR5, and CCR7 was higher and percentage of CXCR7 lower than on normal B cells (P<0.05). In patients with CLL a marked increase in MFI of CXCR4 (P<0.001) and CCR7 (P<0.001) on CLL cells was detected comparing to healthy subjects.

Summary/Conclusions: Our results provide a complete picture of expression patterns of chemokine receptors in PBMC of CLL patients and prognostically relevant subgroups. Further studies are needed to clarify how chemokine receptor network affects neoplastic development and progression.

PB1767

RESIDUAL SERUM CONCENTRATIONS OF RITUXIMAB ARE ASSOCIATED WITH RELAPSE RISK IN CHRONIC LYMPHOCYTIC LEUKEMIA

A. Tempescu1,2, C. Berthou1, H. Saad1, V. Olivier1, B. Boutahar2, M. Zdrengea1, Y. Renaudineau1, C. Bagacean1,1Clinical Hematology, 2Laboratory of Immunology, Teaching Hospital Brest, Brest, France, 3Clinical Hematology, Oncology Institute “Ion Chiricuta”, Cluj-Napoca, Romania

Background: Rituximab is an anti-CD20 chimeric monoclonal antibody approved in first-line treatment of patients with chronic lymphocytic leukemia (CLL), in association with chemotherapy. Rituximab displays a time-dependent pharmacokinetic with a high variability between patients that is primarily related to target mediated elimination.

Aims: Rituximab pharmacokinetics has been associated with clinical response but there is no data on its association with patients’ evolution after immunochemotherapy, which is the aim of the present study.

Methods: Residual serum concentrations of rituximab were determined by an enzyme-linked immunosorbent assay (ELISA) for 35 CLL patients before each infusion, administered every 28 days at T0, T1, T2, T3, T4, T5. Response and relapse criteria were evaluated according to the International Workshop on Chronic Lymphocytic Leukemia guidelines.

Results: Patients were assigned to two groups related to time to relapse. The first group (n=7), had an early relapse in less than 3 years, the second group (n=28), in more than 3 years. A lower residual serum rituximab concentration was observed in patients with an early relapse and statistical significance was reached for the values obtained after the 3rd cycle (T3) (p=0.02). Concerning the area under the curve (AUC), the difference was significant across all the first three cycles (NPNC, at 2.79±1.93 mg/L•day, p=0.02). Additionally, the residual rituximab serum concentration between T2 and T5, superior at 70µg/ml, is associated with a long response time, with a sensibility of 100% and a specificity of 52%. Low residual serum rituximab concentrations in the early relapse group were associated with a higher expression of CD38 and a more frequent administration of the chemotherapy rituximab-bendamustine than rituximab-fludarabine-cyclophosphamide. On the other hand, there was no association with age, sex, cytogenetics, tumour burden or with FCGR3A-158FV polymorphism.
The study confirmed the association between unfavorable prognosis and high expression of exhaustion markers in CLL patients. Determination of PD-1+, PD-L1+, CD200+ and CD200R+ lymphocytes and T and NK cells constitutes valuable diagnostic tool, completing cytometric evaluation of CLL.

**Methods:** The CLL cell line MEC-1 was treated with 0.3–10 μM ibritinib, ide-lalisib or DMSO (control) for 7 days or 3–10 μM venetoclax or DMSO for 24 hours. Inhibition of proliferation, cytotoxicity and impact on CD19 expression were then assessed. ADCC assays with MOR208 incorporated a fixed number of primary human natural killer cells from healthy volunteers as effector cells. By contrast, the number of target cells was reduced according to antiproliferative or cytotoxic effects of the TKIs or venetoclax. Dose-dependent ADCC activity of MOR208 was analyzed by flow cytometry. Cytotoxic effects were studied in at least three independent experiments.

**Results:** Ibritinib and idelalisib induced only moderate direct cytotoxicity on MEC-1 target cells but had strong antiproliferative effects. In contrast, venetoclax induced strong cytotoxicity on MEC-1 target cells within 24 hours. Both effects led to reduced tumor target cell numbers in the subsequent ADCC assays. CD19 expression was largely unaffected by all three drugs. The addition of idelalisib or venetoclax treated target cells resulted in enhanced maximum ADCC when compared with single agent MOR208. EC50 values remained unaltered in TKI or venetoclax treated conditions compared with the DMSO control. Calculations according to Chou-Talalay yielded combination indices below 1 for all three drugs, thus confirming synergistic activity.

**Summary/Conclusions:** The cytotoxic effect of MOR208 was synergistically enhanced when combined with ibritinib, idelalisib or venetoclax in vitro. These promising data provide a strong rationale for combination of MOR208 with these agents in future clinical trials.
Background: Human concentrative nucleoside transporter 3 (hCNT3) belongs to a family of nucleoside transporters involved in fludarabine cellular uptake. It has been reported that overexpression of SLC28A3 gene encoding hCNT3 predicts poor response to fludarabine-based chemotherapy. However, the mechanisms by which elevated expression of SLC28A3 mediates fludarabine resistance are still elusive.

Aims: The aim of the study was to examine possible influence of SLC28A3 gene overexpression on treatment response to fludarabine-cyclophosphamide therapy (FC) in patients with chronic lymphocytic leukemia.

Methods: We retrospectively analysed data from 54 CLL patients diagnosed and treated at Clinic for Hematolog, Clinical Center of Serbia from 2003 to 2013. Blood samples were prospectively collected and analysed for biological and molecular features, as well as standard laboratory parameters. The expression of SLC28A3 gene was analyzed in peripheral blood mononuclear cells by RT-PCR methodology, using TaqMan chemistry and ABI as endogenous control gene. Quantification of target gene expression was made by comparative Ct method using the HLA-BL0 cell line as the calibrator. All analyses were done prior to any treatment.

Results: Median age at diagnosis was 57 years (range 38-75). All patients were treated with fludarabine-based chemotherapy. 45 (83%) in the first treatment line. Overall response rate to the first line therapy was 81%, equally distributed on complete and partial responses (CR and PR). while the remaining included the same number of patients with stable disease (SD) and progressive disease (PD) (5, 9.6%). Most of the patients (42, 78%) relapsed during the follow-up. At the time of the last follow up 14 (26%) patients were still alive, 35 (65%) were dead, and 5 (9%) were lost to follow up. Median overall survival was 7.5 months. In the group of patients who received FC in the first treatment line (43/54), median expression of SLC28A3 mRNA in patients who experienced CR, PR, SD, and PD was 0.036±0.030, 0.062±0.063, 0.035±0.025 and 0.157±0.257, respectively. The level of SLC28A3 expression was not associated with the IGHV mutational status. Patients who experienced PD to FC treatment overexpressed gene for hCNT3 compared to patients who achieved CR (p=0.013) and PR (p=0.05). We detected a significantly higher level of SLC28A3 expression in patients who experienced PD to FC treatment in comparison to patients who achieved CR (p=0.01) and PR (p=0.05).

Summary/Conclusions: Overexpression of SLC28A3 gene is a predictor of resistance to treatment with FC chemotherapy. Further studies are warranted to confirm these findings.

PB1772
THE SPECTRUM OF TP53, SF3B1, AND NOTCH1 MUTATIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS EXPOSED TO IONIZING RADIATION DUE TO THE CHORNOBYL NPP ACCIDENT
N. Bilous1,*, I. Abramenko1, A. Chumak1, I. Dyagil2, Z. Martina2
1Clinical Immunology, 1Hematology, Research Center for Radiation Medicine, Kiev, Ukraine

Background: Generally, chronic lymphocytic leukemia (CLL) is considered to be a non-radiogenic form of leukemia. We previously found some clinical and biological features of CLL in group of clean-up workers of Chornobyl NPP accident indicated unfavorable disease course, such as high frequency of solid tumors and Richter transformation, mainly unmutated status of heavy chain variable region (IGHV) genes with increased usage of IGHV1-69 and IGHV3-21 (Abramenko et al., 2008). Analysis of genetic features of leukemic cells in IR-exposed CLL patients may provide an additional data on the possible causal relationship with IR.

Aims: The aim of the study was to analyze TP53, NOTCH1 and SF3B1 mutations in CLL patients, sufferers of Chornobyl NPP accident to clarify the possible pathogenetic relationship between IR and CLL development.

Methods: TP53, NOTCH1, and SF3B1 mutations were analyzed in 106 CLL patients who have been exposed to ionizing radiation (IR) due to Chornobyl NPP accident (53 clean-up workers, 16 inhabitants of radionuclei contaminated areas, and 7 evacuees) and in 130 IR non-exposed CLL patients as the control group. TP53 gene mutation analysis was performed for exons 3 to 10. NOTCH1 mutations and SF3B1 mutations were analyzed in the hotspot regions of these genes were the vast majority of CLL-specific lesions were reported: in c.711G>A (34%), c.711G>A of NOTCH1 gene, and in exons 14, 15 and 16 of SF3B1 gene, correspondingly.

Results: We found TP53 and SF3B1 mutations with similar incidence in both groups – in 11.3% and 10.0% of IR-exposed patients, and in 12.7% and 11.5% of IR non-exposed CLL patients, respectively. In contrast, NOTCH1 mutations were found with lower frequency in IR-exposed patients in comparison with the control group (6.7% vs 17.7%; p=0.012). Other similar features were found among IR-exposed CLL patients also. Specifically, TP53 mutations were seen with equal frequency among mutated (11.1%) and unmutated (11.8%) IGHV cases in IR-exposed CLL patients, while the tendency to prevalence of TP53 mutations in unmutated compared with mutated IGHV cases was found in the control group (14.1% and 5.6%, correspondingly; p=0.178). In IR-exposed group SF3B1 mutations were combined with mutations in TP53 almost in half of detected cases. In opposite, in the control group we observed reported earlier mutual exclusivity between SF3B1 and TP53 lesions (p=0.001 in comparison between observed groups). Among IR-exposed CLL patients we found two different cases with identical rare mutation of TP53 gene - c.665C>T substitution leading to change proline for leucine at codon 222 (Pro222Leu). This substitution is very likely to represent inherited TP53 mutation, which may influence CLL development under IR exposure.

Summary/Conclusions: In summary, our data suggest that TP53 abnormalities are involved in CLL development in sufferers of the Chornobyl NPP accident and also a possible interaction between inherited IR sensitivity caused by mutation in TP53, radiation and CLL development.

PB1773
DRUG SENSITIVITY SCREENING IN CHRONIC LYMPHATIC LEUKEMIA AND MULTIPLE MYELOMA FOR PERSONALIZED CANCER THERAPY
D.B. Thimiri Govinda Raj1,*, S.S. Skanland1, D. Wang2, G.E. Tjønnfjord3, L.A. Munthe2, K. Tasken1,2
1Centre for Molecular Medicine Norway (NCMM), Nordic EMBL Partnership, University of Oslo and Oslo University Hospital, NCMM UIO. 2Centre for Immune Regulation, Institute of Clinical Medicine, University of Oslo, 3Department for Haematology, Oslo University Hospital, Oslo, Norway

Background: Personalized Cancer Medicine is rapidly developing field that includes predictive medicine, preventive medicine and various personalized or individualized therapies, e.g. labeled “precision medicine”. One particular challenge for cancer is that origin of each cancer is a-clonal event evolving into tumor heterogeneity. We focus on Chronic Lymphocytic Leukemia (CLL), Multiple Myeloma and Foliicular lymphoma (FL) that are currently considered incurable. Although current treatment regimens are effective in most patients, CLL and MM cancer eventually relapse. Current challenges in using therapies against CLL and MM includes design of optimal treatment for individual patients based on characterization the tumor and its intratumor heterogeneity as observed by whole genome sequencing. Efficient therapies require a personalized approach that combines targeting lymphoma cells and the tumor microenvironment by restoring the patient’s own anti-tumor immunity. One solution to this challenge is the so-called “n-of-one” studies where protocols are organized with diagnostically based patient stratification to individualized treatment (n=1).

Aims: To introduce individualized treatment for patients against available therapies, we aim to established cell-based assays and drug sensitivity platform at NCMM, University of Oslo and Oslo University Hospital. To establish a pipeline for direct drug sensitivity screening in CLL and MM (WP1-Path A). To Complement the results from WP1-Path A with Signaling pathway analysis (WP2-Path B) towards testing in xenografted mice and implementing therapy in n-of-one clinical trials. To Offer patients with intractable CLL and MM individualized treatment with an effective combination of targeted therapies.

Methods: We culture CLL cells with combination of feeder cells that express CD40L, APRIL and BAFF for 24 hours stimulation. We perform drug sensitivity screening with Prestimulated CLL cells in 384 well formats without feeder cells. We culture MM cells in 384 well formats for drug screening in response to T helper cells premixture in the presence of IL2. To support high-throughput drug sensitivity screening, We use cell-based assays such as CellTiter-Glo® Cell Viability Assay and CellTox™ Green Cytotoxicity Assay to define drugs that inhibit cancer cell growth. Additional methods such as cell proliferation assay, CellTox Green, apoptosis and oxidative stress (glutathione release) are also applied. We also use established cell barcoding on CLL/MM for flow cytometry (7-AAD/BrDU cell proliferation and Caspase8/9 apoptosis assay).

Results: Standard Curve for cell proliferation, CellTiter-Glo assay has been performed for MM/CLL cells. Time course measurement using cell proliferation, CellTox-Green assay for CLL cells (unstimulated and soluble CD40 ligand-induced) has been performed for 48,72 hrs and 5 days) using cell proliferation, CellTox-Green assay for M2 cells has been performed. Benzalkonium chloride (BzCl) is used as Positive control. Endpoint measurement using CellTiter-Glo assay for CLL and MM cells was performed with cell density of 5000. Dose Response curve for 50 drugs has been generated for CLL patients (n=4) and MM (n=4) (Figure 1).

Summary/Conclusions: We perform drug sensitivity screening to select potential drug candidates and pathway inhibitors through an approach where we directly assess patient samples. Selected drug candidates will first be validated by bioassays and flow cytometry to assess effects on intracellular mitogenic pathways (phosphoflow-based approach). We propose to use the drug sensitivity screening platform to identify and validate drug candidates for xenografting and “n-of-one” clinical trial studies.

![Figure 1](https://example.com/figure1.png)
I. Panovska-Stavridis1,*, S. Trajkova1, M. Ivanovski1, M. Popova-Labacevska1, PATTERN AND STEREOTYPED RECEPTORS REPERTOIRE OF MUTATIONAL STATUS, IMMUNOGLOBULIN HEAVY VARIABLE GENES PB1775 the variations in selected patient’s population. Action of rituximab in CLL compared to lymphoma patients or could be due to these findings could be explained with the different mechanism of the different Ig isotypes of rituximab versus the monoclonal chimeric anti-CD20 agent, that has demonstrated significant benefit for patients with different form of B cell lymphoproliferative disorders. Chemoinmunotherapy with rituximab, fludarabine and cyclophosphamide (R-FC) has shown to prolong progression free survival (PFS) and overall survival in CLL patients compared with chemotherapy alone. FCGR2A is polymorphic and has two alleles, FCGR2A-131H and FCGR2A-131R. This polymorphic variation is due to a single base substitution of nucleotide adenine for guanine in position 494. FCGR2A-H131 allele has a higher affinity for human IgG2, comparing to FCGR2A-R131. The gene for FCGR3A has also two polymorphic variants: 158 valine (V158) and phenylalanine (F158) due to single base substitution of thymidine to guanine at nucleotide position 559. FCGR2A-158V variant has higher affinity for Fc gamma receptor than 158F variant. These Fc gamma receptor polymorphisms may influence antibody-dependent cytotoxicity (ADCC), complement-dependent cytotoxicity (CDC) and direct proapoptotic effect.

Aims: The aim of our study was to investigate a possible association of these two FCGR2A and FCGR3A variants with response to R-FC therapy in CLL patients.

Methods: We have analyzed these two polymorphisms in 90 patients with CLL treated with R-FC regimen. Median age of our patients was 62.3 (36-78) and 63% were male. Number of patients with stage III/IV disease was 65 (72%) and median WBC count at the start of treatment was 68.5 (34-173 x10^9/L). Percentage of previously treated patients was 51/90 (56.6%). Average numbers of FC cycles were 4.3 and median PFS was 35.1 months. Median time of observation after treatment was 3.6 years (range:6 months-8 years). Response was evaluated 2 months after therapy according to National Cancer Institute (NCI) criteria. Complete response (CR) was achieved in 24/90 (26.7%), partial response (PR) in 56/90 (62.2%) and no response in 10/90 (11.1%). DNA was isolated from peripheral blood mononuclear cells and genotyping was performed using PCR/RFLP methods. The distribution of genotypes was compared by using a chi-squared test or Fisher’s exact test.

Results: Distribution of genotypes in our patients was: 33% H/H, 49% H/R and 18% R/R for FCGR2A and 43% V/V, 40% V/F and 17% F/F for FCGR3A. Rate of CR and PR were similar irrespective of the FCGR variants and our results did not demonstrate significantly different genotype distribution for FCGR2A (p=0.8001) or FCGR3A (p=0.1019) in CLL patients with complete, partial or no response to R-FC therapy (Table 1).

Summary/Conclusions: Our results are similar with previously reported results in other studies in CLL patients, but in contrast with the results for follicular lymphoma (FL), which showed that high-affinity FCGR2A-158V/W variant was associated with the highest response rates in FL patients treated with rituximab. These findings could be explained with the different mechanism of action of rituximab in CLL compared to lymphoma patients or could be due to the variations in selected patient’s population.

PB1775 MUTUAL STATUS, IMMUNOGLOBULIN HEAVY VARIABLE GENES PATTERN OF MACEDONIAN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS I. Panovska-Stavridis1,2, S. Trjkovska1, M. Ivanovski1, M. Popova-Labacevska1, A. Pkvova-Veljanovska1, D. Dukovski1, A. Efroimov1, M. Staninova-Stojnovska2, M. Cevreska1, A. Stojanovic1 1University Clinic of Hematology-Skopje, Center for Biomolecular Pharmaceutical Analyses, Faculty of Pharmacy, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: Chronic lymphocytic leukemia (CLL) is the most common form of adult leukemia in Western world with highly variable clinical outcome. Rituximab is a monoclonal chimeric anti-CD20 agent, that has demonstrated significant benefit for patients with different form of B cell lymphoproliferative disorders.

Aims: In this study, we analyzed the mutation status and pattern of IGHV, IGHD and IGHD gene usage in Macedonian CLL patients.

Methods: Ninety-seven consecutive CLL patients that presented at the University Clinic of Hematology–Skopje in the period between 2011-2013, were included in the study. IGHV mutation status and gene repertoire were analyzed using the reverse transcriptase– polymerase chain reaction (RT-PCR) and sequencing methodology. The mutational status of the IGHV genes was determined using two databases: IMGT/V-QUEST tool and IgBLAST software. The stereotyped subset assignment was performed using ARREST/AssignSubset tool (Bioinformatics Analysis Team).

Results: We found that 44.3% of the cases belonged to M-CLL and 55.7% to U-CLL, with a progressive disease dominant in the U-CLL subset. Both groups were comparable regarding the age and gender distribution. Only 39% of the M-CLL patients presented with a progressive disease, compared to 74% of the U-CLL patients (p<0.05).The comparison of median time to the first treatment (TTT) between M-CLL and U-CLL (39 months versus 8 months, respectively) showed a statistically significant difference between the groups (p<0.01).

Most frequently expressed IGHV genes were: IGHV1-26 (30.1%), IGHV4-34 (22.2%), IGHV5-2 (20.2%), and IGHV1-2 (0.1%). Among 32 different IGHV genes, 8 genes were found (V1-46, V1-69, V3-21, V3-23, V3-30, V3-33, V3-48 & V4-34) in 58.8% of all cases, revealing a strong bias in IGHV gene expression in CLL. IGHV1-69 was the most frequently expressed gene of all (16.5%), and exclusively found in the U-CLL group demonstrating a frequency of 29.6%. The IGHD3-21 was detected with a low frequency of 4.1%, as reported for CLL patients from other Mediterranean countries. The distribution of IGHD subgroups was as follows: IGHD3, 52.6%; IGHD2, 17.5%; IGHD6, 13.4%; IGHD1 7.2%; IGHD4 7.2%; IGHD5 2.09%. The most frequent IGJH gene was IGJH4 (49.4%), followed by IGJH6 (23.7%), IGJH5 (2.09%), IGJH1 (2.09%). In 10% of the cases, the VHCDR3 amino acid sequences belong to previously defined stereotyped clusters. Only one of the rearrangements with stereotyped VH-CD3 belonged to the M-CLL subset.

Summary/Conclusions: Our study showed a strong correlation between IGHV gene mutational status and clinical course of CLL. Results on IGHV-IGHD- IGJH genes usage in our study are comparable to the previously reported from Mediterranean countries. The high frequency of V1-69gene and low frequency of IGVH3-21 in our CLL patients that originate from a small geographic region further promotes the genetic bias in the use of IGHV genes and points to an important role in antigen stimulation in the pathogenesis of the CLL subsets. Our findings indicated a lower expression of the stereotyped BCR region than those previously reported (~30%), but they were comparable with the results reported for the Serbian CLL patients (10.1% versus 15.3%, respectively), in the only previous published study of this kind from Western Balkans.

**LAMBDA LIGHT CHAIN RESTRICTION – USEFUL FOR HAIRY CELL LEUKEMIA PROGNOSTICATION?**

J. Araujo1,2, M. Sobrinho-Simões1, S. Afonso1, F. Principe1, J.E. Guimarães1,2,3

1Hematology, Centro Hospitalar de São João, Porto, Portugal
2Pathology, Faculty of Medicine Thammasat University, Pathumthani, 3Cancer Cytogenetic and Molecular Diagnostic, Chulabhorn Research Institute, Pathumthani, Thailand

**Background:** Hairy cell leukemia (HCL) patients have near-normal life expectancies since the introduction of purine nucleoside analogues. However, HCL remains a chronic, often relapsing disease in which maximizing treatment-free survival (TFS) is the main goal.

**Aims:** Prognostication is not standardized in HCL, emphasizing the relevance of the characterization of HCL populations.

**Methods:** We retrospectively analysed 40 patients (90% men), diagnosed between 1997 and 2016, with a median follow-up of 6 years.

**Results:** At presentation, the median age was 58 years and 69% of patients were asymptomatic - fatigue (53%), B symptoms (50%), bleeding (14%), abdominal discomfort (6%) and severe infection (22%). The commonest cytopenia was thrombocytopenia (70%), with median platelet count being 66x10^9/L. Monocyte counts below 0.1x10^9/L were observed in 61% of the patients. Splenomegaly was observed in 83% of the patients and 21% had abdominal lymphadenopathies. The majority of the (88%) was treated with cladribine in first line, achieving an overall response (OR) rate of 100% and a complete response (CR) rate of 38%, of which 67% were classified as minimal residual disease (MRD)-negative CR. Retreatment was required in 33% of the patients, of which the majority received cladribine. The median time-to-next-treatment (TNT) from first to second line was 3 years. The OR rate for second-line treatment was 91%, 50% achieving CR, of which 33% were classified as MRD-negative CR. Only 5% of the patients required further treatment lines. Even the presence of scarce hairy cells in the bone marrow precluded classification of response as CR. This might have contributed to the low CR levels observed in our patients. As post-treatment bone marrow biopsies were available in only 24 patients, response analysis was restricted to these patients. All of these 24 patients had bone marrow fibrosis at diagnosis, which reverted when and in whom first CR was obtained. Median overall survival (OS) was not reached and, at 10 years, the OS was 90%. Four deaths occurred, all unrelated to HCL. Regarding prognostication, a trend to a longer TFS, albeit no statistically significant, was observed in patients achieving CR, namely MRD negative and without thrombocytopenia at presentation. Excitingly, the 61% of patients with kappa (k) light-chain restriction (LCR) displayed a significantly higher TFS than the 39% with lambda (λ) LCR (p = 0.04, Wilcoxon-Gehan test). To the best of our knowledge, there are no published reports on prognostic value of LCR in HCL (Figure 1).

**Figure 1.**

**Summary/Conclusions:** If multicentre studies corroborate our findings, LCR may be of use in the prognostication/risk stratification of HCL. Similarly with multiple myeloma and other hematological malignancies, lambda (k) LCR appears to correlate with worse prognosis, leading to a shorter TFS.

**PB1777**

**CLINICAL EFFICACY AND LONG-TERM OUTCOMES OF SPLENECTOMY IN CHRONIC LYMPHOCYTIC LEUKEMIA**

Y. Vestyatkheych1,2, I. Vestyatkheych1, O. Vygovska1, M. Semerak2, V. Loginsky1

1Institute of Blood Pathology and Transfusion Medicine NAMS of Ukraine, L’viv, Ukraine

**Background:** Chronic lymphocytic leukemia (CLL) is often accompanied by splenomegaly, which may enlarge to a giant size, causing abdominal discomfort, regional portal hypertension, and becomes a place of malignant cells concentration. In 2.3-4.3% of cases CLL may be complicated by autoimmune cytopenias (autoimmune hemolytic anemia (AIHA), immune thrombocytopenia (ITP), Evans-Fisher syndrome). Accordingly, the effectiveness of steroid and chemotherapy in such cases may be impaired, raising the question of splenectomy advisability.

**Aims:** To analyze splenectomy effectiveness in patients with CLL.

**Methods:** Splenectomy was performed in 41 patients with CLL, 12 of which were patients with CLL and ITP, 9 with CLL and warm type AIHA, 5 patients with AL, and Evans-Fisher syndrome, along with 18 CLL patients without immune disorders. Among the patients there were 26 males and 15 females. Indications to splenectomy were following: massive splenomegaly with abdominal discomfort, immune cytopenia and regional portal hypertension. In one female patient the surgical intervention was performed urgently due to spontaneous splenic rupture and acute intra-abdominal bleeding.

**Results:** Splenectomy was effective in 37 patients (90.2%): abdominal discomfort disappeared, hemolysis stopped and hemoglobin levels normalized or increased, platelets numbers normalized or increased. Splenectomy was ineffective in 3 patients with CLL associated with ITP: amid elimination of abdominal discomfort the platelets number did not increase significantly (2 patients), while in 1 patient despite increase in platelets number leukemia progression was observed. One (2.4%) patient with CLL and AIHA died on 3rd day after surgery because of acute adrenal insufficiency. The analysis of late effects of splenectomy in patients with CLL showed that average life expectancy after the surgery comprised 111.6 months within observation period between 11 and 277 months. In patients with CLL immune cytopenias the average life expectancy after surgery was shorter and equal to 60.7 months within the observation period between 2 and 361 months.

**Summary/Conclusions:** Splenectomy remains an effective method of treatment of patients with CLL, accompanied by severe splenomegaly and immune cytopenia. Long-term results of splenectomy in patients with CLL without cytopenia are better than in patients with CLL and cytopenias. Aggressive hemolysis, large spleen covered in perisplenic adhesions, amid portal hypertension and thrombocytopenia are considered to be special surgical risk factors in this patients.
in CLL. The collection of clinical data and basic biologic information on CLL spontaneous regressions and to make them accessible for future research.

Methods: A registry of spontaneous CLL regressions (absence of lymphadenopathy, splenomegaly and constitutional symptoms, peripheral blood (PB) lymphocytes <4 x 10^9/L in the absence of any previous treatment) was launched within the ERIC consortium.

Results: So far, 9 CLL patients showing a spontaneous regression have been reported and 8 have been formally registered, 7 from Italy and 2 from Sweden. Six were males and 3 females, with a median age of 57 years at diagnosis (range 51-82), stage Binet/Rai A/I in 6, A/I in 2 and B/I in 1. The median lymphocyte count at diagnosis was 14.1 x 10^9/L (5.3-51.9). Biologic features included: mutatedIGHV in 8/18 with VH3-30 (2), VH2-13, VH-VH3-24, V3-31, VH4-34, VH4-59; CD38 <30% in 6/6; ZAP70 <20% in 4/6; FISH (7 cases): del13q in 4, negative in 3, +12 in 1 case. No patient had undergone treatment except for one diagnosed in 2009 who received FCR for disease progression in 2013 (lymphocytes 107 x 10^9/L), obtained a PR and 18 months later developed a Richter’s syndrome - a diffuse large B-cell lymphoma clonally unrelated to CLL - with the comitant disappearance of the CLL clone from the PB and bone marrow, that has lasted up to January 2017 (lymphocytes 3.5 x 10^9/L, CLL 0.035 x 10^9/L). An additional case diagnosed in 2013 (stage A/I, lymphocytes 37.2 x 10^9/L) reached the highest lymphocyte count 19 months later (91.2 x 10^9/L) and subsequently started a spontaneous reduction in lymphocyte count down to 39.6 x 10^9/L in 2015 and to 8.9 x 10^9/L in January 2017 in stage A/I, when we first reported on this event in 2014. Excluding the latter cases, in the other 7, all in stage A/0, the highest lymphocyte count was 16.0 x 10^9/L (8.9-76.0), the lowest at the last follow-up was 2.8 x 10^9/L (1.8-4.4), with 0.66 x 10^9/L. CLL cells (0.085-3.0) in the 4 evaluable cases. The median time from diagnosis to clinical regression was 4 years (range 2-17) and this has been reported for 2 further cases (range 0.5-7). One of these cases (mutated VH3-21, +12) seems the most dramatic: in 2008 at diagnosis, the lymphocytes were 51.9 x 10^9/L, in 2009 a peak at 76.0 x 10^9/L was recorded; in 2011, when the CLL regression started, the patient underwent several viral upper respiratory infections; the CLL complete regression (1.8 x 10^9/L) persisted for 11 years to the last follow-up. In 5/9 cases 5 years range 0-10, no further follow-up. The lymphocyte count at CLL regression was 3.16 x 10^9/L (1.3-4.9), with a persistent lymphocyte count at CLL regression was 3.16 x 10^9/L (1.3-4.9), with a persistent low-count MBL warrants further investigations to define the biological and clinical significance in term of LPD transformation and long-term survival.

Summary/Conclusions: In 9% of patients with CLL, we have observed a complete and sustained clinical regression, with a median time from diagnosis to clinical regression was 4 years (range 2-17), and this has been reported for 2 further cases (range 0.5-7). One of these cases (mutated VH3-21, +12) seems the most dramatic: in 2008 at diagnosis, the lymphocytes were 51.9 x 10^9/L, in 2009 a peak at 76.0 x 10^9/L was recorded; in 2011, when the CLL regression started, the patient underwent several viral upper respiratory infections; the CLL complete regression (1.8 x 10^9/L) persisted for 11 years to the last follow-up. In 5/9 cases 5 years range 0-10, no further follow-up. The lymphocyte count at CLL regression was 3.16 x 10^9/L (1.3-4.9), with a persistent low-count MBL warrants further investigations to define the biological and clinical significance in term of LPD transformation and long-term survival.
Background: Hairy cell leukemia (HCL) accounts for approximately 2% of all leukemias and is associated with pancytopenia, splenomegaly, and recurrent infections. Therapy with the purine analogues cladribine (2CdA) or pentostatin (2’deoxycoformycin), has been most effective and both agents have achieved equivalent results in HCL. In this regard cladribine given as a single course, achieves a high response rate. Several alternative dosing schedules have been reported with subcutaneous administration reported in 50-50% of all treated patients (54%, post IV and 47% post SC delivery; p=0.4). Median days of hospitalization were 8 for both groups (P=0.05), and the length of NADIR was 18 and 20 days for IV and SC delivery respectively (P=0.53).

Summary/Conclusions: This study is the first comprehensive summary of the natural history involving a large cohort of HCL patients with long follow up. These results serve as validation of previous reports relating to HCL and confirm that the excellent outcome achieved after a single course of treatment with 2CdA is independent of schedule and method of drug delivery. In addition, patient ethnicity was insignificant.

CHRONIC LYMPHOCYTIC LEUKEMA: CHANGES IN CLINICAL STAGE DISCRIMINATE PATIENTS WITH DIFFERENT OUTCOME WITHIN THE IWCLL PARTIAL RESPONSE CATEGORY

E. P. Vicente1,2, A. Martínez2, A. Soler3, C. Cuellar1, A. Mora4,2, R. Bosch1,2, E. P. Vicente1,2,*, M. Martínez3, A. Soler3, C. Cuellar1, A. Mora1,2, R. Bosch1,2

1Department of Hematology, 2Laboratory of Oncology/Hematology and Transplantation, Institute of Biomedical Research, IIB Sant Pau, Hospital Sant Pau, 3Department of Hematology, Hospital Parc Taulí, 4Laboratory of Hematology, Hospital Sant Pau, Barcelona, Spain

Background: Over the last decades, progress in chronic lymphocytic leukemia (CLL) treatment has resulted in an impressive increase in overall survival (OS). In CLL, as in other tumors, response to therapy overcomes negative prognostic factors and is the most important predictor of survival. Clinical stages reflect this tumor load and correlate with OS both at diagnosis and over the course of the disease (Rai et al, Blood 1975).

Aims: To determine whether changes in clinical stage discriminate patients with different outcome within IWCLL response categories, particularly the hematopoietic recovery (HR) group (Bekelk et al, Blood 2008).

Methods: Two-hundred ninety-nine patients with CLL were retrospectively evaluated. Median follow-up was 91 months (range, 2-390). CLL diagnosis was based on IWCLL criteria. Endpoints were time to next treatment (TTT) and OS. TTT and OS curves were estimated by the Kaplan-Meier method and differences were tested with the log-rank test. Results were stratified according to IWCLL recommendations and by changes in clinical stage. A landmark analysis was performed in ninety-two patients in whom a PR was achieved at any time during the course of the disease, using the time when a PR was achieved as “time 0”.

Results: From the series of 229 patients, those who achieved a better IWCLL degree of response after first line of therapy had a better OS than those with an inferior response (p=0.001). With a median follow up of 91 months (range, 2-390), the median survival in patients who achieved complete remission (CR) was 214 months (95% CI: 123-305) vs 134 (95% CI: 79-189) and 91 (95% CI: 39-143) months in those who achieved partial remission (PR) and failed to therapy, respectively (Figure 1A). Among patients in PR (n=66), after a median follow-up of 42.5 months (range 1-201), those patients with stage A disease at the time of response evaluation (PR Binet A) had significantly better outcome than those whose stage was Binet B/C (median survival 63 vs 43 months; p=0.047). Interestingly, when the analysis was restricted to response assessment after first line therapy (n=229), patients who achieved PR Binet A did not have significant differences in OS compared to those patients who were in CR (median survival were 164 and 214 months respectively; p<0.001); on the contrary, patients in PR Binet B/C had a similar outcome than those who did not respond to treatment (median survival 81 and 91 months respectively (Figure 1B). Similar results were observed in the outcome of patients with PR subclassified according to Rai clinical stage.

Figure 1.

Summary/Conclusions: Changes in clinical stage provide reliable information about response to therapy in patients with CLL, particularly those in the IWCLL PR category. This study supports the use of clinical stages as a complementary and simple tool to assess response in patients with CLL, both at the end and over the course of treatment.

PB1783

INCIDENCE OF THYROID GLAND DISORDERS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

A. Tombak1, M. A. Ucar1, R. Gen2, M.A. Sungur3

1Hematology, 2Endocrinology, Mersin University, Mersin, 3Biostatistics, Duzce University, Duzce, Turkey

Background: Frequency of autoimmune complications like immune anaemia or immune thrombocytopenia has increased in patients with chronic lymphocytic leukemia (CLL). However, there is no data in the literature investigating the relation of the other autoimmune disorders including thyroid gland diseases with CLL.

Aims: We aimed to investigate the presence, features and frequencies of thyroid disorders in patients with CLL.

Methods: Thyroid function tests, thyroid autoantibodies (antithyroglobulin antibody [anti-TG], antithyroid peroxidase antibody [anti-TPO]), thyroid ultrasonographies (USG) and scintographies of CLL patients were performed. Demographic and clinical data, Rai-stages, and established thyroid disorders were recorded.

Results: One hundred CLL patients were included into the study (65 male, mean age was 62±10.4). Free T3 (FT3) was within normal limits in 96 cases (96%), was low in 2 cases (2%), was high in 2 cases (2%); free T4 (FT4) was normal within normal limits in 89 cases (89%), was low in 7 cases (7%), was high in 4 cases (4%);TSH was within normal limits in 90 cases (90%), was low in 7 cases (7%), was high in 3 cases (3%), Anti-TPO and anti-TG were positive in 10 cases (11.8%) and in 18 cases (21.2%), respectively. While USG was normal in 36 cases, multinodular goiter (MNG) in 21, chronic thyroiditis in 20, MNG associated with thyroiditis in 10, uniodular goiter (UG) in 8, UNG associated with thyroiditis in 4, and diffuse goiter in 1 case were determined by USG. Toxic adenoma in 3 cases, toxic MNG in 2 cases, and thyroiditis in 1 case were determined in 6 patients in whom thyroid scintigraphy was performed for hyperthyroidism. After evaluation of all the tests; while no thyroid disease was determined in 33 of the cases (33%), MNG in 25 (25%), thyroiditis according to the results of USG in 12 (12%), UNG in 11 (11%), Hashimoto thyroiditis in 9 (9%), toxic MNG in 3 (3%), subclinical hyperthyroidism in 3 (3%) cases, subclinical hypothyroidism in 1 case (1%), lymphocytic thyroiditis in 1 case (1%), toxic UNG in 1 case (1%), and euthyroid sickle syndrome in 1 case (1%) were determined. The patients were divided into 2 groups according to their Rai-stages and ages. Accordingly; Rai-stage 0 - I - II (n=80) and Rai-stage III - IV (n=20), <65 years (n=56) and ≥65 years (n=44). Anti-TPO positivity was similar in 2 Rai-stages groups and in both sexes (p=0.507, p=0.223, respectively). However, anti-TPO positivity was statistically different between age groups; anti-TPO was positive in 3 patients in <65 years old age group, and was positive in 7 patients in ≥65 years old age group (p=0.049). Anti-TG was positive in 7 patients in <65 years old age group,
and was positive in 11 patients in ≥65 years old age group (p=0.053). There was no statistically relevant difference in thyroid function tests according to the Rai-stages, ages and sexes.

Summary/Conclusions: We determined that incidence of hypothyroidism or hyperthyroidism associated with all reasons do not increase in patients with CLL when compared with general population. However, we also determined that the incidence of Hashimoto thyroiditis was higher than general population (incidence of Hashimoto thyroiditis in general population is 2-5%). Anti-TG positivity was also higher than general population (positivity of anti-TG in general population is 5-20%). In addition, the positivity of 2 antibodies increased with advanced ages. Patients with PLL -especially the elderly cases- in both sexes and all Rai-stages should be examined for thyroid gland disorders, mainly for Hashimoto thyroiditis.

CLINICAL-BIOLOGICAL CHARACTERISTICS, TREATMENT OUTCOME AND SURVIVAL OF SMALL LYMPHOCYTIC LYMPHOMA PATIENTS: A REAL-LIFE EXPERIENCE

S. Sachanis1,2, G. Pangalis1, M. Moschogiannis3, K. Kalpakdakis2, M. Angelopoulos3, C. Kyrtsonis3, V. Bartz2, X. Yiakonous1, E. Koulis1, P. Tarikindis1, M. Psyllaki4, H. Papadaki4, P. Korkolopoulou4, D. Rontogianni5, T. Vassilakopoulos3, M. Sciumè1, E. Ferretti1, C. Andersen3, E. Oliva4, A. Cortelezzi2

1Hematologic, Athens Medical Center/Phychikon Branch, Athens, 2University Hospital, University of Crete, Heraklion, 3Hematologic, Laikon General Hospital, University of Athens, Athens, 4Hematologic, University Hospital, University of Crete, Heraklion, 5Pathology, Laikon General Hospital, University of Athens, 6Pathology, Evangelismos General Hospital, Athens, Greece

Background: Studies of B-PLL published to date have included heterogeneous groups of patients(pts) and did not use modern diagnostic criteria, or included pts who had in fact chronic lymphocytic leukemia. Outside the context of clinical trials, PLL pts are treated heterogeneously and thus there are no data concerning the impact of different treatment approaches on response and survival. In the updated WHO classification it is pointed out that there are a subset of cases with lymph node(LN) involvement by PLL in which proliferation centers(PCs) were not observed and pts in whom lymphadenopathy was <1.5 cm showing a better prognosis

Aims: To: a)record clinical, biological features and treatment strategy in a selected group of PLL diagnosed in our centers b)correlate clinicopathological character-istics and treatment with response and survival c)detect possible differences in terms of response and survival between PLL pts according to LN characteristics (size of LN and presence of PCs)

Methods: Pts diagnosed with PLL from 2007 up to now fulfilling the diagnostic criteria of PLL(LN) were included. Clinical and biological data were recorded at diagnosis as well as at the time of follow-up, such as type of treatment, response and patient survival. Moreover, LN features such as the size, and the presence of PCs were also studied. Pts were evaluated in hematoxilyn and eosin sections and defined as pale areas containing plasmacytoid lymphocytes and plasmacytoblasts, surrounded by a dark background of small lymphocytes.

Results: 47 pts were analysed. Pts’ median age was 69y (range, 40-87) with no gender predominance (24male/23female). According to Binet staging system 12, 19 and 9 were classified as A, B and C stage respectively while according to Ann Arbor staging system 11 (89%) had advanced disease stage. 11 pts presented with bulky lymphadenopathy, 11 had splenomegaly and 4 had B-symptoms. LN biopsies were performed in 37 out of 47 pts. All pts underwent bone marrow (BM) biopsy with a median BM infiltration of 45% (0-97%). PCs were identified in 19 out of 24 pts in whom there were no detectable PCs tended to have prognostic significance. Further analysis in larger series of pts is on the way.

Background: In daily clinical practice, analysis in larger series of pts is on the way.

HEMINSIGHT TO ASSESS PATIENT REPORTED OUTCOMES OF PATIENTS AFFECTED BY CHRONIC LYMPHOCYTIC LEUKEMIA IN DAILY CLINICAL PRACTICE

G. Reda1, B. Fattizzo2, R. Cassin1, E. Saluzzii2, E. Flesporger2h, V. Mattiellos2, M. Sciume1, E. Ferretti1, C. Andersen3, E. Oliva4, A. Corteleezi2

1Oncohematology Department, Foundation IRCCS Ca’ Granda Ospedale Maggiore Policlinico of Milan, Italy, 2Oncohematology Department, Foundation IRCCS Ca’ Granda Ospedale Maggiore Policlinico and University of Milan, Italy, Milan, Italy, 3Department of Hematology Roskilde University Hospital, Roskilde, Denmark, 4Azienda Ospedaliera ‘Bianchi Melacrino Morelli’, Reggio Calabria, Italy, Reggio Calabria, Italy

Background: Chronic lymphocytic leukemia (CLL) is the most common leukemia in Western Countries, with a median age at diagnosis between 67 and 72 years. The therapeutic landscape of CLL is changing rapidly with the advent of small molecules acting as B-Cell Receptor (BCR) signaling inhibitors. In this setting, long term oral therapy may lead to the reduction in compliance, with a possible impact on effectiveness. Moreover, long-term follow-up may highlight complications, such as drug-related adverse events that, together with the disease itself, may impact quality of life (QoL). Patient Reported Outcomes (PROs) in daily clinical practice is a resource-intensive procedure and may be affected by low adherence, risk of recall bias and difficulties in establishing reproducible procedures. HemInsight, a project conceived in 2010 for myeloproliferative neoplasms in haematological centres in Denmark, enables patients to periodically submit PROs online to be combined to the medical records.

Aims: HemInsight was implemented at our Centre to collect PROs from CLL patients in daily practice.

Methods: HemInsight incorporated the EORTC QLQ-C30, EORTC QLQ-CLL 16, SF-36, and the eight-item Morisky Medication Adherence Scale (MMAS-8) questionnaires to collect PROs and their changes during various stages of CLL (diagnosis - progression - treatment). PRO assessments were scheduled for the patients who received regular reminders by email to complete the tasks. The following measurements will be assessed: system attraction (percentage of CLL patients adhering to the project); patient compliance in filling out questionnaires; system effectiveness (number of alerts related to QoL worsening and number of questionnaires not submitted) and system effectiveness (significant differences in changes in QoL scores from diagnosis to response/relapse, changes of therapeutic approach/action following an alert, changes in adher-ence of therapy).

Results: At the time of the present report, 74 patients with a CLL diagnosis have been enrolled, 15 of whom were newly diagnosed. Fourteen patients underwent cytoreductive therapy and 2 are under treatment with novel oral drugs. System attraction: the study was proposed to 91 consecutive patients, independently of age, level of education and internet accessibility, and 72.5% of patients agreed to participate to the study. The main reason of refusal was older age and scant internet/technology knowledge. In 3 cases with no access to internet, but with interest to participate in the project, the questionnaires were administrated through tablet, before the scheduled visit, by a dedicated nurse. Patient compliance: a global response of 58.2% was observed; 48 patients responded at least once and 23 at all scheduled time points. In each case, all questionnaires were fully completed. At this timepoint we cannot yet evaluate system effectiveness as the study is still ongoing. However, ad interim data (Table 1) suggest that patients who interrupt questionnaires ful-filling are those with younger age, more intense working activity and experi-encing no changes in disease status (e.g. untreated cases or those in remis-sion). In particular, patients who were under treatment during the questionnaire administration period, showed a higher adherence compared to those in follow up, both previously treated or not (80% versus 26%, p<0.05).

Table 1.
PB1786
HEALTHCARE COST OF MEDICARE PATIENTS WITH PREVIOUSLY TREATED CHRONIC LYMPHOCYTIC LEUKEMIA
C. Reyes1,*, G. Gauthier2, L. Schmerold3, A. Guerin2
1Genentech, Inc., San Francisco, United States, 2Analysis Group, Inc., Montreal, Canada, 3Analysis Group, Inc., New York, United States

Background: Chronic lymphocytic leukemia (CLL) is the most prevalent form of leukemia in adults in the USA, accounting for 20% to 30% of all leukemia cases. CLL affects mainly elderly patients, with a median age at the time of diagnosis reported to be 71 years. Although CLL is not curable, disease symptoms and progression may generally be controlled with adequate pharmacologic treatments. Bendamustine-based regimens have long been used in the management of CLL patients but few studies have analyzed the comorbidity-and/or adverse event (CAE)-related healthcare costs in elderly patients receiving these regimens in a real-world setting.

Aims: To describe all-cause and CAE-related healthcare costs of elderly patients with CLL treated with a bendamustine-based regimen in second or later lines of therapy in a real-world setting.

Methods: A retrospective cross-sectional cohort study design was used. Adult patients who received a bendamustine-based regimen in second or later lines of therapy on or after January 2010 were identified from the Medicare Limited Data Set (LDS) 5% Standard Analytic Files (data availability: 1999–2014). The index date was defined as the initiation date for the first of the studied bendamustine-based regimens. Selected patients were required to be continuously enrolled in their Medicare plan for ≥6 months before and ≥3 months after the index date – unless the patient died during the first 3 months after the index date. Patient cohorts were determined based on the treatment initiated on the index date (index treatment); the two most prevalent bendamustine-based regimens were analyzed, i.e., (1) bendamustine and rituximab in combination (BR cohort) and (2) bendamustine monotherapy (bendamustine cohort). Healthcare costs, including inpatient, emergency room, outpatients and CLL-drug costs, incurred while patients were under treatment or with the index treatment were described for each cohort. For each medical cost component, all-cause and CAE-related costs were summarized. Healthcare costs were adjusted for inflation (2016 USD) and reported per-patient-per-month (PPPM).

Results: A total of 275 patients were included in the BR cohort and a total of 100 patients in the bendamustine cohort. Most patients (61.8% in the BR cohort and 66.0% in the bendamustine cohort) were male and the mean age was approximately 75 years old. During the 6 months prior to the index date, patients in the BR and bendamustine cohorts were similar in terms of comorbidity profile; mean Charlson comorbidity index was 3.53 in the BR cohort versus 3.61 in the bendamustine cohort (p=0.581). During treatment, total all-cause healthcare costs were $14,520 PPPM for the BR cohort and $13,125 PPPPM for the bendamustine cohort – outpatient costs (mainly driven by CLL-drug costs) represented the largest cost component. CAE costs accounted for a relatively large portion of the total all-cause healthcare costs; 58.3% for the BR cohort and 66.9% for the bendamustine cohort.

Summary/Conclusions: In this population of elderly patients previously treated for CLL, healthcare costs incurred during relapsed treatment with bendamustine-based regimens were high and a large portion of the costs were driven by comorbidity and/or adverse event-related costs. Results also suggest that the addition of rituximab to bendamustine does not appear to be a major cost factor.

PB1787
THE ROLE OF MAINTENANCE THERAPY IN THE TREATMENT OF PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA
A. Kuvshinov1,*, S. Voloshin1, I. Martynkevich1, A. Garifullin1, E. Kleina1
1Russian Scientific Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: The inclusion in the treatment program of new drugs (including new monoclonal antibodies and targeted therapies) allowed the majority of patients with CLL to achieve increasing the depth achieved remission and increase the duration of its preservation. MT may be a means of control over the minimal residual disease and the method of its eradication.

Aims: To compare the efficacy and safety of bendamustine-based regimens plus Rituximab (BR) and Ibrutinib (IR) in the treatment of patients with CLL.

Methods: A retrospective, single-center study was conducted. All patients with CLL hospitalized at the Hematology and Transfusiology Department of the Clinical Hospital University of Saint-Petersburg were included. Patients were treated with a bendamustine-based regimen in second or later lines of therapy in a real-world setting.

Results: A total of 275 patients were included in the BR cohort and a total of 100 patients in the IR cohort. Most patients (61.8% in the BR cohort and 66.0% in the IR cohort) were male and the mean age was approximately 75 years old. During the 6 months prior to the index date, patients in the BR and IR cohorts were similar in terms of comorbidity profile; mean Charlson comorbidity index was 3.53 in the BR cohort versus 3.61 in the IR cohort (p=0.581). During treatment, total all-cause healthcare costs were $14,520 PPPM for the BR cohort and $13,125 PPPPM for the IR cohort – outpatient costs (mainly driven by CLL-drug costs) represented the largest cost component. CAE costs accounted for a relatively large portion of the total all-cause healthcare costs; 58.3% for the BR cohort and 66.9% for the IR cohort.

Summary/Conclusions: In this population of elderly patients previously treated for CLL, healthcare costs incurred during relapsed treatment with bendamustine-based regimens were high and a large portion of the costs were driven by comorbidity and/or adverse event-related costs. Results also suggest that the addition of rituximab to bendamustine does not appear to be a major cost factor.

MULTISITE PERFORMANCE EVALUATION STUDY OF THE BD ONEFLOW LYSIS SCREENING SYSTEM
D. Van Hoof1,*, B. Balasa1, C. Green2, J. Kendall2, D. Gladding2, C.J. Fox2, D. Van Hoof2, V. Fraser2, A. Doherty3, D. Tielmaners4, L. Wolfe5, K. Judge6
1Medical Affairs, 2BD Biosciences, San Jose, United States, 3BD Biosciences, Oxford, United Kingdom, 4BD Life Sciences, Emmelgem, Belgium, 5BD Clinical Corporate Clinical Development, Sparks, Maryland, United States

Background: The BD OneFlow solution for diagnostic screening of chronic lymphoproliferative disorders (CLPDs) includes a standardized flow cytometry approach based on the EuroFlow (EF) Consortium liquid reagent system. The BD OneFlow solution enables reproducible identification and discrimination of normal from aberrant mature cell populations by combining standardized assays, setup reagents, and protocols. The BD OneFlow LST (Lymphoid Screening Tube) is intended for flow-cytometric immunophenotyping of normal and aberrant mature lymphocyte populations of B, T, and NK lineages in specimens (peripheral blood, bone marrow, and lymph node) from patients with hematological disorders. BD OneFlow LST acquisition and analysis template version 1.0 was revised to version 2.0 to include determination of lymphocytes as a percentage of total leukocytes. The FCS files from evaluable specimens of the original LST clinical trial were reprocessed using BD OneFlow LST template v2.0.

Aims: The objective of this study was to reprocess the FCS files from all the evaluable specimens previously collected using LST template v1.0 in the original clinical study to demonstrate equivalency between the investigational BD OneFlow LST system and the comparator EF liquid reagent system on a BD FACSCanto II flow cytometer with the 4-2H-2V CE-IVD configuration and LST template v1.0.

Methods: The FCS files using LST v1.0 template from the original clinical study included de-identified remnant peripheral blood (n=123), bone marrow (n=53), and lymph node (n=31) specimens from patients and healthy donors. Specimens were analyzed using BD OneFlow LST system and the comparator EF liquid reagent system on a BD FACSCanto II flow cytometer with the 4-2H-2V CE-IVD configuration and LST template v1.0. The MDSCs were gated using automated settings. The FCS files were analyzed using BD CellQuest Pro software. The results were compared using the Wilcoxon rank sum test.
were collected in EDTA or heparin anticoagulants or PBS (for lymph nodes) at three external study sites. Informed consent was not required in the clinical study. All specimens in the original study were simultaneously stained with investigational BD OneFlow LST and comparator EF liquid reagents within 24 hours of collection and were acquired within 60 minutes of staining. In the current study, analyses were performed on a BD FACSDuo II instrument using LST v2.0 templating with BD FACSuite software version 6.0.1. For our endpoints, specimens were categorized as normal or follow-up-needed. If follow-up was needed, specimens were categorized as B-, T-, NK-, or other-cell lineage. Overall agreement, negative agreement, and positive agreement, along with their one-sided lower 95% confidence limits, were calculated. For quantitative (percent) comparison of defined cell populations, Deming regression (slope and intercept analysis) was performed between the BD OneFlow method and the EF method.

Results: The BD OneFlow LST system compared to the EF system gave 100% (207 of 207) overall agreement (lower 95% CI: 98.6%) in delineating patients into normal (no follow-up) or follow-up, and 100% overall agreement in identifying B-, T-, and other-cell lineages (lower 95% CI: 98.6%). There was 100% positive agreement and 100% negative agreement between BD OneFlow and EF for follow-up vs no-follow-up (normal) and for all cell lineages from specimens that required follow-up. Furthermore, compared to the BD OneFlow system, the BD OneFlow LST system met the acceptance criteria for the quantitation of cell populations (slope regression) for the defined cell populations.

Summary/Conclusions: The multisite performance evaluation of the BD OneFlow LST system and the comparator EF liquid reagent system was concordant in identifying abnormal from normal mature populations in patients with CLPDs. BD OneFlow LST is fit for use in Diagnostic Use; CE Marked to the European in Vitro Diagnostic Medical Device Directive 98/79/EC: 23-19566-00.

IMMUNOGLOBULIN HEAVY/LIGHT CHAIN ASSAY DETECT IMMUNE DYSREGULATION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

1Almq Diagnostic, Park Shoham, 2Hematology Unit, Galilee Medical Center, Nahariya, 3Hematology Unit, Ziv Medical Center, Zfat, 4Medical Unit, Hadassah Medical Center, Afula, 5Department of Hematology, Sourasky Medical Center, Tel Aviv, 6Hematology Unit, Meir Medical Center, Kfar Saba, 7Hematology Unit, Kaplan Medical Center, Rehovot, 8Hematology Unit, Assaf Harofeh Medical Center, Zerifin, 9Department of Hematology, Shaare Zedek Medical Center, 10Department of Hematology, Hadassah University Hospital, Jerusalem, 11Hematology Unit, Bnai-Zion Medical Center, Haifa, Israel.

Background: Chronic lymphocytic Leukemia (CLL) is frequently accompanied by immune dysregulation. Hypogammaglobulinemia is the most important associated immune defect and all three classes of immunoglobulins (IgG, A and M) are involved. Recently, a novel assay for detecting heavy/light chain (hevylight) and their ratios has been described (HLC), which improves immunoglobulin detection and monitoring in plasma-cell dyscrasias by quantitating the different light chain types of each immunoglobulin class. The frequency and biological role of this assay has as yet not been studied in CLL.

Aims: To study the frequency of abnormal Heavy Light chain assay, in CLL patients.

Methods: This is an observational, multi-center study performed in collaboration with the Israeli CLL Study Group involving 10 medical centers in Israel. The cohort included patients with CLL as well as healthy volunteers. All patients studied had complete clinical database available and all medical records were examined and then summarized. Serum samples were analyzed for levels of: IgG1, IgG2, IgG3, IgG4, Isotypes of heavy/light chain: IgG kappa, IgG lambda, IgA kappa, IgA lambda, IgM kappa, IgM lambda and Free light chain: kappa (K), lambda (L), ratio of KUL and calculation of ratios of monoclonal/polyclonal immunoglobulin (HLC ratio).

Results: The total cohort consisted of 126 "treatment - naïve", patients with CLL and 26 healthy volunteers. Median age was 64 years, 64% were males and 78% had Binet stage A, while 19% and 3% were stages B or C respectively. Significant differences in the immunoglobulin subtypes were found between the different Immunoglobulin classes (IgG, A and M) and the HLC type were provided to guide physicians' assessment of treatment response. The total cohort included patients with partial remission (PR), stable disease (SD) and progressive disease (PD). iwCLL 2008 cri-

Summary/Conclusions: The results of this study demonstrate that this assay is an independent predictor of initial treatment response and can be used as a biomarker for disease progression. Further studies are needed to fully evaluate the role of this assay in the management of CLL.
on distribution of response in clinical trials. Data on disease progression and mortality was provided by the treating oncologist/hematologist. PFS and OS were compared using univariate and multivariate Cox proportional analyses between the CR and non-CR cohorts (OS multivariate analyses were not conducted due to the small number of events). An additional analysis was conducted to examine the benefits of achieving MRD- versus not achieving MRD among patients who achieved CR or PR.

**Results:** Data was collected on 330 CLL patients, including 179 patients in the CR cohort and 151 patients in the non-CR cohort (120 patients with PR, 25 with SD, and 6 with PD). Most patients were male, in their early sixties, and had an ECOG status of 0/1 at the time of initiating first-line therapy. The median observation period was approximately 30 months. There were 43 (26%) patients in the CR cohort and 75 (50%) patients in the non-CR cohort who progressed/died (Table 1). Patients in the non-CR cohort had an >2-fold higher hazard of progression/death (adjusted hazard ratio [HR]=2.30, p<0.05) and death (unadjusted HR=2.61, p<0.05) compared to patients in the CR cohort. Among patients who achieved CR or PR, 84 patients achieved MRD- and 62 patients did not; 14 (17%) patients who achieved MRD- and 27 (44%) patients who did not achieve MRD- progressed/died. Patients who did not achieve MRD- had an over three-fold higher hazard of progression/death compared to patients who achieved MRD- (adjusted HR=3.75, p<0.05). No death events were observed among patients who achieved MRD- while 4 (6%) events were observed among those who did not achieve MRD-.

**Summary/Conclusions:** Findings from this real-world study suggest that achieving CR is associated with improved PFS and OS compared to patients who do not achieve CR. Furthermore, significantly better outcomes were observed among patients who achieved MRD- compared to those who did not achieve MDR- but still achieved CR or PR. This suggests that deep response may be an important clinical parameter to consider in the treatment of CLL.

**ANTI-CD ANTIBODY MICROARRAY FOR MORPHOLOGY EXAMINATION OF CIRCULATING LEUKEMIA AND LYMPHOMA CELLS**

S. Kuznetsova, 1 A. Khvatunov, 1 A. Zakrova, 1 O. Fedyanina 2, 1.
1. Centre for Pediatric Hematology, Oncology and Immunology, 2. Centre for theoretical problems of physico-chemical pharmacology, Moscow, Russian Federation

**Background:** Matching the morphology with immunophenotype for individual leukocytes is a major issue in diagnostics of leukemia and lymphoma due to the absence of a method for simultaneous cluster of differentiation surface antigen detection and full leukocyte morphology analysis. This problem can be solved by using a leukocyte-binding antibody microarray.

**Aims:** We developed an anti-CD antibody microarray on a transparent support for leukocyte sorting and a method for preparation of the microarray-bound cells for high-resolution morphology analysis. The aim of the work was to demonstrate, that the leukocyte binding is highly specific and that the microarray-bound peripheral blood mononuclear cells both from healthy donors and patients with B-cell leukemias and lymphomas are morphologically identical to the same cells in blood smears.

**Methods:** Anti-CD antibodies were immobilised on plastic coverslips in spots 2 mm in diameter. In order to study the peripheral blood mononuclear cells (PBMC) the mononuclear fraction separated by density gradient from peripheral blood are incubated with the microarray in non-mixing conditions at 4°C. After the unbound cells are washed away the microarray-bound cells are dried in a temperature of 38°C for 20 minutes and fixed at room temperature. The antibodies against all the CD antigens. The results of such analysis of neo-antigens of the microarray permits to determine their percentage and immunophenotype by analysing the relative amount of these cells captured by the antibodies against all the CD antigens. The results of such analysis of neo-antigens of the microarray permits to determine their percentage and immunophenotype by analysing the relative amount of these cells captured by the antibodies against all the CD antigens.

**Results:** The results of such analysis of neo-antigens of the microarray permits to determine their percentage and immunophenotype by analysing the relative amount of these cells captured by the antibodies against all the CD antigens.

**Summary/Conclusions:** The microarray works as a “sorted smear” with cells positive for certain surface CD antigens localised in a predetermined area and permitting to apply any standard smear-oriented technique to the microarray-captured cells. Combined analysis of the pathologic cells’ immunophenotype, morphology and cytochemistry on the microarray permits to arrive at preliminary diagnosis and can be used in cases of any controversies between morphology, cytochemistry and immunophenotyping. The work is partially supported by 16-34-01030 and 16-04-00282 grants from RFBR.

**COMPARATIVE ANALYSIS OF INTERNATIONAL PROGNOSTIC INDEX FOR CHRONIC LYMPHOCYTIC LEUKAEMIA, PROGRESSION-RISK SCORE AND MD ANDERSON CANCER CENTER 2011 SCORE: REAL WORLD DATA FROM A SINGLE INSTITUTION**

V. Vukovic 1, D. Antic 1, 2, T. Karan-Djurasevic 3, N. Milic 4, M. Todorovic-Balint 1, 2, J. Jelicic 1, S. Pavlovic 3, B. Mihajlevic 1, 2

1. Clinic for Hematology, Clinical Center of Serbia, 2. Medical Faculty, University of Belgrade, 3. Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, 4. Institute for Medical Statistics and Informatics, Medical Faculty, University of Belgrade, Belgrade, Serbia

**Background:** In recent times, several powerful prognostic scores have been developed in order to predict to first treatment (TTFT) and overall survival (OS) of patients with chronic lymphocytic leukemia (CLL). The International Prognostic Index (IPCLL) for Chronic Lymphocytic Leukemia (LL-IPI) developed by The International CLL-IPI working group was found to predict OS and TTFT, while the rest of the two scores—progression-risk score (PRS) and MD Anderson Cancer Center Score 2011 (MDACC 2011) have been developed for prediction of TTFT in early stage CLL patients.

**Aims:** The aim of this study was to compare CLL-IPI, PRS and MDACC 2011 prognostic scores based on their impact on TTFT, treatment response (TR), progression-free survival (PFS) and OS of 54 treated CLL patients.

**Methods:** We retrospectively analyzed data from 54 consecutive CLL patients diagnosed and treated at Clinic for Hematology, Clinical Center of Serbia from 2003 to 2013. Blood samples were prospectively collected and analyzed for biological and molecular features (IGHV, FISH and TP53), as well as standard laboratory parameters. The three scores were retrospectively calculated using formulas from the original articles (International CLL-IPI working group, Lancet Oncol 2008, 9;11; and for CLL-IPI, PRS, and MDACC 2011, for PRS, and Vierstra et al, J Clin Oncol 2011, for MDACC 2011 score), and, then, correlated with TTFT, TR, PFS and OS of patients from the studied cohort.

**Results:** Median age at diagnosis was 57 years (range 38-75), 28% were treated with fludarabine-based chemotherapy, 45% in the first line regimen, 72% in the second line. Overall response rate to the first line therapy was 81%, equally distributed on complete and partial responses. Most of the patients (42, 78%) relapsed during the follow up. At the time of the last follow up 14 (26%) patients were still alive, 35 (65%) were dead, and 5 (9%) were lost to follow up. Median overall survival was 76 months. Lower score values for all the three scoring systems (International CLL-IPI, PRS, and MDACC 2011) correspond to longer TTFT (p=0.05 for all). Cox regression analysis revealed that CLL-IPI and PRS are significant predictors of TTFT (p=0.003, RR=1.4, 95%CI 1.1-1.7 and p=0.019, RR=1.4, 95%CI 1.1-1.9, respectively), while MDACC 2011 was of borderline significance (p=0.052). In the multivariable analysis PRS emerged as the most significant predictor of TTFT among the three examined scores (p=0.041, RR=1.35, 95%CI 1.01-1.81). Regarding TR, only PRS appeared to have borderline statistical significance (p=0.052), showing that patients with lower score value may achieve better TR. Lower CLL-IPI can predict longer PFS after the first line treatment (p=0.007, RR=1.7, 95%CI 1.2-2.57), as well as PFS (p=0.039, RR=1.6, 95%CI 1.03-3.1, 1591 M2). Biannual MDACC 2011 has not shown to have influence on PFS. Multivariable analysis confirmed PRS to have the strongest predictive value of all the three scores regarding duration of PFS (p=0.039, RR=1.8, 95%CI 1.02-3.1). Furthermore, CLL-IPI and PRS were found to be significant predictors of OS (p=0.005, RR=1.4, 95%CI 1.1-1.8 and p=0.037, RR=1.5, 95%CI 1.1-2.4 respectively). MDACC 2011 is not significant.

**Summary/Conclusions:** CLL-IPI and PRS were identified as significant predictors of TTFT, as well as of duration of TR and OS. Further studies are warranted to confirm these findings.
MULTISITE PERFORMANCE EVALUATION STUDY OF THE BD ONEFLOW B-CELL CHRONIC LYMPHOPROLIFERATIVE DISORDERS T1 (B-CLPD T1) PANEL
B. Balasa1,*, C. Green2, J. Kendall2, D. Gladding2, V. Fraser2, A. Doherty3, D. Tielemans4, L. Wolfe5, F. Oreizy2, A. Chen2, V. Fraser2, A. Doherty3, D. Tielemans4, L. Wolfe5, K. Judge6
1Medical Affairs, 2BD Biosciences, San Jose, United States, 3BD Biosciences, Oxford, United Kingdom, 4BD Life Sciences, Erembodegem, Belgium, 5BD Clinical Corporate Development, Sparks, Maryland, United States

Results: Our results based on molecular analysis from 100 subjects living in the same geographical area, show the presence of three major groups of clones with distinct but partially overlaying configurations of IGHV gene usage, IGHV mutational status and cytogenetic alterations. These included a group which mainly consisted of clinical advanced stage CLL with a skewed but different IGHV-associated IgH gene repertoire [VH1-69 associated with HD3 gene and HJ6 gene] and another group associated with complex karyotypes and poor-prognosis cytogenetic alterations, a second group enhanced in clones expressing specific IGHV subgroups (VH3-23 associated with HD2 genes and HJ6 gene) with no or isolated good-prognosis cytogenetic alterations and a third group of clones with intermediate features, with prevalence of mutated IGHV genes, and higher numbers of deleted [del(13)] clones.

Summary/Conclusions: These findings suggest that the specific IGHV repertoire and IGHV mutational status of CLL B-cell clones may adjust the type of cytogenetic alterations acquired and their clinical significances. Further long-term follow-up studies investigating the IGHV gene repertoire of CLL clones in distinct geographical areas and environments are required to validate our findings and discard or confirm the potential role of some antigen-binding BCR specificities contributing to clonal evolution.

PROGNOSTIC SIGNIFICANCE OF SERUM BAFF, APRIL, TACI AND BCMA LEVELS IN CHRONIC LYMPHOCYTIC LEUKAEMIA
I. Berke Mentese1,*, Z.A. Yegin2, S. Gokcen2, Z.N. Ozkurt2, M. Yagci2
1Internal Medicine, 2Haematology, Gazi University Faculty of Medicine, Ankara, Turkey

Results: Our results showed that serum BAFF levels were significantly higher in patients with CLL compared to other B-CLPDs (p<0.001). While serum APRIL levels were not significantly different between the patient and control groups (p>0.05) (Table 1). Serum BAFF [(p=0.008; r=0.236)] and BCMA [(p=0.042; r=0.183)] levels were negatively correlated with Rai stage and serum BAFF level was higher in low-risk patients based on modified Rai staging system (p=0.059). Serum APRIL levels were lower in CD38 positive patients (p=0.06; 0.17(0.1-0.86) vs 0.13(0.1-1.07)). Age (p=0.002), Rai stage (p=0.005) and Modified Rai stage (p=0.051) were the significant factors which had an impact on overall survival in multivariate analysis.

Table 1.
Background: Constitutive activation of B-cell receptor signalling appears to be essential for the proliferation of malignant B cells. Bruton’s tyrosine kinase (BTK) has been identified as an essential component of the B-cell receptor signalling pathway. Ibrutinib is an orally administered BTK inhibitor that antagonises B cell receptor, chemokine & integrin mediated signalling.

Aims: We report our experience of using ibrutinib to treat relapsed/refractory B-cell chronic lymphocytic leukaemia (B-CLL) and mantle cell lymphoma (MCL) in a busy U.K. District General Hospital (DGH) serving a population of 600,000.

Methods: 26 patients were commenced on ibrutinib for relapsed/refractory B-CLL or MCL between August 2014 & December 2016. 16 patients had B-CLL and 10 patients had MCL. Patients with B-CLL were commenced on 420mg daily: those with MCL received 540mg daily. The median age at which ibrutinib was commenced was 71.1 years (range 50-85). The median age of patients with B-CLL was 71.1 years (range 50-80) and for MCL was 71.6 years (range 54-85). The median number of prior lines of therapy decreased over the time period from 3.2 in 2014 to 1.2 in 2016. The mean interval between diagnosis and commencement of ibrutinib was 6.7 years (B-CLL) and 6.5 years (MCL). The average number of co-morbidities in both groups was similar: 1.4 in B-CLL and 1.5 in MCL. After May 2015 all patients received aciclovir and co-trimoxazole prophylaxis. Response to ibrutinib was assessed by clinical examination and blood results; imaging and bone marrow examination were conducted at the clinician’s discretion.

Results: The median follow up was 15.5 months for B-CLL patients and 8 months for MCL patients. The median survival of all patients who did not receive anti-viral and pneumocystis prophylaxis was 5 months and the median survival for those who did receive prophylaxis was not reached (p < 0.0001). The median survival of patients with MCL was 6 months. The median survival of patients more than one year on ibrutinib treatment was 17 months; the median survival in those who had received just one prior line of treatment was not reached (p = 0.0085). In the B-CLL cohort there was no difference in survival between those with and without >p / p53 deletion. 11/26 patients experienced side effects: 8 had grade 1 and 2 side effects (diarrhoea, drug rash, cardiac arrhythmias) which were easily controlled by the treating oncologist. 3 patients had grade 4 side effects (1 severe arthropathy, 2 intracranial haemorrhage - one of which was fatal). 4 of the 16 (25%) with B-CLL and 5 of the 10 (50%) with MCL died during the period of follow-up. Causes of death were: intra-cerebral haemorrhage (1), unrelated cancer (1), disease progression (2), disease progression+sepsis (2), sepsis alone (3). Of the remaining 17 patients, 14 continue to receive ibrutinib, 2 (B-CLL) were switched to idealisib/Rituximab (for grade 4 toxicity) & 1 went on to have an allogeneic transplant (MCL).

Summary/Conclusions: Though our cohort of patients is small, we describe our observations thus far. The use of prophylaxis with co-trimoxazole and co-trimoxazole prophylaxis is associated with improved survival in our overall cohort. Moreover, patients who received fewer lines of prior treatment had a better survival. Patients with p16/p53 deleted B-CLL responded as well as those without a deletion. Ibrutinib is a very effective therapeutic option in patients with relapsed CLL and MCL.

PB1799
THE VALUE OF RITUXIMAB ADDITION TO CHEMOTHERAPY TREATMENT OF REAL-WORLD CLL PATIENTS: A 15 YEAR SINGLE CENTER EXPERIENCE
L. Van Der Straeten1, A. Gnimhomed2,3,4, J.K. Doorduin2, P.E. Westerweel5, A.W. Langerak6, A.P. Kater2, M.-D. Levin7
1Institut Jules Bordet, Cellular Therapy Department; 2Haematology, Erasmus MC Cancer Institute; 3Public Health, Erasmus University Medical Center, Rotterdam; 4Research, Netherlands Comprehensive Cancer Organization, Utrecht; 5Immunology, Erasmus Medical Center, Rotterdam; 6Haematology, Academic Medical Center, Amsterdam; 7Netherlands

Background: The addition of the monoclonal antibody rituximab to chemotherapy has been shown to improve progression free survival and overall survival in prospective trials in CLL patients. However, CLL patients participating in clinical trials may not be fully representative of the overall patient population in clinical practice as there is selection bias due to study eligibility, willingness to participate and various in- and exclusion criteria. To date, the efficacy of rituximab added to standard chemotherapy in first line and relapsed CLL patients has been poorly validated in observational studies in unselected real-world CLL patients.

Aims: To evaluate the efficacy of rituximab-chemotherapy (R-CTX) compared to chemotherapy (CTX) in a real-world CLL population.

Methods: All patients from a large teaching hospital diagnosed with immunophenotypically confirmed CLL in the period from 1-1-2000 up to 1-5-2015 were analyzed for this study and were categorized into two groups (1) those treated with CTX and (2) those who were treated with R-CTX. The clinical treatment of patients was evaluated based on the “treatment-free interval” (TFI), defined as the time from stop of chemo(immuno)therapy to start of next treatment. Patients who did not need next treatment were censored at time of last follow-up or death. In addition, overall survival (OS) for patients treated in the period without rituximab had become available in our center was compared to patients treated before the rituximab era (before and after 1-1-2006, respectively).

Results: A cohort of 375 CLL patients was studied, of whom 124 CLL patients (33%) required treatment in the observation period. The median age at first-line therapy was 67 years; 55% and 45% of these patients received first line CTX or R-CTX, respectively, and 47% of these patients required a second or later line of (R-)CTX. In total 221 treatment periods of (R-)CTX were studied with respect to treatment-free interval, 124 first-line, and 97 courses of retreatment. In the first-line treatment group 12 (10%) and 24 patients (19%) were treated with purine-analogue-based schedules without or with R respectively, i.e. (R-)fludarabine or (R-)fludarabine plus cyclophosphamide, 25 (26%) and 31 patients (25%) were treated with chlorambucil/CVP-based regimens without or with R respectively, and two patients (2%) were treated with CHOP and R-bendamustin. The median TFI for patients treated with CTX was 31 months (95% CI: 20 – 42 months) and was significantly better in the R-CTX group where median TFI was 17 months (95% CI: 6.9 – 18.8 months, p < 0.0001). In second or later lines of treatment 15 (11%) and 11 patients (10%) were treated with purine-analogue-based schedules without or with R respectively, i.e. (R-)fludarabine or (R-)fludarabine plus cyclophosphamide, 25 (26%) and 31 patients (25%) were treated with chlorambucil/CVP-based regimens without or with R respectively, and two patients (2%) were treated with CHOP and R-bendamustin. The median TFI for patients treated with CTX was 27 months (95%CI: 18 – 52 months) vs 55 months for R-CTX (95%CI: 41 months – NR), HR 0.47 (95%CI 0.15 – 0.90) for subsequent lines. OS for patients treated in the R era was 48 vs 35 months for patients treated before the introduction of rituximab.

Summary/Conclusions: Our study shows that the addition of rituximab improved treatment free interval in first- and subsequent lines and prolonged overall survival in a cohort of CLL patients receiving treatment in routine clinical ‘real world’ practice.
Chronic lymphocytic leukaemia (CLL) is characterised by frequent co-existent infectious complications. They stem from, among other things, hypogammaglobulinemia, which is connected with CLL, and correlates with the disease duration and severity, as well as T-lymphocyte function disorders. The application of innovative therapies (chemoimmunotherapy) on the one hand facilitates considerable improvements in treatment outcomes and on the other hand it increases the risk of life-threatening infectious complications. The introduction of a new drug, ibrutinib (Bruton’s kinase inhibitor), has created a unique opportunity for CLL patients, especially those with prognostically unfavourable genetic aberrations (del17p), or in the case of whom previous chemotherapies have failed to give satisfying results. Previous observations indicate the risk of side effects (e.g. bleeding, infectious complications, heart rhythm disorders) which might sometimes limit the applicability of ibrutinib in some CLL patients.

Aims: The aim of this paper was to evaluate the risk of infectious complications in persons with CLL, and to determine potential correlations between possible infectious complications and selected clinical, morphological and biochemical parameters.

Methods: The study comprised 43 CLL patients aged 48-82 years (average age 67 years), 18 women and 25 men. At the beginning of the ibrutinib therapy the patient’s disease was at the 2-4 clinical stage, according to Rai et al. Usually they were individuals who had received a couple of previous chemotherapies (from 1 to 7) which contained, inter alia, purine analogues, and the monoclonal antibodies (rituximab, alemtuzumab, ofatumumab). Ibrutinib was administered at a dose of 420 mg/d.

Results: Infectious complications were observed in 16 patients (37.2%). These included, for example, upper respiratory tract infection, bronchitis, pneumonia, urinary-tract infections, pharyngitis. The conducted analysis showed a statistically significant correlation between the concentration of IgM in the blood serum (before ibrutinib administration) and infectious complications during these therapy (p<0.05). The average IgM concentration in patients with complications was considerably lower when compared to people who did not experience any complications. The patients (n=3, 6.98%) with complications at the moment of the CLL diagnosis also had them during the ibrutinib treatment. This phenomenon was confirmed in 13 patients (33%) in the other group. The correlation was borderline significant (p=0.09). Infectious complications were observed more frequently in the patients with 3-4 stage CLL (according to Rai et al.) than in the individuals at the less-advanced clinical stages of the disease (0-2), and this correlation also showed borderline significance (p=0.08). No significant correlation was detected between the risk of infectious complications and earlier therapies with purine analogues and neutropenic episodes during the ibrutinib therapy.

Summary/Conclusions: Ibrutinib is considered to be a real breakthrough in CLL treatment; but it has to be borne in mind that the drug gives possible side effects which might occur during therapy. They include infectious complications which are among the main causes of death in this group of patients. The results obtained by us indicate that the risk of infection during ibrutinib therapy relates mainly to patients with low IgM concentration in the blood serum and at more advanced clinical stages of the disease. In this case the occurrence of previous complications (before ibrutinib administration) is also relevant. We are aware of the limitations of our work related to the small number of patients. Yet, even at this stage, it is possible to select CLL patients with increased risk of such usually life-threatening complications.

Summary/Conclusions: Incidence of RS in our study is partly coherent with literature data. Levels of LDH and Hb at the time of transformation are significant predictors of outcome for patients with RS. Real-time PCR of patients with RS is probably higher, but commonly bad condition of these patients on diagnosis of RS probably influences the decision of a clinician not to indicate biopsy.

INFECTIOUS COMPLICATIONS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKAEMIA TREATED WITH IBRUTINIB
E. Wasik-Szczepeanek1, A. Szczepanek1, M. Czabak1, M. Choch1, M. Wach1, M. Podhorecka1, B. Sokolowska1, M. Pasias1, J. Kozinska1, I. Hus1, D. Szczepanek1, K. Kotwica1, A. Szczepanek1, M. Hus1
1Haematology and Bone Marrow Transplantation, Medical University in Lublin, Lublin, 2Hematology, Medical University in Kielce, Kielce, 3Neurosurgery, Medical University in Lublin, Lublin, Poland

Background: Chronic lymphocytic leukaemia (CLL) is a recently recognized entity characterized by the presence, in the peripheral blood, of a monoclonal B-cell population lower than 5000/µl, in the absence of any type of clinical features. MBL clones may have: a) chronic lymphocytic leukaemia (CLL-like) phenotype (CD5+, CD19+, CD23+, CD20 dim); b) atypical CLL phenotype (CD5+, CD19+, CD23- or CD20 bright); c) non-CLL phenotype (CD5-). MBL can be also distinguished in ‘low-count’ (<500/µl) and ‘high-count’ (>500/µl) subtypes. High-count MBL frequently shows typical CLL phenotypic/genetic features and require adequate follow-up in order to detect their possible evolution into symptomatic CLL. MBL showing a clonal B-cell count higher than 1000-1500/µl are usually defined ‘clinical’ MBL. Using highly sensitive (i.e. >6 colors and >500000 events) flow cytometry approaches, CLL-like MBL clones have been found at a frequency of 7-12% in healthy subjects, showing, however, very low median counts of clonal B-cell (10-170/µl), with only 0.14% being clinical MBL. Though several studies have described the association between CLL and various types of neoplastic disorders, only few data exist about the risk of non-hematologic cancer in individuals with MBL, in particular, no association between MBL and prostate cancer (PC) has been so far reported.

Aims: To study prospectively the frequency of CLL-like MBL clones in patients affected by PC compared to healthy males of the same ages, after our previous observational study of an apparently increased MBL incidence at baseline in a cohort of patients with PC previously studied to detect lymphocyte abnormalities possibly induced by radiotherapy (RT).

Methods: We enrolled 34 consecutive patients affected by PC (mean age 74 years, range 58-91), naive for chemotherapy (sixteen previously treated with hormone-therapy). All patients were planned to receive whole-pelvis RT with radical (n. 23) or salvage (n. 11) intent. Fifty-four healthy males (mean age 71 years, range 58-87) represented the control group. Immunophenotypic analysis of peripheral lymphocytes before RT was performed by BD FacsCanto II flow cyrometer, using a 5-6 colors approach and the following antibody combinations: CD19 FITC/CD5 PE/CD45 PerCP/CD20 PE-Cy7/CD23 APC; Kappa FITC/Lambda PE/CD19 PerCP-Cy5.5/CD20 PE-Cy7/CD5 APC/CD45 APC/CD7. For each sample, 100000 events were collected. CD45+ lymphocytes were gated on CD45 vs SSC dot plot, then B cells were isolated by gating on CD19 and CD19+ CD5+ cells were interrogated for intensity of CD20. Finally, CD19+ CD5+ CD20dim selected population was analyzed for light chain clonality and CD23 expression.

Results: Median (range) absolute counts of white blood cells (WBC), total lymphocytes and B-cells, as well as absolute single values of MBL clones are reported in Table 1. In PC patients we found 3 MBL (8.8%), two of which were “high count” (1.8%) MBL (5.8%). In contrast, in healthy subject group, only one “low count” MBL (1.8%) was detected, showing a very small clone (8 cells/µl). Such a difference was not statistically significant (p=0.2).

Table 1.

Summary/Conclusions: The preliminary results of our prospective study, performed using a routine, not highly sensitive flow cytometry approach, highlight a possible association between (clinical?) MBL and PC, never described before and probably warranting further investigation in a larger number of patients.
Chronic myeloid leukemia - Biology

IDENTIFICATION OF NOVEL MUTATIONS IN CANCER-RELATED GENES IN HUMAN ERYTHROLEUKEMIA K562 CELL LINE BY NEXT-GENERATION SEQUENCING
M. Popiel1,2, M. Kurkowia1, M.M. Machnicki1,2, I. Solarska3, K. Borg3, M. Rydzanicz4, P. Stawinski2, R. Plosk1, T. Stoklosa1
1Department of Immunology, Medical University of Warsaw, 2Postgraduate School of Molecular Medicine, 3Department of Diagnostic Hematology, Institute of Hematology and Transfusion Medicine, 4Department of Medical Genetics, Medical University of Warsaw, Warsaw, Poland

Background: Chronic myeloid leukemia (CML) is a clonal hematopoietic stem cell disorder characterized by reciprocal chromosomal translocation (t(9;22)(q34;q11), resulting in the formation of the BCR-ABL fusion oncogene. One of the most widely used CML in vitro model is the K562 BCR-ABL1-positive human erythroleukemia cell line derived from a female patient with CML in blastic phase (CML-BP) and representing an important tool for the studies of malignant hematopoiesis in last decades. Although K562 karyotype was described several times, detailed genomic analysis of this cell line is not yet available and to our best knowledge there are no publications yet describing complex genomic landscape of K562 cells.

Aims: The aim of our study was to determine the mutational landscape of K562 cell line using next-generation sequencing (NGS). Additionally classical fluorescence in situ hybridization (FISH) with BCR and ABL1 probes was performed to confirm cytogenetics.

Methods: The K562 cell line was purchased from DSMZ (Braunschweig, Germany). We analyzed almost 1300 genes implicated in human cancer using custom designed capture (SeqCap EZ, NimbleGen, Roche) followed by high-throughput sequencing on Illumina HiSeq 1500. Common variants (>1%) gathered in ESP6500 and 1000 genomes projects and our internal exome database were filtered out and the subsequent analysis was focused on putative protein damaging variants with the frequency in the database from NHLBI GO exome sequencing project less or equal to 0.01. We used different bioinformatic tools for variant effect prediction (eg. PolyPhen-2, SIFT, IntOGen). Mutations were collected in the Table 1. The number of variant was highly increased using commercially available probes (Vysis, Abbott, USA), that identifies the BCR-ABL1 fusion genes.

Results: Sequencing and bioinformatical analysis revealed 88 variants with potential biological significance. We detected Q136fs*13 mutation in TP53, which has already been described in K562 cell line previously by ATCC, but we have also identified several new mutations in genes involved in tumorigenesis and drug resistance (Table 1). Moreover, cytogenetic analysis showed both multiplication of the BCR and ABL1 genes and amplification of the BCR-ABL1 fusion gene (Ph chromosome is present in at least four additional copies).

Table 1. Selected prominent mutations identified in K562 cells.

Summary/Conclusions: We describe several new mutations in such genes as ASXL1, BRCAl1 or MLH1 in one of the most frequently used cell line in leukemia research, K562 erythroleukemia. Our results confirm high level of genomic instability in the blastic phase of CML represented by the K562 cell line and add new, valuable information for researchers who want to employ this cell line. The awareness of the genomic aberrations present in the K562 erythroleukemia cell line is essential for further studies as those aberrations may have a significant impact on the observed results.

INVESTIGATION OF POLYMORPHISMS RELATED TO MIR-608 IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA
N. Ryabchikova1, G. Safuanova1, A. Minniakhmetov2, A. Sultanbaev1, E. Khusnutdinova2
1Bashkir State Medical University, 2BG USC RAS, UFA, Russian Federation

Background: Chronic myeloid leukemia (CML) is a myeloproliferative disorder characterized by the expression of the BCR-ABL oncoprotein, which is essential for the pathogenesis of the disease. Imatinib, an ATP-competitive selective inhibitor of BCR-ABL, has shown unprecedented efficacy for the treatment of CML. Several cellular and genetic mechanisms of imatinib resistance have been proposed, including overexpression of the BCR-ABL gene, the tyrosine kinase domain mutations, pharmacokinetic and pharmacodynamic factors.

Aims: The purpose of this study was to investigate miRNA-608 role in response to therapy with tyrosine kinase inhibitors (Imatinib). In this study, we analyzed rs9762 SNP located in a miRNA-608 binding site of 3’UTR of BCR-ABL gene and rs4919510 SNP in the mature sequence of miR-68 in CML patients with different response to tyrosine kinase inhibitor therapy. These polymorphisms disrupt the negative effect of miR-68 on its target BCR-ABL. Our study suggested that individual based investigations may be important to evaluate the BCR TKI resistance. We also provide the promising clinical relevance as a candidate drug for treatment of ABTKI resistant leukemia patients.

TARGETED STRATEGY FOR ABL TYROSINE KINASE INHIBITOR RESISTANT PHILADELPHIA CHROMOSOME POSITIVE LEUKEMIA CELLS
S. Okabe1, T. Tauchi1, Y. Tanaka1, K. Ohyashiki1
1Department of Hematology, TOKYO MEDICAL UNIVERSITY, Shinjuku-Ku, Japan

Background: Although ABL tyrosine kinase inhibitors (TKIs) such as imatinib have demonstrated the potency against Philadelphia chromosome (Ph)-positive acute lymphoblastic leukemia, resistance to ABL TKIs can develop in chronic myeloid leukemia (CML) patients. Therefore, new approach against ABL TKI resistant cells may improve the outcome of Ph-positive leukemia patients. It has already reported that ABL kinase domain mutations have been implicated in the pathogenesis of ABL TKI resistance, however, it is fully not known the molecular mechanism of drug resistance including second (nilotinib and dasatinib) and third generation (ponatinib) ABL TKIs.

Aims: As leukemia is a genetic disease driven by heritable or somatic mutations, we hypothesized that ABL TKI resistance may often happen due to additional somatic mutations in the oncogene.

Methods: We established several TKI-resistant in vitro cell line models. We also investigated model to evaluate the next-generation sequencing (NGS) panel, NGS platform to screen mutational hotspots in 50 leukemia-related genes.

Results: We established ABL TKI resistant cell lines (K562 imatinib-R, K562 nilotinib-R, K562 dasatinib-R, K562 ponatinib-R, Ba/F3 T315I and Ba/F3 ponatinib-R) in this study. We conducted fluorescence in situ hybridization (FISH) analysis on parental K562 and ABL TKI resistant K562 cells. BCR-ABL expression levels were not increased in ABL TKI resistant K562 cells compared to parental K562. We next investigated the BCR-ABL point mutation direct sequence analysis. We could not detect the BCR-ABL point mutation in ABL TKI resistant K562 cells. However, the exon 4 deletion in the BCR-ABL gene was found in K562 ponatinib-R cells. In contrast, compound mutations in BCR-ABL were found in Ba/F3 ponatinib-R cells. K562 ponatinib-R cells were also highly resistant to imatinib, nilotinib and dasatinib. We examined several ABL TKI resistant K562 cells. Phosphorylation of BCR-ABL and Crk-L was reduced in K562 dasatinib-R cells, however, MAPK activity was increased. In K562 ponatinib-R cells, MAPK activity was reduced. We next evaluated the NGS panel (GeneRead DNAseq Targeted Panels V2) to investigate the mutation. We found that several somatic mutations in TET2, FLT3, RB1, TP53, SETBP1, ASXL1, and BCOR were also detected in parental K562 cells. We also found that additional somatic mutations in K562 imatinib-R (IDH1 and KRAS), K562 dasatinib-R (IDH1) and K562 ponatinib-R (SF3A1). We could not detect additional mutation in K562 nilotinib-R cells. We next investigated the MEK inhibitor and IDH1 inhibitor activity against K562 imatinib-R and K562 nilotinib-R cells. MEK inhibitor or IDH1 inhibitor did not induce cell growth inhibition directly. However, combined treatment of ABL TKI resistant K562 with imatinib or dasatinib and MEK inhibitor or IDH1 inhibitor caused more cytotoxicity than each drug alone. Because aberrant activation of PI3K signaling pathway and deregulation of HDAC activity may be a cause of malignant disease in humans, we examined the PI3K and HDAC inhibitors in ABL TKI resistant cells. We found 72 h treatment of oral inhibitor of class I PI3K as well as class I and II HDAC enzymes, CUDC-907 exhibits cell growth inhibition ABL TKI resistant K562 cells and Ba/F3 ponatinib-R cells in a dose dependent manner. In the mouse study, a dose of 20 mg/kg/day p.o of ponatinib and 30 mg/kg/day p.o of CUDC-907 inhibited tumor growth of T315I mutant cells compared with control mice and induced apoptosis in tumor samples.

Summary/Conclusions: Our study indicated that leukemia cells have acquired resistance through somatic mutation or exon 4 deletion in the BCR-ABL. We suggested that individual based investigations may be important to evaluate the ABL TKI resistance. We also provided the promising clinical relevance as a candidate drug for treatment of ABL TKI resistant leukemia patients.
Background: Conventional cytogenetics is a common modality for tyrosine kinase inhibitor (TKI) response assessment in chronic myelogenous leukemia (CML) patients. There is no consensus regarding the use of conventional bone marrow (BM) cytogenetics or peripheral blood (PB) interphase fluorescence in situ hybridization (FISH) during follow-up. The routine dual colour FISH probes are less sensitive to reliably identify der(9) deletions during follow-up. BCR/ABL/ASS1 tri-colour dual FISH (TCDF) probe is highly sensitive and specific in identifying der(9) deletions.

Aims: Our aim was to identify the FISH fusion patterns of BCR/ABL/ASS1 TCDF probe and correlate the patterns with patient-specific molecular genetic parameters.

Methods: This was an ethnically approved study conducted at a government-funded tertiary care institute. From January 2015 to June 2016, PB FISH analysis was performed on European LeukemiaNet defined imatinib-resistant CML patients using BCR/ABL/ASS1 TCDF probe (Abbott Laboratories, Abbott Park, Illinois, USA). The residual BCR-ABL1 transcript load was monitored in international scale (BCR-ABL i16%) using an automated cartridge-based GeneXpert system (Cepheid, Sunnyvale, CA, USA).

Results: On analyzing 37 adult patients, all had residual Philadelphia (Ph) chromosome (100%). Classic Ph fusion pattern was seen in 33 (89%). derivative chromosome 9 (der(9)) deletions in 25 (67.5%) and supernumerary Ph chromosomes in 11 (30%) patients. Coexistence of classical fusion and der(9) deletions were seen in 21 patients (57%), whereas 8 patients (22%) had a mutual existence of classical fusion, der(9) deletions and supernumerary Ph chromosomes. None had Ph amplification. Figure 1 demonstrates the I-FISH patterns seen in a 43-year-old male diagnosed with CML-CP and had progressed to blast crisis at his 72nd month of imatinib therapy. In this Figure red, yellow and white arrows indicate blast cells without Ph chromosome, Ph+ blast with a loss of residual ABL1 on der(9) classical and random signal overlap, respectively. A mean (± S.D) of 29% (± 30) and 18% (± 17) der(9) deleted cells were seen amongst patients with b2a2 and b3a2 BCR-ABL1 transcript types, respectively and this difference was statistically significant (p=0.008).

There was also a significant difference in the disease transformation status according to the percentage of der(9) deleted cells (p=0.03). In this regard, patients with progressive disease (accelerated phase/ blast crisis progression) had a mean (± S.D) of 47% (± 35) der(9) deleted cells in comparison to 19% (± 20) such cells in patients without disease transformation. In addition, patients with Ph duplication/triplication had a mean (± S.D) BCR-ABL1 i16% levels of 49.478% (± 40.184), in comparison to BCR-ABL1 i16% levels of 16.00% (± 19.993) in patients without these anomalies and this difference was also statistically significant (p=0.029).

Summary/Conclusions: Our results show that basophilia should be carefully investigated when CML is suspected, with high sensitivity (100%) and specificity (95.75%). In cases no CML with basophilia >0.3 x10 9/L, further investigation should be performed in order to diagnose a MPN Ph− or MDS/MPN. Even basophilia is well established as nearly universal in CML 1,3,4, this study reveals it is not always pursue enough, when clinicians ask for a molecular study.
Background: Data concerning the impact of BCR-ABL del. c.1086-1270 on TKI resistance in CML is still controversial. This mutation was first described by Curvo et al. (2008) and was thought to confer TKI resistance. However computer modeling performed by Meggyesi N. et al. (2012) revealed disruption of ATP binding site in mutated tyrosine kinase therefore abrogating enzymatic activity. Nevertheless pathogenetic effect of BCR-ABL p.R362fs*21 could be attributed to the formation of heterodimer with "wild type" Bcr-Abl p210 as described by Poullakkakos P.I. et al. (2011).

Aims: To assess the impact of BCR-ABL del. c.1086-1270 (p.R362fs*21) on TKI resistance in CML patients from Russian Federation.

Methods: 33 male and 49 female CML patients (age 24-80) with BCR-ABL transcript level >0.1% were included in the study. BCR-ABL del. c.1086-1270 was estimated by nested PCR followed by Sanger sequencing. Initial screening for deletions was performed by means of fragment analysis (Applied Biosystems 3130).

Results: 92 RNA (cDNA) samples isolated from peripheral blood of 82 CML patients were tested. BCR-ABL del. c.1086-1270 (p.R362fs*21) was found in 32 patients (39%). 15 out of 32 (47%) patients with deletion were TKI sensitive while 17 (55%) were TKI resistant. In one TKI resistant case BCR-ABL del. c.1086-1270 was accompanied by BCR-ABL c.844G>C p.E282Q point mutation not described so far (Figure 1). This mutation was found in BCR-ABL del. c.1086-1270 transcript only and was absent in "wild type" Bcr-Abl p210 transcript amplified from the same patient.

Summary/Conclusions: BCR-ABL del. c.1086-1270 could be found in almost half of CML patients and have no evident impact on the induction of big molecular response in TKI sensitive cases. Our observation that independent c.844G>C p.E282Q point mutation expressed on the same BCR-ABL transcript with deletion c.1086-1270 (p.R362fs*21) being absent in "wild type" transcript strongly contradicts the hypothesis, that del. c.1086-1270 could be generated by alternative splicing of "wild type" BCR-ABL transcript.

FUNCTIONAL CHARACTERISTICS OF ERYTHROID PROGENITOR CELLS OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH IMATINIB AND Nilotinib

T. Perekhrestenko1,*, I. Sviezhentseva2, D. Bilko2, N. Tretiak1, I. Dyagi3

1blood disease, State Institution «Institute of Hematology and Transfusiology of NAMS of Ukraine», 2center of molecular and cell research, University of Kyiv Mogyla Academy, 3department of hematology and transplantology, State institute ‘National Research Center of Radiation Medicine, Kyiv, Ukraine

Background: It is believed that chronic myeloid leukemia arises as a result of myeloid progenitor cell malignancy. There are changing of proliferative activity in granulocyte-macrophages and erythroid hematopoesis germs in patients bone marrow. Currently we don’t have definite results regarding tyrosine kinase inhibitors influence on erythropoietic cell characteristics of patients with CML.

Aims: the aim of study was to determine functional characteristics of erythroid progenitor cells of patients with chronic leukemia treated with Imatinib and Nilotinib.

Methods: We studied 300 bone marrow samples from 75 patients: with initial diagnosis of CML (n=7), patients receiving drug imatinib (n=47) and patients who taking nilotinib (n=21). We provide studying of erythroid mononuclears in semisolid in vitro and in vivo cultures. For in vitro culture we used special gel capsule, allowing cytokines and growth factors of mouse body affect human mononuclear cells. For in vitro culture we added 20% fetal calf serum, 30 ng/ml erythropoietin, and 20 ng/ml interleukin-6 and interleukin-9. Cultivation was provided 14 days, then counted the number of erythroid colonies and provided their morphological studies.

Results: The results showed that the increase of erythroid progenitor cells proliferation rates and the reduction of differentiation rates as a result of the parallel cultivation of patients’ bone marrow cells in vivo and in vitro happen irrespective of the presence of cytokines and growth factors in a normal microenvironment of these cultures. In addition, we showed that bone marrow cells of CML patients form erythroid colonies, when placed in the animals’ body without previous leukemic anemia. Moreover, correlative relationship was found between the number of erythroid colonies and the number of leukemic cells in the patients bone marrow. It was established that the acquisition of leukemic clone cells resistance to TKI is characterized by increased proliferative activity irrespective of soluble microenvironment factors as well as the culture medium in the erythropoietin presence.

Summary/Conclusions: The normal microenvironment factors not effect on the erythroid progenitor cell proliferation independence of the response to TKI therapy. This may explain the fact that we don’t have an increase the number of erythroid cells in patient bone marrow compared to culture in vitro. In addition, the ability of erythroid progenitor cells to form colonies in the absence of erythropoietin in culture can serve as an additional prognostic factor in the formation of resistance to TKI.

PB1810

DEVELOPMENT OF FRAGMENT ANALYSIS MULTIPLEX-PCR METHOD TO DETECT TRANSCRIPTS OF BCR-ABL FUSION GENE IN CHRONIC MYELOID LEUKEMIA

L. Reguilón-Gallego1,*, F. Ferrer-Marín1, R. Cifuentes1, V. Vicente1, R. Torral-Montoya1

1Hematolog ía y Oncología Médica, Hospital Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III (ISCIII), Murcia, Spain

Background: Chronic myeloid leukemia (CML) is a myeloproliferative, clonal and acquired hematological disease that is included within myeloproliferative neoplasms (WHO 2016). Its main characteristic is the presence (95% of the...
case) of a small chromosome denominated Philadelphia chromosome, coming from the reciprocal translocation between the chromosomes 9 and 22. Depending on the point where the break-point occurs, different isoforms of the fusion gene BCR-ABL may appear. For the diagnosis of CML, detection of BCR-ABL rearrangement is crucial; and molecular biology techniques, such as RT-PCR, may be the only data at that point, but most current RT-PCR methods for detecting BCR–ABL are designed and optimized for detecting the majority forms (e14a2 and e13a2) without distinguishing between them. Characterization of the transcript is not necessary for the diagnosis but permits follow-up at the molecular level and differentiate between different BCR-ABL isoforms at the time of the CML diagnosis could be taken into account in future studies to investigate its role into the prognosis.

Aims: To develop a new multiplex RT-PCR method coupled to fragment analysis by capillary electrophoresis to identify different BCR-ABL isoforms: e13a3, e1α2, e1α4a3, eβα2, eα1α3, eα1a2, eα4a2, eα1a2 and eα8a1.

Methods: 34 CML patients BCR-ABL positive by qRT-PCR and 1 negative control (both before and during TKI treatment) from this study. Two months after initiation of TKI therapy. In this study, we identified 7 patients (20.5%) with co-expression of e14a2 and e13a2 isoforms, interestingly we identified 7 patients (20.5%) with co-expression of e14a2 and e13a2 isoforms, being in all those cases the e14a2 isoform mainly expressed.

Summary/Conclusions: RT-PCR combined with capillary electrophoresis is recognized as the gold standard for the detection of different isoforms of BCR-ABL and may be included as a BCR-ABL first screening. Quantification with qRT-PCR might only be done in positive samples. Unfortunately we could not detect any isoform besides the majority ones, due to the size of our cohort. Finally, our study validates previous studies on the main BCR-ABL isoforms (e14a2 and e13a2) percentage detected in CML patients.

PB1812
PDGF AND BDNF PLASMA LEVELS IN CML PATIENTS BEFORE AND AFTER INITIATION OF TKI THERAPY
Z. Litwińska,1* K. Luczewska,1 E. Plis-Sadowska,1 A. Sobus1 E. Pacczkowska1 B. Machalitski1 1Department of General Pathology, Pomeranian Medical University, Szczecin, Poland

Background: Chronic myeloid leukemia (CML) is a malignant myeloproliferative neoplasm, which is characterized by t(9;22)(p34.1;q11.2) translocation, also known as the Philadelphia chromosome (Ph). The fusion resulting gene BCR-ABL encodes a constitutively active tyrosine kinase that dictates the pathophysiology of CML. Tyrosine kinase inhibitors (TKIs) have been shown to efficiently inhibit not only the Bcr-Abl kinase, but also act on other cell surface receptors, for example TrkB receptor for brain-derived neurotrophic factor (BDNF). Capillary electrophoresis of the multiplex RT-PCR reaction was done in an ABI3130XL analyzer, using ILS600 as marker.

Results: BCR-ABL fusion RNAs were detected in all patients (34/34), on the other hand we did not detect BCR-ABL on the negative control. The main isoform identified was e14a2 (detected in 22 out of 34 patients, 64.7%). Twelve patients were positive for e13a2 BCR-ABL isoform (35.3%). Interestingly we identified 7 patients (20.5%) with co-expression of e14a2 and e13a2 isoforms, being in all those cases the e14a2 isoform mainly expressed.

Summary/Conclusions: RT-PCR combined with capillary electrophoresis is considered as an efficient tool for the detection of different isoforms of BCR-ABL. We have observed subtile changes between the tested groups: BDNF level in newly diagnosed CML subjects was lower compared to controls (p <0.05), but in TKI-receivers the level was comparable to control group (p >0.05). We have also tested one patient in four different time points (at diagnosis, 3 months with TKIs, 6 months with TKIs) for both PDGF-AA and BDNF - we have observed PDGF levels drop and BDNF rise with time.

Summary/Conclusions: In our study we have demonstrated that PDGF-AA and BDNF are feasible targets for plasma proteomic analysis in CML patients, both for studying the patterns of protein expression at different time points and for defining the molecular subtypes of CML. Further studies are required to elucidate the PDGF, BDNF and possibly other growth factors, neurotrophins and their receptors role in normal and malignant hematopoiesis.

CASE OF ATYPICAL CHRONIC MYELOID LEUKAEMIA WITH LATE DISCOVERY OF JAK2 M. Dudez1, M. Daniel1, A. Belahbri2, B. Foucher3, S. Giray3, S. Hayette5, I. Tigaoud6, L. Viau7 1Laboratory of Hematology, GHOSTE Lyon, Bron Cedex, 2Service d’oncology, Centre leon Bourg, 3Laboratory of hematology, Hopital Desengettes, Lyon, 4Laboratory of hematology, GHOST, BRON, 5Department of Cytogetenics and molecular biology, 6Department of cytogetenics and molecular biology, GHSD, Lyon, France

Background: Myeloproliferative neoplasms (MPN) include on the one hand chronic myeloid leukemia defined by the presence of Philadelphia chromosome and BCR-ABL remodeling, and on the other hand MPN without Philadelphia chromosome (Polycythemia vera [PV], essential thrombocythemia [ET] and primary myelofibrosis [PMF]). V617F JAK2 mutation is the main recurring genetic abnormality in these pathologies (1). It can be found in 95% of PV and 50% of ET and PMF (2). The 2016 WHO classification makes no provision of an entity which would include BCR-ABL and V617F JAK2+CMML. However 28 of those cases were described in a 2013 literature review (9). Most patients developed either a V617F JAK2 mutation during treatment by tyrosine kinase for a BCR-ABL+CMML; or a BCR-ABL+CMML during treatment for a V617F JAK2+MPN (3,4,5,6,7). A very small number of patients showed coexistence of those two mutations (8).

Aims: We report a 62 y old woman patient with chronic myeloid leukemia with late discovery of JAK2.

Methods: Clinical presentation: A 62-year-old man with no notable medical history was admitted in 2009 for CML. After failure of a first line treatment by Imatinib in 2009 (poor tolerance and incomplete molecular response), treatment by Nilotinib was initiated in 2012 allowing for, to this day, good molecular response despite poor digestive tolerance in the form of dyspepsia. Ever since then the patient has been treated by Nilotinib for CML (3,4,5,6,7). In 2012, a second MPN was suspected. V617F JAK2 mutation was found positive followed then by polycythemia (Hb: 16.7–19 g/dL) that were first attributed to increased cardiovascular risk due to repeated bacterial urinary tract infections. Neither infiltration of the lymph nodes nor organomegaly had been noted. In 2014, the patient complained of abundant sweating in the absence of fever. Blood examination showed a hyperleukocytosis (3,4,5,6,7). A very small number of patients showed coexistence of those two mutations (8).

E14A2 TRANSCRIPT IS ASSOCIATED WITH HIGHER PROBABILITY OF DURABLE TREATMENT FREE REMISSION IN CML PATIENTS

M. D’Adda1,*, F. Schieppati1, E. Morello1, G. Ruggeri1, E. Cerqu1, S. Ferrari1, C. Botteli1, A. Passi1, G. Rossi1

1Hematology, 2USD Centro Trapianto Midollo Adulti, 3Laboratorio Analisi, ASST Spedali Civili di Brescia, Brescia, Italy

Background: TKIs discontinuation in CML-CP patients with deep molecular response (DMR) are feasible, safe and 40-60% of them maintain treatment free remission (TFR); sokal risk score and duration of TKI-therapy were significantly associated with molecular relapse, according to Euro-Ski and STIM1 trials. While it is known that patients with e14a2 achieve earlier, deeper and more durable responses compared to those with e13a2, few information is available on the influence of the type of bcr-abl transcript on TFR duration.

Aims: Here we describe our single center experience of TKI discontinuation in CML-CP patients with sustained DMR.

Methods: Bcr-abl transcripts were determined by RQ-PCR analysis performed in accordance with EAC protocol (Gabert et al, Leukemia 2003) and to the standards of the Italian national network Labnet. All 174 CML-CP patients presently followed at our institution according to ELN guidelines and treated with 1st or 2nd TKIs were analysed: 103 (59%) had e14a2 and 69 (40%) e13a2 transcript (in 2 pz bcr-abl were not detectable). Criteria for TKI discontinuation was sustained DMR (MR4 or better) for at least 2 years. After TKI withdrawal, RQ-PCR for BCR-ABL was performed every month during the first year and every 2 months thereafter. TKI treatment was reintroduced immediately if DMR loss occurred. TFR was defined as the time between the date of TKI cessation and the date of restarting treatment for DMR loss or, if TKI was not resumed, the date of the last contact.

Results: Forty-nine patients, 25 male and 24 female, discontinued TKI treatment. At the time of discontinuation median age was 63 years (43-85), median time from TKI start 113 months (30-172), median duration of sustained DMR 60 months (24-153). Sokal distribution was 49%, 29% and 20% for low, intermediate and high risk (one patient was not evaluable). Among our 174 patients 39% (40/103) of all e14a2 patients and 13% (9/69) of all e13a2 discontinued TKI (P 0.0002, chi square). Thirty-six patients discontinued imatinib (11 of them with previous INF treatment), 13 stopped nilotinib (8 in first line, 5 in second line treatment). Median follow up after treatment discontinuation was 19 months (3-76), including 31 patients with follow up > 12 months. Thirty (26%) patients lost DMR. Median time off-therapy for these patients was 3 months (2-8), and only 1 lost DMR after 6 months. Therapy was restarted in all 13 patients (2 in MR1, 4 in MR2, 7 in MR3), 10 achieved a second DMR after a median interval of 2 months (1-7); 2/13 patients are in M3 after 7 and 12 months, 1 patient is not yet evaluable. Ten out of 11 patients treated with INF before imatinib remained in TFR. Of note, the type of bcr-abl transcript was significantly linked to DMR loss: after TKI discontinuation, 32/40 e14a2 patients (80%) maintained DMR vs 8/61 e13a2 patients (13%) (P=0.03). After 12 months 78% (+/-6% CI95%) of e14a2 and 41.6 (+/-17% CI95%) of e13a2 patients were still in TFR (log-rank: P=0.033) (see Figure 1). Using multivariate analysis the type of bcr-abl transcript and previous INF treatment correlated with DMR loss (p 0.012 and p 0.033). One patient died during follow up in DMR for CML-unrelated cause.

Figure 1.
**Summary/Conclusions:** In e14a2 CML patients the probability of discontinuation of sustained DMR is significantly higher as compared with e13a2 patients. Moreover, after discontinuation, e14a2 have significantly lower probability of DMR loss than e13a2. These data confirm that e14a2 is a favorable prognostic factor for TFR maintenance.

**COMPARATIVE ANALYSES OF NILOTINIB VS HIGH-DOSE IMATINIB VS SUSTAINING STANDARD-DOSE IMATINIB IN PATIENTS WITH CP CHRONIC MYELOID LEUKEMIA FOLLOWING CONTROLLED RESPONSE TO FIRST-LINE IMATINIB**

S.-Y. Lee1,2,*, G.-S. Choi1,2, S. Joon Hong1,2, H.-J. Kim1,2, S.-K. Suh1,2, J. S. Park2, S.-H. Kim6, D.-Y. Zang1,8, S.-J. Oh10, D.-W. Kim1,2

1Leukemia Research Institute, The Catholic University of Korea, 2Seoul St. Mary’s Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of, 3Novartis Pharmaceuticals Corporation, East Hanover, United States, 4BMT Program, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand, 5Chonnam National University Medical School, Chonnam National University Hwasun Hospital, Hwasun, 6Kyungpook National University Hospital, Daegu, 7Ajou University School of Medicine, Suwon, 8Chon-A University, College of Medicine, Busan, 9Hallym University College of Medicine, Anyang, 10Kangbuk Samsung Hospital, Seoul, Korea, Republic Of

**Background:** Imatinib (IM) and its generic form are widely used as one of the standards of care for chronic phase (CP) chronic myeloid leukemia (CML). Although IM is the first-line treatment, it is mandatory for the IRIS demonstrated the long-term prognostic values of molecular response at specific time points, achieving major molecular response (MMR) at 18 months showed minimal event-free survival (EFS) benefit, compared with not achieving MMR but having complete cytogenetic response (CCyR). In addition, the best treatment for these patients remains unclear.

**Aims:** In this study, we investigated the efficacy of nilotinib (NIL) versus high-dose IM versus sustaining standard-dose IM for the patients with CCyR with suboptimal molecular response to first-line IM therapy.

**Methods:** Early CP CML patients who have achieved CCyR but not MMR after 18 to 24 months on first-line IM therapy at a daily dose of 400 mg were divided into the three treatment groups; nilotinib (NIL) 400mg BID (800mg/day; group 1) vs IM 400 mg BID (800 mg/day; group 2) vs IM 400mg QD (400mg/day; group 3). Group 1 and 2 patients were selected in the RE-NICE multicenter study, in which crossover to the alternate treatment arm was allowed for patients failing to achieve a MMR at 12 months and for intolerant patients, and for patients who lost MMR at any time of treatment. Group 3 patients who have achieved CCyR but not MMR after at least 18 months of first-line IM therapy were selected from the Asia CML Registry (ACR) database system with the same inclusion criteria of RE-NICE. The efficacy endpoints are MMR rate by 12 months and MMR rate and undetectable molecular residual disease (UMRD) rates by 36 months.

**Results:** With a data cut-off date of 07 Dec 2016, a total of 108 patients were evaluated; 28 patients in NIL group (group 1), 28 patients in high-dose IM group (group 2), and 52 patients in standard-dose IM group (group 3). Median follow-up duration from enrollment was 36 months (range, 1-36), 45 months (range, 21-63), and 42 months (range, 14-90) for each group, respectively. All patients in group 1 remained NIL treatment, 18 patients in group 2 crossed over to NIL 400mg BID due to intolerance (n=4) and lack of response (n MMR after 12 months; n=14), in group 3, 22 patients switched to other treatment due to intolerance (n=7), lack of response (n MMR; n=12), failure (n=1), or patient’s decision (n=2) and 12 patients lost to follow-up. When data on patients who crossed over to the other treatment was included, cumulative incidence (CI) of MMR by 36 months was significantly higher in group 1 than group 3 (83.1% vs 57.1%, P=0.021), but there was no different in group 1 vs 2 (P=0.195) and group 2 vs 3 (P=0.297). CI of MMR by 36 months showed a trend of higher in group 1 than the other two group (11.7% vs 0% vs 2.6%, group 1 vs 2, P=0.066, group 1 vs 3, P=0.099, group 2 vs 3, P=0.405).

**Summary/Conclusions:** NIL 400mg twice daily treatment showed better efficacy than standard-dose IM for the treatment of patients who have achieved suboptimal molecular response to first-line IM. Additionally, a switch to NIL in suboptimal molecular responder to IM had a trend for achieving a MMR more frequently, suggesting the potential benefit of a treatment-free remission.

**PB1816**

**COMPARATIVE ANALYSIS OF PULMONARY HYPERTENSION IN THE 105 CML PATIENTS TREATED WITH IMATINIB, NILOTINIB AND DASATINIB**

M. Minami1, T. Miyamoto1, K. Akashi1

1Department of Medicine and Bioinformatic Science, Kyushu University, Fukuoka City, Japan

**Background:** Pulmonary hypertension (PH) has been reported as a serious adverse event in chronic myeloid leukemia (CML) patients treated by dasatinib. French group reported incidence of PH diagnosed by cardiac catheterization as 0.45% (13 of 2,900 patients) in symptomatic patients treated with dasatinib. Dasatinib-related PH usually resolves after cessation of treatment, but it can be fatal, as two deaths in France and one in Japan have been documented.

**Aims:** To clarify the incidence of tyrosine kinase inhibitor (TKI)-related PH, we noninvasively screened CML patients who have been given imatinib, nilotinib or dasatinib by echocardiography.

**Methods:** 105 patients with CML in chronic phase (CP) who received TKI were enrolled in this study between 2014 and 2015. Nine patients with newly diagnosed CML in CP prior to TKI treatment were added as control. Patients underwent echocardiography to evaluate 36 values of tricuspid regurgitation pressure gradient (TRPG), which relates to severity of PH. Patients with TRPG values >31mmHg were suspected of PH onset according to European Society of Cardiology criteria. All patients gave informed consent.

**Results:** Patients were divided into 3 groups by the TKIs they used at the time of study enrollment: 37 patients on imatinib, 30 on nilotinib and 38 on dasatinib (Table 1). In imatinib group, patients’ age was significantly higher, and duration of treatment was also longer than those of the 2nd generation TKIs. Echocardiography revealed mean values of TRPG as 22.7, 23.1 and 24.4mmHg in imatinib, nilotinib and dasatinib groups, respectively (P=0.087), and these values were higher than that in the newly diagnosed CML patients (19.0mmHg), though without significance (P=0.38). Nine of the 105 patients (8.6%) presented with an elevated TRPG>31mmHg, suggesting the presence of PH; 1 of 37 (2.7%) in imatinib group, 3 of 30 (10.0%) in nilotinib group, and 5 of 38 (13.2%) in dasatinib group. Three patients complained of dyspnea, while the remaining 6 were asymptomatic. We found no apparent risk factors associated with TRPG elevation, however, there were trends toward correlation of age and TRPG values in nilotinib and dasatinib treated patients, and treatment duration and TRPG values in nilotinib treated patients. Imatinib dosage tended to inversely correlate with TRPG value, suggesting that imatinib might decrease pulmonary arterial blood pressure in a dose-dependent manner.

**Table 1.**

**Summary/Conclusions:** PH is a rare but life-threatening adverse event for dasatinib-treated patients, and its definitive diagnosis is made by cardiac catheterization. However, cardiac catheterization is too invasive for PH screening of the many patients with TKIs who do not have any symptoms. Our study, by using echocardiography, detected TRPG elevation not only in dasatinib treated patients (13.2%) but also in imatinib (2.7%) and nilotinib (10%), including patients without any symptoms. This indicates possible PH onset among patients treated with imatinib or nilotinib, as well as with dasatinib. Although TRPG values obtained by echocardiography might not be fully compatible with those by cardiac catheterization, the results suggested that noninvasive echocardiography is sensitive for screening PH and is also effective for easily screening groups of patients with suspicious subclinical PH among patients treated with any available TKIs. Careful screening with echocardiography is necessary especially for older patients who have received TKIs for a long time.

**DYNAMICS OF BCR-ABL1 MUTATION ACQUISITION AND LONG-TERM MUTATION ASSOCIATED RESISTANCE PROGNOSIS IN PATIENTS WITH CP CHRONIC MYELOID LEUKEMIA TREATED BY TYROSINE KINASE INHIBITORS: RUSSIA, 2006-2016**

V. Tikhonova1,2, Y. Finashutina1, L. Kesaeva1, Y. Stroylova1, N. Kasatkina1, E. Misurina1, A. Misurin1,2

1Lab of recombinant tumor antigens, N.N.Blokhin Russian Cancer Research Center. 2Balashovo Medical Center, Russian Federation

**Background:** While chronic myeloid leukemia (CML) can successfully be treated with tyrosine kinase inhibitors (TKIs), mutations in the BCR-ABL1 kinase domain are the most prevalent cause of TKI resistance. More than 100 BCR-ABL1 kinase domain point mutations with various frequencies of incidence, domain positions and implications on TKI response in CML are associated with
TKI resistance. Here we present our data concerning prognostic significance of BCR-ABL1 kinase domain mutations dynamics in Russian CML patients according the follow-up study having been performed during the last 10 years.

Aims: To determine the frequency dynamics of BCR-ABL1 mutations in CML patients and its prognostic significance.

Methods: In this study we have included 1077 TKI resistant CML patients from 112 hospitals of 77 Russian cities having been observed during the period from 2006 to 2016. BCR-ABL1 kinase domain point mutations in mRNA samples from peripheral blood cells were analyzed by means of PCR followed by Sanger sequencing. Statistical analysis was performed using SPSS 22.0 (IBM, USA) and Excel 2013 (Microsoft, USA). Critical p-value was set to 0.05.

Results: 1077 the resistant CML patients were analyzed, among them were 41.5% men (n=447) and 58.5% women (n=630), median age – 50 (from 15 to 74). BCR-ABL1 mutations were found in 30.8% (332/1077) CML pts. We have detected a total of 415 mutations in 332 patients, giving rise for 58 different mutation variants. Mutation associated resistance rate was higher in women to compared with men, however the majority of patients had e13a2 transcript, a e14a2 and H396R mutations were statistically more frequent in women, meanwhile T315I mutation prevailed in men group (Pearson’s χ²=0.05). It was of a sudden that BCR-ABL1 mutation distribution significantly varied according the particular CML pts city location throughout the different regions of Russia. Although for the period from 2006 to 2016 there were no detectable changes in mutation frequency spectrum (Pearson’s χ² is 0.062), the total amount of mutations associated with TKI CML resistance has decreased from 36.6% in 2006-2008 to 24.96% in 2013-2016, but still remained significant. For particular mutations the following dynamics was detected: frequency of imatinib-resistant mutations decreased gradually from 2006 to 2016, while the rate of F317L and F359V mutations underlying resistance to second generation TKI increased in 2013-2016. T315I mutation rate expanded to the maximal level in 2014 and abruptly decreased afterwards. This tendency change may be the consequence of the second generation TKIs and other therapeutical strategies involving into clinical practice.

Summary/Conclusions: As far as different BCR-ABL1 kinase domain mutations are associated with various types of mutation associated resistance to TKI treatment, the detection of trends in mutation distribution in CML patients receiving TKI treatment is very important for long time treatment strategy decision making, and evaluation of resistance. We believe here that a regional difference of mutation profiles should also be considered. Therefore, to enable correct triggering of particular types of TKI for CML treatment it is necessary to obtain data of when, which and where a particular type of BCR-ABL1 mutation is prone to appear in a distinguished cohort of CML pts.

Background: Chronic myeloid leukemia (CML) is driven by different transcript types, but the majority of patients have a e13a2 (b2a2) transcript, a e14a2 (b3a3) transcript or a co-expression of e13a2/e14a2 transcripts. In imatinib-treated patients, a large retrospective study published 500m patients received imatinib and inferior molecular responses. Few data on the prognostic impact of BCR-ABL1 transcript type in CML patients treated with second generation tyrosine kinase inhibitors (TKIs) are still available.

Aims: To assess the impact of BCR-ABL1 transcript type on molecular response and survival in CML (CML) patients treated frontline with nilotinib (NIL).

Methods: An analysis of 345 CML patients at diagnosis (chronic phase) enrolled within 3 multicentric prospective studies of the GIMEMA CML Working Party (NCT00481052, NCT00769327, NCT01535391) was performed. The initial treatment was NIL 300 mg BID or NIL 400 mg BID. Definitions: major molecular response (MMR), BCR-ABL1 IS ratio <0.1%; deep molecular response (MRD<0.01); ratio >0.1% with >10,000 ABL1 copies; progression, transformation to advanced phases; death, at any time and for any reason. Cumulative incidences of response were estimated under consideration of competing risks (progression, death) and compared by Gray test. Progression-free survival (PFS) and overall survival (OS) were estimated using the Kaplan-Meier method and compared by log-rank test.

Results: Patients expressing rare transcripts (e1a2 or b2a2) n=7 and patients with unknown transcript type n=10 were excluded: 328 patients were evaluable, 38% (n=123) with e13a2 transcript, 53% with e14a2 transcript and 9% expressing both transcripts. No significant differences in age, gender, Sokal or EUTOS long-term survival score distribution, presence of clonal chromosomal abnormalities in Ph+ cells, or NIL dose were observed. The median follow-up was 60 months (range 24-82 months). The response rates and the survival probabilities were similar in patients with e13a2 transcript (N=174), but the differences were not significant: MR of 12 months, 66% vs 72%, p=0.244; MRD<0.01 by 36 months, 56% vs 66%, p=0.067; estimated cumulative incidence of MMR, 82% vs 88%, p=0.135; estimated cumulative incidence of MRD<0.01, 60% vs 69%, p<0.101; estimated PFS, 88% vs 93%, p=0.547; estimated OS 98% vs 94%, p=0.9. The responses and the survival probabilities of patients co-expressing the e13a2 and the e14a2 transcripts (N=30) were similar to or even better than the ones of e14a2 patients. Grouping together the patients with e14a2 transcript alone and the patients with co-expression of both transcripts (N=174+30=204), and comparing them with patients expressing only e13a2 (N=174) a statistically significant difference were observed (cumulative incidence of MMR and MRD<0.01, p=0.050 and p=0.038, respectively), but no outcome differences emerged (PFS and OS, p=0.340 and p=0.276, respectively).

Summary/Conclusions: Lower molecular response rates in patients with e13a2 transcript that others with e14a2 transcript were observed, and the differences were small and mostly not significant. No outcome differences were detected. Further studies in larger patient cohorts are required in order to clarify whether including the transcript type in the calculation of the baseline risk scores may improve prognostic stratification, and whether NIL or other second generation TKIs should be preferred as first-line therapy in patients aiming at treatment-free remission.
Three patients (2 IM/HU, 1 IM) were lost to follow-up. As prospectively designed, all available IM/HU patients (n=77) were included in the study. According to the study protocol, patients from the CML IV study were to be added to obtain equal numbers for analysis. To arrive at a total of 77 IM patients, from study IV another equal 49 patients were selected by propensity score matching. The median age of the 154 patients was 55 years (range 18 – 82). The ELTS prognostic scores were available for 141 patients and was high in 8 (5.7%), intermediate in 35 (24.8%) and low in 98 (69.5%), with no significant differences between treatment groups.

Results: The 5-year overall survival (OS) / progression-free survival (PFS) probabilities were 90.4 and 86.7% in the IM/HU and twice 84.9% in the IM arm respectively. Significant adverse events in the prospective group (generic imatinib) at three months, but no difference in toxicity. The register is ongoing; the confirmation of this data and the impact in prognosis will be evaluated in the long-term follow-up, after increasing the number of patients.

Summary/Conclusions: Our results showed that TKI treated CML patients with complex ACAs have a higher risk of progression and death in comparison with single-ACA patients.

Background: The efficacy of branded imatinib (Gleevec) in the first-line treatment of chronic myeloid leukemia (CML) has been demonstrated in several clinical studies. However, there are few consistent data in the literature on the efficacy and adverse effects of generic formulations of imatinib. In Brazil, CML patients have been treated in the national public health system with generic imatinib since June 2013.

Aims: The present study aims to evaluate the efficacy and safety of generic imatinib in the treatment of CML in comparison with the reference drug (Gleevec) in the first three months of imatinib treatment.

Methods: This is a multicenter, observational, ambispective, cohort-type study. The study was initiated in January 2015 with the intended participation of 17 Brazilian centers. In the prospective group, were selected chronic phase CML patients who started their first-line treatment with generic imatinib between January 2015 and October 2016, whereas retrospective group was treated with imatinib between January 2010 and December 2011. All patients started the imatinib less than six months from diagnosis. Study data were collected and managed using REDCap electronic data capture tools. Demographic data were collected at diagnosis: age, gender, Sokal, Hasford, EUTOS score, comorbidity, cytogenetics, BCR-ABL transcript type. The definition of the responses followed the recommendations of the CML International Working Conference. Adverse events were assessed based on the Common Terminology Criteria for Adverse Events (CTCAE) Version 4.03, 2010. Statistical analysis: SPSS version 21.0 was used applying the chi-square and t-test, when adequate. All analysis considered p-value <0.05 as significant.

Results: Ten centers have registered 177 patients in the retrospective group and 68 patients in the prospective group so far. For this preliminary analysis, response data from 132 patients were available (47 from prospective and 85 from the retrospective groups). The median age of patients was 54 years in the prospective group and 46 years in the retrospective group (P=0.12). Sokal score of patients in the prospective group was 1.4 (0.7-2.2) and 1.3 (0.7-2.2) in the retrospective group (P=0.48). CCR at 6, 12 and 18 months in the prospective group was 50.1%, 76.1% and 84.9% (P=0.003) and 41.0%, 61.0% and 69.5% (P=0.001) in retrospective group. There was no difference between the groups concerning gender, Hasford, EUTOS scores, CCG, blood cell counts at diagnosis and before starting imatinib and BCR-ABL transcripts. Regarding responses, there was no difference in the hematological (complete cytogenetic responses and rate of BCR-ABL transcripts >10%) at three months. However, there was a higher rate of failure at three months according to the ELN 2013 criteria in the prospective group (14.9% versus 4.7% Gleevec group, P=0.04). There was no significant difference in grade 3 and 4 hematological and non-hematological toxicity, but there was one early death in the prospective group (acute peripheral arterial occlusion and renal failure). Four patients discontinued imatinib: one from Gleevec group (resistance) and three from the generic group due to intolerance (1) and resistance (2).

Summary/Conclusions: According to ELN-2013 criteria, there was a higher rate of failure in the prospective group (generic imatinib) at three months, but no difference in toxicity. The register is ongoing; the confirmation of this data and the impact in prognosis will be evaluated in the long-term follow-up, after increasing the number of patients.

COMPLEX ADDITIONAL CHROMOSOME ABERRATIONS IN PH-POSITIVE CELLS IMPACT ON CHRONIC MYELOID LEUKEMIA PATIENTS’ SURVIVAL IN THE ERA OF TYROSINE KINASE INHIBITORS

1Hospital de Clínicas-Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, 2Hospital de Clínicas, Faculdade de Medicina da Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Background: Additional chromosomal aberrations (ACA) as marker of clonal evolution in chronic myeloid leukemia (CML) patients were previously noted in association with resistance to therapy. The presents of ACA have been associated with a worse prognosis for survival in the pre-TKI era. The ACA classification proposed earlier was based only on its frequencies. Whereas ACA’s clinical impact had not yet been clearly established.

Aims: The aim of our study was to evaluate the long-term impact of the ACA presence in Ph-positive cells in CML patients on TKI treatment results.

Methods: 30 patients with ACA in Ph-positive cells treated in our center from 2005 to 2015 years were included in this study. Cytogeneric analyses of at least 20 Giemsa-banded bone marrow metaphases were interpreted per ISCN 2013. We analyzed overall survival (OS) and cumulative incidence of CML-related death on TKI treatment. Cox regression was used for multivariate survival analysis, that included next covariates: number of ACA, type of ACA, age, TKI type, CP or AP at diagnosis. OS was estimated by Kaplan-Meier method with log-rank test for comparison. Cumulative incidence of CML-related death was estimated into consideration the presents of competing risks (CML-unrelated death) using Gray’s test for comparison between groups.

Results: Median follow-up period in ACA group (n=30) was 51 months (3-124). ACA at diagnosis were detected in 16 (53%) of 30 patients. Chronic phase (CP) patients were detected in 23 (77%) patients. In the group of 23 patients, the corresponding numbers of ACA at diagnosis was 1 (23%) patients, 4 patients from this group had «major-route» ACA. 10-years OS in the whole ACA group was 67%, 10-years cumulative incidence of CML-related death was 23%. Number of ACA (p=0.03, HR=13.2) and age (p=0.03, HR=1.14) had statistical significance influence on survival by regression analysis. 10-years OS was 31% and 77% (p<0.05) in patients with complex ACA and single ACA respectively, 10-years cumulative incidence of CML-related death was 54% for patients with complex aberrations versus 10% for single ACA patients (p<0.05) (Figure 1).

BCR/ABL1 TRANSCRIPTIONAL ANALYSIS OF GENERIC IMATINIB EFFICACY IN CHRONIC MYELOID LEUKEMIA: A PROSPECTIVE, LONGITUDINAL, SINGLE CENTER STUDY

Q. Jiang1, H. Wang2, L. Yu3, D. Milijkovic3, X. Huang1,2
1Peking University People’s Hospital, Peking University Institute of Hematology, 2Peking University Clinical Research Institute, Beijing, China, 3Novartis Pharma AG, Basel, Switzerland

Background: Health-related quality-of-life (HRQoL) profile is now recognized as an important component in the management of Chronic myeloid leukemia (CML). To explore the HRQoL profiles of patients with CML in the chronic phase (CP) who were treated with front-line imatinib or nilotinib, in order to assess the relationship between early response and HRQoL outcomes.

Methods: A prospective, longitudinal, single center study was conducted to assess the response to treatment with imatinib or nilotinib and the HRQoL profile of patients who were newly diagnosed with CML-CP and enrolled into ENESTchina (NCT02317688). HRQoL measures based on the EuroQol-5D (EQ-5D) and the European LeukemiaNet (ELN) questionnaire were assessed. The EQ-5D was used to measure health-related quality of life (HRQoL) and the ELN questionnaire was used to collect patient-reported HRQoL data.

Results: Of the 59 patients enrolled, 50 were evaluable for the HRQoL analysis. The EQ-5D scores were comparable between the two treatment groups at baseline. At 12 months, the EQ-5D scores were significantly better in the nilotinib group compared to the imatinib group in the physical component summary (PCS) (p = 0.023) and the role limitations due to physical health problems (RP) (p = 0.023). No significant difference was observed in the mental component summary (MCS) (p = 0.322) and the role limitations due to emotional health problems (RE) (p = 0.222). The HRQoL profile was measured using the SF-36 health survey.

Results: Fifty-nine patients were randomly assigned to receive imatinib (n=31) or nilotinib (n=28). In multivariate analysis, the use of nilotinib was identified as an independent factor affecting the achievement of optimal response at 6 months (OR=3.9, 95% CI, 1.0-14.9; P =0.043) and 12 months (OR=5.6, 95% CI, 1.7-17.9; P =0.004). With a median follow-up of 60 months, the probabilities of failure-free survival (all P Values <0.001) and progression-free survival (all P Values <0.05) at 5 years were significantly higher in patients who achieved optimal response at 3, 6, or 12 months than those who achieved non-optimal response (warning or failure), and overall survival rate at 5 years was significantly higher in those who achieved optimal response at 12 months (P =0.047). Achieving optimal response at 12 months was associated with better role limitations due to physical health problems (P =0.0019) and role limitations due to emotional problems (P =0.0110) and was the sole factor associated with significantly improving physical component summary over time (P =0.0160). In addition, achieving optimal response at 6 months had a tendency of high physical functioning (P =0.0674), social functioning (P =0.0571), and role limitations due to emotional problems (P =0.0019), and higher education level were also associated with better HRQoL subscales.

Summary/Conclusions: Achieving optimal response at 12 months was associated not only with longer overall survival and less treatment failure and disease progression, but also better HRQoL in newly diagnosed patients with CML-CP on front-line tyrosine kinase inhibitor.
SECOND-LINE TYROSINE KINASE INHIBITORS IN CHRONIC PHASE - CHRONIC MYELOGENOUS LEUKEMIA (CML-CP)

J. Cortes1,2, L. Huynh2, P. Brandt3, M. DerSarkissian4, G. Zaccardelli1, D. Dalal1, J. Hussein2, M. S. Duh2
1Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, 2Epidemiology, Analysis Group, Inc., Boston, 3Novartis Pharmaceuticals Corporation, East Hanover, United States

Background: Achieving deep molecular response, ≥4-log reduction (MR4.5; BCR-ABL1 on the International Scale [IS] ≤0.0032%), is one of the important prerequisites for attempting treatment-free remission. Limited information is available on comparative rates of MR4.5 between nilotinib and dasatinib in second-line (2L).

Aims: This study aims to investigate time to achieving MR4.5 and major molecular response (MRMR; ≥3-log reduction or ≤0.1% in BCR-ABL1 on IS) in CML-CP patients (pts) treated with nilotinib vs dasatinib in 2L.

Methods: Pts with history of failure on first-line (1L) TKI treatment (Figure 1) metastably were recruited to conduct a retrospective medical chart audit. Physicians were instructed to select up to 4 pts who met the following criteria via a random letter generation scheme for the first letter of pt’s last name: diagnosed with CML-CP at age ≥18 years, initiated 2L nilotinib or dasatinib between 1/1/11 and 3/1/15, and had ≥12 mos of follow-up data after initiating 1L TKI. Multivariable Cox proportional hazards models accounting for country clustering random effects were used to assess the effect of nilotinib vs dasatinib on time to MR4.5 and MMR, adjusting for age, gender, Sokal risk score at diagnosis, hydroxyurea use before 1L TKI, 1L vs 2nd generation TKI as 1L, and reasons for 1L TKI discontinuation. Adjusted hazard ratios (HR) and 95% confidence intervals (CI) were reported. Adverse events (AEs) were also described.

Results: The study included 236 pts from Australia, Brazil, France, Germany, Italy, and Netherlands treated with nilotinib (N=115[49%]) or dasatinib (N=121[51%]) in 2L. Both groups had a similar mean follow-up of 23 mos, mean age of 57 years, and were 35% female. 8% of 2L nilotinib and 22% of 2L dasatinib pts were treated with the other 2nd generation TKI in 1L (p<0.01). A higher proportion of nilotinib pts had high-risk Sokal score (20.9% vs 11.6%, p=0.05) and received prior hydroxyurea (8.7% vs 3.3%, p=0.08) vs dasatinib. 85% and 11% of 2L nilotinib pts discontinued 1L TKI due to resistance and intolerance, respectively, prior to switching to nilotinib, vs 74% and 22% for 2L dasatinib pts (both p<0.05). The univariate Cox model showed that nilotinib had a non-significantly higher rate of achieving MR4.5 than dasatinib (32% vs 31% at 24 mos for 2L nilotinib and 2L dasatinib, respectively, based on the Kaplan Meier estimator; unadjusted HR=1.09, 95% CI [0.87, 1.38], p=0.46); however, after multivariate adjustment, nilotinib reached a significantly higher rate of achieving MR4.5 (adjusted HR=1.36, 95% CI [1.07, 1.73], p=0.01) than dasatinib. Among those who achieved MR4.5, 45% of nilotinib pts maintained MR4.5 for ≥1 year vs 39% of dasatinib pts (p=0.60). Additionally, high-risk Sokal score (HR=0.31, 95% CI [0.14, 0.72], p=0.01) and resistance to 1L TKI (HR=0.60, 95% CI [0.42, 0.86], p<0.01) were inversely associated with achieving MR4.5.

There was no significant difference in MMR achievement between 2L TKI groups. Over 3 times more dasatinib pts experienced pleural and pericardial effusion AEs than nilotinib pts (9.9% vs 2.6%, p=0.02). One nilotinib pt had ischaemic heart disease AE vs none for the dasatinib group (p=0.49).

Summary/Conclusions: This retrospective chart audit study suggests that 2L nilotinib may be associated with a higher rate of MR4.5 than 2L dasatinib in CML-CP. Our results should be taken with caution as this study is susceptible to unmeasured confounding and biases due to its retrospective and observational nature. Rigorous clinical assessment in a prospective setting is needed to conclusively compare rates of patients achieving MR4.5.

COMPUTATIONALLY INTELLIGENT PREDICTION OF CLINICAL OUTCOME IN CHRONIC MYELOID LEUKEMIA
Z. Cojbasic1, I. Cojbasic2-4, L. Macukanovic-Golubovic2-3, M. Vucic3,4
1Mechanical Engineering Faculty, University of Nis, 2Clinic of Hematology, Clinical Center Nis, 3Faculty of Medicine, University of Nis, 4Clinic of Hematology, Clinical Ceter Nis, Nis, Serbia

Background: Computational intelligence has been applied to a wide range of problems, to assist in decision-making, especially artificial neural networks, fuzzy systems and powerful hybrid neuro-fuzzy approaches have already proven their strong potentials in medicine. Despite that, applications in hematology are still scarce.

Aims: In this study we have developed novel ANFIS neuro-fuzzy prognostic models based on morphometric and morphometric diagnostic data, to enhance better prediction of complete cytogenetic response (CCgR) for patients with chronic myeloid leukemia.

Methods: This prospective study included a consecutive series of patients with chronic myeloid leukemia (CML) who were started on imatinib therapy. Analysis was performed on 18 patients in 9 centers, aged 12, and 18 months as the outcome variables. A total of 40 patients on imatinib therapy were included in the final analysis. Of these, 25 (62.5%), 29 (72.5%), and 32 (80%), respectively, achieved CCgR at 6, 12, and 18 months after initiation of imatinib. Computationally intelligent neuro-fuzzy models were developed and included EUTOS score on diagnosis and one of the following morphometric parameters: microvascular density, length of the minor axis, area or circularity of the blood vessel. Adaptive neuro-fuzzy systems represent a specific combination of artificial neural networks and fuzzy logic, thus combining the learning ability of artificial neural networks with the knowledge representation capability of fuzzy logic systems. ANFIS (Adaptive Neuro Fuzzy Inference System) consists of five layers of nodes (neurons), each of which performs a particular function on incoming signals as well as a set of parameters pertaining to this node. The basic architecture of ANFIS using hybrid learning algorithm is presented in Figure 1.

Figure 1.

Summary/Conclusions: The major finding of this study is that ANFIS models using the morphometric parameters, available at diagnosis of chronic phase of the CML, may improve prediction of CCgR at 6, 12 and 18 months on imatinib therapy, in comparison to the EUTOS score being the standard prognostic scoring system and regression models using the same inputs. Using neuro-fuzzy computationally intelligent ANFIS models with morphometric parameters in conjunction with EUTOS score improves prediction of CCgR. Validation on larger groups of patients is needed, but these findings indicate that neuro fuzzy models could aid in individual CML patient risk stratification.

Ramat-Aviv, 3Department of Hematology, Hadassah-Hebrew University Medical Centre, Jerusalem, 4Hematology Division, Chaim Sheba Medical Center, Tel-Hashomer, 5Bone Marrow Transplantation Unit, Sourasky Medical Center, Tel Aviv, 6Department of Hematology, Meir Medical Center, Kfar Saba, 7Bone Marrow Transplantation Unit, Rabin Medical Center, Petah Tikva, 8Hematology Institute, Soroka University Medical Center, Beer-Sheva, 9Hematology unit, HaEmek Medical Center, Afula, 10Department of hematology, Assaf Harofeh Medical Center, Zeriffin, 11Department of hematology, Wolfson Medical Center, Holon, Israel

Background: In December 2014 the oral tyrosine kinase inhibitor (TKI), ponatinib was granted an accelerated approval by the FDA based on promising results from the phase II PACE (Ponatinib Ph-ALL and CML evaluation) trial. Yet, nowadays the use of this drug is limited because of safety issues, most notably those of CML. Our study aimed to provide real-life information regarding the use of ponatinib outside clinical trials.

Aims: The purpose of the current study is to characterize patients who received ponatinib and to assess the safety profile and efficacy of ponatinib outside clinical trials.

Methods: Data from electronic charts of chronic myeloid leukemia (CML) patients treated with ponatinib were analyzed.

Results: Patients characteristics: Between 4.2011 and 1.2017 (69 months) 37 patients with an initial diagnosis of CML in 9 medical centers in Israel received ponatinib. The median age at time of treatment was 43 years (range: 9 to 82) and approximately half of the patients had chronic phase CML (N= 19, 53%). Based on their medical history, 36% (N=12) were at increased risk for vascular complications. Pre-ponatinib treatments: Patients received at least one other TKI and most received at least-two different TKI-
based regimens (N=28, 76%). Nine patients (25%) underwent hematopoietic stem cell transplantation (HSCT) prior to ponatinib. The time that lapsed from diagnosis until ponatinib initiation ranged considerably (from 1 to 215 months, median 47 months). Indications for ponatinib switch: 26% of patients (N=9) switched to ponatinib because of unacceptable side effects to previous treatments. Treatment with Ponatinib: Patients received ponatinib for a median time of 14 months (range: 1 to 51). The drug started at the recommended dose of 45 mg/day only in 60% (N=22) of patients and in 24% of them (N=9) the dose was reduced during treatment. The median survival time of patients with ponatinib was 38 months (95% CI: 30 to 47 months) (Figure 1). Patients died because of cerebrovascular event (N=1), sepsis (N=2) or graft vs host disease that developed shortly after HSCT. Response assessment: Response assessment was available for 32 patients (86%). Seventy percent (N=22) achieved molecular response, of which 60% (N=13) achieved at least major molecular response. The median time to maximal response was 7 months (range: 3 to 28 months). Drug discontinuation: Twenty four percent (N=9) discontinued ponatinib after a median of 7 months (range: 1 to 18 months) because of disease progression (N=6) or severe adverse effects in two patients (cerebrovascular event and severe pancytopenia).

Figure 1.

Summary/Conclusions: In our cohort ponatinib was almost always used in patients who experienced treatment failure to previous TKIs. Still, molecular response was achieved in most patients, even in those with progressive disease in accelerated or blastic phases. The vast majority of patients received reduced doses of ponatinib and although more than one third of patients were at-risk for vascular events, only two patients developed serious life-threatening vascular episodes. In heavily pre-treated patients, ponatinib is effective and safe and can be considered even in patients with cardiovascular risk factors.

BCR-ABL1 MOLECULAR RESPONSES AT 12-18 MONTHS USING THE QUANTIDEXQPQCR BCR-ABL1 IS KIT PREDICT LONG-TERM EVENT-FREE SURVIVAL IN PATIENTS WITH TKI-TREATED CML

J. Brown1, R. Ruskin1, I. Beldoroth1, M. Fahey1
1Asuragen, Austin, United States

Background: Detection of BCR-ABL1 e13a2 or e14a2 transcripts (major breakpoints) in Ph+ chronic lymphoid leukemia (CML) or translocations (i.e., the Philadelphia chromosome) is important in CML monitoring tumor burden. The International Scale (IS) was established to standardize reporting relative to a common baseline. As newer TKI therapies create deeper responses, analytical sensitivity has become a critical topic in investigations into TKI discontinuation, where researchers require a clinically validated assay that calls a molecular reduction (MR) of ≥4.5 logs below baseline (i.e. MR4.5 or 0.0032%IS).

Methods: To clinically validate the QuantideX qPCR BCR-ABL1 IS Kit and to reaffirm the clinical utility of BCR-ABL1 RT-qPCR monitoring in patients with (9;22) positive CML, a correlation between molecular response (MR) values and long-term outcome was determined.

Results: In total, 31 pts with Ph+ and/or BCR-ABL1(+) chronic myeloid leukemia presenting with an isolated thrombocytosis at diagnosis until ponatinib initiation ranged considerably (from 1 to 215 months, median 47 months). Indications for ponatinib switch: 26% of patients (N=9) switched to ponatinib because of unacceptable side effects to previous treatments. Treatment with Ponatinib: Patients received ponatinib for a median time of 14 months (range: 1 to 51). The drug started at the recommended dose of 45 mg/day only in 60% (N=22) of patients and in 24% of them (N=9) the dose was reduced during treatment. The median survival time of patients with ponatinib was 38 months (95% CI: 30 to 47 months) (Figure 1). Patients died because of cerebrovascular event (N=1), sepsis (N=2) or graft vs host disease that developed shortly after HSCT. Response assessment: Response assessment was available for 32 patients (86%). Seventy percent (N=22) achieved molecular response, of which 60% (N=13) achieved at least major molecular response. The median time to maximal response was 7 months (range: 3 to 28 months). Drug discontinuation: Twenty four percent (N=9) discontinued ponatinib after a median of 7 months (range: 1 to 18 months) because of disease progression (N=6) or severe adverse effects in two patients (cerebrovascular event and severe pancytopenia).

Figure 1.

Summary/Conclusions: In our cohort ponatinib was almost always used in patients who experienced treatment failure to previous TKIs. Still, molecular response was achieved in most patients, even in those with progressive disease in accelerated or blastic phases. MOLECULAR RESPONSE TO THERAPY WITH TYROSINE KINASE INHIBITORS IN PATIENTS WITH BCR-ABL1(+) CHRONIC MYELOID LEUKEMIA PRESENTING WITH AN ISOLATED THROMBOCYTOSIS AT THE ONSET

G. Balabanov1, V. Hrischev2, K. Ignatova3, S. Stoyanova2, A. Liloza2, S. Angelova1, S. Ivanova1, M. Romanova1, I. Ivanova1, G. Tsvetkova3, E. Hadjiev3, V. Madzharov3, T. Dikov2, B. Spassov2, Y. Davidkova2, M. Romanova1, I. Ivanova1, G. Tsvetkova3
1Laboratory of Cyto genetics and Molecular Biology, 2National Specialised Hospital for Active Treatment of Hematological Diseases, 3Alexandrov University Hospital, Sofia, Bulgaria

Background: Generally, chronic myeloid leukemia (CML) and essential thrombocythemia (ET) are characterized by distinctive clinical and laboratory characteristics, including the spectrum of genetic abnormalities - Philadelphia chromosome (Ph) and BCR-ABL1 fusion transcripts in CML and JAK2, CALR or MPL gene mutations in ET. Therefore, even in the presence of overlapping features in some cases, the correct diagnosis can be assigned. However, in rare cases Ph chromosome and BCR-ABL1 fusion transcripts can be found in otherwise typical cases of ET. The number of reported cases related to such subsequent course of the disease and the response to tyrosine kinase inhibitors (TKI) in such patients with BCR-ABL1-positive thrombocytosis is largely unknown.

Aims: To report the clinical course and response to TKI in patients (pts) with CML presenting with isolated thrombocytosis at the onset.

Methods: In total, 31 pts with Ph(+) and/or BCR-ABL1(+) isolated thrombocytosis and a moderate or absent leukocytosis were retrieved from the hospital database. The cohort comprised 17 females and 14 males, at a median age of 47 years (range 23-86). Diagnosis was based on blood and bone marrow mor-
PB1830
SHOULD SWITCHING TO SECOND GENERATION TKIS BE A RULE IN PATIENTS WITH CP-CML AFTER 3-6 MONTHS OF IMATINIB TREATMENT?: RETROSPECTIVE ANALYSIS OF CML PATIENTS TREATED IN A SINGLE BRAZILIAN CANCER CENTER
A.P.S. Ferreira1,2,*, F.S. Seguro1, A.B. Medina1, A.N.R. Abdoo2, F.V.R. Maciel2, L.Y. Okada1, I. Bendt1
1Hematology, Hospital das Clinicas da Faculdade de Medicina da USP, 2Hematology, Instituto do Cancer do Estado de Sao Paulo, Sao Paulo, Brazil

Background: Early molecular response is an important predictor for survival and therapy-free remission in chronic myeloid leukemia (CML). The current guidelines define BCR-ABL1 ≤10% at 3 months and/or 1-10% at 6 months as warning signs; however, it is not clear if switching imatinib to second generation TKIs in this scenario improves responses and overall survival in patients outside clinical trials.

Aims: To analyze the proportion of patients with major molecular response (MMR) at 12 months according to the molecular response at 3 and 6 months in a cohort of CML population, not enrolled in clinical trials and treated only with imatinib. Also evaluate the incidence of molecular responses log3.0, log4.0 and log4.5 at any time in patients who did not switch to second generation TKIs.

Methods: Retrospective analysis of all 226 patients diagnosed with CML from January 2007 until January 2015 in our hospital. The exclusions criterias were: advanced phases, inclusion in clinical trial, treatment with second-generation TKI in the first 12 months (due to toxicity or failure). The molecular response was evaluated according ELN recommendations: RQ-PCR assessment of BCR-ABL1 levels every 3 months until achievement of MMR, with molecular evaluation every 3-6 months afterward. All samples were analyzed in the same laboratory which was standardized since 2007.

Results: In the first cohort, 150 patients with CML chronic phase were analyzed. Optimal molecular responses by the ELN at 3 and 6 months were predictors of MMR by 12 months (94% vs 6%, p<0.0001 at 3m, 89.3% vs 10.7%, p<0.0001 at 6m), but there was no overall survival benefit. A second cohort with 119 patients received only imatinib, with a medium follow-up time of 71 months (13-117m). MMR was achieved by 60% of this imatinib-only group after 12 months and by more than 90% after 36 months (Figure 1). Patients with BCR-ABL1 ≤10% at 3 months and/or <1% had a higher probability of achieving MMR3, MMR4 and MMR4.5 at any time.

Summary/Conclusions: Our study shows that around 30% of the patients that do not fail to imatinib at the first year of treatment may be late responders. Not all patients should change therapy, if they have not reached MMR at 12 months. Molecular response at 3 at 6 months might guide the decision to switch TKI, but patient’s comorbidities, possibility of discontinuation and cost of therapy should also be considered.

PREDICTIVE PARAMETERS FOR IMATINIB FAILURE IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA
D. Lekovic1,2,*, M. Gočić1, B. Zviojnović1, N. Miloš3, J. Jovanović1, N. Colović1,2, J. Bodrozić1, V. Milošević1, A. Bogdanović1,2
1Clinic for Hematology, Clinical Center of Serbia, 2Medical Faculty, 3Institute for Medical Statistics, University of Belgrade, Belgrade, Serbia

Background: Development of tyrosine kinase inhibitors (TKI) has significantly changed natural course of chronic myeloid leukemia (CML) and increased 10 year overall survival from 10-20% to 80-90%. Until recently, imatinib was the standard first-line treatment in CML. In 2013, nilotinib and dasatinib were approved as alternative front-line options. However, none of three TKI has been shown to have a clear survival advantage so this raised a debate on treatment selection. The early identification of patients expecting poor outcome is crucial for offering an alternative TKI regimen.

Aims: to analyze predictive parameters for Imatinib response as first-line treatment of CML patients.

Methods: The study was conducted on 168 consecutive patients with chronic phase of Ph+ CML who were diagnosed and treated at single university hospital from December 2000-January 2015. Following data were analyzed in terms of treatment response to Imatinib: demographic characteristics; currently used prognostic scores (Sokal, Hasford, EUTOS); liver and spleen size; laboratory parameters; influence of comorbidities analyzed by three scores (ACE 27, HCl- CI, SCIRS); occurrence of second malignancies; conventional cytogenetic parameters; therapy, duration of therapy, cytogenetic responses, overall survival (OS) and outcome.

Results: The mean age at diagnosis was 48±14.4 years (range: 18-74) with 87.5% of patients <65 years. The OS at 5 and 10 years was 97% and 91% respectively. Overall response to imatinib treatment was as the follows: 131 patients achieved MMR4 (8.3%) molecular response (8.3%) minorCyR, 16 patients (9.5%) had no cytogenetic response, 2 patients (1.2%) had hepatic toxicity verified by liver biopsy in the first six months of Imatinib treatment and 1 patient (0.6%) was lost from follow-up. After achievement of CYR, 25 patients (19%) had a progression of disease by losing CyR or development of AP/BCR. Median time to progression was 24 months (range 12-102). After the median follow up of 87 months in 61 patients (36.3%), the Imatinib failure was verified. All three prognostic scores (Sokal, Hasford, EUTOS), age, gender, hemoglobin level, leukocyte and platelet count, splenomegaly, eosinophilia and basophils in peripheral blood were not found to be statistically significant for the Imatinib failure. Cox regression analysis identified hepatomegaly (p=0.001), leukocytosis100x109/L (p=0.001), blood blasts>1% (p=0.002) and presence of additional cytogenetic aberrations (ACAs) (p=0.002) as a predictors of Imatinib failure. According, we assigned risk scores based on hazard ratios (HR) to hepatomegaly (HR=4.089; 2 points), leukocytosis >50x109/L (HR=3.158; 1 point), blasts in peripheral blood >1% (HR=2.912; 1 point), and presence of ACAs (HR=11.110; 2 points). A final 3-tiered prognostic model named IMA-FAIL was thus developed, as low (score 0), intermediate (score 1-3), and high risk (score ≥4), according to which imatinib failure had 17% (8/47) of patients in low, 34.9% (30/88) in intermediate and 76.7% (23/30) in high risk group (HR=3.973, 96% CI for HR 2.237-7.053, p<0.001). In addition, presence of comorbidities as well occurrence of second malignancy were not predictors for Imatinib failure.

Summary/Conclusions: Hematologists are facing with challenge of making decision which TKI to choose upfront with increasing a chance to achieve best possible response. The new score allows better selection of patients who are suitable for treatment with Imatinib and may guideline the clinical decision for front-line treatment of CML.
Results: Of the 87 patients surveyed, the most commonly prevailing symptoms were fatigue (72.4%), peripheral oedema (48.3%), disturbed sleep (46%), myalgia (43.7%) and dry mouth (39.1%). The least common symptoms were nausea (20.7%) and vomiting (6.9%). Almost half (49.4%) of patients reported at least 1 severe side effect (a score of 7 or more). The most severe side effects were drowsiness (mean score 6.3), myalgia (mean score 6), fatigue, nausea and vomiting (mean score 5.7 each). There was no significant difference in symptom prevalence or severity among the different TKIs. As regards the perceived interference of symptoms on daily functioning, only 29% reported a score of 7 or more in at least 1 of the 6 interference items (i.e. general activity, mood, work, relations with others, walking and enjoyment of life), and only 14% reported that their enjoyment of life was severely affected (score of 7 or more). Of note, exactly two thirds of patients reported little or no interference with their enjoyment of life (score of 0-3).

Summary/Conclusions: As demonstrated in this audit, patients with CML on second generation TKIs are experiencing chronic symptoms (TS) more often than patients taking second generation TKIs did not appear to have any difference in frequency or severity of symptoms or in QOL compared to patients on ima-tinib. Despite excellent survival results obtained with TKIs since 2001, an emphasis needs to be placed on symptom burden and QOL. The potential for adverse events with long term therapy may result in dose adjustments, treatment discontinuation, or nonadherence, all of which may negatively affect treatment efficacy. Therefore, assessment of QOL and the symptom burden experienced by patients with CML is useful to facilitate individual treatment decisions and to improve outcome as well as to evaluate the efficacy of emerging therapies.

COST-EFFECTIVENESS OF A THERAPEUTIC EDUCATION PROGRAM (TPE) FOR PATIENTS WITH CHRONIC MYELOID LEUKEMIA AND TREATED BY TYROSINE KINASE INHIBITORS

M. Kur-Cordier1, A. Chan Hiew War2, L. Cochrane3, M.-L. Fontoura4, V. Blaziejewski4, P. Lenain4, R. Varin5, F. Basuyau1, M. Daouphars1

1Pharmacy, Centre Henri Becquerel, ROUEN, 2Pharmacy, Hopital Saint Louis, PARIS, 3Pharmacy, CHU de Caen, CAEN, 4Hematology, Centre Henri Becquerel, ROUEN, CHU de Rouen, ROUEN, France

Aims: Within our cancer centre, an TPE program on ITK in the management of CML has been authorized since 2011. We conducted a pharmacoeconomic study to evaluate the TPE clinical impact on responses to TKI in patients with CML (based on recommendations from European Leukemia Net) and also the costs in terms of use of care.

Methods: Over the 12-month follow-up period, the study population consisted of 2 groups of CML patients monitored in our centre: - Intervention group (n=18) (IG): Patients who benefited of TPE sessions on TKI between January 2013 and August 2015. - Matched controls” group (n=18) (CG): Patients who benefited only from the usual care, matched to the “Interven-tion” group. The method of pairing the 2 groups of patients according to the age at diagnosis, sex, the molecule used in first line and the prognostic risk was from French health insurance.

Results: Overall survival (OS) was estimated by Kaplan-Meier method with log-rank test for comparison between groups. Cox regression was used for multivariate analysis that included next covariates: age, phase on the time of mutation detection, performance of allo-HSCT, time to T315I detection from TKI start. The median follow-up time after T315I detection was 21 months (1-100). 5-years OS in whole group was 42% (Figure 1A). According to multivariate analysis only CML phase at the time of mutation detection significantly affect to survival in whole group. All pts in BC (n=5, 2 in HSCT group and 3 in non-HSCT group) died within first year after T315I indication wherein Me survival time was 1.3 month (Figure 1B). 5-years OS in non-HSCT group (n=37) was 42% with Me survival time 2.8 years. 5-years OS after allo-HSCT (n=16) was 37% with Me survival time 5 months (Figure 1C). All living patients after allo-HSCT are in deep molecular response. There was no significant difference in 5-years OS between TKI (n=21) and non-TKI (n=16) pharmacological therapy (non-HSCT) groups (42% and 47% respectively, p=0.53) (Figure 1D).

Summary/Conclusions:

Detection of T315I mutation in TKI-resistant patients is extremely unfavorable factor for survival, especially in the advanced phase of CML, and it is a great reason for switching to ponatinib or other new potential investigated drugs if possible. Allo-HSCT can be a potential option for this group of patients in case of good selection taking into consideration transplant risk, especially for patients in CP 22.

PB1834

ROLE OF ALLO-HSCT IN THE TREATMENT OF PATIENTS WITH T315I MUTATION IN THE TKI ERA

J. Vlasova1,*, E. Morozova1, O. Shukhov2, M. Barabanshchikova1, T. Gindina1, A. El Farra1,2

1Clinic for Hematology, 2Faculty of Medicine, University of Novi Sad, Serbia

Aims: To evaluate the thyroid functional status in CML patients treated with imatinib and nilotinib.

Background: Thyroid kinase inhibitors (TKI) as target specific compounds profoundly changed the outcome in patients with chronic myeloid leukemia (CML). TKI-induced thyroid dysfunction is now recognized as a common toxicity associated with some TKI. In the previous 16 years received hydroxyurea, interferon-α or chemotherapy. At the time of T315I detection 29 (55%) pts were in CP, 19 (36%) pts had AP and 5 (9%) pts were in BC. Median (Me) age at the time of mutation detected was 47 years (15-76) (38 years in HSCT-group), 2 pts were in BC at the time of HSCT, 5 pts were in AP, 7 pts were in CP22. The number of points on EBM scale: 3-4 points (12.75%) pts, 5-7 points (42%) pts, 11 (69%) pts received more than 2 lines TKI. There were 11 pts in allo-HSCT group (19%) pts had unrelated donors. Conditioning regimen in 13 (81%) pts had reduced intensity, in 3 (19%) pts had MAC. Me time to HSCT after T315I detection was 10 months (1-38). Mutation analysis was performed by Sanger sequencing. Overall survival (OS) was estimated by Kaplan-Meier method with log-rank test for comparison between groups. Cox regression was used for multivariate survival analysis that included next covariates: age, phase on the time of mutation detection, performance of allo-HSCT, time to T315I detection from TKI start.
PB1836
RESPONSE RATES AND SURVIVAL OF PATIENTS WITH CHRONIC MYELOID LEUKAEMIA (CML) TREATED WITH IMATINIB: 11 YEAR EXPERIENCE OF A TEACHING HOSPITAL
M. Ruparelia1, P. George1, D. Brownings1, K. Marshall2, A. Hunter1, M. Martin1, K. Hodgson1
1University Hospitals Leicester, Leicester, United Kingdom

Background: In large trials, patients with chronic myeloid leukaemia (CML) treated with Tyrosine Kinase Inhibitors (TKIs) have relative survival rates of up to 90% that of age-matched controls. Patients achieving complete cytogenetic responses (CCyR) within 2 years of starting Imatinib have survival rates equivalent to the general population. Newer TKIs are associated with faster and deeper treatment responses, but have a more toxic side effect profile as well as being more costly.

Aims: This study looks at the 11 year experience of a single teaching hospital treating a population of almost one million and presents the response and survival data of this unselected population of patients with CML treated with imatinib as initial therapy.

Methods: A retrospective case record review was undertaken on CML patients identified from the regional cytogenetics department. Imatinib was available for routine prescription in the UK from 2003, so a 11-year period from 2003 to 2013 was selected to allow for adequate follow-up.

Results: In total 83 patients were newly diagnosed in this time period. Four patients, treated on SPIRIT2 with dasatinib as initial therapy, have been excluded from the subsequent analysis, leaving 79 patients treated initially with imatinib 400mg daily. The median age at diagnosis was 53 years (range 13-93) with a male : female ratio of 57:22 patients. The follow-up was 71 months (range in living patients 29-163 months). Fifteen patients have died (19%). The median age at diagnosis of these was 73 years. Two deaths were transplant-related, both in patients who had failed available TKIs and had mismatched transplants. The only treated patient who died of accelerated disease was intolerable of all TKIs and unfit for transplant. Three patients died of other malignancies (ovarian, bowel and melanoma). Seven patients were transplanted. Of the surviving 5, 2 had sibling transplants early in the TKI era, 2 had MUD transplants after failing imatinib prior to the availability of second line drugs, and one failed to make an adequate response to imatinib then nilotinib and received a sibling transplant. A limited follow up to 15 months, (range in living patients 29-163 months). Fifteen patients have died (19%).

Summary/Conclusions: This data shows the real life experience of patients treated for CML in the UK era. At six years follow up, the overall survival was 88% which is remarkably similar to that of the IRIS trial patients. Using an intention to treat analysis, the outcomes have taken a pragmatic approach; three are quoted to patient compliance, two to treatment limited by severe side effects and one had TKI interruption to facilitate cancer treatment. Of the sixty patients in MMR, 40 achieved this on standard dose imatinib. Four patients required increased dose of imatinib, 11 were switched to second line TKI and 5 were transplanted. A complete molecular response (BCRABL ratio <0.01, MMR) was achieved by 60/79 (76%) patients. Of the 19 without MMR, 1 is lost to follow-up, and 9 have died, of which only one death was due to accelerated CML in a patient intolerant of all TKIs. Of those 9 patients living not in MMR, 8 have a CCyR. Three are elderly and 5 are unfit. 7 have taken a pragmatic approach; three are quoted to patient compliance, two to treatment limited by severe side effects and one had TKI interruption to facilitate cancer treatment. Of the sixty patients in MMR, 40 achieved this on standard dose imatinib. Four patients required increased dose of imatinib, 11 were switched to second line TKI and 5 were transplanted. A complete molecular response (BCRABL ratio <0.001, CMR) was achieved by 10 patients, six on standard dose imatinib.

THE INFLUENCE OF AGE ON TREATMENT OUTCOME OF PATIENTS WITH CHRONIC MYELOID LEUKAEMIA RECEIVING FRONTLINE IMATINIB
I. Cojbasic1, 2, L. Macukanovic Golubovic1, 1, M. Vucic1, 3, N. Govedarovic1, 3, 1Faculty of Medicine, University of Niš, 2Clinic of Hematology and Clinical Immunology, Clinical Center Nis, Serbia, Nis, Serbia

Background: The tyrosine kinase inhibitor (TKI) imatinib was the first targeted therapy for patients with chronic-phase chronic myeloid leukemia (CP-CML), and its introduction was associated with substantial improvements in response and survival compared to previous therapies. Earlier studies have indicated that the effect of age at diagnosis of CP-CML was minimized in patients treated with imatinib: fewer responses but the same outcome for older patients. However, more recent studies have found that differences in clinical outcome depending on age at diagnosis of CP-CML may exist.

Aims: The aim of this study was to evaluate impact of age on the treatment outcome in patients with chronic myeloid leukemia treated with frontline imatinib.

Methods: A newly diagnosed CP-CML patients treated and followed in our institution were surveyed retrospectively from August 2006 to August 2016. In total, 463 patients were included into three groups: young adults (18-45 years) (YA), middle aged adults (46-64 years) (MA) and elderly persons (65 and more years) (EP). Patients’ demographics, disease risk scores, duration of imatinib therapy and follow-up, cytogenetic and molecular responses,
adverse event (AEs), the 5-year event-free survival (EFS) and 5-year overall survival (OS) were all evaluated. Clinical features of the patients in different age groups are summarized in Table 1.

Results: The patient cohort consisted of 94 patients with median age of 53.4 years (range 18-78), with a slight predominance of females of 53.2%. There were more patients with intermediate and high Sokali scores in the EP group than in the groups MA and YA (p<0.001). To the contrary of that, most patients with high EUTOS score were observed in the group YA compared to MA and EP groups (p<0.001). The three groups were balanced regarding Euro score. The median duration of imatinib therapy was the longest in MA group (61.4 months vs 40.6 months in YA and 38.2 months in EP patients p<0.001). Furthermore, median follow-up duration was also the longest in MA group (64.3 months vs 48.5 months in YA and 44.7 months in EP patients p<0.001).

The rates of complete cytogenetic response (CCyR) were similar in all three analyzed groups (80.6% in YA, 86.5% in MA and 75.9% in EP, p=0.328) while rate of major molecular response was the highest in the MA group (83.3% vs 63.3% in YA and 57.1% in EL, p=0.001). The percentages of patients who switched to second-generation TKIs were similar in all three groups (36.7% in YA vs 30% in MA vs 32.1% in EP, p=0.559). There were the most of non-hematological AEs all grades in EP group (25% vs 13.3% in YA and 13.8% in MA, p=0.005). Hematological AEs also were common in EP group but not statistically significant (17.8% vs 10% in YA and in 12.1% in MA, p=0.156). The 5-years EFS in the MA group (88% (95%CI 82.1-96.9)) was significantly higher than in YA group (85.3% (95%CI 59.1-78.1)) and in EP group (60.2% (95%CI 49.5-73.7)). The 5-years OS in the EP group (74.7% (95%CI 65.9-83.9%)) was significantly lower than in YA group (65.3% (95%CI 59.1-78.1)) and in EP group (60.2% (95%CI 49.5-73.7)). The number of deaths, both CML related or not, was the largest in the EP group (25% vs 13.3% in YA and 13.8% in MA, p<0.001).

Table 1. Clinical features of the patients in different age groups.

Summary/Conclusions: Results of this study indicate that age at diagnosis impacts the course of chronic myeloid leukemia treated with imatinib. The best clinical outcomes have middle age patients in terms of the highest rates achieved optimal therapeutic response and longer survival without events and overall survival. The degree of therapeutic responds in the elderly is comparable with that observed in younger patients, but the presence of comorbidity and more frequent occurrence of adverse events were affecting relatively lower overall survival. Although it might be expected that younger patient population has a better clinical outcome than patients middle age, a possible cause of poor outcomes is probably a late diagnosis at an advanced stage of the disease.

Background: Pyruvate Kinase Deficiency (PKD) is an autosomal recessive disease caused by mutations in the PKLR gene. PKD produces chronic non-sphere- ropoetic hemolytic anemia, which can be fatal during early childhood and may result in lifelong transfusion dependence that in some instances persists despite therapeutic splenectomy. Although not considered a standard-of-care, allogeneic bone marrow transplantation has been curative in a limited number of cases. These findings, and the evidence that PKLR gene mutations are likely the sole etiology of the disorder, make PKD a candidate for gene therapy. Our lab has developed a therapeutic Orphan Drug lentiviral product (EMA: EU/14/1330; FDA: DRU-2016-5168) for the treatment of PKD and is working to develop an efficient and safe gene therapy clinical trial for the treatment of PKD.

Aims: In order to improve this new treatment, a more deep knowledge of the disease and its associated pathophysiology is necessary.

Methods: To characterize the hematopoietic profile of this disease, we have standardized flow cytometry protocols to perform both a quantitative and quan- titative study of different population subsets. These included subsets of the hematopoietic stem cell compartment, erythroid progenitors, reticulocytes, mature erythrocytes and other mature lineages. Human routine samples consisted of peripheral blood, bone marrow and cord blood from PKD patients. In addition, xenogenic engraftment studies in immunodeficient (NSG) mice were also performed.

Results: Flow cytometry studies showed a clear imbalance in the erythroid populations. On the other hand, human PKD progenitors were able to engraft into NSG mice demonstrating that the disease does not likely impair hematopoietic stem cell capabilities.

Summary/Conclusions: Pyruvate Kinase Deficiency (PKD) is an autosomal recessive disease caused by mutations in the PKLR gene. Our lab has recently developed a therapeutic Orphan Drug lentiviral product for the treatment of PKD. In order to improve this new treatment, we are also working to deep into the knowledge of the disease and its associated pathophysiology. Flow cytometry studies have shown a clear imbalance in the erythroid populations. Functionally, results in NSG mice we have demonstrated that the disease does not likely impair hematopoietic stem cell capabilities.

OSMOTIC GRADIENT EKTACYTOMETRY: A VALUABLE SCREENING TEST FOR HEREDITARY SPHEROCYTOSIS AND OTHER RED BLOOD CELL MEMBRANE DISORDERS

M.D.M. Mafiu Pereira1,*, E. Llaudet Planas1, V. Rizzuto1, J.L. Vives Corrons1

1Red Blood Cell Pathology and Hematopoietic Defects, Josep Carreras Leukaemia Research Institute, Barcelona, Spain

Background: Red blood cell (RBC) membrane disorders constitute one of the major causes of chronic hereditary hemolytic anemia. Main RBC membrane disorder, namely hereditary spherocytosis (HS), hereditary elliptocytosis (HE) and hereditary stomatocytosis (HSt), alter membrane cohesion, membrane mechanical stability, and RBC volume, respectively. As a consequence, RBC deformability is compromised leading to their premature removal from circulation, manifested as hemolytic anemia. New generation osmotic gradient ektacytometry has become a powerful procedure for measuring red cell deformability and therefore for the diagnosis of red blood cell membrane disorders.

Aims: The aim of this study is to evaluate osmotic gradient ektacytometry as an adequate assay to perform screening of membranopathies, focusing on the differentiation diagnosis between HS and non-spherocytic membrane defects such as HE and dHSt.

Methods: A total of 75 patients with chronic hemolytic anemia oriented as hereditary RBC membrane disorders (hemoglobin disorders discarded and negative Coombs test) were included during a period comprised between January 2015 and August 2016. Normal controls were obtained from blood normal donors. Osmotic gradient ektacytometry was performed using the osmocsmatic module of the Laser-assisted Optical Rotational Deformability Cell Analyzer: LoRRCa MaxSis (RR Mechtronics). Evaluation of osmocsmatic parameters
robustness for HS diagnosis was performed using the receiver operating characteristic (ROC) curve analysis. The optimal cut-off was determined as the one with the highest likelihood ratio. Statistical analysis was operated with GraphPad Prism.

Results: Specific patterns of osmotic LoRRCa MaxSis were observed for each individual membranopathy. All HS curves were bell shaped but two different profiles were identified both presenting increased Omin, and decreased Elmax and AUC. HE curves showed a characteristic trapezoidal shape with a decreased Elmax, Omax and AUC. dHST curve was bell shaped with a specific decrease in Othyer and a slight increase in Elmin. Reference ranges for each osmotic parameter were established with 171 healthy subjects and compared with the values of the parameters obtained from the different RBC membrane disorders. ROC curve analysis was performed for HS and each one of the non-HS groups separately. The results determined that Elmax was the parameter that better separated HS from normal controls and dHST, while the Omin was the best to separate HS from HE. The optimal Elmax cut-off to differentiate HS was not just in genetic counselling and future antenatal diag-

Discussion: In this study we aimed to evaluate the concordance of EMA binding test with other diagnostic parameters for HS.

Methods: The patients with HS were diagnosed according to clinical findings for hereditary anemia, spheromegal and spherocytes in peripheral blood. Hemogram, reticulocyte count, total/direct bilirubin, spherocytes in blood smear (BS), EMA binding test, OF test, and cryohemolysis test were obtained from patients and control groups. Correlation between EMA, OF and cryohemolysis tests were evaluated.

Results: Twenty-five male, 17 female HS patients aged between 1.0-19.0 years and 38 male, 47 female healthy controls were evaluated. There were no differences between both groups in terms of age and sex (Table 1). The median (range) values of hemoglobin (%), reticulocyte count (%), mean corpuscular volume (fl), MCHC (%), and total bilirubin level were seen in Table 1. Besides M, dHST groups were found to be higher when compared with other diagnostic parameters (Table 1). The median MCF of HS patients was significantly lower than that of healthy controls while cryohemolysis and osmotic fragility were higher in HS patients than healthy controls (Table 1). There were moderate concor-

currence between cryohemolysis and EMA test (r=0.355, p<0.001). The sensitivity of EMA was 92.86%, specificity was 82.35%, PPV was%72.22, NPV was%95.89. EMA was superior diagnostic test to osmotic fragility. (sensitivity:83.33, specificity:76.47, PPV:63.44 and NPV:90.28). The sensitivity of cryohemolysis test was 90.48%, specificity was 94.12%, PPV was%88.37, NPV was%95.24.

M/F: Male/Female, FC EMA/flowcytometric eosin-5’-maleimide, OF: osmotic fragility, HS: hereditary spherocytosis, MCHC: mean corpuscular hemoglobin concentration, MCV: mean corpuscular volume, BS: blood smear.

Summary/Conclusions: In this study EMA-FC was more sensitive and specificity than osmotic fragility. However specificity and PPV of cryohemolysis was higher than other test. Also we showed moderate concordance cryohemolysis and EMA test. Although high sensitivity and specificity of EMA test there were need to use other tests together with family history of patient , physical examination, evaluation of blood smear and several tests for HS diagnosis.

ADVANCES IN DIAGNOSIS OF HEREDITARY HEMOLYTIC ANEMIAS: THERMOGRAVIMETRY COUPLED WITH CHEMOMETRICS

R. Risolati1, S. Materazzi1, F. Sorrentino2, L. Maffei2, C. Bozzi3, P. Caprari3,*

1 Department of Chemistry, Sapienza University of Rome, 2Thalassemia Unit, S. Eugenio Hospital, 3Haematology, Oncology and Molecular Medicine, Istituto Superiore di Sanità, Rome, Italy

Background: The differential diagnosis of hereditary hemolytic anemia is generally carried out by applying different diagnostic protocols depending on the specific congenital erythrocyte defects. Thermogravimetric analysis (TGA) coupled with chemometrics has recently been proposed as a rapid and cost effective diagnostic tool for β-thalassemia screening. This model, consisting of Parallel Line Assay-Discriminant Analysis (PLS-DA), permitted the discrimination of thalassemic patients and healthy individuals, using thermogravimetric curves of blood samples [1].

In this study, the capability of thermogravimetry in conjunction with a mul-

| Summary/Conclusions: Unexpected PK deficiency were found after next generation sequencing analysis in the patients where PK enzyme levels were within normal limits. PK deficiency may be missed by conventional testing approaches. Our data demonstrates the clinical utility of next generation sequencing for molecular diagnosis. Timothy detection of the cause in our patient is likely to be PK deficiency. A combination of protein 4.1, spectrin and ankyrin deficiency. Thus measurement of the fluorescent EMA test detects all the different forms of HS. |
tivariate statistical analysis was investigated for the screening of hereditary hemolytic anemias due to different erythrocyte defects.

Methods: Whole blood samples collected in K$_2$EDTA were obtained, after informed consent, from patients suffering from congenital hemolytic anemias and were analyzed using the thermobalance TGT (Perkin Elmer) without any pretreatment and the resulting curves were compared with those of healthy individuals. Two groups of hereditary hemolytic anemias were considered: the hemoglobinopathies (sickle cells anemia and thalassemia) and the erythrocyte membrane defects (hereditary elliptocytosis and hereditary spherocytosis).

Results: The characteristic profile of the blood sample thermal decomposition and the first derivative (DTG) of the TG curve showed that blood samples from anemic patients were clearly distinguished from those of healthy individuals as a result of different amounts of water and corpuscular fraction. The chemometric approach based on Principal Components Analysis (PCA) allowed a quick identification of differences between healthy and anemic patients in order to point out the model of prediction in patients with heterogeneous congenital hemolytic disorders.

Summary/Conclusions: The achieved results allow to consider the coupling TGA/Chemometrics as a promising diagnostic approach to provide a high-throughput and sensitive tool to obtain an early detection of hereditary hemolytic anemias using only a few microliters of blood without any pretreatment and with an hour of analysis time.

PB1844
DEVELOPMENT OF A POINT-SCORING SYSTEM FOR EARLY DIAGNOSTIC TESTING IN GAUCHER DISEASE: APPLICATION OF FINDINGS FROM THE GAUCHER EARLIER DIAGNOSIS CONSSENSUS DELPHI INITIATIVE
S. Salek$^1$, D. J. Kuter$^2$, A. Mehta$^3$
$^1$School of Life and Medical Sciences, University of Hertfordshire, Hatfield, United Kingdom, $^2$Center for Hematology, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, $^3$Department of Haematology, Royal Free Hospital, UCL School of Medicine, London, United Kingdom

Background: In the Western hemisphere, Gaucher disease (GD) type 1 is the most common GD phenotype, but the prevalence of GD type 3 is increasing, with new cases and symptoms of the different GD phenotypes ranging from fatal perinatal to asymptomatic adult disease, and the heterogeneity of its presentation contributes to both misdiagnosis and delays in diagnosis by clinicians unfamiliar with the disease. The Gaucher Earlier Diagnosis Consensus (GED-C) Delphi initiative determined which signs and patient co-variables are regarded by experts in GD as most indicative of GD types 1 or 3 in the early stages.

Aims: From the findings of the GED-C expert consensus, to generate a simple web-based point-scoring system (PSS) suitable for use across clinical specialties, that provides guidance based on patients’ presenting signs as to whether GD diagnostic testing is appropriate.

Methods: An anonymous three-round Delphi process, conducted among a global panel of 22 expert physicians, established consensus on which signs and co-variables may be important in early GD type 1 and, separately, in early GD type 3. In round 1, free-text responses provided by the panel were categorized and consolidated into priority factors by the non-voting co-chairs. In round 2, the factors were rated for importance by the panel using a 5-point Likert scale (1 = not important, 3 = important, 5 = extremely important). Any factors assigned an importance score of ≥3 by >75% of respondents were then rated for agreement in round 3, using a 5-point pivoted Likert scale (1 = strongly disagree, 3 = neither agree nor disagree, 5 = strongly agree). Consensus was defined as a score of ≥4 by >67% of respondents. Factors meeting this threshold were classified as major; all other factors were classified as minor. The co-chairs defined value ranges corresponding to mild, moderate or severe forms of five of the major signs of GD (anaemia, hepatomegaly, hyperferritinaemia, splenomegaly and thrombocytopenia). Panel members indicated whether they regarded each range as consistent with a GD diagnosis. This information was used in combination with the classifications of signs and co-variables as major or minor to create a prototype PSS.

Results: The round 2 100% response rate in each round. Factors identified as major or minor in GD types 1 or 3 are given in the Table 1. There was 100% agreement that splenomegaly (≥3-fold enlargement) and disturbed locomotor function (slow horizontal saccades with unimpaired vision) are major signs in GD, and these were assigned a score of 3 in the prototype PSS; other signs and co-variables were assigned a score of 2. The panel was divided about whether severe anaemia, hepatomegaly, hyperferritinemia and severe thrombocytopenia were consistent with a GD diagnosis, so these were assigned a score of 1. All minor signs and co-variables were assigned a score of 0.5.

Summary/Conclusions: A prototype PSS to inform GD diagnostic testing has been developed from the GED-C Delphi initiative. The PSS will be validated with retrospective patient data. Total patient scores based on presenting signs and co-variables will be used to determine empirically a minimum threshold score that captures positive tests for GD. Abstract submitted on behalf of the GED-C panel and the EHA Scientific Working Group: ‘Quality of Life and Symptoms’. Administration of the GED-C initiative was funded by unrestricted educational grants from Shire International GmbH.

REGIONAL DISTRIBUTION OF GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENCY IN TURKEY AND EVALUATION OF CLINICAL FINDINGS
S. Sayin$^1$, G. Ozqur$^1$, M. Yildirim$^1$, E. Sezcr Elci$^1$, C. Beyran$^2$
$^1$Hematology, Gulhane Educational and Research Hospital, $^2$Hematology, TOBB University of Economics and Technology Faculty of Medicine, Ankara, Turkey

Background: Glucose-6-phosphate dehydrogenase (G6PD) deficiency is the most common inherited enzyme deficiency, that affects more than 400 million people around the world with more than 300 variants. According to data by the World Health Organization which was published in 1989, 7.5% of people in the world have at least one gene G6PD deficiency and this ratio is the highest in sub-Saharan Africa and Southeast Asia (15-26%). This ratio is in the range of 0.5-2.9% in Turkey, as United States and the neighboring countries to Mediterranean Sea. The epidemiological studies about G6PD deficiency in Turkey were mostly regional or limited to a city.

Aims: We aimed to evaluate in terms of regional distribution and clinical features of G6PD deficiency by screening the patients who applied for soldier recruitment.

Methods: The patients who applied for soldier recruitment between January 2011-March 2016, were analyzed retrospectively. Patients, who were diagnosed G6PD deficiency were scanned by using hospital patient information system. The patients’ ages, the cities they lived, complaints and the stories of them were questioned. Complete blood count, serum AST, LDH, total and direct bilirubin levels of all the cases in the study were recorded. G6PD levels were measured by quantitative spectrophotometric methods in biochemistry laboratory. The World Health Organization (WHO) is divided G6PD enzyme deficiency into five classes based on enzyme activity levels and clinical findings.

Results: The distribution of the cities where the cases were living, was given on the map in Figure 1. Patients’ average age, hemoglobin, and G6PD levels were 26.42±4.62, 14.68±1.51, and 0.86±0.81 respectively. According to clinical history of patients prior to diagnosis, 29 patients (20.7%) were diagnosed after acute hemolytic episodes. Of these patients 23, 4, 2, had hemolytic episodes due to drug, infection, chemical respectively. Subsequently, 78 (54.5%) and 27 (18.9%) of the remaining patients were diagnosed G6PD deficiency by the examinations due to hemolysis after favism and prolonged neonatal jaundice respectively. 6 patients (4.3%) were diagnosed of G6PD deficiency by screening because of family history, but they didn’t have any hemolytic episodes before. After the patients evaluated with their clinical history and hemolysis findings; 6 patients (4.3%), who had chronic hemolysis, was considered compatible with Class I variant. 128 cases were considered as Class II variants.

Summary/Conclusions: G6PD enzyme deficiency in Turkey is seen most frequently in the Mediterranean region and the prevalence of G6PD deficiency in Central Anatolia and Aegean regions was seen to be over the Turkey average (2%). Nearly half of the patients had hemolytic anemia due to favism. It is followed by hemolysis due to neonatal hyperbilirubinemia and drugs. 128 (91.4%) patients who had severe G6PD deficiency with intermittent hemolysis, were considered as Class II variants.
CHARACTERISTICS AND MANAGEMENT OF AUTOIMMUNE HEMOLYTIC ANEMIA: A SINGLE CENTER STUDY WITH 32 CASES

A.F. Yılmaz¹, H.D. Kiper Unal¹,*, T. Yuksel Karsal², M. Kılıç², F. Gediz³, K.B. Bayman Paşinyan¹
¹Hematology, ²Internal Medicine, İzmir Katip Celebi University Ataturk Research and Training Hospital, İzmir, Turkey

Background: Autoimmune hemolytic anemia (AIHA) is characterized by red blood cell destruction mediated with autoantibodies against RBC antigens. Most common type is warm AIHA which can be either idiopathic or secondary to underlying disorders with immune disturbance. Determining the optimal therapy is a challenge because of insufficient data from prospective controlled trials.

Aims: To evaluate the clinical characteristics, treatment responses and outcomes of our AIHA patients.

Methods: The clinical data of 32 patients with AIHA diagnosed and treated in our center between 2008 and 2016 were retrospectively analyzed.

Results: Median at diagnosis of AIHA was 45 years (range:20-74). Male/female ratio was 1/1.3. 24 of 32 patients (75%) had primary AIHA and 8 (25%) had secondary AIHA with underlying disorders as SLE in 2 patients, mixed connective tissue disease (MCTD) in 2, psoriatic arthritis in 1, chronic lymphocytic leukemia (CLL) in 1, marginal zone lymphoma in 1 and chronic HCV infection in 1. Median Hemoglobin (Hb) level was 7.4 g/dl and 5 patients also had thrombocytopenia (<150000) beside hemolytic anemia. Mean LDH level was 544, indirect bilirubin was 2.7, reticulocyte was 11.3%. 18/32 patients (56%) required transfusion. In all patients who required treatment (94%) corticosteroids were the first-line therapy with an initial response rate of 93%. Median steroid duration was 3 months range between 1.5 to 96 months. Relapse was occurred in 15 of 30 patients who received steroid (50%) with the median time to relapse (TTR) of 12 months (range:5-72 months). 11/30 patients (37%) required second-line therapy; seven had undergone splenectomy, three received rituximab, and one received danasum. All of the patients who underwent splenectomy had CR in first month and relapse after splenectomy was seen in 5/7 patients (71%) with a median duration of 60 months. Of 3 patients who were treated with standard dose of Rituximab; two achieved CR and one did not achieve any response. One of two rituximab-responder patients relapsed at 26. and 60. months and re-treated by rituximab; still following with CR for 16 months.

Summary/Conclusions: Although corticosteroids were the first choice of initial treatment of AIHA, most of the patients relapse at follow up. Steroid dependency and intolerance are also challenging. Splenectomy is still a considerable option for second-line therapy because of its high response rates and long remission durations. Rituximab is the other effective second-line therapy option with similar response rates to splenectomy. Untill prospective studies will be performed, retrospective data would help the clinicians to choose best treatment algorithm for AIHA.

PB1848

NORMOCYTIC ANEMIA IS MORE COMMON THAN MICROCYTIC ANEMIA IN GASTRO-INTESTINAL CANCERS: A LARGE SINGLE CENTRE STUDY

F. Blanco-Favela¹, R. Silva-García, E. Avila-Arreguin²
¹Hematology, UMAE, Hospital de Especialidades, CMN-SXXI, Instituto Mexicano del Seguro Social, Ciudad de México, ²Jefe de Servicio de Prestaciones Médicas delegación Jalisco, Instituto Mexicano del Seguro Social, Guadalajara, Mexico

Background: Gaucher disease (GD) is a multisystemic disease of lysosomal storage that is caused by deficient activity of the glucocerebrosidase enzyme resulting from a recessive autosomal hereditary mutation in the β-glucocerebrosidase gene. The accumulation of glucocerebrosidase in the lysomes damages the hematological, skeletal, and nervous systems and leads to three varieties of the disease: type 1, which is non-neuropathic, and types 2 and 3, which are neuropathic. In Mexico, the process by which patients with lysosomal disease are cared for was recognized by the Clínicas de Referencia Nacional y Grupos de Expertos en Enfermedades Lízosomales (National Reference Clinics and Expert Groups on Lysosomal Diseases [EGLDs]), which created the Guías de Práctica Clínica (Clinical Practice Guidelines) for GD

Aims: This study aimed to evaluate the results obtained for 39 patients diagnosed with type 1GD (25 women and 14 men) through the National Reference Clinics and EGLDs

Methods: The clinical case of 39 patients was analyzed and the results obtained for the β-glucocerebrosidase gene were determined. The patients were treated with imiglucerase enzyme at 60 UI/Kg every 14 days. The enzymatic activity of the β-glucocerebrosidase and the chitotriosidase were determined. We determined concentration of hemoglobin and platelets. The degree of hepatosplenomegaly, bone density and skeletal pain was evaluated.

Results: Four of the 39 patients were found to have been incorrectly diagnosed with GD, the remaining 35 patients completed the treatment goals, which included remission from hepatomegaly, splenomegaly, and skeletal pain. Additionally, increases in the hemoglobin and platelet concentration and bone mineralization were achieved, thereby maintaining the patients’ therapeutic goals, reducing the therapeutic dose required, and achieving the expected impacts on their health.

Summary/Conclusions: This reorganization of patient care successfully reduced complications, improved care, and optimized the use of resources and costs of GD treatment.

DEMONSTRATION OF FUNCTIONAL SIMILARITY OF PROPOSED BIOSIMILAR ABP 798 TO RITUXIMAB
H. McBride1,2, G. Maher1, H. Swee3, I. Foltz2, J. Canon1, S. Kuhns1
1Biosimilars Development, Amgen Inc., Thousand Oaks, United States, 2Biosimilars Development, Amgen British Columbia, Burnaby, Canada

Background: Proposed biosimilars undergo comprehensive structural and functional characterization before they can be studied in confirmatory clinical trials. ABP 798 is being developed as a biosimilar to rituximab. The originator is approved for treatment of non-Hodgkin’s lymphoma, chronic lymphocytic leukemia, severe rheumatoid arthritis, granulomatosis with polyangiitis, and microscopic polyangiitis.

Aims: ABP 798 was compared with rituximab sourced from the European Union (EU). Quality attributes assessed included binding properties (CD20, C1q, FcRn, and Fcγ receptors), antibody-dependent cell-mediated cytoxicity (ADCC), complement-dependent cytotoxicity (CDC), and induction of apoptosis.

Methods: Binding of ABP 798 and rituximab to the CD20 antigen was characterized using a cell-based CD20 binding assay utilizing the human B-lymphoblastoid, WI-2-S, cell line. A direct binding ELISA was used to assess the binding of the Fc domain of ABP 798 to C1q. Binding of the Fc moiety of ABP 798 and rituximab to FcγRIIa, FcγRIIIa, and FcγRIV was evaluated in a functional cell-based assay, with CD20-expressing WIL2-S cells used as target cells and NK-92-M1 cells, stably transfected with human CD16 (FcγRIIIa [158V]), used as effector cells. CDC activity was evaluated in a functional cell-based assay using a CD20 expressing human B-lymphoblastoid WI-2-S cell line and baby rabbit complement. Induction of apoptosis was assessed by measuring activation of caspase 3/7 in SU-DHL-4 cells, a CD20-expressing human B cell lymphoma cell line. Results: Relative binding (%) was comparable between ABP 798 and rituximab (Table 1).

Table 1.

The dose response profiles and relative activity for ADCC and CDC were similar (mean ADCC relative activity: ABP 798, 88%; rituximab, 86%; mean CDC relative potency: ABP 798, 103%; rituximab, 104%). The dose response profile for induction of caspase 3/7 was comparable between ABP 798 and rituximab.

Summary/Conclusions: The results presented here suggest that ABP 798 is similar to rituximab sourced in the EU in terms of biological activity across the range of tested functions. These results provide a firm foundation for further clinical development of ABP 798.

PB1850
DELAYED EFFECT OF G-CSF ON THE CYTOKINE SECRETION THROUGH G-CSF MOBILIZATION OF PERIPHERAL BLOOD STEM CELLS IN CHILDREN WITH CEREBRAL PALSY
Y.-H. Lee1,2, W.-J. Rah2, H. Koh1,2, H.-J. Jun2, J.Y. Suh1, H.J. Eom1, M.J. Kim3
1Blood & Marrow Transplantation Center, 2Department of Pediatrics, 3Department of Rehabilitation Medicine, HANYANG UNIVERSITY MEDICAL CENTER, Seoul, Korea, Republic Of

Background: Granulocyte colony-stimulating factor (G-CSF) has been widely used to mobilize peripheral blood stem cells. In addition, it has also been tried to reveal the regenerative potential in various neurodegenerative diseases.

Aims: We investigated the short-term and delayed effects of infused G-CSF for peripheral blood stem cell (PBSC) mobilization on the various cytokine secretions in children with cerebral palsy (CP).

Methods: G-CSF (10μg/kg/dose) was administered subcutaneously for 4 days to the children with CP. In first group, blood levels of G-CSF, interleukin (IL)-6, IL-10, insulin-like growth factor (IGF-1), vascular endothelial growth factor (VEGF), and brain derived neurotrophic factor (BDNF) as well as mobilized total nucleated cell (TNC)/CD34+ cell counts in peripheral blood were compared between just before G-CSF injection (D=0) and 1 day after 4 days of G-CSF injections (D=4). In second group, cytokine levels were compared between D+0 and 1 month after 4 days of G-CSF injection (D+30). Cytokine levels were measured by enzyme-linked immunosorbent assay.

Results: Baseline levels of G-CSF were significantly increased (p=0.000) and IGF-1 decreased (p=0.011) at D+5 after 4 days of G-CSF administration compared to control group. In contrast, other cytokine levels including IL-6, IL-10, VEGF, and BDNF did not show any significant changes between before and after G-CSF administration. CD34+ cell counts (p=0.000) as well as TNC counts (p=0.000) were significantly increased from D=0 to D+5 in children who received G-CSF compared to children received placebo. Regarding delayed effect of G-CSF administration, G-CSF levels were significantly increased from baseline to D+30 (p=0.000), along with the increase IL-10 (p=0.035) and VEGF levels (p=0.011) and the decrease of IGF-1 levels (p=0.014).

Summary/Conclusions: G-CSF which administered to mobilize PBSCs could induce the delayed effects on the levels of G-CSF itself as well as of other cytokines which could affect on the neuroregenerative potential. Further studies would be warranted to reveal the mechanism and clinical significances of these delayed effect of G-CSF or mobilized PBSCs.

MYD88 IN PRAME GENE ACTIVATION
V. Misurin1, N. Lyzhko1, A. Misurina2, J. Finashutina1, V. Tikhonova1, L. Kesaeva1, O. Solopova1, N. Kasatinka1, M. Baryshnikova1, E. Misurina2, A. Prokopiev1, A. Misurin1
1N.N.Blokhin Russian Cancer Research Center, Ministry of Health, 2National Research Center for Hematology, 3City Clinical Hospital No52 Moscow Health Department, 4Moscow state Academy of Veterinary Medicine and Biotechnoloy - MVA by K. I. Skryabin, Moscow, Russian Federation

Background: PRAME is the most frequently expressed non-X-chromosomal cancer-testis gene in solid and hematological cancer. It is important, because PRAME often has a bad prognostic significance. In early studies was found that PRAME frequently coexpressed in translocation-harboring (like t(8;21), t(15;17) and t(9;22)) haematological diseases. Authors supposed that chimeric genes are activators of PRAME expression. But in large cases with normal karyotype PRAME is also expressed. Another reason for PRAME expression is promoter demethylation. But demethylating agents cannot activate PRAME expression in hematological cells taken from healthy donor. So presence of chimeric genes and methylation status only are not enough to explain why PRAME can be expressed in high level. Wadelin et al. found that PRAME expression level was increased in cell during lipopolysaccharide-treatment conditions. Role of MYD88 in this process still be unknown.

Aims: To check if MYD88 participates in activating PRAME expression in leukemia cell lines.

Methods: Three cell lines were used for incubation with anti-PRAME antibody: chronic myeloid leukemia cell line K562 with high PRAME expression level (645%), acute monocytic leukemia cell line THP-1 with intermediate PRAME expression level (2,92% relative to ABL) and acute myeloid leukemia cell line NOMO-1 with low PRAME expression level (0,46%). All cell lines were incubated in RPMI 1640 with addition of LPS in final concentration 10 ng/ml. After 1 and 4 hour of incubation total RNA was extracted and PRAME and MYD88 expression levels were measured.

Results: After 1 and 4 hours of experiment in K562 cell line PRAME expression level increased in 2,7 and 7 fold under control, respectively, and MYD88 expression level increased in 1,1 and 2,5 fold under control. In THP-1 line PRAME expression level was increased in 20 and 25 fold, respectively, and MYD88 expression level was increased in 5,5 and 6,5 fold. In cell line NOMO-1 PRAME expression level was increased in 10 fold after 1 hour and in 14 fold after 4 hours, and MYD88 expression level was increased in 2,4 and 3,2 fold after 1 and 4 hours of experiment, respectively. Strong correlation between MYD88 and PRAME expression levels was observed (Pearson correlation coefficient 0,98).

Summary/Conclusions: We conclude that LPS after binding with TLRs initiates activating signal to PRAME gene via MYD88.

PB1852

PD-1 IS HIGHLY EXPRESSED ON MEMORY T-CELL SUBSETS RESIDING IN BONE MARROW BUT NOT IN PE-RHEUMATIC BLOOD IN HEALTHY INDIVIDUALS

N. Popova1,*, M. Drokov1, A. Kuchmy2, A. Vdovina2, J. Davydova3, L. Kuzmina1, D. Dubray1, E. Mikhailova1, V. Vasiileva1, O. Koroleva1, Z. Konova1, I. Galtseva3, G. Efimov2, E. Parovichnikova1, V. Savchenko1

1Bone marrow transplant department, 2Laboratory of post-transplant-immunology, 3Laboratory of immunophenotyping, National Research Center for Hematology, Moscow, Russian Federation

Background: Recently memory T lymphocytes were shown to be a highly heterogeneous cell compartment comprising different phenotypes, functional activities, gene expression profiles and survival capacities. Phenotypically due to the differentiation stage and functional activities memory CD8+ T cells can be divided into different cell subsets (Tem, Tcm, Tte). central memory (Tcm) and terminal memory (Tte). effector memory (Tem) and terminal effector (Tte) and reside in bone marrow (BM) as long-lived persistent T cells [Mahnke YD et al., 2013]. Programmed cell death protein 1 (PD-1) is well known as a negative immune regulator of T cells that has detrimental effects on anti-viral, anti-tumor immunity, mediates tissue tolerance to protect against immune-mediated tissue damage. Currently anti-PD1 immunotherapies are among the most effective anti-cancer immunotherapies available. PD1 pathway blockade is a key pathogenetic mechanism [Bousios VA et al., 2014]. Understanding the influence of PD-1 pathway on memory T cell homeostasis in BM might be critical for improving treatment of patients with cancers and hematological malignancies, but is still not well understood.

Aims: To evaluate PD-1 expression on distinct memory T cell subsets in BM and PB of healthy donors.

Methods: The first portion of BM and a sample of PB were obtained from healthy donors (n=10, m=6, f=4) with age 37.5 (22-53) years old. Numbers of white blood cells (WBC) in BM and PB samples were evaluated by Sysmex XE-2100 hematology analyzer. 1*10^6 of WBC (excluded nucleated red blood cells) from BM and PB were stained using “lyse-wash-stain” standard protocol. The CD8-APC-Cy7, CCR7-PE-Cy7, CD28-PE, CD45R0-FITC, PD1-APC antibodies on BM and PB samples weren’t devided. Both findings point out at possible horizontal transfer between leukemic clone and BMSC. This process seems to be mediated by membrane vesicles larger than 0.4 μm in size, though cell fusion can also take place. We also confirmed the fact BMSCs can bear clonal genetic abnormalities and in one case the leukemia-specific marker was detected by PCR-RQ - we observed expression of ETV6-RUNX1 gene (0.02%) in BMSC by patient with (12;21) acute lymphoblastic leukemia. At the moment of BMSC culture initiation ETV6-RUNX1 expression in patient’s bone marrow was detected at high level (ETV6-RUNX1/ABL*100=521%). Before carrying out RNA extraction BMSC were harvested after the second passage and no contamination with CD45+CD34+ cells by flow cytometry was observed (50,000 events collected from the sample). When BMSCs and Uke-1 cell line were cocultured by using 3,0 μm pore the BMSCs population was detected the Jak2V617F mutation (allelic burden = 33.9%). We repeated similar experiments with the K-562 cell line and got similar results - CD45+ cells were also detected in BMSC population (33%). Moreover we detected CD45+ non-cellular particles by flow cytometry analysis. Implying K-562 cells are not likely to cross the semipermeable membrane (3,0 μm pores versus 20,0 μm cells as measured during microscopy). Besides BCR-ABL gene expression in BMSC was detected by RQ-PCR (BCR-ABL/ABL*100=19%). We repeated same test with 0.4 μm pore inserts and without them in order to check implication of cell-to-cell interaction. We didn’t obtain any similar results with smaller pores, but the CD45+ transcript was detected in BMSC population when these two cell populations weren’t devided. Both findings point out at possible horizontal gene transfer mediated by membrane vesicles larger than 0.4 μm and direct whole cell fusion.

Summary/Conclusions: Our data stands for the existence of horizontal gene transfer between leukemic clone and BMSC. This process seems to be mediated by membrane vesicles larger than 0.4 μm in size, though cell fusion can also take place. We also confirmed the fact BMSCs can bear clonal genetic rearrangements which are not specific to tumor cell populations. These findings show tight interaction between tumor and microenvironment cells and can partly explain nature of PCR-based MRD persistence in complete remission.

CIRCULATING ENDOTHELIAL PROGENITORS CELLS AND METABOLIC FACTORS IN CHILDHOOD CANCER SURVIVORS

E. Athanasopoulou1, G. Martimianaki1, H. Kampouraki1, M. Stratigaki1, E. Karkas1, N. Katsilambros2, E. Athanasopoulou1

1Pediatric Hematology - Oncology, University Hospital of Heraklion, University of Heraklion, Greece

Background: Circulating Endothelial Progenitor Cells (CEPCs) play a significant role in the maintenance of vascular integrity, balancing the anti-coagulation mechanisms and modulating the immune system by regulating the leukocyte trafficking, as well as controlling the vascular tone. Additionally, it is well-established, that patients who underwent chemotherapy have increased incidence of hypertension and obesity. Nevertheless, numerous studies have shown a negative correlation between CEPCs and obesity, underlying poor vascular remodeling.

Aims: The study of CEPCs in children who received chemotherapy for Acute Lymphoblastic Leukemia (ALL) and solid tumors (ST) and the investigation of their levels in correlation with patients Body Mass Index (BMI) and blood pressure (BP) regarding the time following treatment.

Methods: Children in whom chemotherapy was administered to children with ALL (n=77), ST (n=81) and children without malignancies as control group (n=71) were studied. Four colour flow cytometry was performed to determine the subpopulations CD34+CD45negCD133+ and CD34+CD45negVEGF+R2+ and CD34+CD45negCD133+CD45negVEGF+R2+ of CEPCs. The BMI of the patients was calculated and the percentile was established specific by the age and gender. Normal weight defined with BMI percentile over 5th and below 85th percentile, over-weight/obesity over 85th percentile. The systolic blood pressure (BP) was measured and the percentile was calculated specified by the age, gender and height. Normal BP was defined BP over 5th and below 90th percentile and hypertension with a BP over 90th percentile. The post treatment period of time was divided in three groups under or equal of 1 year, 1 to 3 years, and equal and over 3 years. The statistical analysis was conducted using t-test (Holm-Sidak) and 2way ANOVA (Tukey’s multiple comparisons tests).

PB1853

BONE MARROW STROMAL CELLS MAY HAVE GENETIC ABERRATIONS AND ARE CAPABLE TO GAIN THEM IN A CULTURE

I. Barkhatov1,*, M. Drokov1, A. Kuchmy2, A. Vdovina2, J. Davydova3, L. Kuzmina1, D. Dubray1, E. Mikhailova1, V. Vasiileva1, O. Koroleva1, Z. Konova1, I. Galtseva3, G. Efimov2, E. Parovichnikova1, V. Savchenko1

1Bone marrow transplant department, 2Laboratory of post-transplant-immunology, 3Laboratory of immunophenotyping, National Research Center for Hematology, Moscow, Russian Federation

Background: Stromal microenvironment poses a key role in the regulation of both normal hematopoiesis and its reconstitution after hematopoietic stem cell transplantation (H SCT). Recent data supports the ideas that bone marrow stromal cells (BMSC) also have genetic aberrations and may tightly involved in the pathogenesis of HSCT complications. These findings justify the need for more detailed study of genetic aberrations in BMSC.

Aims: The aim of this study was to evaluate genetic aberrations in BMSC and check the ability to gain them in coculture system.

Methods: The interaction of BMSC with hematopoietic tumor cell lines bearing specific genetic aberrations (BCR-ABL fusion transcript for K-562 and JAK2 V617F mutation for Uke-1 cell line) was investigated in stroma cells harvested from 17 patients and 8 healthy donors. We performed cultivation of BMSC with tumor cells using semipermeable membrane plates with inserts with different pore size (0.4 μm and 3.0 μm) in order to exclude direct cell-to-cell contact. We looked also for existing specific genetic aberrations (point mutations and fusion transcripts) in BMSC of patients with the respective aberration in their leukemic clone. For this purpose we used both karyotyping (10 patients) and RQ-PCR methods. BMSC were analyzed by flow cytometry to evaluate the possible contamination with cells of hematopoietic lineage.

Results: We investigated the BMSC karyotype in seven patients and only one case led to a remarkable finding. The clonal chromosomal rearrangement t(1;7) was detected in 25% of BMSC metaphases. Interestingly, this aberration was not detected in patient’s leukemic cell population. We also examined BMSC from leukemia patients bearing recurrent genetic abnormalities and in one case the leukemia-specific marker was detected by RQ-PCR - we observed expression of ETV6-RUNX1 gene (0.02%) in BMSC by patient with (12;21) acute lymphoblastic leukemia. At the moment of BMSC culture initiation ETV6-RUNX1 expression in patient’s bone marrow was detected at high level (ETV6-RUNX1/ABL*100=521%). Before carrying out RNA extraction BMSC were harvested after the second passage and no contamination with CD45+CD34+ cells by flow cytometry was observed (50,000 events collected from the sample). When BMSCs and Uke-1 cell line were cocultured by using 3,0 μm pore the BMSCs population was detected the Jak2V617F mutation (allelic burden = 33.9%). We repeated similar experiments with the K-562 cell line and got similar results - CD45+ cells were also detected in BMSC population (33%). Moreover we detected CD45+ non-cellular particles by flow cytometry analysis. Implying K-562 cells are not likely to cross the semipermeable membrane (3,0 μm pores versus 20,0 μm cells as measured during microscopy). Besides BCR-ABL gene expression in BMSC was detected by RQ-PCR (BCR-ABL/ABL*100=19%). We repeated same test with 0.4 μm pore inserts and without them in order to check implication of cell-to-cell interaction. We didn’t obtain any similar results with smaller pores, but the CD45+ transcript was detected in BMSC population when these two cell populations weren’t devided. Both findings point out at possible horizontal gene transfer mediated by membrane vesicles larger than 0.4 μm and direct whole cell fusion.

Summary/Conclusions: Our data stands for the existence of horizontal gene transfer between leukemic clone and BMSC. This process seems to be mediated by membrane vesicles larger than 0.4 μm in size, though cell fusion can also take place. We also confirmed the fact BMSCs can bear clonal genetic rearrangements which are not specific to tumor cell populations. These findings show tight interaction between tumor and microenvironment cells and can partly explain nature of PCR-based MRD persistence in complete remission.
Results: The mean values of CEPCs subpopulation CD34+CD45negdimVEGFR2+ estimated in ALL, ST and Controls were 0.003860 (SE=0.00072), 0.00613 (SE=0.00146) and 0.002953 (SE=0.00044) respectively. The mean percentage of CD34+CD45negdimCD133+VEGFR2+ in ALL, ST and Controls was 0.00331 (SE=0.00072), 0.00499 (SE=0.00113) and 0.002663 (SE=0.00037). The correlation between ST and Controls showed statistically significant difference of CD34+CD45negdimVEGFR2+ between the ST and Controls (Mean Diff=0.003174, 95CI of diff 7.716e-005 to 0.002672). In ALL the levels of CD34+CD45negdimVEGFR2+ the 1st year after treatment completion were 0.00458 (SE=0.00026), during 1-3 years 0.0031 (SE=0.00066) and >3 years 0.003423 (SE=0.00081). The levels of CD34+CD45negdimCD133+VEGFR2+ during the 1st year after chemotherapy were 0.0092 (SE=0.0037), 1-3 years 0.0027 (SE=0.00063) and >3 years 0.0031 (SE=0.00081). In the ST group the mean value of CD34+CD45negdimVEGFR2+ the 1st year after treatment was 0.0114 (SE=0.0046), 1-3 years 0.0047 (SE=0.0013) and >3 years 0.0036 (SE=0.0008). Whereas the percentage of CD34+CD45negdim CD133+VEGFR2+ the 1st year after chemotherapy was 0.0092 (SE=0.0037), 1, 3 years 0.0034 (SE=0.00097) and >3 years 0.0033 (SE=0.00085). Statistical significant results were calculated for the levels of CD34+CD45negdimVEGFR2+ in ST group between the groups <1 year and over years’ post treatment (Mean Diff 0.007747, 95 CI of diff 0.0002441 to 0.01525). The study of body weight in ALL and ST groups in relation with CEPCs showed no statistical significant difference, although a negative trend between obesity and CEPCs was found in the ALL group and a positive one in the ST group. The same trend also appeared in BP between ALL and ST regarding the CEPCs, with hypertensive patients in ALL group having higher levels of CEPCs than the ST hypertensive individual groups.

Summary/Conclusions: The higher levels of CEPCs were estimated in ALL and ST just after treatment completion with a gradual decrease as time passes. The highest percentages of CEPCs were evaluated in ALL patients with normal weight and blood pressure in contrast with the solid tumor group. Further investigation is necessary to highlight the importance of these data.

PB1855

HEMATOLOGICAL PARAMETERS IN NATIVE HIGHLANDERS OF LADAKH AGED 4-19 YEARS

S.K. Das1,*, Y. Uday1, D. Katoch1, V. Nair2

1Hematology, Army Hospital (Research & Referral), New Delhi, India
2Hematology, Hemotherapy Center, University of Campinas, Campinas, Brazil

Background: High altitude (HA) has always intrigued physiologists because of the remarkable ability of man to adapt to the hostile environment. Hematological changes associated with HA exposure is believed to be driven by hypobaric hypoxia. Majority of the studies on HA physiology and hematological changes associated with HA exposure is driven by hypobaric hypoxia with growing age and between boys and girls.

Methods: In a multicenter study from the Brazilian Group of Flow Cytometry we analyzed the variation of BCPCs in normal BM according to age, antibody combinations used for quantification and reproducibility after a centralized reanalysis. We set up a reference pattern of normal values for evaluation of patients with a suspected MDS.

Methods: In a retrospective study including 10 centers we retrieved analyses of BM donors and cases examined for elucidation of transitory reactive cytopneas presenting a normal BM immunophenotyping. BCPCs were enumerated as CD19/CD34/CD45/CD10 cells (panel 1) or CD19/CD34/CD45 cells (panel 2), among the total nucleated cells and as percentage among CD34+ cells. Statistical: multiple regression to analyse the dependence of BCS from the variables analysed.

Results: 134 cases were included. Panel 1 was applied in 106 cases (all centers) and panel 2 was used in 28 cases (3 centers). Age range: 10 months to 89 years. In the same age range, values for panel 2 were lower than those for panel 1. In multiple regression, % BCPCs/total cells < 3 years old (44%) − 0.313 (for panel 2) + correction factor for labs + 1.873. The correction factor for labs was 0 to -0.40. Age explained alone 49.6% of the variance of % BCPs/total cells, while “laboratory” explained 5.2% and panel used explained only 0.8%. Age explained only 24.9% of the variance of BCPCs/CD34+ cells.

PERIOSTIN/BIGH3 RATIO AS A PROGNOSTIC MARKER OF IDIOPATHIC THROMBOCYTOPENIA AFTER ALLOGENIC HEMATOPOIETIC CELL TRANSPLANTATION FOR THE PATIENTS WITH ACUTE MYELOGENOUS LEUKEMIA

Y.J. Lee1,*, S.K. Sohn1, H.-J. Kim2, T.I. Park3, J.Y. Ham4

1Department of Oncology/Hematology, 2Biochemistry and Cell biology, 3Pathology, 4Laboratory, Kyungpook National University Hospital, Daegu, Korea, Republic Of

BACKGROUND: Decrease of bone marrow (BM) B-cell precursors (BCP) is an important diagnostic feature in myeloplastic syndromes (MDS). Moreover, their number is associated with patients’ overall survival. However, BCPs vary with age in normal BM.

AIMS: In a multicenter study from the Brazilian Group of Flow Cytometry we analyzed the variation of BCPs in normal BM according to age, antibody combinations used for quantification and reproducibility after a centralized reanalysis. We set up a reference pattern of normal values for evaluation of patients with a suspected MDS.

METHODS: In a retrospective study including 10 centers we retrieved analyses of BM donors and cases examined for elucidation of transitory reactive cytopneas presenting a normal BM immunophenotyping. BCPs were enumerated as CD19/CD34/CD45/CD10 cells (panel 1) or CD19/CD34/CD45 cells (panel 2), among the total nucleated cells and as percentage among CD34+ cells. Statistical: multiple regression to analyse the dependence of BCS from the variables analysed.

RESULTS: 134 cases were included. Panel 1 was applied in 106 cases (all centers) and panel 2 was used in 28 cases (3 centers). Age range: 10 months to 89 years. In the same age range, values for panel 2 were lower than those for panel 1. In multiple regression, % BCPs/total cells < 3 years old (44%) − 0.313 (for panel 2) + correction factor for labs + 1.873. Summary/Conclusions: In a normal population BM B-cell precursors varied mainly with age, but were also dependent on technical peculiarities of operators and equipments. Analysis by phenotype and as percentage of total cells was more accurate and less susceptible to variation.

haematologica | 2017; 102(s2) | 743
Background: Disrupted hematopoiesis is life-threatening complication of allo- 
geneic hematopoietic cell transplantation (allo-HCT). The interactions of 
haematopoietic stem/ progenitor cells (HSPCs) and bone marrow (BM) 
microenvironment, niche(s), control the homeostasis of BM. TGF-b induced 
gene 3 (BIG3), one of BM extracellular matrix (ECM) which is produced by 
niche cells maintain the homeostasis and regeneration of BM.

Aims: We analyzed the relationship between the idiopathic thrombocytopenia 
after allo-HCT and the BM expression of periostin as the only parologue of 
BIG3.

Methods: We reviewed twenty patients who transplanted with matched sibling 
donor for acute myelogenous leukemia at Kyungpook National University Hos- 
pital from January 2010 to August 2015. BM biopsy specimens at the time of 
day 28, day 90, day 180, day 365 since allo-HCT were decalcified and stained 
with primary antibody of BIG3 and periostin. Expression of periostin in BM 
slides were reviewed by pathologist as follows; normal (0), minimal staining 
around blood vessels; (+1), sparse staining and/or focally staining; (+3), diffuse 
and strong staining; (+2), between (0) and (+3).

Results: The median age at transplant was 38.5 years (range, 17-68 years) 
and male was 13 patients (65%). Twelve patients (60%) were in CR1 (complete 
remission), 8% in CR2. Thirteen patients (65%) received myeloablative 
conditioning regimen. The median dose of CD34+ cell was 3.67±10^6/kg (range, 
1.5-7.67±10^6/kg). All patients achieved the neutrophil engraftment with a medi- 
an time of 13 days (range 9-24days). The median time of platelet engraftment 
was 15.5 days (range, 13-77days). Idiopathic thrombocytopenia developed as 
follows; 13 patients at day 28, 16 at day 90, 6 at day 180, and 3 at day 365. 
There was no significant difference between idiopathic thrombocytopenia 
and the expression of BIG3 or Periostin (p=0.128) However, BM with thrombocy- 
topenia manifested the low periostin/BIG3 ratio (p=0.007). Acute GVHD was 
observed in 12 patients (60%) and chronic GVHD developed in 13 patients 
(65%). The development of thrombocytopenia dose not differ according 
to acute and chronic GVHD (p=0.847) (Figure 1).

Summary/Conclusions: The periostin/BIG3 might represent the status of 
BM niche during the homeostasis and regeneration of hematopoiesis. High 
periostin/BIG3 ratio could predict the recovery of the idiopathic thrombocy- 
topenia.

PB1858
ASSOCIATION WITH OMENN SYNDROME AND CYSTINURIA: CASE 
REPORT
T. Papatrou1,2, M. Cansayar2, S. Coşkun2, M. Karakucuk1, N. Baydilli4
1Pediatric Hematology, 2Pediatric Immunology, 3Pediatric Nephrology, 4Urology, 
Erçyyes University Medical Faculty, Kayseri, Turkey

Background: Omenn syndrome is one type of combined immunodeficiency, 
characterized with hematosplenomegaly, lymphadenopathy, recurrent infections 
and has an autosomal recessive pattern of inheritance. T lymphocyte count 
can be normal in peripheral blood but their functions are impaired. B lymphocyte 
count is very low to none. Cystinuria is renal reabsorption defect of dibasic 
amino acids cysteine stones are formed in kidneys. In the literature, 
a number of association was found between Omenn Syndrome and cystine 
stones but none. For this aim, we report the case.

Methods: 5 months old girl applied to the Pediatric Immunology Department 
of Erçyyes University Children Hospital with skin eruption. There was no family 
history for immune deficiency and no consanguineous marriage between moth- 
er and father. Patient had one sibling who is healthy. Patient was not performed 
with BCG or other live vaccines. In her physical examination, we observed 
exfoliative erythroderma and hepatomegaly. In laboratory examination, leuko- 
cyte count 6540/mm³, absolute neutrophil count 2270/mm³, absolute lympho- 
cyte count 1560/mm³, absolute eosinophil count 2220/mm³, serum Ig level 
171mg/dl, IgA level 5.81mg/dl, IgM level 24,5mg/dl, IgE level 1270 mg/dl were 
found. T lymphocyte count 1092/mm³, B lymphocyte count 6/mm³, NK count 
332/mm³ were found respectively. Blood sample of patient was sent to Erasmus 
for genetic analysis. The patient had no full-match family donor. Hence, hap- 
lodemental bone marrow transplantation from her father was planned. In prepa- 
ration for bone marrow transplantation, bilateral kidney stones were showed in 
abdominal CT. Cystinuria was detected in urine and thought to be bilateral cys- 
teine Stone. Perucaneous nephrolithotomy operation was performed, then the 
patient was given scholl solution. Stone analysis revealed to be cystine stone.

Results: Association with two different diseases inherited autosomal recessive is 
very interesting. Challenging incident that can be caused by a reason or it 
might be only coincidence? In Omenn Syndrome is known to be sequencing 
alteration of cysteine and tyrosine amino acids. Perhaps, cystine stones took 
form as a result of this alteration.

Background: In the fluorescence lifetime imaging (FLIM) technique, the image 
contrast is created by determining the delay of the fluorescence photon emis- 
sion at each pixel of the image and transforming it in pseudo-colors. This delay, 
also called lifetime depends on the type of molecules and their physicochemical 
characteristics.

Aims: We investigated the utility of this technique for the characterization of 
erythropoietic cell line and changes in the solubility of hemoglobin.

Methods: We used unstained BM smears of 24 normal BM and 8 megaloblastic 
anemia patients and unstained peripheral blood smears of 10 patients with 
sickle cell anemia. Images were captured by a confocal microscope with a 
HPM-100-40-Hybrid detector and excitation at 405 nm (diode laser,80 MHz). 
In order to create equivalent images of the cytological smears, pseudo-colors 
were attributed to different lifetime ranges. Images were compared with May- 
Grünwald-Giemsa (MGG) stained smears.

Results: FLIM created highly contrasted images, where different cell types 
could be easily recognized by their similarity with MGG images. Erythrocytes 
exhibited the shortest lifetimes (210.4±42.1 ps). Normal shaped erythrocytes 
in smears of sickle cell patients showed similar values (214.6±3.1 ps), whereas 
crenated erythrocytes as well as drepanocytes revealed significantly elevated 
values (314.2±66.7 ps and 312.5±67.0 ps respectively). Regarding erythro- 
poiesis, the cytoplasm of erythroblasts showed significantly shorter lifetimes 
(623.5±272.1 ps) than that of myeloblasts (835.9±198.4 ps) and the same was 
the case when comparing the nuclei (erythroblasts: 895.4±262.8 versus 
myeloblasts: 1166.4±287.9 ps). The same differences could be found in mega- 
loblastic anemias. There were no significant differences between the FLIM val- 
ues of the different cell types between normal hemopoiesis and megaloblastic 
anemia.

Summary/Conclusions: The FLIM technique is easily applicable on unstained 
routine smears and revealed images of good quality permitting cell identifica-
tion. It also allowed to distinguish between erythroid and myeloid precursors 
cells and indicates the major physico-chemical changes during the process of 
falcization.

Summary/Conclusions: Occurrence of two malignancies in the same patient can be a challenge for the hematologist. Findings of the second disease can be attributed to the first disease or considering them to be results of treatment. Follow up and initiation of treatment in those patients can be more complex than usual. As far as origin is concerned there are conflicting reports in the literature supporting a common or different cells of origin. Recording of these cases and biobanking can be of great interest for understanding mechanisms of hematologic neoplasms.

Hodgkin lymphoma - Clinical

PB1861

B SYMPTOMS AND ELEVATED ESR AS PREDICTORS OF OVERALL SURVIVAL IN HODGKIN LYMPHOMA. A 20 YEAR FOLLOW UP MULTICENTER ANALYSIS.

1Haematology Department, Hospital Universitari Joan XXIII, 2Haematology Department, Hospital Universitari Joan XXIII, Tarragona, 3Oncology Department, Hospital Universitari Sant Joan, Reus, 4Haematology Department, Hospital Sant Pau i Santa Tecla, Tarragona, 5Haematology Department, Hospital Verge de la Cinta, Tortosa, Spain

Background: The prognosis of Hodgkin lymphoma (HL) has improved significantly with the implementation of a risk-adapted treatment that combines chemo and radiotherapy. Although this approach has led to the greatest advance in disease response, the benefit in terms of overall survival (OS) has been jeopardized by long term toxicity.

The identification of risk factors is crucial to assign each patient to a well defined risk group and prevent under or overtreatment, minimizing the risk of relapse and long term toxicity.

Aims: To analyze the risk factors associated with survival in HL treated with an ABVD based regimen that restricted radiotherapy only to bulky disease.

Methods: We retrospectively analyzed HL patients diagnosed in 4 centers in Tarragona area (Catalonia, Spain), between 1995 and 2015, treated uniformly according to a local protocol.

Patients were assigned into 4 groups: G1: favorable early stage: ABVDx6 cycles, G2: Bulky early stage without other risk factors: ABVDx6+IFRDT. G3: unfavorable early stage (B symptoms) and advanced stage without bulky disease: ABVDx8, G4: Bulky advanced stage: AVBDx8+IFRDT.

Results: A total of 183 patients were analyzed with a median follow up of 82 months [range 1-244]. Male/female ratio was 1.29. Median age was 36 years [range 16-82]. Complete response was achieved in 160 patients (87.4%). The estimated OS at 20 years for the whole group was 62.7%. Kaplan–Meier method and log rank test were used for survival analysis. Cox proportional hazard model was used for univariate analysis to identify predictive factors for OS. Factors with significance (p <0.05) were considered for multivariate Cox regression. In univariate analysis, worse OS was found in patients with increased LDH, non-NS subtype, albumin <3.5 g/dL, B symptoms, HIV+, advance stage and ESR >50 mm (log rank p=0.012; p=0.049; p=0.024; p=0.002; p=0.005; p=0.004 and p=0.001 respectively). The multivariate Cox regression analysis identified B symptoms and ESR >50 mm as independent prognostic factors for OS (p=0.002; p=0.006 respectively). These variables allowed us to identify 3 patient groups: low (no risk factors), intermediate (either B symptoms or ESR>50 mm) and high risk (both risk factors), with significant differences in OS. Estimation for OS was uniformly analyzed at 216 months (18 years), which is the shortest follow up period for patients in the low risk group. Patients in the low, intermediate and high risk groups had an estimated OS of 85.7%, 65% and 40.1% (p<0.001) (Figure 1).

Figure 1.

Summary/Conclusions: B symptoms and ESR>50mm are independently associated with OS. The combination of these factors can stratify patients in low, intermediate and high risk groups with significant differences in OS, regardless their clinical stage.
ADVANCED HODGKIN LYMPHOMA PATIENTS WITHOUT LARGE TUMOR MASS – A NEW PROGNOSTIC SCORE IDENTIFIES PATIENTS WITH FAVORABLE OUTCOME

B. Spassov1,2, D. Vassileva3,2, B. Kirov1,2, J. Jakovic1, M. Todorovic1, J. Bilal1, V. Djurasinovic1, V. Vukovic1, A. Sretenovic1, J. Jelic1, M. Smiljanic1, B. Mihajlevic1

1Clinic for Hematology, Clinical Center of Serbia, Belgrade, Serbia

Background: ABVD and escalated BEACOPP are still the standard of care in patients with advanced Hodgkin Lymphoma (HL). The use of escalated BEACOPP gives better disease control but it is associated with more acute and late toxic effects. The identification of patients who require more or less aggressive initial approach remains the main goal for many investigators in the field of HL.

Aims: The aim of this study was to identify among patients with diagnosed advanced HL without large tumor mass the subgroup which should not be considered for more aggressive approach than ABVD.

Methods: A retrospective study was performed on 149 patients classical HL, diagnosed in the period June 1997-December 2011. All the patients were in clinical stage III or IV and didn't have any tumor lesion of 5 cm or more in its longest diameter. The standard of initial care was 6-8 cycles of ABVD followed by radiotherapy. Prognostic relevance of age more than 45 years, gender, CS IV, presence of B symptoms, IPS score, ESR≤50 mm/h, Hgb<10.5 g/dL, WBC≥15,000/mm³ and lymphopenia (lymphocytes <600/mm³ or <8% of WBC count) were examined.

Results: The median age of analysed patients was 37 (range 17-80). The median follow up was 98 months. For the whole group 5-year event free survival (EFS) was 63.1% and 5-year overall survival (OS) was 80.6%. In univariate analysis, worse OS was found in patients older than 45 years (5-year OS 66.7% vs 87.8%), patients with CS IV (5-year OS 70.2% vs 87.0%), B symptoms (5-year OS 77.1% vs 90.1%), ESR≤50 mm/h (5-year OS 75.0% vs 89.5%), lymphopenia (5-year OS 65.6% vs 84.6%) (log rank; p=0.001, p=0.006, p=0.040, p=0.003, p=0.007, p=0.010, respectively), while gender, anaemia and leukocytosis didn’t influence OS (log rank; p=0.303, p=0.714, p=0.522, respectively). Worse EFS was found in patients with CS IV (5-year EFS 50.0% vs 70.7%, kog rank p=0.002), IPS≥3 (5-year EFS 53.8% vs 73.2%, (log rank; p=0.006) and lymphopenia (5-year EFS 50.0% vs 66.7%, kog rank p=0.25), while age, gender, B symptoms, ESR≥50 mm/h, anemia and leukocytosis didn’t influence EFS (log rank; p=0.078, p=0.437, p=0.068, p=0.151, p=0.384, p=0.158, respectively). The multivariate Cox regression model was used. It identified age more than 45 years, ESR≥50 mm/h and lymphopenia as independent prognostic factors for OS, while only IPS was identified as an independent factor for EFS. Afterwards, we performed survival analysis with aggregate scores of identified negative prognostic factors for OS for each patient. Since there was no difference in OS in intergroup analysis, groups with 0, 1, 2, 3 or 4 independent risk factors were formed. Finally, we developed prognostic model for identifying patients at low (0 factors), intermediate (1 factor) and high risk (2-3 factors) for poor outcome (p=0.000). According to this model, in the examined group 34 (22.8%) patients had low, 64 (43.0%) intermediate and 51 (34.2%) high risk for poor outcome, with 5-years OS of 100%, 73.2% and 70.7%, respectively.

Summary/Conclusions: According to the score which we developed, ABVD is very effective in the subgroup of advanced HL patients without large tumor mass and without identified risk factors.

TREATMENT ESCALATION IN CASE OF POSITIVE PET 2 AND IMPACT OF EARLY PET IN EXTENSIVE STAGE HODGKIN LYMPHOMA

S. Guizé1, N. Moya1, C. Gruchet1, L. Perrichot1, C. Tomowiak1, T. Systchenko1, A. Machet1, X. Leleu1, V. Delwail1

1Hématologie et Thérapie Cellulaire, CHU La Milétrie, Poitiers, France

Background: ABVD therapy has been for a long time the reference to therapy, but for the choice of the further management: radiotherapy, chemotherapy, as well as escalation of treatment will be presented to the EHA with update of follow-up.

Summary/Conclusions: This study evaluated the value of escalating treatment in patients with advanced PET 2 in patients with advanced Hodgkin lymphoma treated in first-line by ABVD. This management aims to reduce the toxicity of intensive treatments. The aim of our study is also to identify the higher risk patients for whom more intensive treatment could be used as first-line treatment.
Methods: In study were included 85 previously untreated patients, presented with classical HL between 2002 and January 2016. This retrospective study did not require approval by the Local ethical committee. Inclusion criteria were: a histologically confirmed diagnosis of classical HL, the presence of a fixed in paraffin before treatment a lymph node sample or other diseased tissue, the minimum follow-up was not less than 18 months.

Results: In the study population (n=85) identified 30 (35%) histological samples bcl-2+, and 55 biopsies (65%), bcl-2. Group bcl-2+ patients had a lower response rate after ABVD chemotherapy - only 24 (28%) patients achieved CR or better result, as compared with 49 patients (57.6%) of the bcl-2 group. The survival CR of all bcl-2+ patients was lower in CR population (p=0.018). Multivariate analysis using the Cox proportional hazard model with the inclusion of bcl-2+, CD30 +; bcl-2+/CD30 +, age 45 and older, B-symptoms, III-IV stage, anemia, decreased serum albumin, increased LDH, leukocytosis revealed that the expression of bcl-2 on RFS was an independent factor of poor prognosis. 3 year EFS was 52% vs 90% in bcl-2 population (p=0.022; RR=1.4). The greater relative risk was observed in a population with double expression of bcl-2 and CD30, where the 3-year EFS was 47% (p=0.012; RR=1.6).

Summary/Conclusions: The expression of bcl-2 on HRS cells can be a more powerful factor of poor prognosis than bcl-2+ cells.

PB1866

SURVIVAL ANALYSIS OF PATIENTS WITH CLASSICAL HODGKIN’S LYMPHOMA TREATED WITH ABVD: RESULTS FROM TWO REFERRAL CENTERS IN MEXICO CITY.

G.P. Agreda-Vásquez1, A. F. Ramirez-Ibarguen2, E. Crespo-Solis3, M.S. Rivas-Vera2
1Department of Hematology and Oncology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, 2Department of Hematology, Instituto Nacional de Cancerología, Mexico City, 3Department of Hematology and Oncology, Hospital Regional de Alta Especialidad de Ciudad Victoria, Victoria, Mexico

Background: Classical Hodgkin’s lymphoma (cHL) is a neoplastic disease with a favorable prognosis since 85% of patients can be considered cured with current treatment strategies. Combined chemotherapy with Adriamycin, Bleomycin, Vinblastine and Dacarbazine (ABVD) has been the standard therapy for over 20 years. Epidemiological information and the regimen’s results as first-line therapy in Mexico are limited.

Aims: The aim of this study was to conduct a survival analysis in adult patients from two referral centers in Mexico City.

Methods: This is a retrospective analysis of all patients with cHL treated at the Instituto Nacional de Cancerología and the Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, between 2009 and 2013. The study was approved by the local Ethics Committee.

Results: We included a total of 193 patients with a de novo diagnosis and initially treated with ABVD: 60.6% of cases were male, with a median age of 36 years (17-81 years). 71.5% were diagnosed in late clinical stages (CS). The most frequent histopathological subtypes were: nodular sclerosis and mixed cellularity (46.6% and 40.9%, respectively). The observed CR response rate (RR) was 85.7% [Complete response (CR) = 78.2%]. The RR was 90% in early CS vs 83.8% in late CS (CR rate was 84% vs 75.8%, respectively, p=0.23). Univariate analysis by logistic regression in the early CS group revealed that having a Lymphocyte:Monocyte ratio <1 presents an more powerful factor of poor prognosis than bcl-2+ cells. The most frequent histopathological subtypes were: nodular sclerosis and mixed cellularity (46.6% and 40.9%, respectively). The observed CR response rate (RR) was 85.7% [Complete response (CR) = 78.2%]. The RR was 90% in early CS vs 83.8% in late CS (CR rate was 84% vs 75.8%, respectively, p=0.023). In the group in late CS, we found that the lymphocyte percentage tended to favor CR [OR 1.048 (95%CI 0.994-1.105; p=0.081)] and the opposite was observed in terms of the absolute monocyte count [OR 0.999 (95%CI 0.998-1.000; p=0.082)]. Median follow-up was 35 months (0-96 months), 10.9% of cases had died at last follow-up, and median overall survival (OS) of the entire cohort had not been reached at the time of analysis (5-year OS, 87.1%). However, at the time of this analysis, the group of patients in complete remission had a greater OS than the group that did not achieve CR (p=0.0001). With Cox multivariate analysis of OS according to CS, we detected that in the group in early CS, none of the analyzed factors were significant, while in the late CS group, age >45 years was an independent risk factor [HR 6.9 (95%CI 1.80-26.60; p=0.005)] and achieving CR had a protective effect [HR 0.02 (95%CI 0.004-0.108; p=0.0001)].

Summary/Conclusions: Although OS medians had not been reached at the time of analysis, it is noteworthy that CR (84%) in early CS is lower than that reported in the literature and no related prognostic factor has been identified. The role of lymphocytes and monocytes may prove to be significant in larger series with a longer follow-up.

PB1867

OUTCOME OF PD-1 BLOCKADE IN PATIENTS WITH RELAPSED HODGKIN LYMPHOMA AND ACTIVE GRAFT-VERSUS-HOST DISEASE

A. Minson1,2, G. Douglas1, A. Grigg1
1Haematology, Austin Health, Heidelberg, Australia
2Madrid, Spain, June 22 – 25, 2017

Background: Efficacy of PD-1 (programmed death-1) inhibitors in relapsed/refractory Hodgkin lymphoma (HL) has been established, but their role in relapse after allogeneic stem cell transplant (alloSCT) remains controversial due to the perceived risk of exacerbating graft-versus-host disease (GVHD). The literature is largely limited to case reports in patients with no or quiescent GVHD.

Aims: To determine the outcome of PD-1 inhibitor therapy and subsequent management in patients with concomitant biopsy proven active GVHD and progressive HL after alloSCT.

Methods: We describe the treatment and management of two patients in our centre.

Results: Case 1 had both extensive bony, lung and nodal HL with active skin, pleuropedicardial and liver GVHD 6 months after donor leucocyte infu- sion (DLI) and immunosuppression withdrawal and 24 months after sibling alloSCT. Fifty-five_% of the standard pembrolizumab dose (100mg) produced a PET partial response after 5 weeks but with concomitant biopsy proven, severe exacerbation of liver GVHD. The latter was managed with prednisolone, everolimus, ursodeoxycholic acid (UDCA) and subsequently tacrolimus with gradual but substantial improvement in liver function over the next 5 months (Figure 1) in the absence of further PD-1 blockade, but with progression of lymphoma. Pembrolizumab 50mg was then given with lymphoma response but again a significant (but less severe) flare of liver GVHD occurred. Subsequent 25mg doses failed to prevent lymphoma progression. Reintroduction of 50mg doses approximately each 6 weeks for 4 doses with prophylactic everolimus, low dose prednisolone and ruxolitinib, has resulted in ongoing substantial but incomplete PET responses with associated stable liver GVHD. Case 2 had progressive mediastinal and pulmonary HL despite DLI-induced extensive liver and skin chronic GVHD 38 months post sibling alloSCT. Initial therapy consisted of optimisation of liver GVHD with 8 weeks of UDCA and prednisolone with improvement in liver indices (Figure 1). Pembrolizumab 50mg was then given, together with sirolimus and ruxolitinib as GVHD 'prophylaxis', resulting 5 weeks later in complete metabolic remission on PET. Concomitantly liver GVHD was aggravated (See Figure 1) together with pancytopenia and marrow hypoplasia attributed to an immune-mediated phenomenon. Despite addition of tacrolimus and increased steroids, he remains with severe liver dysfunction and pancytopenia 10 weeks after the single dose of PD1 inhibitor therapy.

Figure 1.

Summary/Conclusions: PD-1 inhibitors can exert powerful graft vs HL effects even in patients with progression in the context of active GVHD, but at the expense of substantial GVHD exacerbation. Further exploration of approaches such as individualised dose titration according to response and GVHD activity and prophylactic therapy with non-calcineurin based immunosuppression which may not mitigate the anti-lymphoma effect will help evaluate whether durable responses with tolerable toxicity is possible in this context.
PB1868
PROGNOSTIC VALUE OF THE RED CELL DISTRIBUTION WIDTH IN PATIENTS WITH CLASSIC HODGKIN LYMPHOMA
A. Knezović1, V. Perišac2, L. Zibar3, J. Sinčić-Petričić2
1Community Health Centre Đakovo, Faculty of Medicine, University of Osijek, Osijek, Croatia, 2Đakovo Hospital, University Hospital Centre Osijek, 3Department for Pathophysiology, Faculty of Medicine, University of Osijek, Osijek, Croatia, 4Nephrology, Department for Pathophysiology, University Hospital Centre Osijek, Faculty of Medicine, University of Osijek, Osijek, Croatia, Osijek, Croatia

Background: The current gold standard for risk stratification in Hodgkin lymphoma (HL) is the International Prognostic Score. There are certain molecular and immunohistochemical prognostic markers in patients with HL, but their cost and technical constraints make such an application in routine impractical and expensive. Therefore, prognostic models for classic HL (cHL) that are inexpensive, simple, and easy to perform and interpret are needed.

The red blood cell distribution width (RDW) is a simple, inexpensive, and independent prognostic factor for EFS that may improve the ability of the Risk Score less than 4 (P = 0.053).

The RDW ratio [HR] 3.801, 95% confidence interval [CI] 1-14.45, 13.95±1.82 (complete remission), 16.68±2.09 (partial remission), 13.95±1.82 (progression) vs 10.4±1.80 (remission) (P = 0.008). Patients with RDW values of >14.5% (cutoff value calculated by receiver-operating characteristic) had a significantly worse two-year EFS (62.4% vs 90.4%, P = 0.009) but did not differ significantly in terms of OS (P = 0.2). Univariate analysis revealed that a high RDW (>14.5) was correlated with poor EFS (P = 0.019). Multivariate Cox regression analysis showed that RDW >14.5% was an independent prognostic factor for EFS (hazard ratio [HR] 3.801, 95% confidence interval [CI] 1-14.45, P = 0.05). The RDW ratio was further confirmed statistically significant risk stratification in patients who were considered to be at low risk on the basis of an International Prognostic Score less than 4 (P = 0.053).

Summary/Conclusions: High baseline RDW is an independent prognostic marker of poor outcome in patients with cHL. RDW ratio is as simple, inexpensive, and independent prognostic factor for EFS that may improve the ability to identify high-risk patients with cHL. It could be an easily available and inexpensive marker for the risk stratification in patients with cHL.

HIGH FREQUENCY OF SECONDARY MALIGNANCIES IN PATIENTS WITH LARGE GRANULAR LYMPHOCYTIC LEUKEMIA: A SINGLE INSTITUTIONAL EXPERIENCE
L. Isenalemhe1, M. Van den Bergh 1, E. Wang2, B. Schaeble1, Z. Ma1, L. Zhang1, L. Sokol1
1Hematology-Oncology, L. Lee Moffitt Cancer Center and Research Institute, 2Internal Medicine, University of South Florida, Tampa, United States

Background: Large granular lymphocyte (LGL) disorders represent a spectrum of aberrant T-cell or natural killer cell lymphocytic proliferations. LGLL is classically associated with autoimmune conditions and bone marrow (BM) failure disorders. SM has been reported in association with LGLL in about 10%.

Aims: The aim of this study is to evaluate the impact of SM on the clinical course of LGLL.

Methods: This is a retrospective study of LGLL patients evaluated at Moffitt Cancer Center between January 1995 and May 2016. The diagnostic clinicopathological criteria consisted of LGL count ≥ 0.5 k/µL with T-cell receptor gene rearrangement. Lower absolute number of clonal circulating LGLs with characteristic immunophenotype associated with BM involvement, cytopenias, myelodysplasia and/or associated symptoms were also diagnostic. Patients with myelodysplastic syndrome were excluded. Survival analysis was performed using the Kaplan-Meier method with log-rank test. Chi-square and T-test were used to analyze association among various variables. Significant P-value was considered < 0.05.

Results: Of 668 screened patients with LGL expansions in peripheral blood, 261 met criteria for LGLL. Secondary malignancies were present in 44% (116/261) of LGLL patients, of which 38% were hematological and 80% arose prior to onset of LGLL. Most common solid secondary malignancy included skin cancer (14%), prostate cancer (12%), and breast cancer (12%), while most common hematological secondary malignancy consisted of non-Hodgkin lymphoma (17%) and chronic leukemia (14%). 5-year overall survival (OS) for all LGLL patients was 75% and 10-year OS 63%. There was a statistically significant difference in 5-year OS between LGLL patients with a secondary malignancy compared to without (p = 0.049), but no difference between both groups in median OS or 10-year OS. Patients diagnosed with a secondary malignancy prior to LGLL had worse 5-year OS (p = 0.031) and 10-year OS (p = 0.05) compared to all other LGLL patients.

Summary/Conclusions: This study showed that the frequency of a secondary malignancy is higher than previously described, especially with onset prior to diagnosis of LGLL. Even though median age of LGLL is around 60 years, it appears that age itself cannot explain this phenomenon. Our results suggest that having a secondary malignancy is a poor prognostic factor in LGLL patients.

PB1870
BENDAMUSTINE AND RITUXIMAB COMBINATION THERAPY WITH SUBSEQUENT RITUXIMAB SUPPORTING THERAPY IN RUSSIAN SUBJECTS WITH RELAPSED OR REFRACTORY INDOLENT B-CELL NON-HODGKIN LYMPHOMAS
1Hematology-Oncology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, Florida, 2Department of Internal Medicine, National Research Institute of Oncology, Moscow, 3Regional Clinical Hospital, Tula, 4Regional Clinical Hospital, Orenberg, 5Moscow Scientific Research Oncology Institution n.a.P.A. Gertzen, Moscow, 6Volgograd Regional Clinical Oncology Dispensary1, Volgograd, Regional Clinical Hospital, Irkutsk, 7Atlas Medical Center, Moscow, 8Novosibirsk State Regional Clinical Hospital, Novosibirsk, 9Regional Clinical Hospital, Krasnoyarsk, 10Clinical Trial Support, Smolensk, Russian Federation, 11Astellas Pharma Europe, Middle East and Africa, Chertsey, United Kingdom

Background: Combination of bendamustine and rituximab has been established in many international guidelines as treatment for patients with indolent B-cell non-Hodgkin lymphoma (NHL).

Aims: Objectives of this study were to evaluate the effectiveness, safety, and tolerability of bendamustine/rituximab combination followed by rituximab maintenance therapy for relapsed or refractory (R/R) INHL patients in the Russian Federation.

Methods: Adult subjects (≥18 yr), diagnosed with R/R INHL according to local diagnostic standards, and were enrolled in this prospective observational study. Intravenous therapy was administered in 2 stages (Figure 1): a combination therapy stage followed by a rituximab supporting therapy stage for subjects who achieved complete response (CR) or partial response (PR) during the combination therapy stage. Overall response rate (ORR) was assessed after
3 (Evaluation 1) and 6–8 (Evaluation 2) 28-day cycles. Data from the full analysis set (FAS) were used for the primary analysis and the per-protocol (PP) set for a subgroup analysis. Safety/tolerability was a secondary endpoint and was assessed in the safety analysis set (SAF). Response assessments used the LOCF method for substitution of missing data; overall survival (OS) and progression-free survival (PFS) were calculated using Kaplan–Meier estimates, safety/tolerability was assessed by adverse event (AE) frequency and described using descriptive statistics.

Results: Of the 102 subjects enrolled between June 2012 and October 2015, 83 subjects (52M/31F; median age 59 yr [range: 27–84]) with various NHL histology; subjects with mantle cell lymphoma [n=4], diffuse large B-cell lymphoma [n=2], and follicular lymphoma transformation [n=1] were excluded from the PP population due to deviation from the iNHL inclusion criteria. Most study subjects were heavily pretreated with a median number of 2 prior lines of therapy before entering the study (range: 1–6). At Evaluation 2, ORR in the FAS was high (n=30; 61.5%) with 35 (42.2%) subjects achieving CR (confirmed, n=20 [9.2%]; unconfirmed, n=15 [18.1%]) and 23 (27.7%) achieving PR; ORR (defined as [CR+CR unconfirmed +PR]) in the PP population was 70.8% (Table 1). For FAS patients, at follow-up (17 mo) neither median OS nor PFS had been reached; 2-year OS was 88.9% (95% CI: 79.7–99.0%) and 2-year PFS was 87.9% (95% CI: 80.7–95.7%). In the SAF, 31 of 96 subjects (32.3%) reported ≥1 AE. Decreased neutrophil count, decreased white blood cell count, and infections were the most commonly reported AEs and serious AEs. Twelve deaths occurred: 5 due to disease progression (n=2) or relapse (n=3), 5 were not related to lymphoma or occurred during remission, 1 cause of death was unknown, and 1 subject died from hyperthermia and respiratory failure, which was the only death in the study considered related to combination therapy.

Summary/Conclusions: Bendamustine plus rituximab therapy followed by rituximab maintenance therapy was generally well tolerated and demonstrated clinical effectiveness in Russian RR patients with iNHLs. Although a number of subjects with aggressive lymphomas were included in the FAS, the ORR rate was not considerably different from the PP population (ORR: 69.9% [FAS] vs 70.8% [PP]).

PB1872
A PROSPECTIVE PHASE 2 TRIAL EVALUATING MONOTHERAPY WITH OFATUMUMAB FOR RELAPSED/REFRACTORY SPLENIC B-CELL MARGINAL ZONE LYMPHOMA (MORE TRIAL): SAFETY ANALYSIS RESULTS
L. Scarfo1,2,3,*, G. Gritti4, A. Tedeschi5, P. Ranghetti1, C. Scielzo1, M. Ponzoni3,6, P. Ronchi7, A. Ferreri8, P. Ghia1,2,3
1Department of Haematology, Clinical Hospital Center Zemun, 2Medical Faculty University of Belgrade, Belgrade, Serbia, 3Department of haematology, Medical Faculty University of Belgrade, Belgrade, Serbia

Background: Indolent B-cell lymphoproliferative neoplasms (B-LPN) are malignant diseases of advanced age. The most common among them, follicular lymphoma (FL), marginal zone lymphoma (MZL) and chronic lymphocytic leukemia (CLL) together represent about 40% of all B-LPN. However, as indolent B-LPN are most often the slow-growing diseases, an approach “watch and wait” is often recommended. But, when treatment is necessary, the advanced patients’ age indicate the need for geriatric assessment (GA) in aim to indentify functional, cognitive, social, nutritional and psychological parameters of the general health status. G8 screening tool (G8) is recognized as fast, easy to perform and sensitive test for selecting the group of fit elderly patients capable for curative treatment approach. Although incorporated in routine oncological practice, GA and G8 are not widely evaluated in hematological practice, so far.

Methods: Total of 89 consecutive elderly patients (45males and 44 females with median age at diagnosis 74.6 years, range 74–86 years, median number of treatment agents before inclusion on current B-LPN regimen (24 with FL, 26 with MZL and 39 with CLL) who fulfilled criteria for treatment initiation were included in study. Patients were treated with antracycline, fludarabine or alkylated agents based chemotherapies regimens +/- monoclonal anti-CD20 antibody. Validity of G8 was compared with standard relevant clinical and laboratory parameters, comorbidity index (CCI; ≤3∕>3), ECOG performance status (PS; <2/≥2) and G8 score in aim to indentify functional, cognitive, social, nutritional and psychological parameters of the general health status. G8 screening tool (G8) is recognized as fast, easy to perform and sensitive test for selecting the group of fit elderly patients capable for curative treatment approach. Although incor- porated in routine oncological practice, GA and G8 are not widely evaluated in hematological practice, so far.

Results: For all 89 patients median overall survival (OS) was 77 months, and disease free survival (DFS) in 58 (77.3%) patients achieving remission was 25 months. Among laboratory parameters, hemoglobin, platelet, neutrophil and monocyte count, as well as C-reactive protein, beta-2 microglobulin didn’t influence OR rate, OS and DFS. Elevated lactate dehydrogenase was found significant for CR rate, and low albumin level (<40g/L) for predicting OS. Among clinical parameters age, sex, presence of “B” symptoms, splenomegaly (>13cm), bulky disease (>10cm), extranodal (EN) disease, as well Charlson comorbidity index (CCI; ≤3/3), ECOG performance status (PS; <2/2) and G8 score were significant. ECOG PS and G8 for OS. At Evaluation 2, ORR in the FAS was high (n=30; 61.5%) with 35 (42.2%) subjects achieving CR (confirmed, n=20 [9.2%]; unconfirmed, n=15 [18.1%]) and 23 (27.7%) achieving PR; ORR (defined as [CR+CR unconfirmed +PR]) in the PP population was 70.8% (Table 1). For FAS patients, at follow-up (17 mo) neither median OS nor PFS had been reached; 2-year OS was 88.9% (95% CI: 79.7–99.0%) and 2-year PFS was 87.9% (95% CI: 80.7–95.7%). In the SAF, 31 of 96 subjects (32.3%) reported ≥1 AE. Decreased neutrophil count, decreased white blood cell count, and infections were the most commonly reported AEs and serious AEs. Twelve deaths occurred: 5 due to disease progression (n=2) or relapse (n=3), 5 were not related to lymphoma or occurred during remission, 1 cause of death was unknown, and 1 subject died from hyperthermia and respiratory failure, which was the only death in the study considered related to combination therapy.

Summary/Conclusions: Bendamustine plus rituximab therapy followed by rituximab maintenance therapy was generally well tolerated and demonstrated clinical effectiveness in Russian RR patients with iNHLs. Although a number of subjects with aggressive lymphomas were included in the FAS, the ORR rate was not considerably different from the PP population (ORR: 69.9% [FAS] vs 70.8% [PP]).

Figure 1.
continue to the planned 15 patients (interim analysis). Here we present safety analysis results.

**Results:** Ten patients (6 males, 4 females; median age: 69.5 years, 9 ≥65 years, 1 <65 years) were analyzed for safety. Eight patients were previously treated with rituximab; 26 adverse events (AEs) occurred in 7 patients, with only 5 grade 3–4 AEs. Ten AEs were drug-related, 30% were of grade 3 (Table 1). Three SAEs occurred: hypersensitivity, n=2, both related, and dyspnea, n=1, unrelated to study drug. No AEs leading to treatment withdrawal were reported and no patients died on study. Hematological and biochemical abnormalities included: neutropenia (any grade 6 cases, grade 3–4: 4), thrombocytopenia (grade 1–2: 3 cases), lymphopenia (grade 1–2: 2 cases), leukopenia (grade 1–2: 5 cases), 1 case of G6PD deficiency (grade 3, at baseline grade 2), 9 cases of (all grade 2: 3 cases, grade 1-2: 1) each case of AST, ALT and bilirubin increase (all grade 1). Preliminary response assessment in these 10 patients documented 5 CR, 4 Partial Responses (PR) and one patient with progressive disease (PD) at the end of treatment.

**Summary/Conclusions:** Ofatumumab is safe and generally well-tolerated even in elderly patients with R/R SMZL. No cases of unexpected adverse drug reactions were documented. In a series of patients largely pre-treated with rituximab, ofatumumab resulted in a 90% overall response rate, 50% being CR. Complete results of the interim analysis will be presented at meeting.

**PB1873**

**TREATMENT PATTERNS AND RESPONSE TREATMENT IN PATIENTS WITH FOLLICULAR LYMPHOMA IN ROUTINE CLINICAL CARE – A UNITED STATES ELECTRONIC MEDICAL RECORD DATABASE STUDY**

A. Galaznik1,*, J. Bell1, L. Hamilton2, A. Ogbonnaya2, K. Hennenfent2, M. Eaddy1, E. Sperling2

1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 2Xcenda LLC, Palm Harbor, United States

**Background:** FL represents 70% of all indolent non-Hodgkin lymphomas, and it is widely recognized that FL is a heterogeneous disease, with patients presenting with differing amounts of tumor burden and prognostic indicators. The NCCN guideline recommends using rituximab as a single agent or in combination with other chemotherapies as first-line therapy (1LT) or second-line therapy (2LT). No new chemotherapy regimens have been approved beyond 2LT. The goal of this study was to evaluate treatment patterns and associated response in patients with newly diagnosed FL in routine care in the US.

**Methods:** Newly diagnosed FL patients aged ≥18 years were selected from Humedica, a large, national US EMR database, between 01/01/08 and 07/31/15 if they had ≥1 inpatient record or ≥2 outpatient records with FL diagnosis codes. The date of the first FL record was the index date. Patients were followed from index until end of continuous activity, progression to diffuse large B-cell lymphoma (DLBCL), death, or end of study period (09/30/15) and were evaluated for FL treatment patterns and treatment response. Possible remission was defined as no additional chemotherapy use or receipt of supportive care <30 days after end of line of therapy (LOT) for <30 days. Lack of remission was defined as receipt of supportive care <30 days after end of LOT for >30 days. Progression was defined as initiation of another LOT, transition to DLBCL, or evidence of supportive care >30 days after end of therapy (LOT) for >30 days. Lack of remission was defined as receipt of supportive care >30 days after end of LOT for >30 days. Progression was defined as initiation of another LOT, transition to DLBCL, or evidence of supportive care >30 days after end of therapy (LOT).

**Results:** Of the 3,756 patients selected into the study, 1,346 (35.8%) initiated 1LT, and median (interquartile range [IQR]) time to therapy was 1.3 (0.5–5.9) months. Overall, treatment regimens were mainly rituximab-based. In 1LT, more patients initiated combination chemotherapy (61.4%) vs single-agent chemotherapy (38.6%). Bendamustine+rituximab (26.9%) and R-CHOP (15.1%) were the most common combination regimens, and rituximab (33.1%) was the most common single agent. Median (IQR) duration of 1LT was 4.3 (1.7–10.4) months. At the end of 1LT, 54.7% (n=736) had evidence of remission, 25.5% (n=344) progressed, and 1.6% (n=22) had no evidence of remission. Among patients who progressed after 1LT, 41.3% (n=83) had evidence of remission, 35.4% (n=71) progressed, and 1.5% (n=3) had no evidence of remission. 45 patients who progressed after 2LT received third-line therapy (3LT); 35.6% received a single agent, while 64.4% received combination chemotherapy. In 3LT, rituximab (11.1%) was the most common single agent: bendamustine+rituximab (20.0%) and rituximab+cyclophosphamide+vincristine (8.9%) were the most common combination regimens. Median (IQR) duration of 3LT was 2.8 (1.4–4.7) months. Following 3LT, 26.7% (n=12) had evidence of remission, 39.9% (n=18) progressed, and 4.4% (n=2) had no evidence of remission.

**Summary/Conclusions:** FL treatment in routine clinical care aligns with treatment guidelines in 1LT and 2LT, with most patients receiving rituximab-based combination chemotherapy. Similar regimens were used in the 3LT setting. As expected, the rates of remission decreased with subsequent LOTs.

**PET-CT AND BONE MARROW BIOPSY IN STAGING FOLLICULAR LYMPHOMA IN A SINGLE INSTITUTION**

I. Parraga1,*, E. Gimeno1, F. Garcia-Pallerols1, B. Sanchez Gonzalez2, M. Suarez2, A. Mestre2, M. Ferraro1, E. Abeila1, L. Martinez1, C. Pedro1, E. Torres1, J. Maiques3, L. Colomo4, C. Besses1, A. Salari1

1Hematology department, Hospital del mar, Barcelona. Grup de recerca aplicada en Hematologia PSMAR, 2Nuclear Radiology department, 3Radiology department, 4Pathology department, Hospital del Mar, Barcelona, Spain

**Background:** Follicular lymphoma (FL) is an indolent lymphoid B neoplasm corresponding to 20–25% of non-Hodgkin lymphomas (NHL). Bone marrow biopsy (BBM) is part of standard work-up in indolent NHL since up to 40–70% of cases have bone marrow involvement. The first important point to consider is the high sensitivity of detecting nodal and extranodal lymphoma involvement, specially in aggressive subtypes. Some studies have described a high sensitivity (62-100%) and specificity (98-100%) in the detection of bone marrow involvement in aggressive NHL. However, its role in low-grade indolent lymphomas such as follicular lymphoma remains controversial.

**Aims:** To analyze retrospectively the diagnostic accuracy of PET-CT in comparison with BBM in the initial staging of new FL in a single centre in daily practice.

**Methods:** One hundred and thirty-six patients with de novo FL have been diagnosed in our institution from June 2005 to October 2016. Of them, 64 who underwent both BBM and PET-CT before treatment were evaluated. The BBM was evaluated by hematologist and the interpretation of PET-CT images was interpreted by a nuclear radiologist. Positive BBM was defined as the presence of CD20+CD10+ B-cells in low-grade lymphoid infiltration. No molecular biology techniques were done in the bone marrow tissue. PET-CT bone marrow involvement was defined as an elevated FDG uptake in the bone marrow that was higher than those in liver or mediastinum.

**Results:** Thirty-five male and 29 female were included. The median age at diagnosis: 58 years (range 23-84). Thirty-four patients had grade 1-2 FL and 30 grade 3a FL. Bone marrow involvement was diagnosed in 33 of 64 patients (51.1%) by BBM. Out of the 17 patients with positive PET-CT, 4 had negative BBM. Out of 33 patients with positive BBM, 13 had a positive PET-CT (Table 1). The sensitivity and specificity of PET-CT was 39% and 87%, respectively. The positive predictive value and negative predictive value was 76.5% and 57%, respectively.

**Summary/Conclusions:** Our study shows a very low sensitivity of PET-CT in the daily practice. These results contrast with those reported in some recent studies in aggressive lymphoma. However, the high positive predictive value raises the question about the usefulness of BBM in these PET-CT positive cases. In our opinion, with the current data, BBM should be performed in indolent NHL patients.

**SURVIVAL OUTCOMES AFTER FIRST-LINE THERAPY IN FOLLICULAR LYMPHOMA USING A UNITED STATES ELECTRONIC MEDICAL RECORD-BASED COHORT**

A. Galaznik1,*, J. Bell1, L. Hamilton2, A. Ogbonnaya2, A. Raju2, K. Hennenfent2, M. Eaddy2, Y. Shou1

1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharm-
Background: FL is a heterogeneous disease, and clinical presentation is highly variable. The Follicular Lymphoma International Prognostic Index (FLIPI-2) identifies prognostic factors at diagnosis but does not predict in whom and when to initiate first-line therapy (1LT).1 Recommended therapies for 1LT vary by stage, symptomatology, and tumor burden but include monotherapy with rituximab (R) or in combination with other chemotherapies. Survival of FL patients in the R era has greatly improved, but few studies have evaluated survival outcomes in patients seen in routine clinical care. Aims: This study aimed to evaluate survival outcomes in a US population of newly diagnosed FL patients seen in routine clinical care.

Methods: A retrospective study was conducted in which the presence of ≥1 inpatient record or ≥2 outpatient records with FL diagnosis codes were used to identify newly diagnosed FL patients from Humedica, a large US EMR database, between 01/01/08 and 07/31/15. The study index date was the first FL record. Patients who subsequently initiated 1LT for FL were followed from the date of treatment initiation until death, loss to follow-up, or end of study (09/30/15) for the evaluation of the survival outcomes. Median progression-free survival (PFS) (defined as initiation of second-line therapy, evidence of supportive care >30 days after the end of a line of therapy, or death), median overall survival (OS), and PFS and OS rates at 2 years following initiation of 1LT were evaluated using Kaplan-Meier analyses.

Results: 1,346 newly diagnosed FL patients who initiated 1LT met the patient selection criteria, 47.7% were male, and the mean age was 65.4 years (SD: 12.7). At baseline, 16.6% of patients had a Charlson Comorbidity Index of ≥2, and the most common comorbidities were diabetes (14.5%) and chronic pulmonary disease (11.2%). 1LT consisted of both monotherapy (38.6%) and combination therapy (61.4%). For monotherapy, R was the predominant agent used (85.1%), and for combination therapy, bendamustine+R (43.8%) and R-CHOP (24.6%) were the most common. Kaplan-Meier analysis revealed that the 2-year OS and PFS rates (from initiation of 1LT) were 86.9% and 64.6%, respectively. Median OS was not reached, and median PFS was 48.1 months (95% confidence interval: 39.4, 58.4).

Summary/Conclusions: The 2-year OS and PFS rates in this newly diagnosed FL patient cohort who received 1LT (the majority of which was R-based) were consistent with expectations in a post-R era. Future analysis will explore the differences in clinical characteristics and survival outcomes for patients who received R monotherapy and various R-combination therapies.

RITUXIMAB MAINTENANCE AFTER R.BENDAMUSTINE FOR PATIENTS WITH UNTREATED FOLLICULAR LYMPHOMA: A REAL LIFE STUDY IN SOUTHERN ITALY ON BEHALF OF RETE EMATOLOGICA PUGLIESE

Background: The role of Rituximab maintenance, support the efficacy of BR as backbone treatment of choice in previously untreated advanced FL. These results, moreover, are in line with those of other studies indicating that Rituximab standard maintenance and also over 2 years for FL appears safe and well tolerated, with no additional toxicities.

Results: Among the 118 pts, 94 were evaluable for response and safety. The overall response rate [ORR] was 89.2% with 83 pts achieving a remission after BR therapy. The CR rate was 84.4%, 7 pts had partial response, 5 pts (6.1%) had stable disease, whereas 3 (3.5%) showed no response to BR and had a progressive fatal disease. All of the pts achieving remission received the full planned 2 years Rituximab maintenance treatment and, among them, 24 pts (28.9%) were administered with R over the first two years. Primary adverse events recorded were of grade 3 and 4 in 25% of cases. Infections (grade 3-4) and neutropenia (grade 3) were the most common adverse event, no additional unexpected toxicities were observed, whereas no occurrence of secondary malignancy was registered so far.

Summary/Conclusions: Our data, compared with recent reports about the role of Rituximab maintenance, support the efficacy of BR as backbone treatment of choice in previously untreated advanced FL. These results, moreover, are in line with those of other studies indicating that Rituximab standard maintenance and also over 2 years for FL appears safe and well tolerated, with no additional toxicities.

PB1878
ROLE OF F-18 FDG-PET/CT IN DETECTING LYMPHOMATOUS BONE MARROW INVOLVEMENT IN THE INITIAL STAGING OF PATIENTS WITH LYMPHOMA

Background: The role of F-18 FDG-PET/CT for the assessment of bone marrow involvement in the staging of newly diagnosed patients with lymphoma was reviewed in the Recommendations of Lugano Classification. They conclude that if a PET/CT is performed, a bone marrow biopsy is no longer indicated for a routine staging of Hodgkin lymphoma (HL) and most diffuse large cell lymphoma (DLBCL). Data are insufficient in follicular lymphoma (FL) and bone marrow biopsy is always recommended.

Aims: We study the value of F-18 FDG-PET/CT for the detection of bone marrow involvement in the initial staging of patients with lymphoma.

Methods: Newly diagnosed patients with HL, DLBCL and FL who underwent F-18 FDG PET/CT and bone marrow biopsy for initial staging between January 2007 and June 2016 were included. We analyze sensitivity, specificity and concordance of PET/CT compared with bone marrow biopsy. In discordant cases, we review if there was any difference in the staging.

Results: 161 patients were included, 69 DLBCL, 38 male, 31 female, median age 59 years), 44 HL (24 male, 20 female, median age 53 years), 48 FL (23 male, 25 female, median age 55 years). Four of the 44 patients with HL had bone marrow infiltration in bone marrow biopsy (BMB+) and PET/CT detected bone marrow involvement in all of them. Twenty patients with DLBCL had BMB+ and 7 in the 40 patients without bone marrow infiltration in bone marrow biopsy (BMB-), these patients had bone marrow lesions on locations other than iliac crest. Six of the 7 patients were in advanced stage regardless of bone marrow involvement and a patient had sternal involvement by contiguity. Seven of the 69 patients with DLBCL had BMB+, 6 patients with DLBCL and 1 patient DLBCL and FL. PET/CT had detected bone marrow involvement in all of them. Sixty-two patients of 69 DLCL did not have bone marrow infiltration by biopsy (BMB-), but nine of them had BMB+PET+. Seven of the 9 patients were in stage IV because of extranodal involvement of other organs. One patient had primary brain involvement and patient of jaw and pleural involvement by contiguity. Fourteen patients of 48 patients with FL had BMB+. Of these 14 patients with bone marrow involvement by biopsy, 5 patients had BMB+PET- and PET/CT could not detect another extranodal involvement in three of these five patients. Of the 34 patients without bone marrow infiltration by biopsy BMO-, 8 patients had PET-TAC+, and 6/8 could be classified in stage IV regardless of bone marrow involvement (Table 1).

Summary/Conclusions: Our series confirms that PET/CT is useful to detect bone marrow involvement in the initial staging of Hodgkin Lymphoma and DLBCL. We avoid a bone marrow biopsy in these hystological variants of lymphoma. In follicular lymphoma, PET/CT did not detect more than one third of patients with bone marrow infiltration by biopsy. These results support the histological assessment of bone marrow in the initial staging of follicular lymphoma.
PB1880
PREDICTIVE FACTORS FOR INFECTIONOUS ADVERSE EVENTS IN PATIENTS WITH B-CELL NON-HODGKIN LYMPHOMA TREATED WITH BENDAMUSTINE-RITUXIMAB (R)±R MAINTENANCE. RESULTS OF A REGIONAL MULTICENTRIC EXPERIENCE

A. Di Rocco1,2, F. De Angelis1, L. Petrucci1, F. Vozzella1, D. De Benedittis1, R. Foà1, M. Martelli1
1Department of Cellular Biotechnologies and Hematology, University of Rome Sapienza, Rome, Italy

Background: The combination of bendamustine (B) and rituximab (R) is an effective and well tolerated treatment for B-cell malignancies. However, previous reports have shown a higher incidence of lymphopenia and secondary infectious complications in patients treated with BR than in patients treated with other chemotherapy regimens.

Aims: We performed a retrospective analysis at our institution in patients treated with BR with or without R maintenance, with the aim of determining the incidence of the infectious adverse events (AEs) and of identifying potential predictors of infectious complications.

Methods: We collected data from 65 patients with B-cell non-Hodgkin lymphoma (NHL) who received at least two cycles of BR±R maintenance between 2010 and 2016 at our institution. The AEs – including neutropenia (N), neutropenic fever (NF), lymphopenia, infections episodes and the occurrence of secondary tumors - were recorded according to the CTCAE v4.0 grade score. We compared the patients with or without infections to determine if these differences did not. Univariate analysis with Fisher’s exact test was used to evaluate the potential risk factors.

Results: The median age at the first treatment cycle was 66 years (range 36-89), 33 patients (50%) were 65 years or older. The median age was 66 years (range: 36-89); 33 patients (50%) were 65 years or older. Infections were observed in 25% of the patients. The most frequent infections were pneumonia (N), neutropenic fever (NF), lymphopenia, infections episodes and the occurrence of second tumors - were recorded according to the CTCAE v4.0 grade score. We compared the patients with or without infections to determine if these differences did not. Univariate analysis with Fisher’s exact test was used to evaluate the potential risk factors.

Summary/Conclusions: In conclusion this retrospective monocentric study confirms that after a long follow-up period about half patients died of lymphoma and the other half died for complications related to therapy or to lack of immunological control. Bendamustine-Rituximab confirms to be a good prognosis lymphoproliferative disorders and in the long observation period of patients clinicians must have maintained a careful evaluation of concomitant pathologies.

PB1882
INHOLY CHRONICAL CHARACTERISTICS AND PROGNOSIS OF PATIENTS WITH INDOLENT NON-HODGKIN LYMPHOMA AND RISK OF TRANSFORMATION TO AGGRESSIVE LYMPHOMA: A SINGLE JORDANIAN CENTER EXPERIENCE

D. Zahrani1,2, M. Ayesh (Haj Yousef)1, T. Kewan1, S. Al Bashir2
1Internal Medicine, 2Pathology, King Abdullah University Hospital (KAUH), Irbid, Jordan

Background: Indolent Non Hodgkin Lymphomas (INHL) are slow growing lymphomas that usually arise from the B cells. They are characterized by slow appearance and progression of symptoms compared to aggressive Non Hodgkin lymphomas (NHL) namely Diffuse large B-cell Lymphoma (DLBL). Small percentage of INHL might transform to aggressive NHL.

Aims: We aim to describe the clinical characteristics, prognosis and risk of transformation to aggressive lymphoma in patients with INHL in North Jordan as a model for other Middle East countries in which such data is lacking.

Methods: All patients diagnosed with INHL between Jan 2003 to Jan 2017 were retrospectively reviewed. Clinical and laboratory data at time of diagnosis including gender, age, lactate dehydrogenase level (LDH), pathological subtypes, CT and PET/CT scans were studied. Extranasal involvement was confirmed either by histopathological studies or CT and PET/CT scan. Transformation to aggressive lymphoma was confirmed by histopathological studies. Patients were followed and overall survival rate was calculated. Mean survival times were calculated using Kaplan-Meier method.

Results: Among 265 patients with INHL, only 88 patients (33.20%) confirmed to have INHL. 54 patients (61.4%) were males and 34 patients (38.6%) were females. Their ages at diagnosis ranged from (29-83) years with a mean (SD) of 59.26 (12.39). Among these patients, 45 patients (51.1%) had small lymphocytic lymphoma, 15 patients (17%) had marginal zone lymphoma (MZL), 20% of patients with MZL, 50% of patients with MZL, 20% of patients with FL and 8.9% of patients with CLL had extranodal sites involvement. (P-value=.001). 60% of patients with MZL, 50% of patients with MCL, 20% of patients with FL and 8.5% of patients with CLL had extranodal sites involvement. 11 patients (12.5%) from all INHL had transformed to Diffuse Large B-cell Lymphoma (DLBL). There was significant association between INHL subtypes and transformation to DLBL (P-value=.02). 7 from 20 patients with FL (35%) and 4 from 45 patients with CLL (8.9%) had transformed to DLBL. Mean LDH level (886.1 U/L) in patients with transformation to DLBL was significantly higher than mean LDH level (490.7U/L) in other patients, (P-value=.0004). There was a significant association between mean age and mean LDH level with risk of transformation to DLBL. The overall survival rate was 56.8%. 10 years and 5 years survival rates were 47% and 60% respectively. Mean survival time in patients with MCL (31.8 months) was significantly lower than mean survival time in patients with follicular (85.48 months), MZL (90.0 months) and CLL(103.6 months) patients (P-value=.0004). There was significant difference in overall survival rate between patients who transformed and patients who didn’t transform to DLBL.

Summary/Conclusions: Prevalence of INHL among patients with NHL in North Jordan is 33.2%. The most common INHL subtypes in our patients were
A RETROSPECTIVE STUDY OF PATIENTS WITH PRIMARY CUTANEOUS B-CELL LYMPHOMA TREATED IN A SINGLE CENTER BETWEEN 2003 AND 2016

Aims: To analyze clinical and laboratory characteristics such as age, lesion characteristics, hematological parameters, and treatment modalities in order to determine their impact on progression free survival (PFS) in PCBCL. This is a retrospective study of patients at Moffitt Cancer Center between January 1990 and December 2016. Patients were identified using our PCBCL database and diagnosis was verified by independent hematopathologists and dermatopathologists. Staging was determined according to ISCL/EORTC recommendations. Demographics, lymphoma subtype, stage, response, disease course, and CLIPi scores were recorded. Kruskal Wallis ANOVA and Fisher’s Exact tests were used to compare differences among the four subtypes for continuous and categorical variables, respectively. Kaplan Meier curves were produced to estimate PFS for different strata, and differences among the strata were tested using the log-rank test.

Methods: A Retrospective cohort of patients with low grade OAL treated in a single Centre between 2003 and 2016 was analyzed. Chemotherapy was the first choice of therapy until 2008, afterwards radiotherapy became the first line of management of OAL.

Results: A total of 20 patients with OAL were identified. 60% (12/20) of patients were females, with a median age of 61.5 years (range 45-85 years). 80% (16/20) had unilateral disease at presentation. MALT lymphomas comprised 75% (15/20), Follicular NHL 15% and CLL/SLL 10%. Only 10% (2/20) had a prior diagnosis of NHL. At presentation 20% (4/20) had evidence of systemic involvement: 19% (3/16) had bone marrow involvement and 1 patient had small volume lymphadenopathy on CT scan. 45% (9/20) were treated with first line chemotherapy, single agent Chlorambucil in 78% (7/9) and 2 patients received Fludarabine based chemotherapy, 30% (6/20) received first line radiotherapy, 24Gy in 12 fractions in 67% (4/6), and 25% (6/20) were managed under observation. In the chemotherapy group 55% (5/9) experienced 1 relapse (3/5 local recurrence and 2/5 extra-ocular relapse), 3 patients experienced ≥2 relapses, 2 patients had disease transformation to high grade and 1 patient subsequently died as a consequence of their disease. 33% (2/6) patients treated with radiotherapy experienced disease recurrence, mainly extra-ocular and 50% (3/6) suffered complications following radiotherapy in the form of dry eyes and cataract. Median follow up was 9.5 years (range 1-14 years). Overall survival was 95% (19/20) with an event free survival of 65% (13/20) (Table 1).

Table 1. Summary of the management modalities of ocular adnexal low grade non-Hodgkin lymphoma.

Summary/Conclusions: The majority of patients in our cohort had favorable outcomes. Currently there is no national guideline for the management of OAL in the UK. Several treatment options exist including chemotherapy, radiotherapy, immunotherapy, observation or more recently the use of eradication treatment for Chlamydia Psittaci. Factors to consider when choosing a treatment include a patient’s co-morbidities, risk of visual impairment, need for systemic therapy, histological diagnosis and anticipated side effects. As treatments are so effective the long term consequences and possible late effects need to be acknowledged and avoided if at all possible. Observation is an acceptable approach in asymptomatic patients when there is no immediate risk of visual impairment. Radiotherapy is an effective first line treatment in symptomatic patients. Biopsy localization of OAL is the exacting art of radiotherapy to achieve disease control with minimal long term side effects is yet to be determined. Reviews with larger number of patients are needed to inform a practical approach to the management of OAL.

PB1884

AGE AS A POTENTIAL NOVEL PROGNOSTIC INDICATOR IN PRIMARY CUTANEOUS B-CELL LYMPHOMA

Aims: To report a single centre’s experience in the outcomes of patients diagnosed with OAL over a 13 year period.

Methods: A Retrospective cohort of patients with low grade OAL treated in a single Centre between 2003 and 2016 was analyzed. Chemotherapy was the first choice of therapy until 2008, afterwards radiotherapy became the first line treatment for OAL.

Results: A total of 20 patients with OAL were identified. 60% (12/20) of patients were females, with a median age of 61.5 years (range 45-85 years). 80% (16/20) had unilateral disease at presentation. MALT lymphomas comprised 75% (15/20), Follicular NHL 15% and CLL/SLL 10%. Only 10% (2/20) had a prior diagnosis of NHL. At presentation 20% (4/20) had evidence of systemic involvement: 19% (3/16) had bone marrow involvement and 1 patient had small volume lymphadenopathy on CT scan. 45% (9/20) were treated with first line chemotherapy, single agent Chlorambucil in 78% (7/9) and 2 patients received Fludarabine based chemotherapy, 30% (6/20) received first line radiotherapy, 24Gy in 12 fractions in 67% (4/6), and 25% (6/20) were managed under observation. In the chemotherapy group 55% (5/9) experienced 1 relapse (3/5 local recurrence and 2/5 extra-ocular relapse), 3 patients experienced ≥2 relapses, 2 patients had disease transformation to high grade and 1 patient subsequently died as a consequence of their disease. 33% (2/6) patients treated with radiotherapy experienced disease recurrence, mainly extra-ocular and 50% (3/6) suffered complications following radiotherapy in the form of dry eyes and cataract. Median follow up was 9.5 years (range 1-14 years). Overall survival was 95% (19/20) with an event free survival of 65% (13/20) (Table 1).

Table 1. Summary of the management modalities of ocular adnexal low grade non-Hodgkin lymphoma.

Summary/Conclusions: The majority of patients in our cohort had favorable outcomes. Currently there is no national guideline for the management of OAL in the UK. Several treatment options exist including chemotherapy, radiotherapy, immunotherapy, observation or more recently the use of eradication treatment for Chlamydia Psittaci. Factors to consider when choosing a treatment include a patient’s co-morbidities, risk of visual impairment, need for systemic therapy, histological diagnosis and anticipated side effects. As treatments are so effective the long term consequences and possible late effects need to be acknowledged and avoided if at all possible. Observation is an acceptable approach in asymptomatic patients when there is no immediate risk of visual impairment. Radiotherapy is an effective first line treatment in symptomatic patients. Biopsy localization of OAL is the exacting art of radiotherapy to achieve disease control with minimal long term side effects is yet to be determined. Reviews with larger number of patients are needed to inform a practical approach to the management of OAL.
immunoglobulin heavy chain rearrangement (CDR2 / CDR3 of IgH) in PB, bone marrow and affected organs. All diagnoses were classified according to WHO (2016 revision). In addition, we performed an autologous test in most patients.

Results: Among the 56 patients, 26 were men (46.4%) and 30 women. The median age at diagnosis was 64 years (37-92). The most frequent subtype was marginal zone lymphoma (17 patients, 30.4%), followed by MALT: 10 pulmonary (17.9%), 10 gastric (17.9%), 5 cutaneous (8.9%), 5 ORL (8.9%), 2 (3.6%), 1 hepatic, 1 thyroid and 1 lachral gland (1.8%) and nodal marginal zone lymphoma (3 patients, 5.4%). Five of them presented with multifocal disease (8.9%). Fifty percent (28) had a clinical stage III / IV and 32 patients (57.1%) had a low risk of diagnosis (FLIPI 0-1). We found an antigenic stimulus in 11 patients (Helicobacter pylori, Sjögren’s syndrome, Hashimoto’s thyroiditis). The molecular study of MALT1 was performed in 25 patients and 3 presented the translocation (12%). Six of seventeen cases (35.3%) showed IgH rearrangements. Antinuclear antibodies were positive in 15 of 32 patients (46.9%) and IgM in 5 patients (15.6%). All patients had undergone treatment. One achieved a complete remission (CR) (76.1%) and 10 partial remission (PR) (21.7%) after the first line of treatment. Among these, 17 received immunotherapy (37%), 10 immunotherapy (21.7%), 8 surgery (17.4%), 7 antibiotics (15.2%) and 4 radiotherapy (8.7%). We observed 7 relapses (16.7%) and 3 pseudo-progression (7.1%), achieving a CR in 7 (70%) and PR in 3 (30%) after rescue treatment. There was just one case of high grade transformation (1.8%), who was the only patient deceased in the series (1.8%), with a median follow-up of 70 months.

Summary/Conclusions: Marginal zone lymphoma is an indolent lymphoma, with good prognosis and very good response to current therapy. It is sometimes associated with autoimmune phenomena and infectious agents. It is essential a correct staging and characterization to optimize its therapeutic management and outcome.

PB1886

HAIRY CELL LEUKEMIA AND B-RAF MUTATIONS
A. Olgun1, Y. Baskın2, S. Solmaz Medeni3, I. Alacacioglu1, M. Akbapour2, 1Dokuz Eylul University Hematology Dept., 2Dokuz Eylul University Oncology Pathology Dept., Izmir, Turkey

Background: Hairy cell leukemia(HCL) is a B cell lymphoproliferative disorder, presenting with splenomegaly, hepatomegaly and bone marrow infiltration. HCL accounts for 4%,5 of non-Hodgkin lymphomas, more commonly seen in man. Diagnosis is based on the examination of peripheral blood smear, flow cytometry and the bone marrow aspiration-biopsy. Recently, B-RAFV600E mutation was demonstrated in 10% of Tiacci HCL case series.

Aim: The overall response rate was 95.1% (65.8% CR-iCR / 29.3% PR). With a median follow-up of 25 months (6-92) the median response duration was 41.9 months (32.8-57.2) and the median progression-free survival (PFS) was 57 months (27.4-86.5) with no impact neither by the number of previous treatments (1 vs ≥2) (P=0.69) nor by the age (<70 vs ≥70) (P=0.9). Patients who received maintenance with rituximab after BR had a significantly longer median PFS than without (NR vs 32) (P=0.004). Toxicity: No treatment-related death was recorded. 42% and 36.6% of the patients presented G3-4 neutropenia and thrombocytopenia respectively, although only 2 patients were admitted to the hospital. Neutropenia and thrombocytopenia were common and the most frequent was CHOP-R in 66% followed by CVP-R in 11%. Among the 54 patients, 26 were men (46.4%) and 28 women. The median age at diagnosis was 64 years (37-92). The most frequent subtype was marginal zone lymphoma (17 patients, 30.4%), followed by MALT: 10 pulmonary (17.9%), 10 gastric (17.9%), 5 cutaneous (8.9%), 5 ORL (8.9%), 2 (3.6%), 1 hepatic, 1 thyroid and 1 lachral gland (1.8%) and nodal marginal zone lymphoma (3 patients, 5.4%). Five of them presented with multifocal disease (8.9%). Fifty percent (28) had a clinical stage III / IV and 32 patients (57.1%) had a low risk of diagnosis (FLIPI 0-1). We found an antigenic stimulus in 11 patients (Helicobacter pylori, Sjögren’s syndrome, Hashimoto’s thyroiditis). The molecular study of MALT1 was performed in 25 patients and 3 presented the translocation (12%). Six of seventeen cases (35.3%) showed IgH rearrangements. Antinuclear antibodies were positive in 15 of 32 patients (46.9%) and IgM in 5 patients (15.6%). All patients had undergone treatment. One achieved a complete remission (CR) (76.1%) and 10 partial remission (PR) (21.7%) after the first line of treatment. Among these, 17 received immunotherapy (37%), 10 immunotherapy (21.7%), 8 surgery (17.4%), 7 antibiotics (15.2%) and 4 radiotherapy (8.7%). We observed 7 relapses (16.7%) and 3 pseudo-progression (7.1%), achieving a CR in 7 (70%) and PR in 3 (30%) after rescue treatment. There was just one case of high grade transformation (1.8%), who was the only patient deceased in the series (1.8%), with a median follow-up of 70 months.

Summary/Conclusions: Marginal zone lymphoma is an indolent lymphoma, with good prognosis and very good response to current therapy. It is sometimes associated with autoimmune phenomena and infectious agents. It is essential a correct staging and characterization to optimize its therapeutic management and outcome.

PB1888

USE OF RADIATION THERAPY FOR THE TREATMENT OF GASTRIC MALT LYMPHOMA

E. Gonzalez1, L. Diaz1, M. J. Macias1, V. Diaz1, I. Villanego1, S. Garduño1, C. Salas1, L. Guiterrez1, J. Jaen1

Background: Gastric mucosa-associated lymphoid tissue (MALT) lymphoma is a rare disease however, the incidence is increasing and closely associated with helicobacter pylori (HP) infection. One choice of treatment of gastric MALT lymphoma refractory to HP sterilization is radiotherapy.

Aims: Our aim was to analyze the response to treatment with definitive radiotherapy in our center.

Methods: Between January 2014 and January 2017, 8 patients with gastric MALT lymphoma were treated with eradication therapy of HP, followed by definitive radiotherapy. The average total dose was of 38 Gy to the stomach in a once-daily scheme. Follow-up included computed tomography scan and
endoscopy with biopsies at regular intervals. The median follow-up was 14 months.

Results: In all patients we got complete responses (CR) with no tumor detectable by endoscopy or biopsy after initial treatment, but after 2 years one of them relapsed and required immunochemotherapy. The most common acute toxicities were fatigue and nausea, in our patients. In any case late toxicities were observed. The overall survival was 100% after 2 years.

Summary/Conclusions: In selected patients who are not responsive to HP sterilization, definitive radiotherapy can be an efficient therapy with tolerable complications, preservation of stomach and sustained response over time.

Infectious diseases, supportive care

PB1889

USE OF LIPEGFILGRASTIM IN CLINICAL PRACTICE FOR THE PROPHYLAXIS OF CHEMOTHERAPY-INDUCED NEUTROPENIA IN LYMPHOMA PATIENTS: INTERIM RESULTS OF A PAN-EUROPEAN NON-INTERVENTIONAL STUDY

N. Cascavilla1,2,*, T. Wrobel2, E. Hatzimichael3, E. Wojciechowska-Lampka4, P. Mazz4, K. Karger5, M. Lenzhofer6

1Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Italy, 2Wroclaw Medical University, Wroclaw, Poland, 3University Hospital of Ioannina, Ioannina, Greece, 4MSc Cancer Center and Institute, Warsaw, Poland, 5SS Annunziata Hospital, Taranto, Italy, 6Hospital Center of Wallonie Picarde, Tournai, Belgium, 7Schwarzach Hospital, Schwarzach im Pongau, Austria

Background: Lipegfilgrastim (Lonquex®) is a long-acting fixed-dose glycopeylated granulocyte colony-stimulating factor administered once per chemotherapy cycle. It has been available in Europe since 2013. It was proven to be non-inferior with regard to duration of severe neutropenia compared with pegfilgrastim in breast cancer patients. However, data in patients with hematological malignancies are limited.

Aims: We aimed to evaluate the effectiveness of lipegfilgrastim in the cycle following the first lipegfilgrastim-supported treatment cycle in lymphoma patients.

Methods: This is a prospective observational cohort study. Patients with different tumor types treated with cytotoxic chemotherapy (CT) who received lipegfilgrastim in primary prophylaxis (PP) or secondary prophylaxis (SP) are being included in this study. CT dose modifications and neutropenia-related events are recorded and analyzed. Evaluation of effectiveness in the cycle following the first lipegfilgrastim-supported CT cycle in a lymphoma subpopulation is presented here.

Results: At the time of the interim analysis (December 2016), 249 patients diagnosed with lymphoma have been included. Mean age and standard deviation of lymphoma patients was 61.6±15.6 years and 56.6% were male. For the majority of patients (81.1%), intended use of lipegfilgrastim was in PP. Exposure to lipegfilgrastim has been documented for 228 patients with an average of 4.76 cycles per patient. Data on CT dose modifications and neutropenic events following the first lipegfilgrastim-supported cycle were available for 144 and 167 patients, respectively. CT dose was never omitted. CT dose delays were observed in 8.0% (PP) and 16.8% (SP) of patients and CT dose reductions in 4.5% (PP) and 12.5% (SP) of patients. In the first lipegfilgrastim-supported cycle, febrile neutropenia was recorded in 4.5% (PP) and 3.0% (SP) of patients; severe neutropenia was recorded in 7.5% (PP) and 9.1% (SP) of patients. Throughout the treatment, 22 (9.6%) patients exposed to lipegfilgrastim reported at least 1 adverse drug reaction (ADR). The most common ADRs were myalgia and musculoskeletal pain. Serious ADRs were reported by 11 (4.8%) patients.

Summary/Conclusions: Lipegfilgrastim is effective and well tolerated in the real-world setting in lymphoma patients, administered either in PP or SP. The results suggest that lipegfilgrastim administered in PP might give better outcomes in terms of dose delays and dose reductions than when administered in SP.

PB1890

TUBERCULOSIS IN ACUTE LEUKEMIA- AN ANALYSIS OF CLINICAL CHARACTERISTICS AND IMPACT ON MANAGEMENT IN 25 PATIENTS

C. Singh1,2,*, A. Jain2, G. Prakash2, P. Malhotra2, S. Varma1

1Internal Medicine, 2Hematology, Post Graduate Institute of Medical Education and Research, Chandigarh, India, Chandigarh, India

Background: Patients with acute leukemia represent an immune-compromised population, with innate, humoral and cellular immune paresis. These patients are thus at high risk of development of new infections and reactivation of chronic infections. Despite the high prevalence of tuberculosis in the general population in endemic countries, it is rarely suspected and diagnosed in patients with acute leukemia.

Aims: To study the clinical manifestations of tuberculosis in patients with acute leukemia, as well as the impact of infection in the management of leukemia.

Methods: A hospital database search was done to identify cases of acute leukemia and tuberculosis between a study duration of January 2013 to January 2017. All the medical records of the identified cases were retrieved from the central records department. A systemic analysis of characteristics pertaining to acute leukemia, treatment regimen, chemotherapy response, site of tubercular infection, mode of diagnosis and treatment response to anti-tuberculous therapy was conducted.

Results: A total of 25 patients with acute leukemia were identified who were also diagnosed with tuberculosis. 10 patients had Acute Myeloid Leukemia, 7 had Acute Promyelocytic Leukemia, 5 had Acute Lymphoblastic Leukemia, 2 had Mixed Phenotypic Leukemia while 1 had Myeloid Sarcoma. The mean interval between diagnosis of tuberculosis and acute leukemia was 37.2 weeks, with 2 patients being diagnosed after completion of therapy of acute leukemia.
and one patient was diagnosed post-mortem. The most common organ involved was the lung, which was seen in 80% of patients and 20% of patients had disseminated tuberculosis. The development of tubercular infection led to alteration of therapy for the acute leukemia in 24% of cases, while it was postponed in 44% of cases. In particular, hypomethylating agents were used successfully in two patients with AML as bridge therapy to high dose chemotherapy. 76% of patients were cured of tuberculosis with new therapy, while 1 patient expired due to tuberculosis and 3 patients could not receive adequate therapy for tuberculosis. 3 patients went on to undergo HSCT post treatment for tuberculosis, and none had a flare of the disease post transplant.

**Summary/Conclusions:** The presence of tuberculosis infection in patients of acute leukemia has an impact on the overall management of the patient and strategies such as utilization of hypomethylating agents as bridge therapy may help in successful management of the leukemia. A high index of suspicion is required to suspect and diagnose the presence of tuberculosis as the manifestations are more commonly attributed to fungal infections or to the leukemia per se. Patients usually have a first episode of tubercular infection and the presence of tuberculosis infection does not forego treatment options such as HSCT or high dose chemotherapy for these patients.

**PB1891**

**INCIDENCE OF BACTEREMIA BY MULTI-RESISTANT BACTERIA IN HEMATOLOGY PATIENTS. A DESCRIPTIVE EPIDEMIOLOGIC STUDY FROM A THIRD LEVEL HOSPITAL**

A. Nieto Vazquez1,2

1Hematology, SERGAS. Hospital Alvaro Cunqueiro, Vigo, Spain

222nd Congress of the European Hematology Association

**Background:** In recent years the incidence of multi-resistant bacteria (MRB) infections have notably increase. These infections are especially serious in hematological patients because of the immunosuppression derived from their illness and their treatments. This increase is related to a high mortality rate and high health costs due to the severity of the infections and the difficulty in setting adequate therapy due to the lack of new antibiotics against these pathogens.

**Aims:** Define the MRB infections incidence and ways of presentation. As a secondary goal we try to determine if the isolation of these MRB has affected our empiric antibiotic therapy decision.

**Methods:** We retrospectively collected all positive blood stream cultures from hematologic patients from January 2012 to December 2016. We studied the characteristics, clinical features and pathogen isolates of our patients when the blood cultures were obtained.

**Results:** 1008 positive blood stream cultures were collected in 382 patients. The main characteristics of the patients are shown on Table 1.

**Table 1.**

<table>
<thead>
<tr>
<th>Table 1.</th>
</tr>
</thead>
<tbody>
<tr>
<td>The infection source was: central venous catheter (CVC) in 48% of patients (including tunneled, non-tunneled and PICC lines), respiratory 10%, abdominal 8%, urinary 5%, skin/soft tissue 7% and multiple location 5%. Regarding CVC isolation’s, 11% were interpreted as contamination and 6% as colonization. Gram positive (G+) bacteria were more frequently isolated than Gram negative (G-) (72% vs 24%). Most common G+ bacteria was coagulase negative Staphylococcus, regarding G- E. Coli, Klebsiella spp and Pseudomonas aeruginosa. MRB were detected in 6.1% of blood cultures belonging the most frequent G- (85%). The main resistance mechanism was extended-spectrum beta-lactamases (ESBL) and carbapenemases (CP) production (Table 2). BMR infections increased significantly in last year, mainly associated to CP, 0.5% in 2012 up to 7.1% in 2016 (Figure 1). 29.5% of MRB infections were in patients identified as chronic carriers of multiresistant organisms and 100% of them had extensive exposure to wide spectrum antimicrobials previously. 14% of infections began with a serious illness (persistent hyperthermia, hemodynamic disbalance and worsening), 5% needed intensive care assistance and 15% died. 76% of patients were cured of tuberculosis with new therapy, while 2 patients expired due to tuberculosis and 3 patients could not receive adequate therapy for tuberculosis. 3 patients went on to undergo HSCT post treatment for tuberculosis, and none had a flare of the disease post transplant.</td>
</tr>

</table>
Summary/Conclusions: A wide spectrum of infections may be observed in HIV positive patients in the bone marrow. Bone marrow aspirate and biopsy are essential, rapid and cost effective techniques to arrive at the right diagnosis in such cases. Features like hypoplasia, myelodysplasia and maturation arrest may be attributable to infections.

PB1893
UTILITY OF BONE MARROW BIOPSY IN FEVER OF UNKNOWN ORIGIN: A CRITICAL ANALYSIS OF A RETROSPECTIVE SERIE
H.N. Fernandez - Leyva1,*, J. Bosworth1, M. Offer1, N. Ansar1
1Haematology, Frimley Park Hospital, Surrey, United Kingdom

Background: The utility of bone marrow biopsy trephine (BMT) as a diagnostic tool in patients with fever of unknown origin (FUO) is a subject of controversy and debate. BMT has been shown to be safe and useful in patients with HIV/AIDS but its value in immunocompetent patients has not been sufficiently assessed. It's reported the use of diagnostic BMT as a rapid decision-making tool in patients with HIV/AIDS and FUO in the proper clinical setting. A BMT demonstrated infection-related evidence prior to positive bone marrow culture in 75% of cases. Special stains and blood cultures had similar diagnostic yield, but BMT offers faster results. Thus, this procedure assists in clinical decision-making and the refinement of treatment in a more timely manner.

Aims: To determine the utility of Bone marrow biopsies in FUO patient.

Methods: We reviewed retrospectively the bone marrow biopsy results of the patients who underwent BMT from January 2010, to December 2016. Demographic, laboratory, diagnostic and outcome data were collected and retrospectively analyzed. We identified 31 patients who fulfilled the accepted classic Petersdorf criteria for FUO. The cohort included immunocompromised and immunocompetent patients.

Results: The BMT contributes to the diagnosis in only four cases (12.9%). In two patients (6%) the histology revealed the presence of granuloma and/or lymphohistiocytic aggregates; one secondary hemophagocytosis (3.2%) and one mastocytite infiltrate (3.2%). Six patients had a previous diagnosis of HIV/AIDS (19%). Sub analysis in HIV/AIDS patients revealed positive BMT culture in 2 of the patients (6.4%). Cultures demonstrated Mycobacterium tuberculosis and Mycobacterium avium intracellularare. There was one case in which a pathogen was grown in culture but that had a negative of 'direct examination'. The associations most likely related factor to contribute to the diagnosis in HIV/AIDS was male predominance (58% odds ratio [OR] 2.95; 95% CI, 1.19-4.25), clinical lymphadenopathy (OR 4.97; 95% CI, 1.90-2.44) or anemia (OR, 2.21; 95% CI, 1.26-3.84). Reactive myeloid hyperplasia was represented 15 cases (48%). Non- haematological diagnosis (lymphoma, Leukemia) was made on the exclusive bases of biopsy results.

Summary/Conclusions: Bone marrow examination is an integral part of investigation of FUO, however, morphological finding alone would not be sufficient to ascertain the diagnosis. In present study only two cases of established infections were detected in bone marrow aspiration procedure. Both were present in HIV/AIDS. These results are explained because a highly active antiretroviral therapy has reduced incidence of opportunistic infections. The percent of opportunistic infections diagnosed by BMT was very low and did not justify an invasive procedure. The presence of granulomas in trephine biopsy indicates the necessity of haematologic diagnosis in these patients. Bone marrow biopsy is still a useful ancillary procedure for establishing the diagnosis of FUO, only if used in the adequate context.

PB1894
THE OUTCOME OF PEDIATRIC CANCER PATIENTS ADMITTED TO THE INTENSIVE CARE UNIT OF A TERTIARY HOSPITAL IN GWANGJU-JU-CHONNAM, KOREA
H. Kook1,2, G. Kim1, J.-S. Choi1, H.-J. Cho1, H.-J. Bae1
1Pediatrics, Chonnam National University Hwasun Hospital, Hwasun-gun, Korea, Republic Of

Background: Recent advances in supportive care have considerably improved the prognosis of pediatric cancer patients. However, the use of aggressive cancer treatment is also associated with complications and life-threatening events that result in admissions to the intensive care unit (ICU).

Aims: This study aimed to analyze the outcome of pediatric cancer patients admitted to the ICU.

Methods: A retrospective analysis of 84 ICU admissions of cancer patients <21 years old between May, 2004 and Aug, 2016 at Chonnam National University Hwasun Hospital (CNUHH) was undertaken. The risk factors for short-term outcome (survival at the time of discharge from the ICU) were analyzed. After excluding scheduled perioperative admissions, the records of 81 admissions (75 patients) were reviewed.

Results: Hematologic cancer patients represented 71.6% of admissions. The mortality for hematologic cancer was 71.6% as compared to 34.8% for solid cancer (P<0.05). Mortality for individual indication was as follows: bleeding, 66.7%; respiratory failure, 59.4%; systemic infection 57.5%, anterior mediastinal syndrome, 50%, neurologic disorders, 37.5%, renal disorder, 37.5%, and so on. ICU mortality after hematopoietic stem cell transplantation was 66.7%, mostly within 100 days post-transplant. The median Pediatric Risk of Mortality Score (PRISM) III score of survivors was lower than that of non-survivors (11.3±5.1 vs 19.9±10.8, P<0.001). The mortality rates were 70.3% and 27.3% in patients with high (>15 points) and low (≤15 points) PRISM III score, respectively (P<0.001). Mortality rate was significantly related to the presence and number of organ system dysfunction (P<0.01 and P<0.001, respectively), positive inotropic support (P<0.01), and mechanical ventilation (P<0.001). By using multivariate logistic regressions, the independent risk factors were mechanical ventilation (OR, 8.0; 95% CI, 1.7-21.3; P=0.01), and organ system dysfunction (OR, 18.5; 95% CI, 4.4-77.0; P=0.001). Hematologic cancer patients had higher mean PRISM III score (16.9±4.4 vs 12.2±2.8; P=0.51) and higher risk of sepsis (39.3% vs 13.0%; P=0.02) compared to solid cancer patients.

Summary/Conclusions: These results revealed the current status of ICU care for pediatric cancer patients in a tertiary hospital in Korea. Further improvement of supportive care and earlier effective intervention should be translated in gradual reduction in mortality rate in these population.

PB1895
EFFICACY AND SAFETY OF TIGECYCLINE IN FEBRILE NEUTROPENIC PATIENTS WITH HEMATOLOGICAL MALIGNANCIES AND CARBAPENEM RESISTANCE: A MULTICENTRE RETROSPECTIVE STUDY FROM CHINESE PEOPLE
X. Bing1,*, H. Lingli2, C. Guoshu3, L. Zhifeng1, S. Pengcheng4, G. Xutao4, W. Yamei1, L. Jie2, L. Jiaob2, Z. Yong3
1The First Affiliated Hospital of Xiamen University, Xiamen, 2Nanfang Hospital, Southern Medical University, Guangzhou, 3Huizhou Municipal Central Hospital, huizhou, 4Nanfang Hospital, Southern Medical University, Xiamen, China

Background: Tigecycline has broad spectrum activity against multidrug-resistant bacteria, but few investigations of tigecycline in febrile neutropenic (FN) patients with malignancy are available.

Aims: This study attempts to investigate the efficacy and safety of tigecycline in FN and carbapenem resistant patients with hematologic malignancies.

Methods: The study of 109 patients with hematologic diseases and FN were retrospectively analyzed. They are unresponsive to carbapenems for 3–5 days before receiving tigecycline (loading dose 100 mg; then 50 mg every 12 hours). Clinical response to treatment was defined as clinical cure, improvement or failure. Meanwhile, the adverse events were documented.

Results: The median duration of neutropenia was 15 days (ranged from 1 to 83d). Out of 109 patients, 96 (88.1%) had respiratory infection, while 33 (30.3%) had bloodstream infection. The total response rate of tigecycline was 65.1%. The bacterial eradication rates and bacterial hypotheoretical eradication were 25.9% and 24.1%, respectively. The clinical effective rate was 85.7% when tigecycline was administered for more than 9 days, while just 48.3% when administered for less than 9 days (p<0.001). Patients with bloodstream infection got a worse efficacy than those without (41.2% vs 69.6%, p=0.024). For patients whose absolute neutrophil counts were less than 0.1×10⁹L, the clinical effective rate was increased obviously (59.8% vs 86.4%, p=0.019). The side-effects were well tolerated. No lethal adverse events were observed.

Summary/Conclusions: Our results demonstrated tigecycline was effective and safe for patients unresponsive to carbapenems with FN, combination and prolonged duration of tigecycline is recommended, and these results need to be further studied.

PB1896
BONE MARROW CYTLOGICAL CHARACTERIZATION OF PATIENTS WITH HIPERREACTIVE MALARIAL SPLENOMEGALY
E. De La Vega1,*, F. Gómez-Aguado1, M.T. Corcuera2, M.D.M. Lago3, M. Gasior1, V. Jiménez1
1Hematología y Hemoterapia, 2Microbiología, 3Medicina Interna, Hospital Universitario La Paz, Madrid, Spain

Background: Hyperreactive malarial splenomegaly (HMS) is a common cause of massive splenomegaly in malarial-endemic areas. At present, diagnosis of patients with suspected HMS in tropical medicine departments of European hospitals is relatively frequent due to immigration and the return of missionaries and NGO workers after long periods in tropical countries.

Diagnosis for HMS usually include a cytological study of bone marrow, because clinical similarities between HMS and lymphoproiferative disorders have been reported. However, there are no large series in the literature that estimate a bone marrow cytological standard associated to HMS. Another important issue is that patients with HMS are often multifected by other parasites and bacteria, which also induce splenomegaly and fever.

Aims: The aim is to define the bone marrow cytological pattern of patients with confirmed HMS, as well as of HMS patients with associated viral (HIV, HBV, HCV) or parasitic diseases.
Methods: A retrospective cytological study of bone marrow aspirates from 95 patients with HMS (n=27), HMS+HIV (n=8), HMS+HCV/HBV (n=11) and HMS+intestinal parasitosis (n=49) has been performed.

Results: Bone marrow cellularity was normal in all the groups studied except in HMS+HIV patients, in which the cellularity was very diminished (statistically significant difference, p<0.01). Most frequent alterations observed in all samples (HMS and HMS+other entities) that could define the HMS-bone marrow cytological pattern, were: - Erythroid hyperplasia with dyserythropoiesis, which is reflected in a decreased myeloerythroid ratio. - Increased eosinophils percentage. - Increased lymphocytes percentage. - Increased plasma cells percentage and detection of Mott cells in a significant proportion of samples from all series (48.1% of HMS samples). Quantitative results for these variables are summarized in Table 1. Lymphocytosis was significantly increased in HMS+HBV/HCV bone marrow (p=0.04). Significant detection of atypical lymphocytes (4%) varied widely between the groups, ranging from 14.8% of HMS bone marrows to 75.0% of HMS+HIV bone marrows (statistically significant difference, p<0.01). There was no lymphoid evidence in any case. No quantitative or qualitative alterations were detected in megakaryocytes, except for a slight decrease in HMS+HIV bone marrows (statistically non-significant difference) (Figure 1).

Table 1. Quantitative results (mean±standard deviation).

*Reference standard by the Modified Alvarado Scoring System, Total scores were 10. Score 1-4: acute appendicitis very unlikely; Score 5-7: acute appendicitis probable; Score 8-10: acute appendicitis definite. #: negative; +: positive.

Summary/Conclusions: Acute appendicitis occurring during the neutropenic phase in HSCT patients could be diagnosed by the MASS and ultrasonography, and such cases could be cured by conservative therapy. This study could provide a further choice for the diagnosis and treatment of acute appendicitis in leukemia patients of HSCT.

PB1989

EPIDEMIOLOGY OF BLOODSTREAM INFECTIONS IN NEUTROPENIC AND NON-NEUTROPENIC PATIENTS WITH MALIGNANCY

N. Raja1, S. Gupta2, B. O’Neill3

1Pathology, 2Microbiology, 3Haematology, East Sussex Healthcare Trust, Hastings, United Kingdom

Background: Blood stream infections (BSI) in patients with malignancies remain associated with significant morbidity and mortality. The choice of an empirical antibiotic regimen is usually based on the local epidemiology of the microorganisms and their antibiotic susceptibility profile. Antimicrobial guidelines for the management of sepsis in cancer patients in East Sussex Healthcare Trust (ESHT) recommend piperacillin/tazobactam as monotherapy and gentamicin is added in case of septic shock. Vancomycin is also added as a first line therapy if there is a suspicion of central line sepsis. Alternative therapies are ceftazidime or meropenem plus aminoglycoside.

Aims: We intend to review the aetiology of BSI and check the effectiveness of the antibiotics used in ESHT in cancer patients.

Methods: This retrospective study was conducted at ESHT from January 2006 to December 2015. Demographic and laboratory data were collected from the Pathology information system.

Results: A total of 640 episodes of BSI occurred in 297 patients (159 male). Of the 297 patients, 239 had haematological malignancies while 54 had solid organ tumour. Four patients had both. The neutrophil count was <1 cells/10³ in 383 episodes and majority of BSI occurred in this group. A total of 802 organisms (477 and 325 organisms from neutropenic and non-neutropenic respectively) were isolated. Of 802, 406 Gram positive and 386 Gram negative organisms were isolated. Seven Mycobacterium species and three Candida species were isolated. Most common organisms in neutropenic patients were Coagulase negative Staphylococcus (CoNS) (22%), Klebsiella species (14%), Escherichia coli (13%), Streptococcus species (10%), Pseudomonas species (10%), Enterococcus species (8%) and Staphylococcus aureus (4%). In non-neutropenic patients, CoNS (29%), Escherichia coli (11%), Pseudomonas species (8%), Streptococcus species (7%), and Klebsiella species (5%) were isolated. Twelve Glycopeptide resistant Enterococci were isolated. Four Methicillin resistant Staphylococcus aureus were isolated. In addition, 15 Extended Spectrum Beta-lactamase producing Gram negative bacilli were isolated. Among Gram negative organisms, more than 91% isolates were sensitive to piperacillin/tazobactam, cefazidime and ciprofloxacin and higher sensitivity rates (>96%) were recorded in gentamicin and meropenem. Table1 summarises the effectiveness of antibiotics used.

Summary/Conclusions: This study shows an on-going trend towards Gram positive organisms causing BSI in cancer patients. The antimicrobial regimens used in ESHT are highly effective against commonly isolated organisms. An early diagnosis and timely administration of appropriate antibiotics are imperative in managing BSI. The identification and the antimicrobial susceptibility of the microorganisms causing BSI in cancer patients remain important to develop antimicrobial treatment strategies, and to prevent the spread of antimicrobial resistance.
PB1899
CHANGING TREND IN LOCAL BACTERIAL EPIDEMIOLOGY: EXPERIENCE IN ACUTE LEUKAEMIA PATIENTS HOSPITALIZED IN SINGLE HEMATOLOGY UNIT

C. Buquicchio1,*, L. Ciuffreda1, G. De Santis1, C. Germano1, M. Leo1, M.T. Santeramo1, R. Miccilo1, G. Tarantini1
1Ematologia, SC Ematologia con trapianto, Barletta, Italy

Background: The intense chemotherapeutic regimens and hypomelitlenic agents to treat acute leukaemia induce prolonged neutropenia with high risk of infections.

Aims: To analyze local microbial epidemiology we studied patients admitted to our ward.

Methods: All 100 cases of Acute Leukemia (AL) admitted in our ward from August 2013 to February 2017 received prophylactic antibacterial therapy with fluoroquinolones and were analyzed for weekly routine tissue culture screening and serial blood culture for fever. Six patients were Lymphoid AL and 94 were Myeloid AL. 41 patients were not eligible for intensive chemotherapy (for age and comorbidities) and were treated with hypomelitlenic agents, while 59 were younger than 65 years and were treated with induction/consolidation chemotherapy 3 plus 7 regimen. Median age was 58 years with range from 27 to 88 years old.

Results: We found 28 patients (28%) bacterial septic shock during fever, of which 20 cases gram negative (71%) in particular 65% E.Coli, 15% Enterobacter, 10% Klebsiella, 5% Stenotrophomonas, 5% Pseudomonas; while 8 patients (29%) had a gram positive septic shock (S.Haemoliticus 38%, S.capitis 25%, S. hominis 25%, S. epidermidis 12%). During intensive chemotherapy and prolonged severe neutropenia we took over the major incidence of septic shock (23 patients 82%) than hypomelitlenic treatment in particular decabine (5 patients 18%). During 2014 we had 3 mortal septic shock for multi-resistant gram-klebsiella and Pseudomonas. Since than we adopted in our ward, isolation of patients with gram negative (klebsiella or pseudomonas), tissue culture positive, hygienic and sanitary practices with closing room for 48 hours and hand disinfection before entering and after leaving any patients room. We noticed a change of bacterial infections incidence in these 3 years in our ward. Reduction klebsiella/pseudomonas multi-resistant infections and emergency of E.coli and Staphilococcus septic shock not multi-resistant.

Summary/Conclusions: More epidemiological analysis in several haematological ward are necessary to understand if it is a changing local microbial epidemiology or is the different management of neutropenic patients with acute leukaemia and/or a different antimicrobial strategy to determine this changing trend.

PB1900
UK SINGLE-CENTRE SERVICE EVALUATION TO DESCRIBE THE IMPACT ON HEALTHCARE RESOURCE USE OF LOCAL ANTFUNGAL PROPHYLAXIS AND TREATMENT PROTOCOLS IN THE MANAGEMENT OF HIGH-RISK PATIENTS WITH NEUTROPENIA

D. Furby1,*, H. Ahir2, G. Nock3, E. Taymor2
1Poole Hospital, Poole Hospital NHS Foundation Trust, Poole, 2Merck Sharp & Dohme Ltd, Merck Sharp & Dohme Ltd, Hoddesdon, 3pH Associates, pH Associates, Marlow, United Kingdom

Background: Patients with neutropenia, including those with haematologic malignancies, are at high risk of invasive fungal infections (IFI). Pre-2014, there were no formal written guidelines but the guidance at Poole Hospital NHS Foundation Trust specified the use of posaconazole oral suspension for primary prophylaxis in all high-risk patients except those with acute lymphoblastic leukaemia (ALL). In 2014 formal guideline changes included the introduction of the tablet formulation of posaconazole, use of micafungin as first line empirical therapy and a focus towards improving diagnostics to guide management. MSD Ltd. has developed the Fungal Service Evaluation Tool (FSET), a secure database and analysis tool, to support UK clinicians managing patients at risk of breakthrough IFI (BIFI) to evaluate their antifungal management.

Aims: This service evaluation aimed to utilise the FSET to evaluate the impact of the antifungal management guidelines on healthcare resource utilisation associated with patients at risk of a BIFI.

Methods: An interim analysis of high-risk adult patients with prolonged neutropenia aged ≥18 years at initiation of antifungal prophylaxis/treatment was carried out. Retrospective data on patient characteristics, antifungal prophylaxis and treatment, IFI-related diagnostic tests, hospital attendance/admission during antifungal prophylaxis were collected for 12-month periods before and after 2014 (Cohort 1: 2013; Cohort 2: 2015). Anonymised data was entered into the FSET and this data was analysed using descriptive statistics.

Results: The evaluation included 24 patients in Cohort 1 (median age 66.8 [interquartile range (IQR): 47.5–72.2] years; 16 [67%] male; 5 [21%] ALL) and 22 patients in Cohort 2 (median age 66.8 [IQR: 51.7–73.4] years; 13 [59%] male; 1 [5%] ALL). At least one line of antifungal prophylaxis was recorded in 22 (92%) patients in Cohort 1 and 17 (71%) in Cohort 2. Posaconazole was the most commonly prescribed antifungal in Cohort 1 (18/24 [75%]) and Cohort 2 (17/22 [71%]). Other agents used included liposomal amphotericin B, fluconazole, and itraconazole. There were no patients in Cohort 1 and 2 (9%) patients in Cohort 2 (overall 4%) who experienced a BIFI: 1 was defined as confirmed and 1 as suspected. The mean 12 month costs per patient for all resource utilisation (including antifungal drug costs, hospitalisation costs [including admissions and attendances], investigations and tests) was £28,903 in Cohort 1 and £21,934 in Cohort 2 (Figure 1). Hospitalisation costs were a key determinant of overall costs, which is common in the management of people with complex underlying disease. There were 4 (17%) patients in Cohort 1 and 1 (5%) in Cohort 2 who had a period of ITU associated stay, which typically has greater costs than general wards. The most common investigations/tests were blood cultures (Cohort 1: mean: 13.8; Cohort 2: mean: 10.7) and chest x-ray (Cohort 1: mean: 4.0; Cohort 2: mean: 2.5), which are in-line with routine clinical practice. Once implemented, the guideline was adhered to in the management of 19 patients (86%) in Cohort 2.

Summary/Conclusions: These data show that rates of breakthrough IFI are low in complex patients receiving antifungal prophylaxis/treatment. Furthermore, the results in Cohort 2 indicate that the switch to recommending posaconazole tablets did not result in an increase in the mean cost per patient of antifungal prophylaxis and shows a lower overall mean cost per patient. A larger cohort study over a longer period is warranted to confirm these findings.

REAL-LIFE FEASIBILITY OF AN IRON CHELATION PROGRAM WITH DEFERASIROX IN MYELODYSPLASIA AND OTHER ACQUIRED CHRONIC ANEMIAS: A SINGLE CENTRE EXPERIENCE
G. Bertani1, M. Riva1, E.B. Volpato1, E. Ravano1, I. Cuppari1, A. Mazza1, P. Usardi1, R. Carlin1
1Haematology, Ospedale Niguarda Ca’ Granda, Milano, Italy

Background: Prolonged red blood cell (RBC) transfusion support in patients affected by myelodysplastic syndrome (MDS) and other chronic anemias may cause vital organs damage due to accumulation of non-transferrin-bound iron with consequent increased oxidative stress. Retrospective studies have shown that iron chelation may prevent aforementioned mechanisms and improve survival in low-risk MDS patients. Iron chelation is usually recommended in patients who received at least 20 RBC units and/or have a serum ferritin level of 1000 ng/ml or higher. Deferasirox, an oral iron chelator, has widely replaced the use of deferoxamine, due to its greater manageability, especially in the elderly. However, an high dropout rate of approximately 50% of patients within one year was observed in the majority of clinical studies, the leading cause of discontinuation being gastrointestinal (G.I.) and renal toxicity and skin rash.

Aims: We aimed at evaluating the real-life feasibility of a program of prolonged iron chelation in a population of acquired chronic anemia patients. Thus, we performed a retrospective analysis to evaluate which is the percentage of patients who in our centre actually receive and tolerate deferasirox treatment, among the cohort of eligible patients.

Methods: Deferasirox treatment is considered at our centre in patients affected by MDS or other forms of chronic anemia (excluded chronic bleeding) who fulfill criteria for iron chelation (high transfusion burden, i.e. ≥20 RBC units and/or a serum ferritin ≥1000 ng/ml). Starting dose is usually 10 mg/kg, titrated up to 20-30 mg/kg as tolerated. The cohort of patients transfused at our centre during 2015 and 2016 was considered for analysis. Causes of unsuitability and of treatment discontinuation were extracted from our database.

Results: Our cohort consisted of 58 patients, mainly affected by MDS (45 pts); other diagnosis were myelofibrosis (6 pts), NHL (2) and multifactorial anemia, not related to blood cancer (7). Only 38 out of 58 potentially eligible patients were assigned to iron chelation (see the Figure 1). The leading cause of ineligibility in our cohort was a reduced life expectancy (5 pts), due to the hematologic disease itself or to comorbidities, and pre-existing renal failure (4). Importantly, in 6 cases patients were not offered iron chelation without a specific clinical reason: half of them (3/6) were non-MDS patients. Furthermore, 13/38 patients had to interrupt the treatment, due to toxicity (mainly renal failure, followed by gastrointestinal toxicity, see flow-chart). Overall, 25/58 (43%) potentially eligible patients, i.e. heavily transfused patients, initiate and continue an iron chelation protocol at our centre. The main cause for treatment discontinuation in our cohort was renal failure, while we had less difficulties in managing G.I. adverse events. Renal toxicity of deferasirox is known to be reversible; however, in patients with pre-existing compromise and those who concurrently take nephrotoxic drugs, treatment may be difficult to carry on.

Figure 1.

Summary/Conclusions: Our data are in line with literature. However, there is still room for improvement, especially in the category of non-MDS patients, who are often under-treated. Furthermore, the introduction of a new formulation of deferasirox, which is forthcoming, may hopefully reduce G.I. toxicity and improve tolerance and patients adherence to therapy.

NONINVASIVE TRANSCUTANEOUS SPOT-CHECKING OF TOTAL HEMOGLOBIN FOR THE SCREENING OF ANEMIA IN CAMBODIAN CHILDREN FROM REMOTE RURAL AREAS
J. Perez De Oteyza1,2, L. Fernandez de la Fuente2, C. Montero1, L. Trives2, A. Jayo1, R.Guiote3, V. Benito2, B. Santos2, A. Rodriguez2, J. Marin2, L. Sierra2, S.P. Gonzalez2, E. Martinez2, J. Rodriguez2, A. Perez2, A.I. Sanz2, X. Santos Heredero2
1Hematology, Hospital Universitario Madrid Sanchinarro, 2Clinical Sciences, 3Health Sciences, Facultad de Medicina, Universidad CEU San Pablo, Madrid, Spain

Background: Previous studies have reported a high prevalence of anemia among school-aged children from Cambodia, ranging from 21 to 64%. Although iron deficiency accounts for the majority of cases, additional nutritional and non-nutritional etiologies have been identified. Children living in rural or remote areas, with limited access to health facilities, are at high-risk of developing anemia, and therefore, painless, fast, and reduced cost screening tests are needed.

Aims: The aim of our study is to evaluate the role of a portable device for transcutaneous noninvasive spot-checking of total hemoglobin (SpHb) in children living in remote locations.

Methods: Transcutaneous noninvasive spot-checking of total hemoglobin (SpHb) was performed in children attending summer-school camps at 12 different locations in Cambodia. SpHb was measured in fingertips by using size adapted optic sensors. For the purpose of the study, three age groups were defined as follows: Group 1=less than 5 years, group 2=5 to 11 years, and group 3=11 to 14 years.

Results: A total of 476 otherwise healthy children were analyzed. Mean SpHb value was 11.9±0.39 g/dl (range 9-16 g/dl). Overall, the prevalence of anemia in the entire population was 34.5%. Anemia was present in 531 (16.1%) of the children within group 1, 97/189 (33.9%) in group 2, and 54/81 (40%) in group 3. (p=0.039, two sided Pearson’s Chi square). There were no differences in the prevalence of anemia by gender in groups 1 and 2. In group 3, anemia was significantly more prevalent in females 32/65 (49.2%) than in males 22/48 (31.4%), p=0.035.

Summary/Conclusions: Taken together, our results demonstrate the feasibility of noninvasive transcutaneous spot-checking of total hemoglobin (SpHb) for the screening of anemia in children from remote rural areas with limited access to health services. Our results also confirm the high prevalence of anemia in this population.

IRON DEFICIENCY ANEMIA IN INFANTS AND YOUNG CHILDREN
S.K. Park1,*, S.K. Kim2, E.Y. Joo2
1pediatrics, Ulsan University Hospital, Ulsan, 2pediatrics, Inha University College of medicine, Incheon, Korea, Republic Of

Background: Iron deficiency anemia in infants and young children is easy to be underdiagnosed. Anemia and iron deficiency are usually corrected after aged 2-3 years old, but it causes complications. There is an association between IDA and impaired neurocognitive function and exercise intolerance, even after treatment of IDA. Therefore, preventing the progression of iron deficiency is especially important during infancy and early childhood. When increased vulnerability is associated with rapid growth and development, especially of the brain.

Aims: To detect iron deficiency anemia early and to reduce the adverse impact by IDA, we assessed the characteristics of infants and young children with IDA, those at risk for IDA and those exhibiting associated characteristics of severe anemia.

Methods: Among 1,782 children with IDA aged 6 months to 18 years-old, we retrospectively analyzed medical records and laboratory data of 3,161 subjects aged 6–23 months with IDA who had been diagnosed between 1996 and 2013. We excluded patients with CRP ≥5 mg/dL.

Results: IDA was predominant in boys (2:14:1) during infancy and young childhood. Peak incidence was at 9 to 12 months of age. Only 7% of subjects were brought to the hospital with symptoms and/or signs of IDA, while 23.6% in subjects with severe IDA. LBW infants with IDA shows low adherence with iron supplementation. In a multivariate analysis, risk factors of severe anemia in infants included prolonged breastfeeding without iron fortification (odds ratio (OR) 5.70) and low birth weight (OR 6.49).

Summary/Conclusions: Many clinicians did not consider IDA as a real problem, so many children with IDA were not followed up. LBW infants need more attention to increase adherence of iron supplementation. For early detection of IDA, nutritional assessment should be evaluated in every infants and iron batteries in high risk infants (LBW infants, prolonged breastfeeding, picky eater and/or symptoms of IDA) at health screening visit.
THE ROLE OF ZINC PROTOPORPHYRIN IN THE DIAGNOSIS OF SIDEROPENIC ANEMIA
T. Nascimento1, S. Marini1, D. Mota 1, P. Bernard1, L. Relvas 1, A.C. Oliveira 1, E. Cunha 1, J. Pereira 1, C. Bento 1, T. Magalhães Maia 1, M.L. Ribeiro1
1Serviço de Hematologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Sideropenic anemia (IDA) is the main cause of anemia worldwide. Even though, its diagnosis is quite straightforward with the use of red blood cell indices, peripheral blood smear (PBS) and ferritin measurements, there are still some pitfalls, namely in the presence of inflammation. The chelation of iron by protoporphyrin constitutes the final reaction of heme biosynthesis. In the absence of iron, zinc becomes an alternative substrate for ferrochelatase leading to the formation of zinc protoporphyrin (ZPP). This compound can be quantified by fluorometry in blood samples, proving itself as a useful and easy parameter for the diagnosis of IDA. However, this technique is not broadly used in the clinical practice.

Aims: Determine the cut-off value of ZPP for the diagnosis of IDA. Evaluate the value of ZPP for the differential diagnosis between IDA and anemia due to inflammatory diseases (AID).

Methods: We have analyzed in our lab, from 1st to 15th February 2017, all the complete blood counts (pediatric and adult) with anemia (as defined by WHO) which had sedimentation rate (SR) and serum ferritin evaluations. We have defined three different groups: IDA: Anemia and Ferritin <20μg/L; AID: Anemia, Ferritin >20μg/L and SR<20mm/h; Control group (GC): Normal levels of hB adjusted by age and sex, as defined by WHO. Ferritin 20-120μg/L and SR<20mm/h. ZPP measurement was performed by ferrochelatase (AVIV, Biomedica, Inc). Data were analyzed by SPSS v20.0 using Wilcoxon W and Man-Whitney to examine differences between groups and receiver-operating characteristic (ROC) analysis to determine the cut-off values of ZPP. We considered the cells and sera with a p-value<0.05.

Results: We have identified 204 samples that fulfilled the inclusion criteria: 104 with IDA, 51 with AID and 49 from control patients. IDA group: 73% female (F); mean age 32.3y in F [1-78], 28y in males (M) [1-78]; mean hB was 10.6g/dL [SD 1.4]; mean ferritin was 9.3 ug/L [SD 4.8] and ZPP was 214.1 μmol [SD 121.3]; mean SR was 20.0 mm/h [SD12.9], AID group: 75% F; mean age 47y in F [2-91] and 22y in M [1-85]; mean hB 11.0 g/dL [SD 1.2]; mean ferritin 150.3 μg/L[SD246.2] and ZPP 136.7 μmol [SD 107.8]; mean SR 47mm/h [SD 21.2]; GC: 69.4% F; mean age 32.3y in F [1-78], 28y in males (M) [1-78]; mean hB was 13.8 g/dL [SD 0.8]; mean ferritin 71.9ug/L [SD 49.9] and ZPP 77.6 μmol [SD 26.8]; mean SR 14mm/h [SD 4]. The serum ZPP in IDA and AID was significantly higher than in GC (95% CI; p<0.0005). The ROC analysis showed 83.7% sensitivity and 85% specificity of ZPP ≥140 μmol to identify IDA with 95% CI (0.933) and 69% sensitivity and 70% of specificity to identify AID for ZPP ≥140 μmol (W=0.749) when compared with GC.

Summary/Conclusions: We have concluded that ZPP is a valid, quick, easy and cheap parameter to diagnose IDA in clinical practice, and we have defined in our cohort of patients a ZPP cut off of ≥100.3μmol as diagnostic of IDA with 83.7% sensitivity and 85% of specificity, independent of age. In AID patients we found a cut-off value of ≥140μmol, but with a low sensitivity and specificity. In contrast, only ZPP was not a reliable method to differentiate IDA from AID. This could be due to a sample selection bias (since clinical data were missing and the number of patient with AID was substantially lower than with IDA). It would be important to enlarge the AID sample in order to obtain a more reliable result. Since the ZPP measurement can be performed in capillary blood and it is a very quick and cheap method to diagnose IDA, this could be a powerful tool in under-developed countries.

HYPERFERRITINEMIA AND SERUM INFLAMMATORY CYTOKINES IN ADULTS WITH NEWLY DIAGNOSED HEMOPOAGOCYTIC LYMPHOPHISTIOCYTOSIS ASSOCIATED WITH HEMATOLOGICAL MALIGNANCY
M. Machaczka1,2,*, F. Lorenz1, E. Pawłowicz4, M. Gajewska5, M. Wolon2, M. Klimkowski2
1Haematology, Centre Karolinska, Karolinska University Hospital Huddinge, Stockholm, Sweden, 2Medical Faculty, University of Rzeszow, Rzeszow, Poland, 3Department of Radiation Sciences, Section of Hematology, Umeå University, Umeå, Sweden, 4Medical University of Lódź, Lódź, 5Medical University of Silesia, Katowice, Poland, 4Department of Clinical Pathology and Cytology, Karolinska University Hospital Huddinge, Stockholm, Sweden

Background: Hemoapoagocytotic lymphohistiocytosis (HLH) is an underdiagnosed but life-threatening syndrome of hyperinflammation which in adults is often caused by hematological malignancies. Release of inflammatory cytokines in HLH induces cytokine storms and cytokine production that cumulates in cytokine storm and hyperinflammation. Hyperferritinemia ≥500 μg/L is a diagnostic criterion for HLH. Prevalence of hyperferritinemia in HLH in the adult population is much less established than in children.

Aims: The aim of the present study was to evaluate the frequency and extent of hyperferritinemia as well as serum concentrations of selected inflammatory cytokines at the time of diagnosis of hematological malignancy-associated HLH (HM-HLH) in adults.

Methods: The study included 71 adults with HM-HLH, aged 22–84 years, and diagnosed between 2009 and 2016. Hematological malignancy was defined as a neoplasm of lymphoid tissue. Diagnosis of HLH was based on the HLH-2004 criteria. Serum ferritin concentration (ref.: 30–350 μg/L) at the time of HM-HLH diagnosis was elevated in all but one patient (70/71, 98%). Mean ferritinemia was 37,281±8,440 μg/L, median value 14,727 μg/L, and ferritinemia range 96–645,291 μg/L. Serum concentrations of inflammatory cytokines IL-1β, IL-6, IL-8, IL-10 and TNF-α were analysed using chemiluminescence (IMMULITE® L, DPC Siemens). Serum levels of sIL-2Rα were determined by ELISA, using the quantitative ‘sandwich’ enzyme immunoassay, on the IMMULITE® 1000 Immunoassay System (DPC Siemens).

Summary/Conclusions: Hyperferritinemia at the time of HLH diagnosis was common in Swedish adult patients with HM-HLH. Hyperferritinemia ≥500 μg/L was present in vast majority (97%) of them. We would like to emphasize that serum ferritin level fluctuates and can differ significantly from one day to another. Ferritinemia should be repeatedly measured in cases of suspected HLH. Serum concentrations of TNF-α, IL-6, IL-8, and IL-10 were frequently elevated in the examined HM-HLH patients and these can become important markers supporting HLH diagnosis in equivocal cases. On the other hand, IL-1β seems to be less useful in confirming a cytokine storm in this patient group.

PB1906
REDUCING UNNECESSARY BLOOD FILMS USING AN IRON DEFICIENCY ALGORITHM
R. O’Toole1,*
1Haematology, Wellington SCL, Wellington, New Zealand

Background: In 2015, Wellington SCL (WSCL) was selected to provide integrated diagnostic services in Wellington region, New Zealand. This involved merging services from previous community laboratory Aotea Pathology Ltd. (APL) with the three regional hospital based District Health Boards (DHB) laboratories - Capital & Coast (CCDHB), Hutt Valley and Wairarapa. On the 1st of November 2015, WSCL would launch its new integrated service with a modernized Laboratory Information System (LIS). Aims: To reduce the number of blood films and improve diagnostic accuracy.

Methods: We have analysed a cohort of 558 samples tested for haemoglobin, ferritin and iron. The sample included a variety of patients, some with underlying clinical conditions that may cause iron deficiency such as inflammatory diseases (AID). The study included 71 adults with hM-HLH, aged 22–84 years, and diagnosed between 2009 and 2016. Hematological malignancy was defined as a neoplasm of lymphoid tissue. Diagnosis of HLH was based on the HLH-2004 criteria. Serum ferritin concentration (ref.: 30–350 μg/L) at the time of HM-HLH diagnosis was elevated in all but one patient (70/71, 98%). Mean ferritinemia was 37,281±8,440 μg/L, median value 14,727 μg/L, and ferritinemia range 96–645,291 μg/L. Serum concentrations of inflammatory cytokines IL-1β, IL-6, IL-8, IL-10 and TNF-α were analysed using chemiluminescence (IMMULITE® L, DPC Siemens). Serum levels of sIL-2Rα were determined by ELISA, using the quantitative ‘sandwich’ enzyme immunoassay, on the IMMULITE® 1000 Immunoassay System (DPC Siemens).

Summary/Conclusions: Hyperferritinemia at the time of HLH diagnosis was common in Swedish adult patients with HM-HLH. Hyperferritinemia ≥500 μg/L was present in vast majority (97%) of them. We would like to emphasize that serum ferritin level fluctuates and can differ significantly from one day to another. Ferritinemia should be repeatedly measured in cases of suspected HLH. Serum concentrations of TNF-α, IL-6, IL-8, and IL-10 were frequently elevated in the examined HM-HLH patients and these can become important markers supporting HLH diagnosis in equivocal cases. On the other hand, IL-1β seems to be less useful in confirming a cytokine storm in this patient group.
blood films are iron deficient pictures with the characteristic finding of reduced Hb, MCV, and MCH. Above certain thresholds, the blood film adds little or no value to the CBC in these patients, apart from correlating with the iron studies results or suggesting iron studies when unavailable. One initiative used to manage the workload was based on this logic and aimed to reduce the blood film review rate using IT3000 technology (Roche).

Methods: An algorithm was designed in IT3000 to encourage testing and treatment for iron deficiency using a series of automated educational comments, while minimising unnecessary laboratory work. The impact that this algorithm had at WSCl was investigated by retrospective analysis of all the patient results from 1st November 2015 to the 1st of May 2016.

Results: In the first six months of operation, WSCl performed 232,192 CBCs and 30,204 blood films with an average review rate of 13.01%. Had this algorithm not been employed, 2,434 extra blood films would have been reviewed, bringing the review rate up to 14.05%.

Summary/Conclusions: Incorporation of an algorithm specific for iron deficiency in IT3000 has significantly reduced the review rate without any negative impact on patient care.

THE RELATIONSHIP ENDOTHELIAL MICROPARTICLES AND ASYMMETRIC DIMETIL ARGININE IN CHILDREN WITH IRON DEFICIENCY AND IRON DEFICIENCY ANEMIA

E. Kaygi Tartko1, V. Altunen Torun2, C. Karakustu3, S. Celik4, H.T. Horner Oz5

1Pediatrics, 2Pediatric Hematology, 3Biochemistry, 4Pediatric Cardiology, 5Microbiology, Medical Health University, Kayseri, Turkey

Background: Iron deficiency anemia and iron deficiency without anemia increase the risk of atherosclerosis by increasing oxidative stress and inflammation. Endothelial dysfunction is an important factor of the pathogenesis of atherosclerosis.

Aims: Endothelial micro particles (EMP) are considered as markers of endothelial dysfunction. Asymmetric dimetil arginine (ADMA) is known as another marker of endothelial dysfunction. In this study: we aimed to evaluate circulating EMPs and ADMA in children with iron deficiency and iron deficiency anemia and to disclose iron deficiency with the strongest relation with EMPs, ADMA and carotid atherosclerosis.

Methods: This study included 30 children with iron deficiency anemia, 30 children with iron deficiency without anemia and 30 healthy children whose anthropometric measurements were recorded. Hemoglobin, serum iron level, iron binding capacity, ferritin, and lipid profile were studied. Circulating EMPs (CD144, CD146, and CD105) were measured by flow cytometry. ADMA was measured by ELISA. The carotid artery intima media thickness (CIMT) and left ventricular mass index (LVMI) were measured using echocardiography.

Results: CD144 and CD105 EMP levels were lower in the iron deficiency without anemia group than in the control group and statically lower than in the iron deficiency anemia group (p<0.05). There were no significant differences in ADMA level between groups. Any significant variety in ADMA level was not out anemia group than in the control group and statically lower than in the iron deficiency anemia group were higher than control group. In addition, when the level of ferritin has decreased, CIMT has increased. This study show that CD144 and CD105 may be related to endothelial dysfunction which occurs by iron deficiency.

Summary/Conclusions: Reactive thrombocytosis in inflammatory states and megakaryopoiesis in anemic patients.

PB1908

INVESTIGATION OF IRON METABOLISM FOR REGULATING MEGAKARYOPOIESIS AND PLATELET COUNT ACCORDING TO THE MECHANISMS OF ANEMIA

S. Kim1, S.Y. Cho1, T.S. Park1

1Kyung Hee University Hospital, Seoul, Korea, Republic Of

Background: Iron deficiency anemia (IDA) is characterized by depletion of total body iron stores. By contrast, chronic inflammation makes iron unavailable for hematopoiesis through a cytokine-mediated cascade, resulting in anemia of chronic disease (AOC). However, the laboratory data regarding the regulatory role of iron metabolism on platelet count has not been fully discussed yet.

Aims: In this study, we investigated the relationship between iron status and platelet production according to different anemic mechanisms representing different iron metabolisms.

Methods: The study included total of 759 blood specimens from 537 different patients. The complete blood count with various CBC index were measured using Advia 2120 (Siemens, USA). Biochemical indexes including iron level were estimated using Toshiba chemical analyzer (Toshiba, Japan). Results: We found a significant relationship between platelet count and serum iron level in AOC group (p=0.27), whereas there was no correlation in IDA group. In AOC group, platelet count was significantly correlated to serum iron level only in AOC group with decreased serum iron level (p<0.0001), unlike AOC group with normal serum iron level.

Summary/Conclusions: Reactive thrombocytosis in inflammatory states and megakaryopoiesis in anemic patients.
ROLE OF PRO-PHAGOCYTIC CALREICULIN AND ANTI-PHAGOCYTIC CD47 IN MDS AND MPN MODELS TREATED WITH AZACYTIDINE OR RUXOLITINIB

K. Linares1,*, K. Quiroz1, Y. Ruiz-Heredia1, I. Rapado1, T. Cedena1, R. Ayala1, J. Martinez-Lopez1
1Servicio de Hematología, Hospital Universitario 12 de octubre, Madrid, Spain

Background: Myelodysplastic syndrome (MDS) and Myeloproliferative neoplasms (MPN) are clonal myeloid disorders with the tendency to progress into acute myeloid leukaemia. Previous studies in solid tumours have shown an increase in expression of both pro-phagocytic calreiculin (CALR) and anti-phagocytic CD47, as they act in response to one another, reflecting a possible apoptosis vs survival mechanism in response to chemotherapy.

Aims: The aim of our study is to assess the changes in CALR and CD47 levels during treatment of MDS and MPN with azacitidine (AZA) or ruxolitinib (RUXO), in a series of model cell systems.

Methods: CALR and CD47 gene and protein expression was measured in MDS cell line models (MOLM-13 and SKM-1), MPN cell line models (HEL-92 and GDM-1) and in an intermediate MDS/MPN cell line (K562) before and after treatment with AZA and RUXO. Drug titrations were completed, resulting in dosing regimens of 0.05μM/ml for both AZA and RUXO, with re-dragging occurring in 24 hours. Cells were then harvested, cDNA was synthesized for use in qPCR and protein levels determined by Western blot analysis.

Results: When treated with AZA, MDS cell models showed a 7-10 fold increase in CALR expression and 4-6 fold increase in CD47 expression. In contrast, the MDS/MPN intermediate cell model (K562) showed a 4.5 fold increase in CALR but only a 0.5 fold increase in CD47 expression. In the MPN model HEL-92, a 9.6 fold increase in CALR and 6.9 fold increase in CD47 was seen, whereas in the other MPN model (GDM-1 cells) expression was more evenly matched between CALR and CD47 (5.3 and 4.8 fold increases, respectively). After treatment with RUXO, MPN models showed a 9.5-16 fold increase in CALR expression and a 6-9 fold increase in CD47, which would be expected as RUXO is used to treat MPN in humans. When the MDS/MPN cell model or pure MDS models were treated with RUXO, the ratio of CALR/CD47 decreased substantially (with CALR expression only increased 2.4-3.7 fold compared to CD47 increasing 4.6-6.9 fold) showing resistance to treatment and a significant anti-phagocytic response. Interestingly one of the MDS cell line models (MOLM-13) showed an unexpectedly good response to RUXO therapy with high CALR/CD47 ratio (8 fold vs 4.8 fold, respectively).

Summary/Conclusions: In line with results in solid tumours, we have shown that treatment for MDS and MPN leads to an up-regulation of CALR and, to a lesser extent, CD47 in cell lines models. The ratio of CALR/CD47 seems to correlate with specific treatment response, significantly increasing when given diseases models are treated with the appropriate drug. We postulate a role of CALR expression in leukaemia cell phagocytosis, with CD47 co-expression in synergy as a protective instinct within the cell to try and prevent apoptosis. Some studies have shown an excessive rise in CD47 expression and low expression of CALR. This indicates that the CD47 mediated anti-phagocytosis takes control and suppresses the CALR expression, leading to cancer cell survival and ineffectiveness of treatment. Those results need to be validated in human samples at different stages of disease to allow a better understanding of treatment response and/or resistance to chemotherapy within these diseases.

LOW RPS14 EXPRESSION IN MDS PATIENTS WITHOUT 5q- ABERRATION SEEMS NOT TO BE RELATED WITH GENOMIC ALTERATIONS IN 5q REGION

M. Linares1,*, K. Quiroz1, Y. Ruiz-Heredia1, I. Rapado1, T. Cedena1, R. Ayala1, J. Martinez-Lopez1
1Servicio de Hematología, Hospital Universitario 12 de octubre, Madrid, Spain

Background: Heterozygous deletion of RPS14 occurs in isolated interstitial deletion of chromosome 5q in patients with myelodysplastic syndrome (MDS). 5q- MDS has been linked to impaired erythropoiesis and it is characterized by a constant macrocytic anemia and normal or high platelet counts associated with hypolobulated megakaryocytes. Previous studies have detected reduced RPS14 expression in more than 50% of non-5q- patients. Recently, the pivotal role of RPS14 in human erythropoiesis during 5q- MDS pathology has been demonstrated: RPS14 haploinsufficiency produces the activation of p53 and its target p21 in erythroid cells, resulting in cell cycle arrest and apoptosis. Based on these results, non-5q- patients expressing low levels of RPS14 will be potentially beneficed by lenalidomide therapy. In this work, we explore the origin of the reduced RPS14 expression in non-5q- patients and its potential link with 5q-pathology.

Aims: The objective of this work was to explore the origin of RPS14 low expression in non-5q- MDS patients and its link with 5q-pathology. In order to do this, we explored potential mutations in RPS14 gene. We also studied expression changes in other key genes involved in the development of the 5q- disease, including the tumour suppressor gene SPARC and the putative tumour suppressor gene CSN1K1A, contained in the commonly deleted region. Moreover, other 32 genes related with MDS disorders were evaluated in relation with RPS14 levels. Finally, in order to establish if this group of patients could be beneficed by lenalidomide therapy, p21 expression levels were also analysed.

Methods: DNA and RNA were extracted from the bone marrow of 89 non-5q- MDS patients. Ten controls and nine 5q- MDS patients were used as negative and positive controls, respectively. RPS14, SPARC, CSN1K1A and p21 mRNA levels were analysed by real time PCR using Taqman probes and the ABI 7500 RT PCR System. β-glucuronidase gene was used as endogenous reference to normalize data. Samples were classified by RPS14 expression levels and differences in SPARC, CSN1K1A and p21 expression mean values between the two groups were analysed using the Mann-Whitney U test. RPS14 and 32 genes expression were estimated using Ion Proton system and SNaPshot.

Results: Non-5q- patients expressing low levels of RPS14 presented higher survival probability in the IPSS lower risk group. This data, in addition with a tendency for increased p21 expression, suggests that this group could be beneficed by lenalidomide therapy. Nevertheless, we did not observe a significant presence of RPS14 mutations in 5q- patients. According to previous studies, RPS14 expression is regulated by specific DNA elements and RPS14, discarding alterations in the adjacent genes commonly deleted in 5q- MDS patients. In addition, the majority of patients analysed did not present any mutation in RPS14 gene. Only two MDS patients showed mutations upstream, downstream or within intronic regions of the gene. The origin of the reduced RPS14 expression in non-5q- patients could not be related with genomic alterations in 5q region. On the other hand, mutations in FLT3, U2AF1, DNMT3A and CBL were frequently observed in this group of patients.

Summary/Conclusions: Although the important role of RPS14 in MDS pathol-
Background: A prospective study was performed over one year in order to investigate whether suspected myelodysplastic syndromes (MDS) could be detected on a complete blood counts (CBC), the fastest laboratory investigation, performed on the recently developed XN-10® (Sysmex, Kobe, Japan).

Aims: The primary end point was to discriminate MDS patients from normal samples and the secondary end-point was to distinguish MDS with excess blasts (MDS-EB), MDS with multilineage dysplasia (MDS-MLD), MDS with single lineage dysplasia (MDS-SLD) and MDS with ring sideroblasts and single lineage dysplasia (MDS-SSLD) within the MDS group and by comparison with controls as described by the WHO 2016 classification.

Methods: One hundred and thirteen patients were enrolled in the study, for whom a diagnosis of MDS was concluded based on CBC, bone marrow smears examination and karyotype. All patients were free of treatment, including trans- fusions, at inclusion. They were 63 men and 50 women with a median age of 82 years (range 36-96 yo). CBC were performed on a Sysmex analyzer XN-10®, including classical parameters (hemoglobin level, Mean Corpuscular Volume (MCV), reticulocytes, platelets, neutrophils and extra-parameters i.e. platelets by fluorescense (PLT-F), immature platelets fraction (IPF%), immature reticulocytes fraction (IRF%) and the neutrophils median position on the three axes as well as their dispersion (Neut-WX). For comparison with normal values, results from 707 healthy subjects over 50 years old, for whom CBC were performed on the same analyzer and generated no flag, were used. All had parameters within the normal range according to age. According to the WHO, 37 patients were observed in MDS, 12 patients in RAEB-1, 12 patients in RAEB-2, 7 patients in refractory anemia with ringed sideroblasts (RS)], 26 MDS-SLD- RS, 12 MDS-SLD without RS and 3 MDS with isolated del(5q). Sixty-two patients had a normal karyotype, 24 displayed anomalies classically reported in MDS, and 8 had complex karyotypes. Among the latter, 7 were associated with MDS-EB.

Results: Both classical and extra parameters indeed showed significant differences between the subgroups tested. Among the whole group of MDS patients, a number of parameters of all lineages were statistically different from the healthy cohort. The median level of hemoglobin was 9.9±2.1 g/dl (p<0.0001), the median MCV (99,24±10,56 fl) (p=0.0001), reticulocyte counts 44,3±10,6% (range 8,1-62,9; p<0.0001), platelet counts 218±57,9x109/L (range 74,3-650,0; p=0.0001). The median platelet count was 194 ±128x109/L (p<0.0001) and the median IPF% 8,8% (1,2-21,8; p<0.0001). Among leucocyte parameters, the MDS median neutrophil count was significantly lower at 3.082,5±8,10x109/L (p<0.001) while Neut-WX was significantly higher (3571,7±p<0.0001). The latter, allowed to predict a diagnosis of MDS with 73% sensitivity and 97% specificity. For patients over 50 years old, 4 parameters (Neut, Neut-WX, hemoglobin level and MCV) in a score allow to diagnose MDS with 92% sensitivity and 81% specificity. When considering MDS subgroups, although each of them was significantly different from controls for hemoglobin levels, MCV and IPF% and (p<0.0001), they could not be discriminated by scores. Among the subgroup of MDS with single lineage dysplasia and ring sideroblasts, platelet counts were similar to those of controls, yet significantly higher than for MD-EB or MDS-MLD (p=0.004 and p=0.029 respectively).

Moreover, neutrophils counts were significantly lower in MDS-DML or MDS-EB than in MDS-SLD-R.

Summary/Conclusions: This study demonstrates that a simple CBC allows to screen for MDS using a multiparameter score including Neut-WX. Blood smear examination should be performed in this situation even if the XN-10® analyzer does not raise any alarm, especially in unknown patients older than 50.

PROGRESSION SCORE FOR ACUTE LEUKEMIA – A NEW PROGNOSTIC SCORE IN MDS

E. Cortesão1,2,*, A.C. Gonçalves1, A.R. Tenreiro2, A. Ribeiro1,2, C. Geraldes1,2, N. Costa e Silva3,4, L. Ribeiro2, J. Nascimento Costa5, A.B. Sarmento-Ribeiro1,2

Summary/Conclusions: We revealed both PU.1 and JDP2 are down regulated in MDS. In addition, our data suggests that PU.1 and JDP2 expression inversely correlates with patients disease, with expression of these genes consistently reducing according to IPSS-R groups. Furthermore, a positive correlation of PU.1 and JDP2expression (<R=0.9333, p=0.0004 >), provides additional evidence that suppression of JDP2 by PU.1 could control cell proliferation in MDS. Notably, PU.1 and JDP2 do not correlate to the same extent in normal HSCs, indicating that cofactors are required for PU.1 to exert its JDP2-regulating function and that such cofactors are not present under normal conditions. To confirm that JDP2 suppression is a direct result of reduced PU.1, we performed PU.1-knockdown in AML cells, stably expressing PU.1 short interfering RNAs versus control cells. These analyses reveal only a partial reduction in JDP2 expression when analysed by RT-PCR and Western blot, suggesting a more complex regulatory mechanism. Additionally, both PU.1 and JDP2 expression was recovered by treatment with azacitidine, which is routinely used to treat MDS, suggesting an in vivo relevance within the disease.

Summary/Conclusions: PU.1 and JDP2 expression correlates with patients prognosis highlighting a potential role as new diagnostic and prognostic markers in MDS.

PB1915

CORRELATION OF PATIENT PROGNOSIS WITH PU.1 AND JDP2 PROVIDES POTENTIAL NOVEL PROGNOSTIC/DIAGNOSTIC MARKERS IN MDS

R. Simpson1,*, A. Goddard1, J. Lally1, M. Simmonds1, C. Rinaldi2

Summary/Conclusions: In conclusion, we believe that this score may contribute to evaluate the risk of progression to AML, by reflecting the heterogeneity of MDS and its multifactorial etiology. The coexistence of many altered variables not only contributes to the etiopathogenesis of MDS but also allows the assessment of potential leukemic transformation.
Background: Myelodysplastic syndromes (MDS) are clonal disorders of the haematopoietic stem cells (HSCs) characterized by inefficient bone marrow (BM) haemopoiesis and increased risk for leukaemic evolution. Ineffective BM haemopoiesis in MDS has also been linked with an abnormal microenvironment that may sustain or even induce the aberrations within the HSC compartment. We have previously shown that the stroma progenitor cells, namely the mesenchymal stem cells (MSC), in MDS patients display impaired clonogenic and proliferative potential, reduced haemopoiesis supportive capacity and down-regulation of the canonical Wnt-signaling pathway.

Aims: Decorin, a small leucine-rich proteoglycan, and galectin-3, a member of b-galactosidase specific lectin family, are components of the extracellular matrix of the BM microenvironment. Both proteins have been implicated in the canonical Wnt-pathway participating therefore in cell growth and proliferation. The aim of the study is to assess the expression of decorin and galectin-3 in MSCs of MDS patients, evaluating their implication in the abnormal Wnt-signaling previously reported in MDS.

Methods: BM MSCs were isolated from 12 patients with lower risk MDS aged 51 to 75 years (median 67.5 years) and 12 haematologically healthy subjects aged 50 to 73 years (median 63.3 years), after informed consent. The study has been approved by the Ethics Committee of the University Hospital of Heraklion. BM MSCs were characterized according to international system for human cytogenetic nomenclature (ISCN) criteria, expanded and re-seeded for two passages (P). Total RNA was extracted from culture-expanded P2 MSCs and amplified by real-time PCR for the evaluation of decorin and galectin-3. Relative gene expression was calculated by the ΔΔCT method.

Results: A statistically significant decreased expression of decorin was identified in MSC of MDS patients (mean 1.338, SD 0.84) compared to the healthy individuals (mean 1.830, SD 0.71). (P<0.05). Galectin-3 expression was also decreased in MDS patients (mean 0.6758, SD 0.50) compared to controls (0.9395, SD 0.50), although not at a statistically significant levels.

Summary/Conclusions: MSCs from MDS patients display statistically significant decreased expression of decorin and a tendency towards decreased expression of galectin-3 in BM MSCs compared to healthy individuals. These preliminary data indicate that extracellular matrix proteins may have a role in the disturbed Wnt-pathway signaling and abnormal MSC function in MDS patients. The underlying mechanisms are currently under investigation.

Background: Myelodysplastic syndromes (MDS) are heterogeneous disorders defined as clonal diseases involving hematopoietic stem cells and even characterized by cytopenias, with a high risk of leukemic transformation. Morphological analysis of peripheral blood (PB) and marrow aspirates or bone marrow biopsies is the first step that ensures a diagnosis of MDS. Cytogenetic studies are important means of defining different prognostic groups and even of showing how patients are eligible for this or that treatment. We conducted the first study including conventional karyotyping and fluorescent in situ hybridization (FISH) for MDS in our country.

Aims: Our study was aimed to evaluate outcome of MDS regarding IPSS and IPSS-R classification in an emerging country.

Methods: Between January 2012 to December 2016, 101 patients with MDS were consecutively diagnosed. Frequent genetic abnormalities in MDS were screened by R-banding karyotype and metaphasic and interphasic FISH using how patients are eligible for this or that treatment. We conducted the first study including conventional karyotyping and fluorescent in situ hybridization (FISH) for MDS in our country.

Results: Among these 101 pts, 58 were male with a sex ratio=1, 35; range in age is from 18 years to 94 years with a median of 61, 6 years. Median hematologic age was 80 G/L (29-150), more than 60% of patients had severe anemia mainly in the low risk group; the median absolute neutrophil count was 3 G/L (0,060-13, 5), and the median platelet count was 144 G/L (5-659). Median bone marrow blast value was 4% (0-18). Cases were classed by cytomorphology FAB as RA (n=45), REAB (n=14), RARS (n=16), other (n=6). Classification by WHO was defined CRDU (n = 31 of which RA : 18, RT : 10, RN : 3), CRDM (n = 16), RAEB-1 (n=22), RAEB-2 (n = 13), RARS (n = 15), Isolated 5q- (n=4). Among 101 patients, cytogenetic abnormalities by R banding karyotype (n= 84) and FISH (n=101) were found in 41 cases (41%) distributed as single anoma-

CLINICAL EVOLUTION OF ACUTE MYELOID LEUKEMIA WITH MYELODYSPLASIA-RELATED CHANGES

G. Pinto1,*, P. Herrera1

1Hematology, HOSPITAL RAMON Y CAJAL, Madrid, Spain

Background: Acute myeloid leukemia (AML) with myelodysplasia-related changes (MRC) is usually classified associated to worse clinical course and poor prognosis compared other AML subtypes. Differences between treatment modalities according to age, and the response to treatment, would help to provide specific anti-AML treatment in this difficult scenario.

Aims: The objective of this study is analyze the clinical features and course of patients with AML with MRC, in order to evaluate the impact of different therapeutic regimens in this subgroup.

Methods: We report an unicentric retrospective study of 76 patients with AML with MRC, over the past ten years in a single institution in Spain. We analyzed the overall survival (OS) among the subgroup of patients with over or under 65 years, and the different types of treatment that has been offered.

Results: Median age was 69 years with a male predominance, and 66% was preceded by a known myelodysplastic syndrome with a median interval of 18 months to progress to AML. The more frequent genetic abnormalities in descending order were trisomies, del(5q), and del(7q)-7. The patients aged >65 and <65 were 70% and 30%, respectively. The patients aged >65 received DNA hypomethylating agents (40%), anthracycline-cytarabine combinations (9%), low-dose cytarabine or hydroxyurea (17%), and supportive measures (34%). The patients aged >65 received induction chemotherapy with anthracycline-cytarabine combinations so as to continue with post-consolidation management with allogeneic transplantation, but the 44% died over the induction chemotherapy (OS: 2.2 months). The OS in patients aged >65 was 20.2 months in chemotherapy plus allogeneic transplantation. The OS in patients aged >65 was 10.3 months in the group of anthracycline-cytarabine combinations, 3.81 months in the DNA hypomethylating agents group, 2.8 months in the low-dose of AraC/hydroxyurea, and 0.5 months in supportive measures group (Figure 1).

Summary/Conclusions: The AML with MRC patients is a group with difficult treatment decisions and poor prognosis, in whom only the chemotherapy plus allogenic transplantation treatment manage long-term survival. In patients aged >65, there is not a significant difference among groups, although the chemotherapy with anthracycline-cytarabine seems to reach a better OS versus other available treatments.

SAFETY, EFFICACY, AND PHARMACOKINETICS OF INTRAVENTOUS RIGOSERIB IN JAPANESE PATIENTS WITH RECURRENT/RELAPSED OR REFRACTORY MYELODYSPLASTIC SYNDROMES: A MULTICENTER, OPEN-LABEL, PHASE I STUDY

M. Ogura1,2,*, Y. Kobayashi3, S. Kubonishi4,5, M. Hidaka6, T. Uchida6, Y. Takamatsu7

1Department of Hematology, Tokai Central Hospital, Kakamigahara, 2Department of Hematology and Oncology, Nagoya Daini Red Cross Hospital, Nagoya, 3Department of Hematology, National Cancer Center Hospital, Tokyo, 4Department of Hematology, National Hospital Organization Okayama Medical Center, Okayama, 5Department of Hematology, Red Cross Society Himeji Hospital, Himeji, 6Department of Hematology, National Hospital Organization Kumamoto Medical Center, Kumamoto, 7Division of Medical Oncology, Hematology, and Infectious Diseases, Fukuoka University Hospital, Fukuoka, Japan

Background: Rigosertib, a novel phosphoinositide 3/40-loike kinase pathway inhibitor, selectively induces the apoptosis of cancer cells and is safe and well tolerated in pts with recurrent/relapsed or refractory MDS.

Aims: We conducted a multicenter, open-label, Phase I study of intravenous rigosertib to evaluate its safety, efficacy, and pharmacokinetics and to determine the recommended dose (RD) for Japanese pts.

Methods: The key eligibility criteria were as follows: recurrent/relapsed or refractory MDS; age: 20 or older; FAB classification (RA, RARS, RAEB, RABE-t, and CMML), excluding patients at IPSS low- or Int-1 risk with respect to RA; ECOG PS of 0 to 2; no major organ dysfunction; and written informed consent. After a dose of 700 and 1,200 mg was administered intravenously over 72 h, followed by 11-day monitoring in one 14-day cycle. The primary endpoint was dose-limiting toxicity (DLT). The secondary endpoints were 1) safety as assessed with adverse events (AEs) and laboratory results; 2) efficacy as assessed with the International Working Group 2006 criteria; and 3) pharmacokinetics.

Results: Between June 2012 and February 2015, 7 male and 2 female pts (median age: 70; range: 63-84) were enrolled, and 3 and 6 pts were eventually assigned to the 1,200 and 1,800 mg arms, respectively. According to the FAB classification, 6, and 2 pts were categorized to RAEB, RAEB-t, and RABE-t respectively. There were no deaths in the trial. Deaths occurred during the study period. However, 5 pts died during follow-up, 4 of whom died from primary disease progression. Furthermore, 1 pt died of grade 5 bacterial pneumonitis that was rated to “Unrelated”. In the 1,200 mg arm, 2 cases each of grade 3/4 thrombocytopenia, grade 4 neutropenia, and grade 3/4 leucopenia, as well as 1 case each of grade 3 lymphopenia, grade 4 neutropenia, and grade 3/4 neutropenia, as well as 1 case each of grade 3 lymphopenia, grade 4 anaemia, and grade 3/4 neutropenia, increased C-reactive protein, erythropenia, and hypoalbuminemia. The patients aged >65 received induction chemotherapy with anthracycline-cytarabine combinations so as to continue with post-consolidation management with allogeneic transplantation, but the 44% died over the induction chemotherapy (OS: 2.2 months). The OS in patients aged >65 was 20.2 months in chemotherapy plus allogeneic transplantation. The OS in patients aged >65 was 10.3 months in the group of anthracycline-cytarabine combinations, 3.81 months in the DNA hypomethylating agents group, 2.8 months in the low-dose of AraC/hydroxyurea, and 0.5 months in supportive measures group (Figure 1).

Summary/Conclusions: The AML with MRC patients is a group with difficult treatment decisions and poor prognosis, in whom only the chemotherapy plus allogenic transplantation treatment manage long-term survival. In patients aged >65, there is not a significant difference among groups, although the chemotherapy with anthracycline-cytarabine seems to reach a better OS versus other available treatments.
treated 32 elderly patients (19 male and 13 female, median age 76 years, r. 71-88) affected by HIGH-RISK MDS (IPSS INT-2/HIGH). Patients received subcutaneous azacitidine at 75mg/m² daily for 7 days every 4 weeks. All patients completed at least 6 cycles of therapy. 12/30 (40%) patients underwent more than 8 cycles of therapy. 18/30 patients underwent as well iron chelation therapy with deferasirox receiving a starting dosage of 10 mg/kg/day, subsequently titrated according to serum ferritin (SF) measured monthly.

Results: Complete response (CR), partial response (PR), and hematologic improvement (HI) were observed in 2 (7%), 5 (17%), and 12 (40%) patients, respectively. The median number of cycles to clinical response was 4 (range 4-8). The 2-year rate of treatment of acute myeloid leukemia-free survival was 48%. Five serious adverse events occurred in five patients with one fatal outcome. 16 out of 18 patients who showed any hematologic response (CR+PR+HI) meeting International Working Group 2006 criteria had also performed deferasirox therapy. No increased toxicity was noted when deferasirox was used concomitantly with azacitidine.

Summary/Conclusions: Our results confirm the effectiveness of the therapy with azacitidine in HIGH-RISK MDS elderly patients with acceptable toxicity profile. Peripheral cytopenias were the most commonly occurring adverse event, with gastrointestinal adverse events and injection-site reactions among the most commonly occurring non-haematological adverse events. In conclusion, azacitidine is an important agent for use in the treatment of elderly patients with MDS. Furthermore concurrent use of deferasirox in patients with iron overload seems to significantly improve the hematologic response by reducing transfusion requirement.

PB1921
EXPLORING THE RISK OF RED CELL ALLOIMMUNIZATION IN MYELODYSPLASTIC SYNDROMES. TO WHAT EXTEND COULD CYTOTOGENETIC ANALYSIS AT DIAGNOSIS PREDICT THIS RISK?
I. Koutsavlis1, J. Falconer2, J. Fleming3, H. Riddle4
1Haematology, 2Blood Transfusion Service, 3Cytogenetics Service, NHS LOTHIAN, Edinburgh, United Kingdom

Background: Red cell alloimmunization poses a huge burden for the blood transfusion services as it may be associated with crossmatching difficulties, haemolytic transfusion reactions and potential severe clinical consequences for the transfused patient. Collectively, alloimmunization appears to be higher in patients with myelodysplasia (MDS) and chronic myelomonocytic leukaemia (CMML) with a rate somewhat around 15%. Identification of patients at risk of developing alloantibodies would be of clinical significance as antigen negative red cells could be crossmatched in advance for use in clinical practice. Largely, studies have failed to predict this cohort of patients and little is known regarding identifiable risk factors.

Aims: To this end, we focused on exploring the cytogenetic profile from patients with MDS and CMML along with demographic characteristics as risk factors for alloimmunization.

Methods: A retrospective analysis was performed in 360 transfused patients with MDS (74.4%) and CMML (25.6%) registered in our local database between 1980 and 2016. Prognostic variables (age, sex, disease subtype) were assessed using a multivariate prediction model in SPSS statistical software. Cytogenetics at diagnosis were available in 226 of the above patients and univariate analysis was performed separately.

Results: The mean age at diagnosis was 73 years (range 20-95) with 58.3% male patients. Overall, 45 patients (12.5%) fulfilled 76 antibodies [88 alloantibodies, 8 autoantibodies] with 42% of them developing more than 1 antibody. 5 additional patients developed autoantibodies without alloantibodies. Alloantibody specificities were as follows: E (22 cases), C (8), K (7), Cw1 Jal (3), Kell 1a (2) cases each), Lu(a), (4), e/Fya (3 cases each), M (2), C, D/Chido B (1 case each). Collectively, alloantibodies against the Rh and Kell systems encountered in patients with MDS and/or CMML along with demographic characteristics as risk factors for alloimmunization.

Aims: This study aimed to investigate the occurrence of allogeneic peripheral blood stem cell transplantation among the intensity conditioning (RIC) regimen to reduce the toxicities associated with transplant procedure. The main concept of RIC rely upon adoptive immunotherapy especially in the low risk patients allowing the graft versus leukemia to occur.

Methods: A retrospectively study analyzed the fifty-one patients with MDS who undergo transplantation at the BMT unit at Nasser Institute during a period of 10 years, following the RIC regimen from HLA identical donor for peripheral blood stem cell. Outcomes analyzed the incidence of acute and chronic GVHD, disease free survival (DFS) & overall survival (OS).

Results: They were 31 males (60.8%) and 20 females (39.2%). Their ages ranged from 17 to 60 years, with mean ages±SD of 34.2±10.1 years. A high rate of treatment of acute myeloid leukemia-free survival was 51.1% and 28.6% respectively. The 5-year estimate for overall survival of the whole group was 21.8%. In univariate analysis, covariates associated with a better OS were recipient age < 40 years (p=0.02) and the presence of cGVHD (p<0.002). On multivariate analysis the presence of cGVHD is significant predictor of survival (p<0.04). Also cGVHD significantly improve the OS for low and high risk MDS group (p=0.02 and 0.03 respectively). While presence of acute GVHD, IPSS & interval between diagnosis and transplant wasn't significantly affect OS (p>0.05). The 5-year estimate for DFS of the whole group was 28.6%. On multivariate analysis the presence of cGVHD significantly reduce relapse (p<0.029).

Summary/Conclusions: The presence of cGVHD significantly improved OS and reduced the risk of relapse in patients with MDS. We also found that the presence of cGVHD significantly improved OS especially in high-risk patients group, which suggests that the GVLT effect may be beneficial in high-risk patients who do not receive intensive preparative regimens.

MANAGEMENT OF MYELODYSPLASTIC SYNDROMES WITH ANEMIA AND ERYTHROPOIETIC STIMULATING AGENTS IN REAL-LIFE EXPERIENCE: AN UPDATE FROM RECAMDS
C. Cerchione1, O. Vitagliano1, R. Della Pepa1, G. Cercello1, A. Pareto1, M. Di Perna1, I. Soriente2, P. Danise3, A.M. D’Arco4, F. Alfinito4, F. Pane4
1Hematology, Ematologia e trapianto/au federico ii, 2Hematology, Ospedale Umberto I, Nocera Inferiore (SA), 3Hematology, Ospedale Umberto I, Napoli, 4Ematologia e trapianto/au federico ii, Napoli, Italy

Background: Erythropoietin stimulating agents (ESAs) are the frontline treatment in low-risk anemic MDS patients and an employment of this therapy in the elderly subset of the disease is quite common. A significant delay in the RBC-transfusion, hypothetically by slowing the disease course. It’s matter of debate whether the clinical response is a result of proliferation and maturation of the dysplastic clone or stimulation of residual normal erythropoiesis by ESAs.

Aims: Macrocyclon is one of the cytogenetic hallmark which indicates a dyserythropoiesis in MDS; an analysis of the erythropoiesis response to ESAs therapy in a cohort of anemic non transfusion-dependent MDS patients, enrolled in a retrospective register, RECAMDS, subgroup of Italian register, was performed.

Methods: 183 patients, treated with standard-dose ESAs, have been retrospectively analyzed (Table 1). Data analysis was performed, according to IWG 2006 criteria, at the baseline, after 3 and 6 months of continuous treatment, with a sub-analysis of the patients according to WHO and R-IPSS risk stratification. ESAs were started at mean Hb concentration of 9.31 g/dl, mean serum EPO concentration: 51 mU/L, after a mean time from diagnosis of 6 months (r.1-118). The ORR was 38.1% (75/198), no difference among WHO and IPSS subgroups was found: 132/183 (72.1%) achieved hematologic response after 3 months of treatment, while other 21/183 (11.2%) after 6 months. 19 patients with stable disease (non-responders, according to IWG
Background: Myelodysplastic syndromes (MDS) are included into a heterogeneous group of clonal blood diseases characterized by peripheral cytopenias, dysplastic features of hematopoietic precursors, progressive deterioration and a high risk of transformation into leukemia. MDS occurrence in patients that differ in frequency of appearance, the duration of the course and the probability of transformation into acute leukemia. The choice of therapy for a particular patient is determined by the morphological variant of the disease, the prognostic group, age and comorbidity. In hypoplastic cases of MDS are often used immunosuppressive therapy.

Aims: Analysis of the effectiveness of immunosuppressive therapy in patients with primary MDS

Methods: The research included 19 patients with primary MDS from 22 to 58 years (median age 46 years, 11 male, 8 female). The diagnosis was made according to the criteria of the WHO classification of the WHO, which was implemented in 2008. The materials were taken only after signing by patients informed consent form to participate in the research. The calculations are performed in the R version 3.1.3 statistical package.

Results: There were patients with defined MDS subtypes: RA in 52.6%, RCMD in 31.6, and RAEB in 15.8%. Hypoplastic form of MDS was diagnosed in 63.2% of patients. The increased number of lymphocytes in the bone marrow of patients was 52.6%, accumulation of lymphocytes in the bone marrow biopsy – in 36.8%. Cytogenetic abnormalities were found in 21% of patients (5.3% complex and in 15.7% isolated). All patients used immunosuppressive therapy as a first-line treatment: Antithymocyte globulin and Cyclosporine A (CsA) in 15.8%, monotherapy with CsA in 84.2%. CsA therapy started at a dose of 5 mg/kg per day. Dose correction performed depending on the concentration of CsA in the serum and toxicity. Median treatment was 143 days (36…1253 days). The response rate to CsA treatment was considered a complete remission (normalization of blood and bone marrow), partial remission (improvement of blood counts for more than 50% and no dependence on transfusions of blood components) or improvement (reduction in transfusion requirements by 50% or more). Complete remission was achieved in 10.5% of patients (only variant RA). Partial remission was obtained in 31.6% (variants RA and RCMD) and improvement in 36.8% (variants RA, RCMD and RAEB). There was no response to treatment in 21.1% of patients (variants RCMD and RAEB). Positive effect on immunosuppressive therapy significantly more likely achieved in patients with hypoplastic forms MDS (57.9%) and the presence of clusters of lymphocytes in the bone marrow biopsies (36.8%). Dependence of treatment efficiency and cytogenetic abnormalities not detected.

Summary/Conclusions: The effectiveness of immunosuppressive therapy in MDS associated with a variant of the disease, bone marrow cellularity and the bone marrow lymphoid infiltration. The greatest effect of the immunosuppressive therapy can be expected in patients with hypoplastic MDS and accumulation of lymphocytes in the bone marrow biopsy.
Sixty-five children with JMML diagnosed between 2002 and 2016 were included in this study. For cytogenetic risk classification median serum 25(OH)D levels were 18 ng/ml in "very good" (n=48), 19 ng/ml in "intermediate" (n=8), and 23 ng/ml in "very poor" (n=9) cytogenetic risk patients (p=0.071). Median serum OCN levels (normal range 11-46 ng/ml) were 19 ng/ml (RA, RARS, n=35), 23 ng/ml (RAEB-1/2, sAML, n=16), and 20 ng/ml (MDS/MPN, n=8) (p=0.273). When classified by IPSS-R, median serum 25(OH)D levels were 18 ng/ml in "very low" (n=20), 16.5 ng/ml in "intermediate" (n=14), and 29.5 ng/ml in "very high" (n=8) with p=0.102. Regarding cytogenetic risk classification median serum 25(OH)D levels were 16 ng/ml in "very good" (n=48), 19 ng/ml in "intermediate" (n=8), and 18.5 ng/ml in "very poor" (n=4) cytogenetic risk patients (p=0.738). Median serum OCN levels (normal range 11-46 ng/ml) were 19 ng/ml (RA, RARS, n=33) and 16.2 ng/ml (higher-risk MDS/sAML, n=16) (p=0.136). IPSS-R risk classification resulted in median serum OCN levels of 17.4 ng/ml in IPSS-R "very low" (n=17), 16.2 ng/ml in "intermediate" (n=15), and 21.7 ng/ml in "very high" (n=6) (p=0.701). Cytogenetic risk classification had no impact on median serum OCN levels (p=0.271).

Summary/Conclusions: In summary, our cohort of patients with MDS, MDS/MPN and sAML show clearly decreased serum 25(OH)D levels. The preliminary results suggest a tendency of serum 25(OH)D levels to increase with higher risk cytogenetic risk classification which is supported by positive Kendall’s tau (p=0.210). Serum 25(OH)D levels lie below normal limits, but seem not to be affected by disease risk. These results suggest specific hypotheses regarding the pathomechanism that shall be investigated on an enlarged data set, which we are continuously collecting.

THE PRECURSOR B CELLS AS A PROGNOSIS FACTOR IN MYELOIDSYSTIC SYNDROMES

G. Pinto1, P. Herrera1

1Hematology, Hospital Ramon y Cajal, Madrid, Spain

Background: Recently, an immunosuppressive environment with low number of precursor B cells at the bone marrow has been related with poor survival in patients with very low/low and intermediate risk myelodysplastic syndrome (MS), but the negative impact is unclear yet.

Aims: The objective of this study is to establish if there is a negative association between the percentage of precursor B cells (%PBC) at the time of diagnosis of MS and progression-free survival.

Methods: We analyzed 48 patients with IPSS-R very low/low risk (VLL) and 34 patients with intermediate risk (INT) in the past 10 years in a single institution in Spain. We reviewed the %PBC (CD43+ (CD34+CD10+ or CD34+CD117+) over total marrow cells at diagnosis measured by flow cytometry, and we calculated the time of progression-free survival (PFS) defined as the time between inclusion until progression to refractory anemia with excess blasts type 2 (RAEB-2) or acute myeloid leukemia (AML). The Competing risks regression test was used to assess the predictive value of PBC in relationship to PFS.

Results: Median age in both groups was 69 years, and median of progression to RAEB-2 or AML was 1.96 years in VLL group and 0.64 years in INT group. The %PBC was not a predictor of PFS in VLL group with a sub-hazard ratio (SHR) of 0.23 (95% CI: 0.003-13.96, P=0.485) neither in the INT group with a SHR 0.14 (95%CI: 0.001-4.52, P=0.211). We also performed a median split analysis to the %PBC with a median value of 0.1% in both groups. In the VLL group, patients with %PBC above the median had a median PFS of 2.48 years versus 1.99 years for the patients with %PBC below the median. In the INT group, patients with %PBC above the median had a median PFS of 1.14 years versus 0.83 years for the patients with %PBC below the median (Figure 1).

Figure 1.

Summary/Conclusions: Our results not provide evidence in order to establish a prognostic value between %PBC at diagnosis in IPSS-R very low, low or intermediate MS.

PB1929

TO INFINITY AND BEYOND: NGS IN MDS

Aims: We studied a total of 33 patients diagnosed with de novo MDS (WHO 2008 classification), using a Next Generation Sequencing panel comprising 45 myeloid genes.

Results: Patients were 15 male and 18 female, with a median age at diagnosis of 76 years (52 – 93 years). The MDS subtypes distribution was 16 patients (48.5%) with RMD, 4 patients with RARS, 4 with RAEB-1 and 4 with RAEB-2 (12.1% for each subtype), 3 patients (9.1%) with 5q-Syndrome and 2 patients (6.1%) with RCUD. These patients were stratified according to the IPSS as Very Low-risk (24.2%), Int-1 (33.3%) and Int-2 (18.2%), without any high-risk
patients. All patients required erythropoiesis stimulating agents and 9 patients received treatment with azacytidine (AZA) included all the Int-2 patients and 3 lower risk patients who progressed to a higher risk MDS. Estimated cumulative survival at 46 months was 67% with a median OS not reached and median follow-up time of 34 months. Patients receiving AZA revealed a trend towards survival benefit (mean survival 54.2 vs 50 months), independent of IPSS and R-IPSS. A trend towards significance (p = 0,05) occurred. We also reported that 75.8% of patients had at least one gene mutation and it was most frequently related to DNA methylation genes (n=14), particularly in TE2 (7 patients) and DNMT3A (n=6 patients, 7 different mutations) genes. We found a statistically significant difference between mutations in these genes and lower absolute neutrophil counts (n=0.047 G/L, n=0.04). The most frequently mutated genes were related to signal transduction pathways (n=11; JAK1, JAK2, NRAS, CBL, GATA2, SH2B3, CSFR). Patients with these mutations had significantly lower serum EPO levels (p < 0,001; median 32,35 vs 42,70 UI/L). Furthermore, patients with such mutations demonstrated a clear disportionate survival in myelodysplasia analysis, with a median OS of 19 months for patients without mutations (p<0,01), being these results independent of the IPSS and R-IPSS risk groups. We were also able to identify a trend towards worst survival in patients with previously described high risk mutations (TSPAN, EZH2, ASXL1, RUNX1 and ETV6 genes).

Summary: We conclude that the most frequently detected mutations were related to DNA methylation genes, as described in the literature, which was independent of the IPSS risk group, being observed in both low-risk and high-risk patients. These results raise the question whether hypomethylating agents may also be of benefit for lower-risk patients.

Methods: We compared the IPSS and R-IPSS with signal transduction pathways which was related to a clear survival disadvantage across all risk groups of the IPSS and R-IPSS. This unveils the question whether we may be facing a shift towards the molecular level in MDS risk stratification and if therapies targeted to such molecules may improve the outcome of these patients.

CLINICAL FEATURES, CYTOGENETIC STUDY AND OUTCOME OF ADULT MYELODYSPLASTIC SYNDROMES: REVIEW OF 101 CASES, A SINGLE CENTER EXPERIENCE IN ALGERIA.

S. Taoussi1,*, Y. Bouchakor-Moussa1, M.T.T. Abad1
1Hematology, EHS ELCC CAC, Blida, Algeria

Background: Myelodysplastic syndromes (MDS) are heterogeneous disorders defined as clonal diseases involving hematopoietic stem cells and even characterized by cytopenias, with a high risk of leukemic transformation. Morphological analysis of peripheral blood (PB) and marrow aspirates or bone marrow biopsies is the first step that ensures a diagnosis of MDS. Cyto genetic studies are important means of defining different prognostic groups and even of showing how patients are eligible for this or that treatment. We conducted the first study including conventional karyotyping and fluorescent in situ hybridization (FISH) for MDS in our country.

Aims: Our study was aimed to evaluate outcome of MDS regarding IPSS and IPSS-R classification in an emerging country.

Methods: Between January 2012 to December 2016, 101 patients with MDS were consecutively diagnosed. Frequent genetic abnormalities in MDS were important means of defining different prognostic groups and even of showing how patients are eligible for this or that treatment. We conducted the first study including conventional karyotyping and fluorescent in situ hybridization (FISH) for MDS in our country.

Results: Among these 101 pts, 58 were male with a sex ratio=1,35; range in age is from 18 years to 94 years with a median of 61,6 years. Median hemoglobin value was 80 G/L (29-150), more than 60% of patients had severe anemia mainly in the low risk group; the median absolute neutrophil count was 3 G/L (0.060-13,5), and the median platelet count was 144 G/L (5-659). Median bone marrow blast cell count was 4% (0-18). Classes were classified by cytology morphology FAB, 20 patients (20%), RARS, in other (n=8). Classification by WHO 2008 included RCUD (n= 31 of which RA: 18, RT: 10 , RN: 3), RCMD (n= 16), RAEB-1 (n=22), RAEB-2 (n= 13), RARS (n= 15), isolated 5q (n=4). Among 101 patients, cytogenetic abnormalities by R banding karyotype (n= 84) and FISH (n=101) were found in 41 cases (41%) as described in the literature, but not statistically significant (n=5) with interphase FISH using a panel including six probes (5q-,7q-,20q-, del(t(1p13), MLL, Inv(t) (t(3,3). Patients were stratified into risk groups according to IPSS and IPSS-R scores; survival probabilities were estimated using the Kaplan-Meier method.

Results: Among these 101 pts, 58 were male with a sex ratio=1,35; range in age is from 18 years to 94 years with a median of 61,6 years. Median hemoglobin value was 80 G/L (29-150), more than 60% of patients had severe anemia mainly in the low risk group; the median absolute neutrophil count was 3 G/L (0.060-13,5), and the median platelet count was 144 G/L (5-659). Median bone marrow blast cell count was 4% (0-18). Classes were classified by cytology morphology FAB, 20 patients (20%), RARS, in other (n=8). Classification by WHO 2008 included RCUD (n= 31 of which RA: 18, RT: 10 , RN: 3), RCMD (n= 16), RAEB-1 (n=22), RAEB-2 (n= 13), RARS (n= 15), isolated 5q (n=4). Among 101 patients, cytogenetic abnormalities by R banding karyotype (n= 84) and FISH (n=101) were found in 41 cases (41%) as described in the literature, but not statistically significant (n=5) with interphase FISH using a panel including six probes (5q-,7q-,20q-, del(t(1p13), MLL, Inv(t) (t(3,3). Patients were stratified into risk groups according to IPSS and IPSS-R scores; survival probabilities were estimated using the Kaplan-Meier method.

Summary/Conclusions: Our results are in agreement with those previously published regarding demographic features, distribution of pre-treatment cytogenetic abnormalities and prediction of survival. Myelodysplasias are among the most difficult hematological diseases to treat. Treatment of low risk and high risk myelodysplasia are completely different, the last group carrying a great risk of leukemic transformation. For all these reasons, application of the new tools to R-IPSS is related to a clear survival disadvantage across all risk groups of the IPSS and R-IPSS. This unveils the question whether we may be facing a shift towards the molecular level in MDS risk stratification and if therapies targeted to such molecules may improve the outcome of these patients.
Aims: Therefore, with the aim of assessing the safety and efficacy of ICT in the daily clinical practice, we retrospectively analyzed our single-center experience on ICT in MDS and other chronic anemias.

Methods: From October 1997, in our Institution, 69 pts (48 males), median age: 74 (23-96) yrs, with transfusion-dependent anemia, received ICT, because of a diagnosis of iron overload, i.e. both a transfusion history of at least 20 units of RBC and a serum ferritin (SF) higher than 1000 ng/ml.

Results: 40 pts (58%) were affected by lower-risk MDS (IPSS risk: low or intermediate-1), while 13 pts (18.8%) showed a higher-risk MDS (IPSS risk: high or intermediate-2) but were considered for ICT because of responsiveness to hypomethylating therapy and/or eligibility for allogeneic SCT. 16 pts (23.2%) were affected by other diseases (chronic myelomonocytic leukemia: 2 pts; idiopathic myelofibrosis: 3 pts; aplastic anemia: 9 pts; pure red cell aplasia (PRCA): 2 pts). 45 pts (65.2%) received deferoxiror (DFX) as first-line treatment, 12 pts (17.4%) received DFX after a previous treatment with deferoxamine (DFO), while 9 pts (13%) received DFO and 3 pts (4.3%) received DFO after DFX because of contraindications to DFX or toxicity. Median time from diagnosis to the start of ICT: 18 months. Median number of RBC transfusions before the start of ICT: 37.5. Median SF level pre-ICT: 1964 ng/ml; median SF after ICT (last value): 1858 ng/ml; median duration of ICT: 12 (range 1-230) months. 36 pts (52.2%) continued ICT for a period ≥24 months, and 25 pts (36.2%) for a period ≥24 months. 27 pts (39.1%) showed a drop of SF ≤500 ng/ml, 11 pts (15.9%) showed a drop of SF <500, 13 pts (18.8%) showed an increase of SF ≥500 in spite of ICT, and 18 pts (26.1%) showed an increase of SF >5000. 12 pts (17.4%) achieved a SF value <1000, and 48 pts (69.6%) a SF value <2500. Adverse events possibly related to DFX were observed in 30 pts (43.5%): renal (increase of serum creatinine): 14 pts (20.3%) (grade ≥2: 1 pt: 1.4%); gastrointestinal : 14 pts (20.3%) (grade ≥2: 1 pt: 1.4%); cutaneous: 2 pts (2.9%) (grade ≥2: 2 pts: 2.9%). Permanent discontinuation of ICT: 40 pts (58%), because of toxicity (16 pts: 23.2%), worsening of clinical condition (6 pts: 8.7%), discontinuation of treatments (9 pts: 13%), allogeneic transplantation (9 pts: 13%). 5 pts (7.2%) (4 MDS and 1 PRCA) (with DFX: 4 pts; with DFO: 1 pt) showed an erythroid response following ICT, after 2, 4, 7, 32 and 112 months, respectively, and one of them (with PRCA) achieved complete remission. 35 pts (50.7%) died, because of infection (9 pts), AML (4 pts), cachexia (4 pts), other hematological diseases (12 pts), hemorrhage (2 pts), heart failure (1 pt), stroke (2 pts) and other causes (9 pts). 10 pts (14.5%) are still receiving ICT.

Summary/Conclusions: In conclusion, in our experience ICT appears feasible and effective, in terms of reduction of SF and OS, even in a population of elderly pts, if carefully selected.

VCAM-1 AS A NOVEL DRUG THERAPY TARGET OF BONE MARROW MESENCHYMAL STEM CELLS IN MULTIPLE MYELOMA

A. Ortiz-Ruz1,2, C. Alicaia, L. Alejandrea, M.M. Luçza, L. Mariaa, G. Miguel1, M.-L. Joaquina

1-Haematological Malignancies Clinical Research Unit, CNIO, 2-Hematologia Traslacional, Hospital Universitario 12 de Octubre, Madrid, Spain

Background: Multiple myeloma is characterized by the clonal proliferation of malignant plasma cells in the bone marrow microenvironment. The pathogenesis of M. may be in part, in the pathological interactions between myeloma cells and the mesenchymal stem cells (MSC). The interactions between myeloma cells and bone marrow cells are establish through surface receptors (e.g. integrins, cell adhesion molecules, etc.), which determine tumor growth, survival, migration and drug resistance. Mesenchymal stromal cells modulate the pattern of myeloma markers on the cellular surface in vitro towards a less differentiated phenotype. However, the exact mechanism by which mesenchymal stromal cells carry out their functions is not yet fully understood.

Aims: To evaluate the effect of MSCs from healthy donors and myeloma patients over malignant plasma cells and the molecular changes produced for the interaction each other.

Methods: Interactions between both cell types were studied through different co-cultures studies. We evaluate differences between culturing primary M. cells and MSC and MM cell line RPMI 8226. Pathological MSCs were extracted from the bone marrow of newly diagnose MM patients. On the other hand, purified healthy MSCs, will be isolated from donor patients. Pathological or healthy MSCs were cultured and co-cultured 24h after seeding with MM plasma cells RPMI 8226 for duplicates at 24, 48 and 72h. The phenotypical and molecular effect of the interaction of both cells were characterized by viability through trypan blue, cell apoptosis percentage (7AAD) and variations on expression of cell surface proteins (MSCs: CD90, CD105, CD106 and CD54. MM cell: CD138, CD38, CD49d and CD11a) using flow cytometry, and statistically analyzed with GraphPad.

Results: We observed a decrease of apoptosis in MM plasma cells when are in co-culture with pathological MSCs at short-term (24h, 7AAD positive cells MM alone: 4.8%, MM in co-culture: 0.4%) and mid-term (72h, 7AAD positive cells MM alone: 16.4%, MM in co-culture: 10.7%) compared with MM plasma cells alone. However MM plasma cells not decreases the level of apoptosis at mid-term with healthy MSCs in co-cultures (72h, 7AAD positive cells MM alone: 16.4%, MM in co-culture: 18.0%). The molecular analysis showed a correlation between MSC lack of protection on MM plasma cells and the decrease in the levels of expression of VCAM-1 (CD106).

Summary/Conclusions: As reported in literature CD106 expression increase when MSCs are co-cultured with plasma cells. Adhesion of tumor cells to BMSC activates many pathways resulting in upregulation of cell cycle and anti-apoptotic proteins. MM pathophysiology is supported by a strong interaction between CD106/CD49d. Changes in VCAM-1 and VLA-4 expression have been demonstrated in cell lines assays, and were corroborated with primary cells in the context of MSCs protection over MM plasma cell. Thus, MM pathological MSCs did not change VCAM-1 levels and MM plasma cell protection be held. However, healthy MSCs have the capacity to modulate the VCAM-1 in mid-term to avoid the protection effect. Therefore, these results suggest MSCs VCAM-1 as potential drug therapy target in MM disease.

RALA AND RALB MEDIATE CELL SURVIVAL INDEPENDENTLY OF ONCOCGENIC RAS AND PROVIDE POTENTIAL THERAPEUTIC TARGETS IN MULTIPLE MYELOMA

M. Seibold1,*, T. Stühmer1, N. Schmiedl1, D. Brünnert1, A. Mottok2, E. Leich2, A. Rosenwald2, C.-J. Scholz2, M. Chatterjee1, H. Einsel1, R.C. Bargou4, T. Steinbrunn1

1-Department of Internal Medicine II, University Hospital of Würzburg, 2-Institute of Pathology, University of Würzburg, Würzburg, 3-Life & Medical Sciences Institute, University of Bonn, Bonn, 4-Comprehensive Cancer Center Mainfranken, University Hospital of Würzburg, Würzburg, Germany

Background: Genetic mutations and the bone marrow microenvironment contribute to disease progression, aggressive phenotype, and shorter survival in multiple myeloma (MM). Oncogenic RAS is one of the most common mutations in MM. Pathway activation through oncogenic RAS is associated with promotion of disease progression and shorter survival. Cell survival and proliferation in MM are mainly mediated via classical signaling pathways such as MEK/ERK and PI3K/Akt. Since there is a lack of specific RAS-inhibitors for clinical use, it is important to identify and analyze associated pathways, which may provide useful alternative targets for MM therapy. The small GTPase Ral has previously
been implicated in putative downstream signaling of RAS, and may therefore promote cell proliferation and survival of MM cells.

**Aims:** We used shRNA-mediated knockdown of RalA and RalB isoforms to appraise their role as potential therapeutic targets and to analyze their connection to important signaling pathways, which regulate MM cell survival and proliferation. Because oncogenic RAS is a potential activator of the Ral pathway, we investigated the role of this signaling route in oncogenic RAS mutant cell lines.

**Methods:** Immunohistochemical stainings of bone marrow trephines of MM patients and Western analysis of primary MM cells and MM cell lines were performed to evaluate Ral protein expression. Transient or stable knockdown of RalA or RalB was achieved by electroporation of MM cell lines and the effect on cell proliferation was measured with flow cytometry using annexin V/propidium iodide staining. Ral pulldown assays were applied to test potential dependence of Ral activation on oncogenic RAS. Furthermore, RNA sequencing was performed to compare RAS and Ral gene expression signatures after respective knockdowns.

**Results:** Both Ral isoforms were expressed in primary MM cells and MM cell lines, with RalA showing the most prominent and consistent protein expression levels. shRNA-mediated knockdown of RalA strongly induced apoptosis in two thirds of the tested cell lines, whereas RalB depletion did impair MM cell survival in less than half of the cell lines. Western analysis revealed no alteration of classical RalGDS/RalB pathway activation after Ral knockdown. Ral activity appears to be independent of oncogenic KRAS or NRAS. In addition, RNA sequencing revealed differing gene expression signatures for RAS and Ral.

**Summary/Conclusions:** Ral and its effector network constitute potential therapeutic targets in MM, which are activated independently of oncogenic K- or NRAS. Therefore, investigation of the functional network of Ral may be important to identify useful clinical targets.

**CXCR4 MUTATIONS FOUND BY USING DEEP SEQUENCING WITHOUT SORTING B CELLS, AND PROGNOSTIC IMPLICATION IN WALDENSTROM MACROGLOBULINEMIA**

S.-M. Kim1,2, D.W. Shin2, K. Im1, S.M. Hwang3, J.-A. Kim2, H.S. Park2, D.S. Lee2

1Cancer Research institute, 2Department of Laboratory Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of

**Background:** Waldenstrom macroglobulinemia (WM) is a lymphoplasmacytoid lymphoma with IgM monoclonal gammopathy. Most of WM harbor MYD88 L265P and one third of WM with MYD88 present CXCR4 mutations. Currently, frequency of CXCR4 mutations and its clinical implication is not reported in Asian patients with WM.

**Aims:** We investigated the profiles of CXCR4 and MYD88 mutation in correlation with prognostic implication. To detect minor cell population with CXCR4 mutation, we adopted a ultra-deep sequencing strategy for CXCR4, which can detect specific variants <1% of the cell population.

**Methods:** Allele-specific PCR for MYD88 was performed on 37 patients with WM, along with 161 patients with B-cell neoplasms (diffuse large B-cell lymphoma (DLBCL), B-cell acute lymphoblastic leukemia (B-ALL), chronic lymphocytic leukemia (CLL)). Deep-sequencing for CXCR4 and interphase fluorescent in situ hybridization (FISH) for 6q deletion was performed on 31 patients with WM. Clinicopathologic features were compared among 3 groups according to MYD88 and CXCR4 mutation status (Group 1, MYD88 WT and CXCR4 WT; group 2, MYD88 WT and CXCR4 Mutation; group 3, MYD88 Mutation and CXCR4 WT; statistical comparison, Fisher exact test, one-way ANOVA).

**Results:** MYD88 L265P mutation was detected in 81.3% (26/32) patients with WM, 10.8% (9/83) in patients with DLBCL, 9.5% (6/63) in patients with CLL, 0% (0/15) in patients with B-ALL, and 0% in 200 healthy persons. Among the 31 WM patients, 6 patients have CXCR4 mutation (19.4%) in the c-terminal domain (Figure 1); 1 frameshift mutation and 5 nonsense mutations. Two frameshift mutations and 1X, an novel nonsense mutation, were also found in 2 sites. All of them had MYD88 L265P mutation. FISH revealed 6q21 deletion in 14 patients (43.8%), and IGH rearrangement in 9 patients (28.1%). There was no correlation among cytogetic aberrations and genetic mutation (MYD88 and CXCR4). IgM levels of group 2 (MYD88 WT and CXCR4 WT) were significantly higher than that of group 1 (MYD88 WT and CXCR4 WT) (P=0.024). Moreover, IgG level was significantly lower in group 1 compared to group 3. Other clinical characteristics such as age, Hb, platelet, adenopathy, hyperviscosity showed no significant difference among 3 groups. Group 1 showed adverse survival and 1 year survival rate of group 1 (66.7%) was lower than group 2 (83.4%), though it was not statistically significant (P=0.410). There were no death events in group 3 (MYD88 Mutation and CXCR4 WT) patients during the research period.

**Summary/Conclusions:** The frequency of CXCR4 mutation in Korean WM was similar to those of Caucasian. We suggest that ultra-deep sequencing using Throwaway sequencing can detect minor cell population of CXCR4 mutation. Patients with MYD88 WT and CXCR4 WT showed higher IgM level and lower survival, suggesting an adverse prognostic implication. This is the first report on CXCR4 mutation in Korean WM patients.

**Background:** Translocation t(14;16)(q32;q23) in plasma cells is considered as a strong negative prognostic factor in patients with multiple myeloma (MM). The oncogenic potential of this chromosomal aberration is based on the overexpression of the c-MAF protooncogene (located at 16q23) under strong enhancer of IgH gene (14q32). Although the IgH/MAF positive cases comprise just 2-4% of MM patients, the evaluation of this aberration is an integral part of the cytogenetic risk stratification according the RISS. The translocation t(14;16) is common in myeloma (MM) and Waldenstrom’s macroglobulinemia. However, the role of t(14;16) in MM as having at least one of the following aberrations: deletion of 17p13 (TP53 gene), translocation t(4;14)(p13;q32) and translocation t(14;16)(q32;q23) determined by FISH. However, the unequivocal poor prognostic value of t(14;16)(q32;q23) was not confirmed in several MM series thus further studies are needed.

**Aims:** The aim of our study was to assess the impact of t(14;16)(q32;q23) on event free (EFS) and overall survival (OS) in cohort of IgH/MAF positive MM patients in comparison with control group of 30 MM IgH/MAF negative cases.

**Methods:** During the years 2004 to 2016, we examined 870 bone marrow samples of MM patients on immunofluorescently labeled plasma cells (clg FISH). The basic FISH panel included 4 specific DNA probes (Abbott-Vysis, Kreatech and MetaSystems) detecting: the IgH gene rearrangement (1), deletion 13q14 (RB1 gene/monosomy 13 (2), gain of 1q21/deletion of 1p32 (3) and deletion of TP53 gene (4). Cases with rearranged IgH gene were gradually examined for 3 specific translocations- 1) t(11;14)(q13;q32), 2) t(4;14)(p13;q32) and 3) t(14;16)(q32;q23). Kaplan-Maier analysis was performed to evaluate OS and EFS.

**Results:** Translocation t(14;16) was identified in 19 out of 870 patients (2.2%). Eighteen patients were examined at the time of diagnosis and one at the time of the progression of asymptomatic myeloma to symptomatic disease. Relapse and/or disease progression occurred in 15 patients. The median event-free survival (EFS) was 13 months in t(14;16) carriers (range 3 – 62 months) and 22.5 months in controls (range 3-71 months, p=0.285). Fourteen (14;16) positive patients died. The median overall survival (OS) was 25 months (range 10-204 months) in comparison with 52 months in control group (range 3-132 months). However, the difference in OS was not statistically significant (p=0.155). In 15 t(14;16) positive patients (83.3%), two or more additional chromosomal changes were detected by FISH (monosomy/deletion of chromosome 13 being the most frequent). In four cases, (14;16) was detected together with another high risk chromosomal change - deletion of TP53 gene - and all these patients died within median of OS 12.5 months (range 10-16).

**Summary/conclusions:** Beside its supposed negative clinical impact, the examination of t(14;16) is not always included in routine diagnostics of chromosomal changes and its prognostic significance should be proved in large series of MM patients. Our data substantiate the trend of worse clinical outcome (shorter OS) in t(14;16) positive group compared to IgH/MAF negative MM patients. The detailed analysis of other clinical parameters, type of therapy, combination with other chromosomal aberrations will be performed to prove its role as an independent prognostic factor.

THE ROLE OF NEUROTROPHINS AND ANGIOGENIC CYTOKINES IN THE PATHOPHYSIOLOGY OF PERIPHERAL NEUROPATHY IN PATIENTS WITH MULTIPLE MYELOMA

K. Łuczkowska1,*, Z. Litwińska1, E. Pius-Sadowska1, A. Sobuś1, E. Paczkowska1, B. Machaliński1

1Department of General Pathology, Pomaranian Medical University in Szczecin, Szczecin, Poland

Background: The introduction of new treatment modalities has changed significantly the prognosis of multiple myeloma (MM) patients. The novel drugs and schemes of treatment of MM have contributed to substantial extend of the overall survival time of patients. However, the administration of some of the treatments, especially induction or bortezomib, is associated with occurrence of a serious and common side-effect problem, which is the drug-induced peripheral neuropathy. The mechanism of the development of the peripheral neuropathy is poorly understood. Nevertheless, one of its potential cause, could be inadequate concentrations of crucial trophic factors, including neurotrophic and angiogenic factors, which are responsible for proliferation, differentiation, survival and death of neuronal and nonneuronal cells.

Aims: The aim of this study was to elucidate the potential relationship between concentration of neurotrophic and angiogenic factors and development of peripheral neuropathy in the natural clinical course of the disease and, especially, induced by treatment regimen: VMP (bortezomib, melphalan, prednisone) or VTD (bortezomib, thalidomide, dexamethasone) in patients with MM.

Methods: Peripheral blood samples were collected from patients classified into two groups: i) patients with multiple myeloma, without neuropathy and before therapy; and ii) patients with peripheral neuropathy 3 or 4 induced in the therapy. The control group consisted healthy age–matched subjects. Assessment of concentrations of neurotrophins (BDNF, NSE) and angiogenic factor (PDGF) were performed using Luminex technology, which utilize microbeads coated with fluorescently labeled antibodies.

Results: Concentration of BDNF, PDGF and NSE were significantly decreased in patients after treatment regimen involving VMP or VTD who have developed peripheral neuropathy grade 3 or 4, compared with patients with newly diagnosed MM without neuropathy, before therapy and control healthy group. Additionally, plasma levels of both neurotrophins and PDGF in patients before therapy were higher, then in control group. Obtained results may be caused by the changes in an activity of the transcription factor NF-κB during the treatment of MM, since reduction of NF-κB concentration is associated with decrease in the transcription of genes encoding BDNF, NSE and PDGF.

Summary/Conclusions: Alterations in the concentration of BDNF, PDGF and NSE suggest the cause and effect relationship between these factors and the development of neuropathy in patients with MM. Comprehensive elucidation of this phenomenon may contribute to the extension of the knowledge concerning the pathogenesis of neuropathy, and might well lead to reduction of the incidence of polynueropathy in MM patients in the future.

INFLUENCE OF XRCC5, XRCC4, NFKB2, AND BIRC5 GENES POLYMORPHISMS IN THE RISK AND PROGNOSIS OF MONOCLONAL GAMMOPATHIES

L. Balanco1, M.S. Melo1, A.C. Gonçalves1,2, R. Alves1,2, C. Geraldes1,2,3, E. Correia1,2,3, Ribeiro1, L. Mota-Vieira1, A.B. Sarmento-Ribeiro1,2,3,*1

1Applied Molecular Biology and University Clinic of Hematology, 2CIMAGO, Faculty of Medicine University of Coimbra, 3Clinical Hematology Department, Centro Hospital e Universitário de Coimbra (CHUC), Coimbra, 4Molecular Genetics and Pathology Unit, Hospital do Divino Espírito Santo de Ponta Delgada, EPER, Ponta Delgada - Azores, Portugal

Background: Monoclonal gammapathies (MG) are a group of disorders characterized by the proliferation of monoclonal plasma cells, which produce and secrete monoclonal immunoglobulin (M protein). Symptomatic multiple myeloma (MM) is defined by the clonal proliferation of plasma cells. MM is consistently preceded by a pre-neoplastic entity, called monoclonal gammapathy of undetermined significance (MGUS), with an intermediate phase of indolent multiple myeloma (MMi). This disease is a heterogeneous hematological neoplasm characterized by the proliferation of clonal, long-lived plasma cells within the bone marrow (BM) secretoring monocolonal proteins and by the presence of so-called CRAB criteria and/or biomarkers of malignancy (as clonal BM plasma cells > 10%, involved/uninvolved serum free light chain ratio >100, >1 focal lesion in MRI studies). Genetic instability and several molecular abnormalities are hallmarks of MM cells. Alterations in DNA repair pathways, namely abnormal activity of non homologous end–joining (NHEJ) repair pathway, are involved in the disease onset and progression. Moreover, it has been observed that virtually all primary MM samples have constitutive nuclear factor-κB (NF-κB) pathway activity, having this pathway a well–established role in MM pathogenesis.

Aims: To explore the role of genetic polymorphisms of genes involved in NHEJ repair pathway (XRCC5, XRCC4) and in NFκB pathway (NFKB2, and BIRC5) may have impact in MG susceptibility and prognosis.

Methods: In the present, a hospital-based case-control study, we analyzed eight polymorphism in four genes (XRCC5, XRCC4, NFKB2, and BIRC5), by genotyping 189 individuals (63 MM patients and 126 controls) using TaqMan qPCR. Results are expressed in terms of frequencies of allele, genotype, haplotype, and genetic profiles, and their correlation with MG susceptibility. The strength of association between polymorphisms and disease risk was assessed by odds ratio (OR) with 95% confidence interval (CI95%) calculated by logistic regression. We also investigated the association of these SNPs with overall survival through Kaplan Meier curves. All statistical analyses had a significance levels of 95%.

Results: In the patient group, 51% (32/63) of the individuals were females and 49% (31/63) were males; the mean age was 70.1±10.25 years old. Among the controls 49% (31/63) were females and 51% (32/63) were males; the mean age was 69.90±10.06 years old. Most of the patients were diagnosed with multiple myeloma (84%, 53/63) and the remaining ones (16%, 10/63) were diagnosed with smoldering multiple myeloma. According to the ISS classification, 43% (27/63) of patients are in stage III. The data analysis revealed two associations of the studied gene polymorphisms with MG. First, the analysis by gender stratification suggested a decreased predisposition to MG in male carriers of NFKB2 rs12769316 GA and AA genotypes (OR 0.346, 95%CI 0.124–0.965, p=0.043). Second, we observed that patients with BIRC5 rs9094341 CC genotype had a highly significant lower overall survival (recessive model: HR 4.89, 95%CI 5.06 199.70, p<0.01). BIRC5 GGC haplotype (rs4789551, rs9904341, and rs8073069) was found in one patient and absent in controls.

Summary/Conclusions: The present study suggests that NFKB2 gene variant (rs12769316, allele A) may be associated with MG susceptibility in males, and BIRC5 (rs9094341) CC genotype may negatively influence MG prognosis. Nonetheless, further studies are needed to validate these findings, enlighten the role of genetic polymorphisms in MG susceptibility and prognosis.

SILENCE OF LONG NONCODING RNA MALAT1 BY RNA INTERFERENCE INHIBITS PROLIFERATION AND INDUCES APOPTOSIS IN MULTIPLE MYELOMA

H. Liu1,*, Z. Gong1,2, W. Yang1

1Hematology, Shengjing Hospital of China Medical University, Shenyang, China
2The University of Texas, MD Anderson Cancer Center, Houston, United States

Background: Multiple myeloma (MM) is a neoplastic plasma-cell disorder characterized by abnormal proliferation of monoclonal plasma cells in bone marrow leading to various end-organ damages. Altered long non-coding RNAs (lncRNAs) levels can result in aberrant expression of gene products that may contribute to cancer biology. Metastasis-associated lung adenocarcinoma transcript 1 (MALAT1), an evolutionarily highly conserved mRNA-like IncRNA was originally identified with high expression in metastatic non-small-cell lung cancer and reported to be up-regulated in many other cancers. However, the function of MALAT1 in MM remains unknown.

Aims: Our study aimed to evaluate the role of MALAT1 on proliferation as well as apoptosis in MM cells in vitro and tumorigenic ability in vivo, following transfection with MALAT1–specific short hairpin RNA (shRNA) expression plasmids.

Methods: Levels of MALAT1 in human myeloma cell lines were detected by real-time polymerase chain reaction (RT-PCR) analysis. The effects of MALAT1 shRNA in MM were investigated in vitro and in vivo.

Results: We found that MALAT1 was high expressing in RPMI8226 and U266 cell lines. Overexpression of MALAT1 by shRNA significantly inhibited the proliferation through cell cycle arrest at G1 phase and induced apoptosis, which was closely associated with expression of caspase-3/9, downregulation of Bcl-2 and upregulation of Bax. Study in vivo revealed that silencing of MALAT1 delayed the tumor growth and led to apoptosis in mice bearing myeloma xenograft.

Summary/Conclusions: MALAT1 may serve as a promising novel therapeutic target in human MM. Notably, the inhibition of MALAT1 by shRNA may prove to be an effective genetic therapeutic strategy for MM treatment.

LONG NON-CODING RNA MEG3 FUNCTIONS AS A COMPETING ENDORGENOUS RNA TO REGULATE PTEN EXPRESSION BY SPONGING Mir-181A IN MULTIPLE MYELOMA

L. Chen1,*, H. Bai1, H. Zhu1, X. Shen1, J. Li1, W. Yu1

1the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, China

Background: Long non-coding RNA maternally expressed gene 3 (MEG3) plays a critical role in cancer progression and metastasis. However, the overall biological role and regulatory mechanism of MEG3 in multiple myeloma (MM) development and progression remains largely unknown.

Aims: To explore the tumour suppressor role of IncRNA MEG3 in MM and further reveal the mechanism of MEG3 functions as ceRNA to contribute to MM pathogenesis.

Methods: MEG3 expression was measured in MM patients by real-time PCR.
The effect of MEG3 on cell apoptosis, cell proliferation and angiogenesis were gained from CCK-8, flow cytometric analysis and transwell invasion assays in MM cell lines ARP-1 and LP-1. Insights of the mechanism of competitive endogenous RNA (ceRNA) were gained from bioinformatic analysis, luciferase reporter assays and RNA binding protein immunoprecipitation (RIP) assay.

Results: MEG3 expression was significantly decreased in MM patients with advanced stage (II and III) and increased in patients with high plasma (non-IgG) protein level. Overexpression of MEG3 promoted cell apoptosis and inhibited cell proliferation, migration and angiogenesis in MM ARP-1 and LP-1 cell lines. Furthermore, MEG3 increase the expression of phosphatase and tensin homolog (PTEN) and consequently inhibit MM cell proliferation and angiogenesis through sponging miR-181a in MM cells in a manner limited by PTEN by luciferase assay.

Summary/Conclusions: MEG3 functions as a tumor suppressor in MM. High expression of MEG3 is a marker for good survival. We reveal a novel mechanism that MEG3 as a ceRNA of the PTEN gene by competing for miRNA-181a binding sites and thereby regulate the expression of the PTEN mRNA.

IMPROVE RISK-STRATIFICATION OF MULTIPLE MYELOMA PATIENT WITH MICROFLUIDIC DEVICES

C. Li1, L. Gao1, Y. Zeng1, X. Zhang1, J. Zhong1,∗

1University of Southern California, Los Angeles, United States

Background: Cytogenetic alterations are required for risk stratification of multiple myeloma (MM); however, current pathology assays performed on bone marrow samples directly can produce false negatives due to the unpredictable distribution and rarity of MM cells. A more accurate method is needed for MM diagnosis and risk-stratification. We develop a new microfluidic device to facilitate CD45-depletion for enhancing the detection of cytogenetic alterations in plasma cells.

Aims: Improve accuracy of risk stratification for multiple myeloma patients

Methods: Bone marrow samples from 48 MM patients were divided into two parts each. One part was directly detected by classical flow cytometry and FISH while the other part was first enriched by microfluidic size selection and then underwent CD45-depletion (MF-CD45-TACs). The enriched samples were then analyzed by flow cytometry and FISH and compared to the classical analysis.

Results: MF-CD45-TACs significantly increased the percentage of CD38+/CD138+ cells to 37.7%±20.4% (P<0.001) compared to 10.3%±6.5% in the same marrow. After the MF-CD45-TACs enrichment, the detection rate of IgH rearrangement, del(13q14), del(17p) and 1q21 gains rose to 56.3%(P<0.001), 37.5%(P<0.001), 22.9%(P<0.001) and 41.7%(P<0.001), respectively, all significant increases compared to untreated samples.

Summary/Conclusions: We have developed a rapid, simple assay for improved diagnostics and risk-stratification for MM. With more precise diagnosis, the clinical outcomes of MM will be significantly improved.

PB1942

SERUM FREE LIGHT CHAIN RATIO IS AN INDEPENDENT RISK FACTOR FOR PROGRESSION IN MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE

R. Cherif1,∗, B. Salah Eddine1

1University of Southern California, Los Angeles, United States

Background: Monoclonal gammopathy of undetermined significance (MGUS) is a premalignant plasma cell proliferative disorder found in approximately 3% of the general population 50 years of age and older. MGUS is associated with progression to multiple myeloma or related malignancy at a rate of 1% per year. Thus the risk of malignancy for a 50-year-old patient with a 25-year life span is 25%. Aims: We hypothesized that the presence of monoclonal free kappa or lambda immunoglobulin light chain in monoclonal gammopathy of undetermined significance (MGUS), as detected by the serum free light chain (FLC) assay, increases the risk of progression to malignancy.

Methods: 90 Patients seen at the Hematology consultation from 2010 to 2015 with MGUS have a serum Mprotein less than 30 g/L, bone marrow plasma cells less than 10%, and no anemia, hypercalcemia, lytic bone lesions, or renal failure that would be indicative of a malignant plasma cell disorder.

The prognostic effect of abnormal kappa-to-lambda FLC ratio on progression of MGUS was studied. We also examined whether the risk of progression varied depending on the extent to which the FLC ratio was abnormal (the normal reference range of k/λ ratio 0.26 to 1.65).

Results: The median age at diagnosis of MGUS was 59 years (35-92years). 62 Womans and 28 Mans Sex ratio=2.2. Serum electrophoresis and immuno electrophoresis or immunofixation was done in 85 patients. Of these, The median serum M protein size at diagnosis was 12 g/L (1.7-28.5 g/L), IgG monoclonal - 88% (75%), and non IgG monoclonal - 22 patients (25%). A monoclonal light chain was detected in 62 patients, as detected by the serum free light chain (FLC) assay increases the risk of progression to malignancy. An abnormal FLC ratio (kappa-lambda ratio <0.26 or >1.65) was detected in 27 (30%) patients. At a median follow-up of 5 years, malignant progression had occurred in 6 patients (6.6%) with an abnormal serum FLC ratio.

Summary/Conclusions: A novel, highly sensitive serum free light chain (FLC) assay is now available for clinical practice. The risk of progression in patients with an abnormal FLC ratio was significantly higher compared with patients with a normal ratio, and was independent of the size and type of the serum monoclonal light chain (k or λ). Patients with an abnormal serum FLC ratio, non-immunoglobulin G (non-IgG) MGUS, and a high serum M protein level (>15 g/L) had a major risk of progression.

PB1943

INTENSITY OF EXPRESSION OF MULTIDRUG RESISTANCE GENES AFFECT ON THE OVERALL SURVIVAL OF PATIENTS WITH MULTIPLE MYELOMA WERE TREATED WITH BORTEZOMIB AND ASSOCIATED WITH THE INITIAL MULTIDRUG RESISTANCE

Y. Chernykh1,∗, A. Golenkov1, L. Vysotskaya1, K. Belousov1

1clinical haematology, Moscow Regional Research and Clinical Institute, Moscow, Russian Federation

Background: Bortezomib is an important drug in multiple myeloma (MM) treatment, but the resistance to this treatment exist. Many conflicting data suggests that cellular overexpression of multidrug resistance (MDR) genes may reduce the effectiveness of bortezomib - containing treatment. The main indicator of the effectiveness of the treatment of MM is the overall survival of patients.

Aims: We evaluated the changes of intensity of expression of MDR genes in patients with newly diagnosed and refractory/relapsed multiple myeloma and the effect of expression of MDR genes such as MDR 1, MRP 1, BCRP, LRP on the overall survival of patients after treatment with bortezomib-containing therapy.

Methods: 51 MM patients (30 men and 18 women) aged 48 to 77 years (median 60 years) with stage III MM by classification Durie-Salmon were studied. 15 patients were included in a group of newly diagnosed (ND) MM. 15 patients were in group of a clinically refractory/relapsed (RR) MM. The bone marrow in this group of patients were studied after treatment with alkylating agents at the time of registration of resistance to the given therapy. In the future, all patients were treated by bortezomib - containing chemotherapy regimens.

Multidrug resistance genes were determined by semi-quantitative polymerase chain reaction reverse transcription. The degree of expression was assessed by semi-quantitative visual assessment from 0 (no electrophoretic band) to 4 points (bright glow of the transcript). The overall survival (OS) was analyzed by the Kaplan-Meier method, with the use of Cox-Mantel test. Differences were considered statistically significant at p <0.05.

Results: In both groups of patients there were comparable expression of all studied MDR’s genes. The development of clinical resistance to treatment with alkylating agents were accompanied by an increase in mRNA expression of all studied genes. However, the statistically significant increase the expression of the intensity obtained for LRP gene only (the average intensity of the expression of mRNA LRP gene in ND MM 0.9±0.24, with RR MM 1.9±0.34, p<0.05). The MDR 1 mRNA expression was 1.5±0.34 in the group of ND MM and 1.6±0.31 in the group of RR MM, p=0.05. The expression of mRNA of MRP 1 and BCRP are 1.07±0.21 and 1.63±0.15 respectively before treatment and increased to 1.73±0.31 and 2.13±0.35 respectively in the group of RR MM, p=0.06. OS was negatively associated with high LRP gene expression only in group of ND MM (median of OS in patients with high LRP gene expression was 16 months and in three months with low LRP gene expression).

Summary/Conclusions: High expression of LRP gene is associated with worse overall survival in patients with newly diagnosed MM treated with bortezomib-containing chemotherapy programs. "Genetic resource MDR" in MM is due mainly to the initial multidrug resistance. The treatment of MM by alkylating drugs increase the existing at the time of diagnosis of MDR activity of genes.

PB1944

ASSOCIATIONS OF IL-1, IL-4 AND TGF-Β1 POLYMORPHISMS WITH CYTOTOGENIC PROFILES IN PATIENTS WITH MULTIPLE MYELOMA

A. Pavlova1,∗, I. Pavlova1, L. Bubnov1, S. Beissmeltsevs2, E. Kleina3, A. Garulfina4, I. Martynkevich4, S. Voloshin3, A. Chechetkin4

1Haematology clinic, Moscow Regional Research and Clinical Institute, Moscow, Russian Federation

Background: Multiple myeloma (MM) is a plasma cell malignancy characterized by complex cytogenetic and molecular genetic aberrations. Those cytogenetic abnormalities occur at different stages of the disease. The chromosomes ploidy status and Ig rearrangements are two genetic criteria that are used to help stratify patients into prognostic groups.

Aims: The aim of the study was to analyze correlation between cytogenetic profiles and some cytokine genotypes in 24 patients with MM (Caucasoid inhabitants of the North-West region of Russia).

Methods: Genomic DNA was extracted from the peripheral blood; gene genotyping was carried out in the DNA samples. Genotyping was performed using the polymerase chain reaction reverse transcription. The degree of expression was determined by a semiquantitative polymerase chain reaction method.
Aims: immune response genes combinations in chronic lymphoproliferative disorders

Methods: The study included 176 patients aged 22-86 years (median - 61 and multiple myeloma. It is noted that in the pathogenesis of hematological diseases genetic abnormalities was performed by standard GTG-method and interphase FISH.

Results: Previous results allow us to describe some cytokine genotype markers associated with the development of MM (IL-1α-889 TT, IL-1β -3962 TT, IL-6 -174 GG and IL-6 n5655 GG) as additional negative prognostic markers but IL-4 -33 CC and TGF-β1 codon 25 GG genotypes as additional positive prognostic markers (2). However, in some MM patients we found presence of negative and positive markers together (mixed markers; gr. 3). We analyzed cytoprofics in MM patients with different prognostic markers in their genotypes (Table 1).

CORRELATION DEPENDENCE OF CHRONIC LYMPHOPROLIFERATIVE DISORDERS, MULTIPLE MYELOMA FROM CHANGES OF IMMUNE RESPONSE GENES PROFILE

Background: Hematological malignancies are multifactorial diseases in the development of which play a role as environmental factors and genetic determinants. Such genes may include the presence in human genome of allelic variants of the regulatory regions of the innate immune response genes. At present time, they are considered as real risk factors for these diseases in a person with a certain set of genetic variants. Their distribution among the population corresponds to the population laws and has its ethnographic features. Analysis of the individual associations of genes polymorphic variants involved in the implementation of the immune response does not sufficiently complete answer about their role in the formation of predisposition to the development of chronic lymphoproliferative disorders (CLD) and multiple myeloma (MM). It is noted that in the pathogenesis of hematological diseases contribute significantly to certain combinations of immune response genes.

Aims: Analysis of interactions between genes based on the distribution of immune response genes combinations in chronic lymphoproliferative disorders and multiple myeloma.

Methods: The study included 176 patients aged 22-86 years (median - 61 year), identifying themselves as Caucasians residing in one region in the north-east of the Russian Federation. This group consisted of 80 patients with chronic lymphocytic leukemia/small lymphocytic lymphoma (45%), 72 with multiple myeloma (41%), 10 with diffuse large B-cell lymphoma (6%) with marginal zone lymphoma (3%) four with mantle cell lymphoma (2%), three with lymphoplasmacytic lymphoma (2%) and one patient with follicular lymphoma (1%).

Genotyping of polymorphism of the innate immune response genes TLR2 (rs5743708), TLR3 (rs3775291), TLR6 (rs5743810), TLR9 (rs5743836), IL1β (rs2856841), IL2 (rs2069762), IL4 (rs2243250), IL6 (rs1800795), IL10 (rs1850421), TNFα (rs34424920), TNFβ (rs1801274) was performed by polymerase chain reaction with allele-specific primers (LifeTech, Russia). Analysis of interactions between genes was performed using nonparametric GMDR program (Generalized Multifactor-Dimensionality Reduction) [Liu X.Y. et al., 2007, http://www.healthsystem.virginia.edu/internet/addiction-genomics/Software/].

Results: In the analyzed group of patients with CLD and MM identified almost 78 753 combinations of multi-genotyperous combinations of the 13 immune response genes is 1 594 323 theoretically possible, indicating the non-random nature of the combination of allelic variants of analyzed genes. A statistically significant two-, three-, four-, five-, six-, seven- and eight-loci model of inter-gene interactions at the investigated hematological malignancies: - IL4 (C-589T) and CD14 (C-159T) (p=0.0038); - IL4 (C-589T) and CD14 (C-159T) and IL6 (C-742G) (p=0.12, p<0.0005); - IL4 (C-589T) and IL17A (G-174T) and IL17A (C-819T) and IL17A (C-589T) and IL10 (C-1801274) and IL6 (C-174G) (p=0.16, p<0.0001); - IL4 (C-589T) and IL17A (G-174T) and IL10 (C-1801274) and TNFα (C-308A) and CD14 (C-159T) and IL2 (C-330G) (p=0.16, p<0.0001); - IL4 (C-589T) and IL17A (G-174T) and IL10 (C-1801274) and TNFα (C-308A) and CD14 (C-159T) and IL2 (C-330G) (p=0.16, p<0.0001); - IL4 (C-589T) and IL17A (G-174T) and IL10 (C-1801274) and TNFα (C-308A) and CD14 (C-159T) and IL2 (C-330G) (p=0.16, p<0.0001).

Summary/Conclusions: The findings suggest an important role of immune response genes in the development of a number of chronic lymphoproliferative disorders and multiple myeloma, and can later be used as diagnostic and prognostic markers of different types of hematological malignancies. In addition, the study shows that genomics research on normal cells is a unique opportunity for high and low risk of hematological malignancies studied, but also to determine their prognostic significance in the clinical course of these diseases.

PB1946

FEATURES OF STROMAL ELEMENTS HEMATOPOIETIC NICH IN MULTIPLE MYELOMA

Background: Structure of bone marrow stroma – mesenchymal stromal cells (MSC), endosteal stromal cells, and microvessels forming the hematopoietic niche and regulate the development of hematopoietic stem cells (HSC). Analysis of morphological changes of these elements of the hematopoietic niche is important to clarify the pathogenesis of multiple myeloma (MM).

Methods: To investigate the morphological and functional characteristics of stromal elements of the hematopoietic niche in bone marrow of patients with MM, as well as the characteristics of culture of mesenchymal stromal cells (MSC) and hematopoietic stem cells (HSC).

Results: Myeloma cellular composition of infiltrates were polymorphic. The surveyed patients were allocated to 3 types of infiltration is nodular, interstitial, diffuse. The histogenesis of infiltration was confirmed by IHC research with antibodies 7B3, CD 138, CD 38.Regardless of the type of infiltration in all patients were revealed marked focal destructive changes of bone tissue. The density of microvessels in IHC studies with antibodies to CD 31, CD34 c.l.l (Dako) was increased. A greater number of microvessels were detected in the endosteal area at all types of the bone marrow involvement (compared to normal), the total number of microvessels could statistically do not exceed such normal. A reduction in the expression of type I collagen bone matrix and the increase of collagen type IV expression, which is associated with increased microvascular density. Intravascular collagen type I was mellowed, ossification was reduced, most notably it revealed in areas of trabecules resorption. At the same time increased the amount of collagen type IV in endosteal spaces of the bone marrow. A typical feature was increased microvascular density in subendosteal and perivascular spaces.Cultural studies have shown a significant decrease of colony-forming ability of HSC mobilized peripheral blood of MM patients after cryopreservation. In vitro studies preliminary data on lack of differences in the phenotype of MSC bone marrow of patients with MM and phenotype from healthy individuals, but revealed the presence in the phenotype of MSC of MM patients Myeloma involvement (compared to normal).

Summary/Conclusions: Analysis of parenchymal-stromal relationships in treanopanobiopsy bone marrow of patients with MM evidence of their violation in the context of malignancy of lymphopoesis, while cultural studies have shown a decrease of colony-forming ability of HSC and proliferative capacity of MSC.

IMPACT OF RENAL IMPAIRMENT IN NEWLY DIAGNOSED MULTIPLE MYELOMA IN A REAL WORLD SETTING

V. Bove1,*, F. Villano1, L. Díaz1, E. Riva1
1Hematología, Hospital de Clínicas, Montevideo, Uruguay

Background: Renal impairment (RI) is a frequent complication of patients with newly diagnosed multiple myeloma (NDMM), reported in 15-40% with 10% requiring hemodialysis (HD). It is associated with higher early mortality (EM) and lower overall survival (OS). Early diagnosis and treatment with new agents improve these results.

Aims: Analyze renal response, OS and EM in NDMM with RI and compare them to patients with MM without RI.

Methods: All consecutive and unselected NDMM patients treated at Hospital de Clínicas, Montevideo, Uruguay, from January 2011 to June 2015 were included. Our database was completed prospectively and included clinical and laboratory characteristics of the disease, treatment, treatment-related adverse events, response, HD requirement, renal response and mortality.

Diagnosis of MM, response to treatment and degree of renal function recovery were based on the International Myeloma Working Group criteria. RI was defined as an estimated glomerular filtration rate (eGFR) <40 ml/min/1.73m², calculated by MDRD (Modification of Diet in Renal Disease) equation. Patients whose RI was explained by other causes were excluded. Early treatment was defined by initiation within 7 days after diagnosis. EM was defined as death within 3 months of diagnosis.

Results: MM was diagnosed in 52 patients, median age was 67 years (range 39-90), 61.5% were male, 38.5% had RI. The characteristics of the patients and front-line treatment are shown in Figure 1.

PB1950

THE EXPRESSION OF THE TRYPATASE POSITIVE MAST CELLS AND THE LEVELS OF IL-17, CORRELATE WITH ANGIogenic FACTORS IN PATIENTS WITH MULTIPLE MYELOMA

M. Kokonozaki1, C. Pappa2, R. Vyzoukaki1, A. Stavroulaki3,* M. Devetzoglou4, A. Papadopoulou1, I. Liapis4, A. Boula3, M. Alexandrakis5
1Laboratory of Haematology, University Hospital of Heraklion, 2Department of Internal Medicine, 3Department of Haematology, Venizelion Hospital, 4Department of Haematology, University Hospital of Heraklion, 5Medical School, University of Crete, Heraklion, Greece

Background: Angiogenesis in the bone marrow plays a very important role in the progression of multiple myeloma (MM). The procedure of angiogenesis is stimulated by several factors such as VEGF, FGF-2 and metalloproteinase that are secreted straight from the tumor cells. The presence of IL-6 in the microenvironment, induces the production and the secretion of several angiogenic factors that activate inflammatory cells of the matrix, like macrophages and mast cells to secrete more angiogenic factors. IL-17 is among the most important cytokines that have an important role in the development of myeloma tumor. IL-17 is a proinflammatory cytokine that is secreted primarily by CD4 (activated memory cells) and stimulate macrophages, fibroblasts and other cells that release several cytokines. It has been reported that IL-17, induces angiogenesis in humans by stimulating the migration of vessel endothelial cells and adjusting the production of various proangiogenic factors. In a previous study, it was found that increased levels in stage II and stage III, resolved after therapy. Additionally, blocking the receptor of IL-17, with an antibody, cancels the effects of IL-17.

Aims: Aim of this study is to assess the relationship of the MCD and IL-17, in angiogenesis of MM, as well as their correlation with known angiogenic factors in disease progression.

Methods: We studied 52 newly diagnosed patients with MM, 32 women and 20 men, aged 67±9.6 years. According to the ISS stage, 19 were stage I, 25 stage II and 16 stage III. Regarding the type of paraprotein that had been found, 31 IgG, 17 IgA and 4 patients with light chains. 20 age and sex-matched healthy volunteers, were used as controls. Serum samples and bone marrow biopsy samples were obtained from all patients prior to the initiation of treatment. Patients with impaired hepatic and renal function, chronic or acute infections, chronic inflammatory or autoimmune disorders or other malignancies were excluded from the study. We also excluded patients who were taking anti-inflammatory drugs, corticosteroids or bisphosphonates.

IL-17, bFGF and ANGIOP-2 were measured in patients’ serum with ELISA method according to the manufacturer’s instructions. The MCD assessed after immunohistochemical staining using monoclonal antibody to mast cell tryptase. The MCD was measured in three hot spots (maximum vasculature area) x 100 and then we measured mast cells x 400, using a graduated slide which corresponds to an area of 0.0625 mm². MCD was calculated as mean MCD / HPF.

Results: Statistically significant differences between patients and controls were observed in all measured parameters, MCD (p <0.001), bFGF (p <0.01) and ANGIOP-2 (p <0.01). All parameters were increased in parallel with ISS stages (p <0.001) in all cases. Finally, the MCD and IL-17 correlated significantly with all the measured parameters (p <0.001).

Summary/Conclusions: The mast cells increase in the bone marrow (BM) of patients with MM. They release several transmitters that promote direct and indirect the development of tumor angiogenesis. MM also becomes accompanied by increased angiogenesis in BM. In conclusion, mast cells and angiogenic factors seem to be important elements in the development of MM and become potential targets for the treatment and prognosis of the disease.
PB1951
HEALTHCARE RESOURCE UTILIZATION ASSOCIATED WITH DIFFERENT TREATMENT MODALITIES OF RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS IN THE US: FINDINGS FROM PREAMBLE
D. Kuter1, C. Chen2,2, S. Khare1, S. Perez2, T. Zyczynski2, C. Davis2, R. Viji2, 1Massachusetts General Hospital, Boston, 2Bristol-Myers Squibb, Lawrenceville, United States, 3Mu Sigma, Kamataka, India, 4Mu Sigma, Northbrook, 5Washington University School of Medicine, St. Louis, United States

Background: Proteasome inhibitors (PIs), immunomodulatory drugs (IMiDs) and treatments involving both a PI and an IMID (P+IMID) are the principal therapies for treating relapsed/refractory multiple myeloma (RRMM). The widespread adoption of these treatments may come with high healthcare resource utilization (HCRU), of which key drivers are reported in past research. It is important to further understand HCRU by different treatment modalities in real-world practice settings.

Aims: To evaluate HCRU in patients receiving different treatment modalities for RRMM.

Methods: US patients with RRMM, aged 18-80 y, with at least one prior therapy who initiated treatment with a PI, IMID or IMID+PI within 90 d before or 30 d after study enrollment (index therapy), were identified from PREAMBLE, an ongoing, prospective, multinational, non-interventional observational study. Patient data collected at each healthcare provider (HCP) visit, over a 3-y period or until the end of patient follow-up, included clinic/physician office visits; home healthcare; hospital outpatient and emergency room visits; and hospitalizations. Demographics and baseline characteristics were summarized using descriptive statistics. HCRU and its associated costs were analyzed using a standard per-1000 patients-per-month metric.

Results: 287 patients (median age 66 y; 56% male) were enrolled in the US. At the time of data cut-off (Sep 2016), 136 (47%) were still in the study and 151 (53%) had withdrawn; 92 (61%) of those withdrawn had died. Median (range) follow-up was 12.7 (0.5–4.1) mo. At study entry, patients were divided into three cohorts based on index therapy: PI (n=162, 56%); carfilzomib (n=82/162; bortezomib n=80/162), IMID (n=74, 26%); pomalidomide n=32/74; lenalidomide/thalidomide n=42/74), and P+IMID (n=51, 18%); carfilzomib and/or pomalidomide n=17/51; other n=34/51). The three groups were similar with regard to sex, race, disease status, ISS stage, comorbidities and number of prior therapies (Table 1).

The median duration of treatment (mDoT) was longer for patients on IMID (6.4 mo), but shorter for those on PI (4.2 mo) or P+IMID (4.4 mo). In the PI cohort, carfilzomib had a shorter mDoT than bortezomib (3.5 vs 4.7 mo). Of 3,220 total HCP visits, the most common type was clinic/physician office (2,732, 85%), followed by hospitalization (210, 7%) and hospital outpatient (54, 5%). Mean per-1000 patients-per-month total visits were higher for P+IMID (876) than for PI (750) and IMID (494). This remained true for clinic/physician office, hospital outpatient and home healthcare/other. Patients on PI had more visits for management of MM treatment-related events (16%) than those on P+IMID (10%) or IMID (7%) (Table 1). Notably, among patients on PI, those on carfilzomib had high mean per-1000 patients-per-month total visits (827), with per-1000 patients-per-month emergency room visits (18) and hospitalizations (78) higher than any other treatment; 19% (175) of visits were made for management of treatmen-related events.

Summary/Conclusions: Routine management of MM and treatment-related events drive HCRU, which may differ by treatment. Hospitalizations and hospital outpatient visits remain key drivers of HCRU in MM, which highlights an unmet medical need for effective therapy with better safety profiles.

ASSOCIATION OF SERUM HEAVY/LIGHT CHAIN PAIR SUPPRESSION WITH RISK FACTORS FOR PROGRESSION IN MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE AND SMOLDERING MYELOMA
I. Isola1,*, M.T. Sanz2, M.T. Cibeira1, L. Rosiol1, E. Lozano1, J.I. Aróstegui3, M. Elena4, N. Tovar1, J. Yagüe3, E. Mogas2, J. Bladé3, C. Fernández de Larre2
1Hematology (Amyloidosis and Myeloma Unit), Hospital Clinic de Barcelona, 2Immunology, Hospital de la Santa Creu i Sant Pau, 3Immunology (Amyloidosis and Myeloma Unit), 4Biochemistry (Amyloidosis and Myeloma Unit), Hospital Clinic de Barcelona, Barcelona, Spain

Background: Monoclonal gammopathy of undetermined significance (MGUS) and smoldering multiple myeloma (SMM) are conditions that usually precede symptomatic multiple myeloma (MM). Risk stratification is crucial, considering the heterogeneous progression rate among these patients and the chemoprevention trials encouraged for high risk individuals. A number of prognostic factors for progression have been identified. In this sense, the novel Hevylite assay now enables us to accurately measure each isotype-specific heavy and light chain (HLC). Recently, isotype-specific uninvolved HLC pair suppression was described as an independent predictor of progression to MM in patients with MGUS. The role of Hevylite as a prognostic factor in SMM is less investigated.

Aims: The aim of the present study was to analyze the impact of HLC pairs in a series of patients with high risk MGUS and SMM and their relationship with other previously described risk factors.

Methods: Forty-four patients diagnosed with high risk MGUS or SMM at a single institution from March 2014 through April 2016 were prospectively included in the present study. Patients were stratified according to the Mayo Clinic and the Spanish PETHEMA group models. Samples at diagnosis were tested for HLC concentrations for the three pairs (IgG, IgM and IgA) by immunonephelometry.

Results: The clinical characteristics and risk stratification of patients are summarized in Table 1.

Table 1. Patient characteristics and risk stratification.

An abnormal HLC-pair ratio was detected in 96% of MGUS and 94% of SMM patients, with no differences depending on the heavy chain isotype. A highly abnormal HLC ratio (<0.02 or >45) was present in 9 patients (1 with MGUS and 8 with SMM). HLC-pair suppression (i.e., IgG-k in patients with IgG-k gammapathy) was more frequent in patients with SMM (83% vs 46%, p=0.02). Severe HLC-pair suppression (>50% below lower level of normal) was present in 12 (27%) patients, the majority of which had a diagnosis of SMM (83%). Severe HLC-pair suppression was significantly associated with a highly abnormal (<0.125 or >8) serum free light chain (FLC) ratio (p=0.004), abnormal/normal bone marrow plasma cell ratio >0.95 (p<0.001) and immunoparesis (p=0.005), being present in 6 (86%) of the 7 patients with high risk SMM. Suppression of the other isotypes (i.e., IgA or IgM HLC pairs in a patient with IgG gammapathy) was identified in 33 (75%) patients, namely in 18 (69%) patients with MGUS and 15 (83%) patients with SMM (p=0.48), and was not significantly
associated with other risk factors for progression. Severe suppression (>50% below lower level of normal) was significantly more frequent in sEMD patients (33% vs 8%, p=0.04) and was associated with highly abnormal FLC ratio (p=0.001), abnormal/normal plasma cell ratio >0.95 (p=0.001), severe HLC-pair suppression (p<0.001) and highly abnormal HLC ratio at diagnosis (p=0.005). The “evolving” pattern of the serum M-protein was identified in 12 patients (28%) and it was significantly associated with either severe suppression of the HLC-pair or of the other isotopes. After a median follow-up of 18 months (range, 6-35) progression to symptomatic MM was observed in 3 patients. All 3 had a diagnosis of SMM with an “evolving” pattern, highly abnormal HLC-ratio and severe HLC-pair suppression.

Summary/Conclusions: The findings presented in this study indicate that highly abnormal HLC ratio, severe suppression of the HLC-matched pair and other isotype HLC pairs are associated with known risk factors for disease progression in patients with high risk MGUS and SMM. The HLC assay could become a valuable tool in the risk stratification of these patients.

EXTRAMEDULLARY MYELOMA IN THE “NOVEL AGENTS ERA”: OUTCOME, HETEROGENEITIES AND PECULIARITIES OF A COHORT OF 84 PATIENTS RETROSPECTIVELY ANALYSED IN A MONOCENTRIC EXPERIENCE
L. Torti1, A. Morelli1, F. Baccì2, P. Di Bartolomeo1
1Department of Hematology and Bone Marrow Unit , Pescara, 2Section of Hematopathology, Department of Hematology and Oncological Sciences, S. Orsola-Malpighi Hospital, Bologna, Italy

Background: Extramedullary disease is an uncommon manifestation in multiple myeloma (MM) and can either accompany newly diagnosed disease or develop with disease progression or relapse. Extramedullary myeloma (EMM) seems to have a different pathogenesis from its much more frequently encountered medullary counterpart, showing often a poor prognosis. EMM clinical situations are extraordinarily heterogeneous and their management is challenging. This includes organ or tissue involvement resulting from hematogenous-spread and/or bone involvement originating from different kind of bones.

Aims: We evaluated the impact of this disease features on patients’ outcome in the context of novel-agents.

Methods: We reviewed patients presenting EMM (median age 60, range 30-76) describing clinical and biological features (Figure 1B. Our aim was studying prognosis of bone-related extramedullary-disease (bEMD) and its relationship with soft-tissue related EMD (sEMD) in MM patients in our institution.

Results: 42 bEMD and 42 sEMD patients treated at Our Department between 2007 and 2016 were included in this study. Of the first group 10 presented EMM at diagnosis and 32 at relapse as well as 7 and 35 respectively of the second series. 31 among sEMD were dead and 11 were alive, 20 of bEMD patients were dead and 22 were still alive. EM was diagnosed using imaging techniques such as PET-CT (35%) or magnetic resonance MRI (65%). Biopsy was diagnostic only if the lesion was accessible (82%). The treatment was heterogeneous and all patients had received either thalidomide or bortezomib in the first-line of therapy. We showed that sEMD cohort has a significantly poorer survival compared to bEMD patients (median OS from diagnosis of EMD of 13 versus 58 months, P<0.001). Finally lung, liver (parenchyma-EM) and lymph nodes were the most common sEMD patients has shown a poorer outcome when compared to skin and lymph nodes masses respectively median OS of 12 and 10 months versus 18 and 15 months P<0.001). Conversely among bEMD group there wasn’t a significant advantage of outcome regarding the different bones involved. Kaplan-Meier estimates were used for survival analysis and differences between survival-times in patient subgroups were tested using the log-rank test (Figure 1A). Interestingly extramedullary-spread can be triggered by an invasive-procedures (surgery) or by a bone-fracture. In our population we have a case of breast-plasmocytoma diagnosed accidentally after reconstructive breast-surgery;where Polymerase Chain Reaction of immunoglobulin decrease in the breast lesion was excluded confirmed monoclonal-CD 138/lambda plasma-cells. This patients at first was treated with VTD-regimen followed by tandem-ASCT and after EM-relapse achieved complete remission with haploidentical-bone-marrow-transplantation. Allogeneic transplantation should however be remembered in the therapeutic-armamentarium against EM especially in high-risk-young-patients. Furthermore often it has been described in the literature association between EMD, IgD subtype and FLC (free light chain)escape. In fact in our study we have reviewed 6 cases of IgD and 4 FLC-escape, all of them were observed in relapse-setting and in sEMD group. Finally the mechanism of extramedullary spread are poorly estab-lishished so far. The upregulation of expression of integrins and CD56 is involved. In our population absence of CD56 protein was shown in 56% of sEMD group and in 15% of bEMD case-series.

Summary/Conclusions: Clinical features of MM-patients with bEMD were different from the patients with sEMD. Outcome of this population was significantly better than the patients with sEMD, and was comparable to the patients without EMD. Even in the era of novel drugs extramedullary soft tissue has a poor prognosis especially in a relapse-setting. This work shows a significant difference in prognosis for different type of extramedullary-disease even between sEMD (better OS of skin and lymph nodes involvement) suggesting a different biological-behavior.

PB1954
DINAMIC PREDICTIVE FACTORS FOR A BETTER STRATIFICATION OF PATIENTS WITH R-ISS II NEWLY DIAGNOSED MULTIPLE MYELOMA
M. Offidani1,*, L. Corvatta1, L. Maracci1, K. Garvey1, S. Gentili1, S. More1, M. Orsini1, P. Roni1
1Clinici di Ematologia AOU Ospedali Riuniti di Ancona, Ancona, Italy

Background: Revised International Staging System (R-ISS), combining the ISS score with cytogenetics and serum LDH, represents the most recent prognostic model for stratifying newly diagnosed multiple myeloma (MM) patients into three different survival groups. Although data for R-ISS development have been obtained from patients enrolled in clinical trials, this prognostic score has been validated also in real-life scenario (Tandon et al., 2017). In both non-clinical trial setting and IMWG experience, the majority of patients (about 65%) belonged to the intermediate risk group (R-ISS II) that, probably, needs better prognostication.

Aims: The aim of this study was to search for a closer stratification of MM patients with R-ISS II, taking into consideration dynamic aspects, such as therapeutic strategy and response to therapy.

Methods: We investigated the impact of variables, such as initial therapy, response to therapy and maintenance therapy, on PFS and OS in 108 newly diagnosed MM patients classified as R-ISS stage II, diagnosed between 2005 and 2015, who received novel agents such as immunomodulatory drugs and proteasome inhibitors. Score weights of the prognostic factors, found to be significant according to Cox regression model, were determined based on the regression coefficients.

Results: Median age of the 108 patients was 69 years (range 44-93) and 35% of them were older than 75 years. Thalidomide- and lenalidomide-based regi-
men were administered to 12% and 28% of patients, respectively, whereas 60% of the patients received bortezomib (54%) or carfilzomib-based (6%) regi-
ments as induction therapy. Thirty-eight percent of the study population under-
went ASCT and 40% received maintenance therapy. Regarding the response to the therapy, at least CR, VGPR and PR were documented in 35%, 66% and 87% of patients respectively. Five-year PFS and OS were 31% and 65%, respectively, similar to those reported by IMWG. Patients who did not achieve a CR, showed a significantly shorter 5yr-PFS (27% vs 50%; HR=2.9, 95%CI=1.6-4.50; p<0.0001) and 5yr-OS (53% vs 80%; HR=2.8, 95%CI=1.3-5.9; p=0.006) compared to those who did. Moreover, a significant better 5yr-PFS (15% vs 27%; p<0.0001) and 5yr-OS (28% vs 58%; HR=2.5, 95%CI=1.6-3.8; p<0.0001), whereas 5-year OS was 57% vs 80% (HR=1.9, 95%CI=1.1-3.3; p=0.021).

Summary/Conclusions: Our results suggest that in the R-ISS II MM patients,
the outcome of those achieving a CR and undergoing long-term therapy, is comparable with the outcome of the R-ISS I group. On the other hand, patients not achieving CR have a poor outcome, similar to those in the R-ISS III group. Therefore, these patients should require personalized therapy, aimed to achieve CR and to maintain therapy continuously.

PB1955

THE IMPACT OF THE UPDATED IMWG DIAGNOSTIC CRITERIA IN A REAL-LIFE SMM COHORT: A SINGLE CENTER EXPERIENCE

M. Fernández-Caballero1,*, F. de Arriba1, A. Jerez1, M. D. García1, V. Vicente1

Background: Recently, an update of the diagnostic criteria for smoldering multiple myeloma (SMM) & multiple myeloma (MM) was published by the International Myeloma Working Group (IMWG). In addition to CRAB criteria, 3 biomarkers of disease were introduced being (i) the presence of >60% clonal bone marrow plasma cells (BMPC), (ii) a serum free light chain ratio (FLC-ratio) >100 & (iii) the presence of >1 focal lesion on whole-body MRI (WBMRI). The introduction of these biomarkers has been shown to identify patients having a 70-80% risk of progression to MM over a 2-year time period.

Aims: To evaluate the impact of IMWG criteria in routine practice, focusing on (i) the prevalence of these biomarkers, (ii) the diagnostic strength of BMPC estimation using bone marrow aspirate & biopsy & (iii) the added role of dynamic contrast-enhanced WB-MRI (DCEMRI) in the evaluation of SMM patients.

Methods: We retrospectively identified 28 SMM cases diagnosed between 01/01/99-31/12/14. Sufficient data for analysis was available for 25 patients. All patients underwent standard clinical & laboratory evaluation, bone marrow examination & WB-MRI (T1- (+/-Co) & T2-weighted sequences, diffusion-weighted sequences & additional DCE-MRI sequences using time intensity curves). Time to progression (TTP) is defined as time from diagnosis until MM development. Overall survival (OS) is defined as time from diagnosis until death from any cause. Survival analysis was performed using the Kaplan-Meier method & significance was tested using the log-rank algorithm. Intergroup analysis was performed using non-parametric rank-based analysis & correlation was calculated using the Pearson coefficient. Reported p-values are 2-sided with a significance level of 5%.

Results: Median follow-up was 64.1 months (analysis performed on 01/02/2017). No patients had a FLC-ratio >100 at time of diagnosis. Also, no patients with >60% of clonal BMPCs were seen. In 20 patients BMPC counts using both aspirate & biopsy were available. Analysis showed a significant higher estimate of BMPC levels using biopsy (14,8%, SD 4,99) versus aspirate (6,45%, SD 6,59) (p = 0.002). Sensitivity of bone marrow aspirate was calculated to be 30% considering the 10% BMPC cut-off. Correlation between bone marrow aspirate & biopsy was found in 26.6% of cases. WB-MRI-positivity was seen in 9 patients (36%). Progression was seen in 7/9 patients (78%) where only 1/16 WB-MRI-negative patients (6,3%) developed MM (p = 0.001). Median TTP was 19.9 months versus not reached (p = 0.001) where no significant difference was seen between both groups (p = 0.453). DCEMRI was positive in 14 patients (56%) thus identifying 5 additional WB-MRI-negative patients with measurable bone marrow involvement.

No significant difference concerning progression risk was however seen between WB-MRI-negative patients being DCEMRI-positive (5/19, 26.3%) or -negative (14/19, 73.7%) (p = 0.317). Median follow-up time range was 1-293 months. Among the 164 patients that received IMIDs-based regimen, 27% did not receive any antithrombotic treatment, due to the lack of strong recommendations at the beginning of the use of IMIDs-based regimens. On the other hand, the most common thromboprophylaxis was set with LMWH (54%), followed by low doses of aspirin (13%) and anti-vitamin K (VKA) (6%). Median follow-up time was 779 months (range, 1-293) and VTE occurred in 11% of patients, with a median time from diagnosis of 10 months. IMIDs based-regimen demonstrated to be a risk factor associated on multivariate analysis, and the relevance of thromboprophylaxis has been proven, as the absence of this measure increased significantly the risk of VTE. Other factors that have also demonstrated to be independently associated with a higher risk for VTE were: BMI ≥30 kg/m2, prior Stroke or TIA, prior malignant neoplasm, and the use of high dose of dexamethasone.

Summary/Conclusions: Our data support the actual recommendation of antithrombotic prophylaxis in IMIDs-based regimens, especially in association with high dose of dexamethasone. We recommend the use of a risk factor model including obesity and previous history of thromboembolic disease or cancer, in order to guide the appropriate thromboprophylaxis measures.

PB1956

RISK FACTORS FOR VENOUS THROMBOEMBOLISM IN 401 MULTIPLE MYELOMA PATIENTS: OBSERVATION OVER A 25-YEARS PERIOD IN A SINGLE INSTITUTION

M. Fernández-Caballero1,*, F. de Arriba1, A. Jerez1, M. D. García1, V. Vicente1, V. Roldán1

1Servicio de Hematología y Oncología Médica, Hospital General Universitario Morales Meseguer, Centro Regional de Hemodonación, Universidad de Murcia, IMIB-Arrixaca, Murcia, Spain

Background: Patients with multiple myeloma (MM) have shown an incidence of 3-10% of venous thromboembolic events (VTE). The introduction of immunomodulatory drugs (IMiDs) in the treatment regimen has further increased the risk of VTE, especially when combined with steroids or chemotherapy (20-30%). Actual guidelines recommend thromboprophylaxis measures, but the proposed strategies are the results of expert consensus or derived from the extrapolation of data from many studies.

Aims: The aim of this study is to analyze the development of VTE in a large cohort of MM patients, treated for 25 years in a single institution, to assess risk factors associated in general population, actors suggested VTE risk population, also to confirm the incidence of VTE risk of IMiD-based regimens and the relevance of anticoagulant thromboprophylaxis.

Methods: Four hundred and one consecutive patients diagnosed with MM in a tertiary University Hospital between 1991 to 2015 were included. Data about VTE development, patient characteristics, myeloma-related factors, treatment and thromboprophylactic measures were retrospectively recorded. Multivariable correlates of VTE were assessed using Cox proportional hazards analysis.

Results: The median age at diagnosis was 68 years (range 24-90 years), and 47% were males. The results concerning treatment are extracted from 374 patients (93%). The most common treatments were chemotherapy-based regimens (51%) or new agents (27%) and 21% were immunomodulatory based regimens. Among the 164 patients that received IMiD-based regimen, 27% did not receive any antithrombotic treatment, due to the lack of strong recommendations at the beginning of the use of IMiD-based regimens. On the other hand, the most common thromboprophylaxis was set with LMWH (54%), followed by low doses of aspirin (13%) and anti-vitamin K (VKA) (6%). Median follow-up time was 779 months (range, 1-293) and VTE occurred in 11% of patients, with a median time from diagnosis of 10 months. IMiD-based regimens demonstrated to be a risk factor associated on multivariate analysis, and the relevance of thromboprophylaxis has been proven, as the absence of this measure increased significantly the risk of VTE. Other factors that have also demonstrated to be independently associated with a higher risk for VTE were: BMI ≥30 kg/m2, prior Stroke or TIA, prior malignant neoplasm, and the use of high dose of dexamethasone.

Summary/Conclusions: Our data support the actual recommendation of antithrombotic prophylaxis in IMiD-based regimens, especially in association with high dose of dexamethasone. We recommend the use of a risk factor model including obesity and previous history of thromboembolic disease or cancer, in order to guide the appropriate thromboprophylaxis measures.

LONG TERM SURVIVAL OF IGM MULTIPLE MYELOMA AND WALDENSTRÖM'S MACROGLOBULINEMIA PATIENTS

M. Kraj1,*, R. Pogłóś2, B. Krąk1, K. Warzocha1, M. Prochorec-Sobieszek1

1Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: IgM multiple myeloma (MM) and Waldenström's macroglobulinemia (WM) are two hematologic malignancies with the common finding of monoclonal gammopathy. IgM MM is a rare and poorly characterized disease.

Aims: The paper presents clinical and laboratory results of long term observations of 15 IgM MM patients selected from a group of 889 MM patients (16%) diagnosed and treated for several years at the Institute of Hematology and Transfusion Medicine in Warsaw as well as 15 WM patients investigated and treated at the same period of time at our hospital.

Methods: For analysis of serum proteins new Hyvelfite and Freelite tests (Binding Site Ltd Birmingham, UK) were applied as well as immunofixation using Sebia (Lisses, France) reagents. Fresh and archived frozen serum samples were used for the study.

Results: The clinical presentation of IgM MM patients is heterogenic starting with typical form for non IgM MM through predominant form with characteristic hyperviscosity syndrome and severe disease course to slow and latent form with survival time up to dozens of years. In 2 patients diagnosis of IgM MM was preceded by a 3-year period of monoclonal gammopathy of undetermined significance (MGUS) while in 4 patients (27%) diagnosis of WM was preceded by a 108, 84, 78, 9 months period of IgM MGUS. Median real overall survival of IgM MM patients was 50 months, 5 patients (33%) survived above 7 years and only 3 patients (18%) survived 10 years. Median survival of WM patients was 108 months, 7 patients (47%) survived above 10 years, 3 patients (20%) survived above 15 years. Lytic bone lesions were found in 11 (73%) IgM MM patients and in 3 (20%) WM patients. Urine monoclonal free light chains (FLC) detected by immunofixation was present in 60% of IgM MM patients and in 66% of WM patients. Monoclonal light chain free light chain (FLC) ratio in serum (by Freelite) in 75% of IgM MM patients. It was shown that IgM clonality in IgM MM and WM patients can be determined by using immunoglobulin heavy chain /light chain (HCL) immunoassays- Hyvehty. Immunofixation and HLC ratios were concordant in all assessed IgM MM and WM patients. In IgM MM patients 13 patients with IgM MM at diagnosis revealed a decreased concentration of uninvolved IgM (HLC IgMκ <0.33 g/L, HLC IgMλ <0.20 g/L) in 5 patients and in 13 patients with IgM MM at diagnosis revealed a decreased concentration of involved monoclonal FLC and abnormal FLC κ/λ ratio in serum (by Freelite) in 75% of IgM MM patients. It was shown that IgM clonality in IgM MM and WM patients can be determined by using immunoglobulin heavy chain /light chain (HLC) immunoassays- Hyvehty. Immunofixation and HLC ratios were concordant in all assessed IgM MM and WM patients. In IgM MM patients 13 patients with IgM MM at diagnosis revealed a decreased concentration of uninvolved IgM (HLC IgMκ <0.33 g/L, HLC IgMλ <0.20 g/L) in 5 patients and normal values in 8 patients. Median overall survival in patients with a decreased uninvolved polyclonal IgM <15 months and in patients with normal polyclonal IgM 55 months (p<0.01).

Summary/Conclusions: 33% of IgM MM patients survive above 7 years and 13% above 12 years while 47% of WM patients survive above 10 years and 20% above 15 years. Suppression of uninvolved polyclonal IgM (detectable by using HLC test) at the time of IgM myeloma diagnosis is unfavorable prognostic factor.

Background: The BD OneFlow solution for plasma cell disorders incorporates a standardized flow cytometry approach based on the EuroFlow (EF) Consor- tium validated system for aiding in the diagnosis of plasma cell disorders from bone marrow aspirates. The BD OneFlow PCD system (PCST and PCD tubes) and the EF liquid reagent system was fully concordant in identifying patients with abnormal plasma cell populations. Additionally, all subjects identified as having plasma cell disorder based on clinical results were identified as having plasma cell disorder by the EF methodology. The BD OneFlow PCD system correctly identified 100% of patients who had a plasma cell dis- order based on clinical results.

Summary/Conclusions: The multisite evaluation between the BD OneFlow PB1959 (PCST and PCD tubes) and the EF liquid reagent system was fully concordant in identifying patients with abnormal plasma cell populations. Additionally, all subjects identified as having plasma cell disorder based on clinical results were identified as having plasma cell disorder by the BD OneFlow PCD system. The BD OneFlow PCD panel is a fully standardized and validated system for aiding in the diagnosis of plasma cell disorders from bone marrow aspirates.

PRACTICE GAPS AND BARRIERS TO OPTIMAL MANAGEMENT OF MULTIPLE MYELOMA PATIENTS: RESULTS FROM A MIXED-METHODS STUDY IN 8 EUROPEAN COUNTRIES

S. Murray1, M. Mohty2,*, S. Peloquin1, N.W. van de Donk3, S. Leitao4, S. Labbé1, S. West5, E. Hofstätter-Thalmann6, P. Sonneveld7, M. van der Waal8, U. Popp9, L. Neca8, P. Rekhtman10, P. de Haan11, F. Miceli12, G. Ferraro13, L. Pasquale13, C. Di Bella13, C. Riebeek13, K. Warzocha1, M. Prochorec-Sobieszek1, M. Kraj1,*, R. Pogłóś2, B. Krąk1

1Medical Affairs, 2BD Biosciences, San Jose, United States

Background: Previous studies have identified gaps and barriers in Multiple Myeloma (MM) patient care, especially in relation to treatment decision making. However, there are few studies that better understand the practice gaps, from the healthcare providers’ perspectives, with the purpose to investigate the root causes of those gaps and find solutions to alleviate the challenges.

Aims: We conducted a study to identify the practice gaps and challenges in the diagnosis, treatment and management of MM patients, as experienced and reported by medical oncologists, haematologists and haemato-oncologists (HEM) and oncology nurses (NU) in 8 European countries between February 2016 and June 2016.

Methods: This mixed methods ethics-approved study included exploratory semi-structured interviews (phase 1) designed to generate in-depth discussion of the most common challenges in diagnosis, treatment and management of MM, followed by a quantitative online survey (phase 2) designed to validate the findings from the interviews with a larger sample. Practice gaps were identified through combined analysis of data from the in-depth interviews and online surveys.

Results: A total of 364 participants (HEM=281, NU=83) from France (n=58), Germany (n=58), Russia (n=58), Italy (n=58), Spain (n=58), the Netherlands (n=16), and Belgium (n=25) participated in this study. Thirty-nine (39) interviews were conducted (HEM=28, NU=11) and 325 participants completed the online survey (HEM=253, NU=72). A majority (79%) of the sample had more than 10 years of clinical practice experience and over a third (39%) had over 20% of MM patients in their patient caseload. Three key findings were identified in the management of MM patients: 1) challenges in managing treatment side-effects. Forty percent (40%) of HEM reported lack of skills in managing cardiovascular side effects or symptoms. Over a third of HEM reported difficulties in managing fatigue (40%), skin toxicities (35%) or peripheral neuropathy (34%). NU reported lack of skill in managing infusion-related insufficiency as a side effect or symptom (46%), peripheral neuropathy (36%), thrombosis (37%), and skin toxicities (33%). Additionally, 2) HEM reported challenges in communicating with patients and educating them around their disease, especially in relation to treatment outcomes and long term side effects. For example, 51% of NU reported a lack of skills discussing sexual issues as consequences of the disease/treatment. Finally 3) there was a large variability across countries in the guidelines followed by HEM and NU for the treatment and management of MM patients. Detailed results, including country-specific analyses and investigation of the practice gaps’ causalties, will be presented.

Summary/Conclusions: These findings provide real-life recent evidence of the challenges of HEM and NU in relation to specific aspects of the manage- ment of patients with MM with 3 main areas, challenges in managing side effects, communication with patients and leverage of guidelines which show differences between HEM and NU but also between countries. The findings highlight the need for the development of national and international educational activities and performance improvement interventions, adapted to the local context at a country level. Efforts should aim to address those current challenges before new therapies, such as immunotherapies, become available.

THE EXPRESSION OF APRIL BY MULTIPLE MYELOMA CELLS AND THEIR ROLE IN THE EVOLUTION OF MULTIPLE MYELOMA
A. Kulkarni1, S. Patel2, A. Gerdon3, G. Riddle4, J. Habermann5, A. Rosenzweig6, A. Wohrer6, M. Durie7, J. Davies1
1Blood and Marrow Transplant, Mayo Clinic, Rochester, USA, 2Haematology, Novartis, East Hanover, USA, 3Genentech, South San Francisco, USA, 4Biology, Genentech, South San Francisco, USA, 5Pathology, Mayo Clinic, Rochester, USA, 6Genentech, South San Francisco, USA, 7Blood and Marrow Transplant, Mayo Clinic, Rochester, USA

Aims: The aim of this study was to evaluate the expression of APRIL in multiple myeloma (MM) cells and its role in the evolution of this disease. APRIL is a cytokine that plays a role in the survival and proliferation of B cells and is known to be expressed in MM cells. The study aimed to determine if APRIL expression could be a prognostic factor in MM.

Methods: The expression of APRIL was evaluated in 100 MM patient samples using flow cytometry and immunohistochemistry.

Results: The study found that APRIL expression was significantly higher in MM cells compared to normal plasma cells. The expression was correlated with the stage of the disease, with higher expression in advanced stages.

Summary/Conclusions: APRIL expression in MM cells is a potentially useful prognostic marker. Further studies are needed to validate these findings and to explore the mechanisms by which APRIL expression affects MM cell behavior.

DEVELOPMENT OF SECOND PRIMARY MALIGNANCY AFTER TREATMENT WITH LENALIDOMIDE: A SINGLE CENTRE EXPERIENCE
F. Mcclorey1,2, J. Diefenbach3, D. O'Sullivan3, S. Murphy3, F. Mahony1,2, J. Magee1,2, P. Boland4,5, M. Aiken6, M. Stagg7, K. Sweeney8
1Hematology, St Vincent's University Hospital, Dublin 9, Ireland, 2Hematology, Clinical Excellence Unit, St Vincent's University Hospital, Dublin 9, Ireland, 3Hematology, Ulster Hospital, Dundonald, Belfast, UK, 4Hematology, Royal College of Surgeons in Ireland, St James's Hospital, Dublin 8, Ireland, 5Clinical Pathology, St James's Hospital, Dublin 8, Ireland, 6Hematology, Providence Park Hospital, Co. Down, UK, 7Hematology, Royal Victoria Hospital, Belfast, UK, 8Hematology, St James's Hospital, Dublin 8, Ireland

Aims: To report the incidence and characteristics of second primary malignancies (SPMs) in patients treated with lenalidomide for multiple myeloma at a single centre in Ireland. Lenalidomide is an immunomodulatory drug that has been shown to be effective in the treatment of multiple myeloma.

Methods: A retrospective analysis of patients treated with lenalidomide at St Vincent's University Hospital, Dublin, between January 2008 and May 2016 was conducted. The incidence of SPMs, latency between the development of SPM and primary myeloma, and the distribution of SPMs were recorded.

Results: A total of 137 patients were treated with lenalidomide during the study period. Twelve patients (8.8%) developed SPMs, with a median latency of 39 months (range 1-120 months). The most common SPMs were skin malignancies, accounting for 17% of cases. The incidence of SPMs in patients treated with lenalidomide was found to be consistent with previous reports.

Summary/Conclusions: The incidence of SPMs in patients treated with lenalidomide was found to be consistent with previous reports. Further studies are needed to better understand the mechanisms underlying the development of SPMs in this patient population.

References:
Risk groups were defined based on the overall score. To provide optimal patient care, each OS predictor were multiplied to obtain an overall score for each patient. The 5-year PFS and OS was 61% and 90% respectively, 31% and 74% at 10 years. Although a tendency towards a higher PFE was observed in the EMP group, it was not statistically significant. No differences were found in PFS/OS between age groups (<60 or ≥60 years), axial vs appendicular skeleton location in SBP, type of treatment received, or the presence of MB. Furthermore, no association was found between the presence of MB at diagnosis and progression to MM (Figure 1).

Figure 1.

Summary/Conclusions: The age at diagnosis of SBP is significantly lower than EMP. Moreover, the progression to MM is notably higher in this group of patients. These distinct characteristics in clinical presentation and outcome could suggest a biological difference between both entities.

RISK STRATIFICATION ALGORITHM USING REAL-WORLD DATA FROM PATIENTS WITH RELEASPD AND/OR REFRACTORY MULTIPLE MYELOMA: DESCRIPTION OF CLINICAL OUTCOME BY TREATMENT REGIMEN

R. Hajek1,*, M. Delforge2, M. Raab3, J. Radocha4, J. Straub5, W. Bouwmeester6, Z. Szabo7, L. Pour8, S. Gonzalez-McQuire7, V. Maisnar4 1Department of Haematology, University of Ostrava, Ostrava, Czech Republic, 2Department of Hematology, UZ Leuven, Leuven, Belgium, 3Department of Internal Medicine, University Hospital Heidelberg, Heidelberg, Germany, 4Department of Medicine, Charles University Hospital and Faculty of Medicine, Hradec Kralove, 5Departments of Internal Medicine and Hematology, Prague General Teaching Hospital, Prague, Czech Republic, 6PharmMed International, Rotterdam, Netherlands, 7Amgen (Europe) GmbH, Zug, Switzerland, 8Department of Internal Medicine, University Hospital Brno and Faculty of Medicine, Brno, Czech Republic

Background: Estimation of survival for patients with RRMM, requires prognostic tools that define the relative risk of death after first relapse. We recently developed a risk stratification algorithm (RSA) using real-world data from the Czech Registry of Monoclonal Gammapathies (RMG). Our RSA uses patient and disease characteristics at diagnosis and at initiation of second-line treatment (2L), and previous treatments to stratify patients based on the overall survival (OS) expectations from initiation of 2L treatment (Hajek et al. Blood 2016). The value of such an algorithm depends on its validation, but also on understanding the evidence that explains these differences in survival expectations.

Aims: To describe 2L treatment patterns by RSA group and to report OS, progression-free survival (PFS) and response by treatment received in 2L per RSA risk group.

Methods: Data were collected from the Czech RMG for patients aged ≥18 years who were diagnosed with symptomatic MM between May 2007 and April 2016 and in whom 2L treatment had been initiated. Predictors of OS from the start of 2L were identified using Cox regression analyses. Hazard ratios for each OS predictor were multiplied to obtain an overall score for each patient. Risk groups were defined based on the overall score. To provide optimal patient stratification, cut-offs of the score were estimated using K-adaptive partitioning for survival (KAPS) analysis.

Results: Data from 1418 patients were analysed. KAPS analysis defined four groups based on risk of death: low (LR; score ≤ 4.1; n=403), intermediate-low (ILR; score 4.2–10.3; n=635), intermediate-high (IHR; score 10.4–20.1; n=237) and high (HR; score ≥20.2; n=143) risk. Median OS (months) was 57, 29, 13 and 5 for the LR, ILR, IHR and HR groups, respectively. Following stratification, compared with patients in the lower risk groups, a higher proportion of those in the HR group had LDH levels above 360 U/L and an Eastern Cooperative Oncology Group Performance Status of 3–4 at initiation of 2L. Treatments received at 2L were similar across all risk groups, with bortezomib and lenalidomide being the most common 2L treatments. Patients who received bortezomib at 1L were often given lenalidomide or thalidomide at 2L and those who received thalidomide at 1L were frequently given bortezomib at 2L. This suggests that 2L treatment choice was not defined by the underlying risk of death for each patient, but rather by the type of previous treatment. For patients receiving lenalidomide at 1L (OS months) from start of 2L was 57, 29, 13 and 6 (Figure 1), and median PFS (months) was 18, 12, 8 and 3 in the LR, ILR, IHR and HR groups, respectively. A very good partial response or better (VGPR+) was reported for 29.3%, 31.0%, 18.7% and 16.9% of patients in the LR, ILR, IHR and HR groups, respectively. For patients receiving lenalidomide at 2L, median OS (months) was 45, 29, 14 and 5, and median PFS (months) was 20, 12, 10 and 3 for patients in the LR, ILR, IHR and HR groups, respectively. A VGPR+ was reported for 33.6%, 22.9%, 26.0% and 7.1% of patients in the LR, ILR, IHR and HR groups, respectively.

Figure 1.

Summary/Conclusions: The RSA effectively stratifies patients according to OS from initiation of 2L. However, these results must be validated in an external dataset. The outcomes of each risk group are mainly driven by the underlying risk of death at initiation of 2L; treatment with bortezomib or lenalidomide provided similar outcomes independent of risk group. Use of our RSA at 2L would support physician decision making to improve patient specific care.

LACK OF CD56 EXPRESSION IN MULTIPLE MYELOMA PATIENTS WITH RISS 2 DISEASE IS ASSOCIATED WITH WORSE PROGNOSIS AND ABOLISHED WITH AUTOLOGOUS STEM CELLL TRANSPLANTATION

M. Skerget1,*, B. Skopec1, H. Podgornik1, D. Zontar1, K. Rebersek1, T. Furlan1, P. Cerne1 1Department of Hematology, University Clinical Center Ljubljana, Ljubljana, Slovenia

Background: Multiple myeloma (MM) is a hematologic disease in which accumulation of malignant plasma cells and high levels of monoclonal protein and free light chains lead to bone marrow failure, hypercalcemia, lytic bone lesions and renal failure. Myeloma cells are distinguished from normal plasma cells by an aberrant immunophenotype. They express CD56 on the cell surface in 70-80% and can be used to distinguish myeloma cells by flow cytometry. The expression of CD56 is constant throughout the course of the disease. The lack of CD56 expression in myeloma cells decreases the adherence of myeloma cells to the cell matrix and is associated with higher levels of bone marrow infiltration and peripheral blood involvement, higher incidence of extramedullary disease, renal insufficiency, Bence Jones protein, plasma cell leukemia and t(11;14). The lack of CD117 expression is associated with higher levels of bone marrow infiltration, renal impairment, elevated β2-microglobulin and cytogenetic...
There were 40% (2015) and 32% (2016) pts considered as eligible for ASCT half of 2015 and from 867 patients from 52 centres for the first half of 2016.

**Results:**
Data from 515 patients from 51 centres were available for the first

**Methods:**
We retrospectively analyzed 110 newly diagnosed MM patients from our national registry that had data available at the time of diagnosis. Immunophenotype was determined using a panel consisting of CD19/CD38/CD45/CD56/CD138 to distinguish and to enumerate MM cells. Monoclonal antibodies directed against CD20, CD28, and CD117 were used additionally.

**Summary/Conclusions:**
With our current analysis of a nationwide survey performed with different health care providers in Germany we demonstrate that implementation of ASCT is strongly influenced by the institution initiating primary therapy. Age does not seem to impact usage of ASCT compared to concomitant disease or patients’ and doctors’ preferences. Patients predominantly collect three autologous transplants, enabling a possible tandem ASCT and ASCT for relapsed disease.

**PB1967**

**MODIFIED HYPERCVAD VERSUS BORTezomIb-HYPERCVAD IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA**

E. Sciot¹, M. Saraceni², S. Jing³, S. Modrusan-Tchoketé¹, R. Mezas², E. Medvedova¹

¹Hematology and Oncology, Oregon Health and Science University, Portland, United States

**Background:**
Multiple myeloma (MM) is an incurable plasma cell malignancy, in which aggressive relapses may require salvage cytotoxic infusional chemotherapy. Several clinical trials demonstrating the efficacy of bortezomib led to institutional practice changes where vincristine was replaced with bortezomib in the modified hyperCVAD (mod-CVAD) regimen, creating a new treatment regimen, ‘bortezomib-hyperCAD’ (bort-CVAD).

**Aims:** The primary objective is to describe the safety and efficacy of the hyperCVAD regimen with vincristine or bortezomib in patients with relapsed or refractory MM treated at Oregon Health and Science University.

**Methods:** IRB approval was obtained to perform this retrospective analysis. We describe the effectiveness of the 2 regimens among 33 patients with relapsed and/or refractory multiple myeloma (RRMM). Patients who received ≥1 cycle of mod-CVAD (n= 15) or bort-CVAD (n= 18) from Jan 1 2011 and Dec 31 2015 at the Knight Cancer Institute were included. Most patients were previously treated with refractory to proteasome inhibitors (97%/76%) or immunomodulatory agents (82%/68%) respectively. 13 received prior autologous stem cell transplant (auto-HCT), the median number of prior lines was 3 (range 1-8). High risk cytogenetic factors (t(4;14), t(14;16), or del 17p) were present in 8 and extramedullary disease in 13 patients overall. Regimens contained cyclophosphamide 300 mg/m² IV every 12 hours for 8 doses; doxorubicin 9 mg/m²/day continuous IV infusion every 24 hours and dexamethasone 40 mg by mouth on days 1-4; vincristine 0.4 mg/m² IV infusion every 24 hours on days 1-4; and standard infectious prophylaxis. International Myeloma Working Group uniform response and European Society for Blood and Marrow for minor response (MR) criteria were used.

**Results:**
- The median number of cycles given was 2 (range 1-6). Cycles were resumed every 3 to 4 weeks. Median follow up was 48 and 33 months in mod-CVAD and bort-CVAD respectively. The ORR was 40% in the mod-CVAD group: 6 partial (PR), 6 minor (MR), and 3 stable disease (SD) compared to 44.4% in the bort-CVAD group: 1 complete response, 7 PR, 2 MR, 6 SD and 2 progressive disease ( Fisher’s exact p=0.80). A total of 13 patients proceeded to auto-HCT, the median overall survival for all patients was 16 and 11 months respectively, which was comparable between arms (Log rank test p=0.6635 and 0.7369). New or worsening of peripheral neuropathy occurred in 2 patients in the mod-CVAD and bort-CVAD groups respectively. There was a statistically significant association between treatment and febrile neutropenia (Fisher’s exact p=0.02). The median number of hospitalizations was 0.5 in all patients receiving bort-CVAD and 1 in mod-CVAD (Fisher’s exact test P value >0.05). There were no statistically significant differences in safety and tolerability between treatment arms. Three and 6 patients in the mod-CVAD and bort-CVAD arms discontinued therapy due to toxicity or treatment complications respectively.

**Conclusions:** Overall effectiveness and safety outcomes were similar between mod-CVAD and bort-CVAD, with both regimens demonstrating an impressive response rate among heavily pre-treated patients with relapsed/refractory disease. This is a useful salvage strategy to gain rapid dis...

EFFICACY AND SAFETY OF LENALIDOMIDE AND DEXAMETHASONE IN PATIENTS WITH RELAPSED/REFRACTORY MULTIPLE MYELOMA: A REAL LIFE EXPERIENCE FROM TURKEY

G. Saydam1, N. Soyer1, P. Patir1, A. Uysal1, M. Duran1, R. Durusoy2, F. Sahin3, F. Vural1, M. Tobu1, M. Tombuloglu1

1Hematology, Ege University Internal Medicine, Bornova, 2Public Health, Ege University Medical School, 3Hematology, Ege University Hospital Internal Medicine, Izmir, Turkey

Background: Lenalidomide, an immunomodulatory drug, was approved for treatment of relapse/refractory multiple myeloma (RR-MM). In Turkey, we have been used the combination of lenalidomide and dexamethasone (RD) for RR-MM patients after 2010. Therefore, we analyzed efficacy and safety of RD in Turkish patients with RR-MM.

Aims: We aimed to evaluate the outcome and the tolerability of the RD in patients with RR-MM who had been treated under the standard clinical practice between October 2010 and June 2016.

Methods: This is a retrospective, single center study. Patients’ clinical and laboratory data were collected from patients’ files. The overall and progression free survival (OS and PFS) were calculated from the time of RD initiation. OS was defined as time to death, and PFS was defined as time to disease progression or death. An updated analysis at median follow-up of 14 months (range, 1–72 months) and median DOR was 19 months (range, 12.4–25.6 months). Median OS and PFS were 32 months (95% CI, 15.8–48.1 months) and 21 months (95% CI, 15.8–26.1 months), respectively.

Results: One-hundred and twenty patients (71 male and 49 female) enrolled in the study. The median age at the start of RD was 64 years (range 29–84) and the median number of previous line of treatment was 1 (1–4). Seventy-two patients (60%) received RD as second-line therapy and 51 patients (42.5%) treated with autologous stem cell transplantation (ASCT). With regard to the initial dose of lenalidomide, 82 (68.3%) of the patients received the recommended dose of 25 mg per day for 21 days in a cycle of 28 days. Objective response (≥PR) was observed in 87 patients (72.5%); 23 patients (19.2%) achieved CR. The median follow-up was 14 months (range, 1–72 months), and the median DOR was 19 months (range, 12.4–25.6 months). Median OS and PFS were 32 months (95% CI, 15.8–48.1 months) and 21 months (95% CI, 15.8–26.1 months), respectively. In the multivariate analysis, the independent prognostic factors for OS and PFS were treated with previous ASCT, patients who achieved at least PR, patients receiving RD for more than 12 cycles. Adverse events occurred in 69 of patients (57.5%). Hematological and non-hematological adverse events were found at the same rate (n=47, 39.2%). The treatment discontinuation rate due to AEs was 11.2% (14 patients). The overall incidence rate (IR, events per 100 patient-years) of second primary malignancies (SPMs) was 0.93 (95% CI, 0.04-4.60). The rate of anemia was 12.5% and thrombocytopenia was 9.2% in all grades. Peniculania (15.8%), fatigue (14.2%) and herpes infections (0.8%) have been reported as most frequent non-hematological adverse events.

Summary/Conclusions: RD is a safe, well tolerated and effective treatment in patients with RR-MM. Good response, previous ASCT and using more than 12 cycles are associated with better survival. Higher OS and PFS and ORR seem to be related to using RD in the first relapse. Adverse events are manageable and lower with prophylaxis.

PB1969

OPTIMIZING THE MANAGEMENT OF NON-HEMATOLOGICAL ADVERSE EFFECTS RELATED TO LENALIDOMIDE IN RELAPSED MULTIPLE MYELOMA PATIENTS. ONE CENTER EXPERIENCE

M. Moyá-Arnao1, V. Cabanas-Perianes1, M.J. Moreno Belmonte1, M. Berengue1, I. Martínez Martín1, E. Ferrer, Kaplan–Meier methods. Log-rank test was used to evaluate the variables affecting OS and PFS (univariate analysis). Cox proportional hazards regression was used for multivariate analysis to analyze the independent variables affecting PFS and OS.

Results: One-hundred and twenty patients (71 male and 49 female) enrolled in the study. The median age at the start of RD was 64 years (range 29–84) and the median number of previous line of treatment was 1 (1–4). Seventy-two patients (60%) received RD as second-line therapy and 51 patients (42.5%) treated with autologous stem cell transplantation (ASCT). With regard to the initial dose of lenalidomide, 82 (68.3%) of the patients received the recommended dose of 25 mg per day for 21 days in a cycle of 28 days. Objective response (≥PR) was observed in 87 patients (72.5%); 23 patients (19.2%) achieved CR. The median follow-up was 14 months (range, 1–72 months), and the median DOR was 19 months (range, 12.4–25.6 months). Median OS and PFS were 32 months (95% CI, 15.8–48.1 months) and 21 months (95% CI, 15.8–26.1 months), respectively. In the multivariate analysis, the independent prognostic factors for OS and PFS were treated with previous ASCT, patients who achieved at least PR, patients receiving RD for more than 12 cycles. Adverse events occurred in 69 of patients (57.5%). Hematological and non-hematological adverse events were found at the same rate (n=47, 39.2%). The treatment discontinuation rate due to AEs was 11.2% (14 patients). The overall incidence rate (IR, events per 100 patient-years) of second primary malignancies (SPMs) was 0.93 (95% CI, 0.04-4.60). The rate of anemia was 12.5% and thrombocytopenia was 9.2% in all grades. Peniculania (15.8%), fatigue (14.2%) and herpes infections (0.8%) have been reported as most frequent non-hematological adverse events.

Summary/Conclusions: RD is a safe, well tolerated and effective treatment in patients with RR-MM. Good response, previous ASCT and using more than 12 cycles are associated with better survival. Higher OS and PFS and ORR seem to be related to using RD in the first relapse. Adverse events are manageable and lower with prophylaxis.

PROLONGED THROMBOPROPHYLAXIS IN PATIENTS TREATED WITH LENALIDOMIDE AND DEXAMETHASONE DOES NOT SEEM STRICTLY MANDATORY TO PREVENT LATE THROMBOTIC EVENTS

C.S. Cartia1, S. Mangiacavalii1, V.V. Ferretti1, F. Cocito1, M. Ganzetti1, E. Fugazz1, B. Landini1, M. Catalano1, M. Cazzola1, A. Corso1

1Hematology, IRCCS Fondazione Policlinico San Matteo, Pavia, Italy

Background: Risk of venous thromboembolism (VTE) in general population is 1% annually, significantly higher in oncologic setting, in particular with Multiple Myeloma (MM). Treatment with Lenalidomide plus Dexamethasone represents an additional risk factor for VTE, with most of VTE events observed in the first six months since therapy starting. No definitive data are available on the more appropriate duration of thromboprophylaxis (TP) in patients treated with lenalidomide.

Aims: To explore: I) the incidence of late thrombotic events in a real world population of relapsed MM, treated with Lenalidomide plus low dose Dexamethasone treatment (Len-dex) and concomitant TP with low molecular weight heparin (LMWH) performed for the first 4-6 months of therapy, without TP maintenance, II) the possible correlation between the presence of thrombotic risk factors and the occurrence of a late VTE.

Methods: We performed a retrospective analysis, after regular approval of local ethic committee, on chart data of 103 patients (pts) with relapsed MM treated with Len-dex according to label indication between January 2003 and December 2016 at our single centre institution. VTE prophylaxis was performed with daily dose of subcutaneous LMWH 4000 IU for 4-6 months, with no further TP, regardless of the presence of thrombotic risk factors.

Results: Main features of patients on study were: median age 66.3 years (range 41.9-85.2 years), median previous line of therapy 3 (range 1-7), time from diagnosis to lenalidomide starting 33.3 months (range 0.3-159.9 months), median duration of Lenalidomide treatment 8 months (range 0.4-65.2 months) with the following response: ≥PR 56%, CR 7%. Table 1 shows type and distribution of risk factors for VTE. In details median number of VTE risk factors per patient was 2 (range 0-6), 58.2% of pts had ≥2 risk factors, 41.8% of pts had 0-1 risk factor for VTE. Median duration of TP is 4.8 months (range 0-21). d: 40 mg on days 1, 8, 15, and 22) in 28-day cycles until progression or unacceptable adverse effects, from 2011-2016. All patients received thromboprophylaxis with low-molecular-weight heparin (LMWH) (Enoxaparin 40 mg subcutaneous daily) the first 4 cycles; thereafter, patients were switched to aspirin 100 mg in a day prophylaxis. Bemiparin 7500 anti-Xa IU once-daily dose was employed if enoxaparin was suspended. Clonazepam dose to treat dystonia was 0,5 mg twice daily. Data were analyzed with SPSS statistical v 22.0.

Results: Between 2011 and 2016 a total of 65 patients received Rd in our center. Baseline characteristics are shown in Table 1. Patients received a median of 2 previous regimens (range 1-6). 51.5% of the patients had undergone one previous autologous stem-cell transplant (ASCT). Rash occurring in 12,3% of patients (grade 2), all of them were concurrently receiving enoxaparin. All rashes resolved switching the enoxaparine to bemiparin, maintaining same dose of lenalidomide. Neither treatment with estrogens or antihistaminic were administrated. Dystonias were managed in ≥2 patients (grade 2), all of them dissapeared after treatment with clonazepam without lenalidomide dose reduction.

Table 1.
0.4–6 months). No hemorrhagic events were observed during LMWH. Cumulative incidence of VTE was 11.7% (12/103 pts), similar to that previously reported in the literature in patients with continuous TP. The median time from lenalidomide starting and VTE occurrence was of 12.2 months (range 1-88.2 months), with only one patient developing early VTE among our group. In detail we observed 10 deep vein thrombosis (83%), 1 pulmonary embolism (8.5%), 1 myocardial infarction (8.5%). Most of patients developing VTE had good disease control (≥PR 83%, 10 pts). Concomitant adverse events (AE) was registered in 41.7% of pts (5/12). Most common concomitant AE were infections of respiratory tract (3 pts) and gastrointestinal AE (2 pts). The median number of risk factors for VTE in patients developing or not thrombosis was similar (2.5 vs 2, p=0.092).

Table 1. Baseline distribution of risk factors for thrombosis in the population on study.

Summary/Conclusions: This study shows that LMWH is effective and well tolerated for early VTE prophylaxis during Lenalidomide plus low dose Dexamethasone. Incidence of late VTE without TP maintenance is similar to that reported with long-term antiplatelet therapy. We found no difference in factors predisposing for thrombosis among patients developing or not VTE, with a not negligible proportion of concomitant adverse events observed nearby VTE occurrence.

ELDERLY PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA IN THE REAL WORLD
E. Yamazaki1,2,*, H. Takahashi2, D. Ishibashi3, K. Kishimoto3, K. Miyashita4, A. Numata5, Y. Hatono5, R. Kawasaki5, K. Khorazawa5, K. Fujimakib, J. Taguchib, R. Fujitac, R. Sakac, S. Fujisawad, H. Haranod, H. Nakajima1,1Clinical Laboratory Department, Yokohama City University Hospital, 2Department of Hematology and clinical Immunology, Yokohama City University School of Medicine, 3Department of Hematology, Saiseikai Yokohama Nanbu Hospital, 4Department of Hematology, Yokohama City University Medical Center, 5Department of Medical Oncology, Kanagawa Cancer Center, Yokohama, 6Department of Hematology, Fujisawa City Hospital, Fujisawa, 7Department of Hematology / Oncology, Yamato Municipal Hospital, Yamato, 8Department of Hematology, Shizuoka Red Cross Hospital , Shizuoka, 9Department of Hematology, Yokosuka City Hospital, Yokosuka, 10Department of Hematology, Yokohama City University School of Medicine, Yokohama, Japan

Background: Many new agents for multiple myeloma (MM) were launched during the last decade, and the clinical trial using such new agents showed promising results for MM patients. However, clinical course of elderly patients with newly diagnosed MM (NDMM) in the real world is different from the results of clinical trial.

Aims: We examined the clinical parameter to assess survival in elderly patients with NDMM in clinical practice.

Methods: We performed a retrospective study involving 125 elderly NDMM patients from April 2012 to September 2015. Patients aged 70 years or older, who were ineligible for autologous stem cell transplantation, were selected. The study included 57 males and 68 females, with median age at diagnosis of 74 years (range 60-95 years). ECOG performance status at diagnosis was 0-1, 67; 2-4, 58. We collected pretreatment parameter at diagnosis as follows; monoclonal protein type (IgG,60; IgA,32; IgD,1; BJP,30; non-secretary,2), light chain (kappa, 72; lambda, 52; unknown 1), hemoglobin level (mean 8.9 g/dL [range 5.8-15.2]), estimated glomerular filtration rate (eGFR) (mean 49.3 mL/min [range 3.6-114.2]), calcium level (mean 10.0 mg/dL [range 8.7-20.2]), albumin level (mean 3.4 g/dL [range 1.0-5.3]), beta-2-microglobulin (mean 5.1 mg/L [range 1.6-51.5]), involved/uninvolved serum free-light chain (FLC) ratio (mean 143.8 [1.83-21133]), cytogenetic abnormalities by using fluorescence in situ hybridization (FISH) (none, 53; t(4;14), 7; del(17p), 14; (t(4;14) & del(17p), 5; (t(4;14) & del(14p) & del(17p), 1). Results: Of 125 patients, 76 patients received bortezomib based therapy (VMP, 49; VD, 21; VCD, 6), 6 patients received lenalidomide based therapy (Ld, 6), 10 patients were received MP therapy, 19 patients received dexamethasone therapy (high dose, 16; low dose, 3), 1 patient received radiation therapy as first line therapy, and 13 patients received only supportive care due to their fragility. After induction therapy, the overall response rate (at least partial response, PR) was 52.7% (stringent complete response (sCR) 0.3%, CR 4.5%, very good PR 16.1%, PR 29.5%). Overall survival (OS) was 74.5% at 1 year, 66.2% at 2 years with median follow-up of 19 months (range 1-52) for patients who were still alive at the date of last contact and 14 months (range 1-52) for entire cohort. Death occurred in 41 patients during the follow-up period. International staging system (ISS), with ISS1, 19; ISS2, 42; ISS3, 60; N/A, 4, can divide elderly patients into three distinct survival groups (P<0.001) (Figure 1A).

Figure 1. Summary/Conclusions: Renal dysfunction and hypercalcemia at diagnosis is predictive of poor OS for elderly NDMM patients in real world.

PB1972
RETROSPECTIVE ANALYSIS OF 121 MULTIPLE MYELOMA PATIENTS USING THE R-ISS PROGNOSTIC STAGING SYSTEM AND RESPONSE TO FIRST LINE OF TREATMENT
R. Ghonema1,*, S. AlShemmari1, R. Pandita3, M. Hasanen3, M. Al-Drees1,1Hematology, Kuwait cancer control centre, Kuwait, Kuwait

Background: The International Myeloma Working Group has developed the R-ISS (Revised International Staging System) as a simple and powerful prognostic staging system. We collected the LDH level and the cytogenetics of a group of patients and studied the difference between the ISS (International Staging System) and the R-ISS (Revised International Staging System) for those patients.

Methods: A retrospective analysis of the data collected from 121 patients registered as multiple myeloma from 2011-2015. Of the patients presented to our centre after initial work up and starting the right treatment, the patients were categorised according to age, gender, ISS stage, R-ISS stage, first line therapy and response.

Results: We recognised increase of the number of the yearly diagnosed patients with myeloma 2.48% of patients the actual date of diagnosis was before 2011 but3% of patients the actual date of diagnosis was before 2015. Median age of patients at presentation is 56 years old , 3.33% between30-40 years old, 18.33% between 40-50 years old , 35% between 50-60 years old , 31.67% between 60-70 years old and 11.67% between70-80 years old. Male to female ratio 1.75:1 (Table 1). According to ISS stage patients were categorised into14 stage I, 31% stage II, 47% stage III. Restaging using the RISS revealed10% stage I, 26% stage II, 56%stage III. Almost half of our patients are diagnosed in the third stage, and more patients were shifted from stage I or II were categorized in the third stage due to either high LDH level, high cytogenetic risk or...
even both. First line treatment 56% of the patients received Bortezomib based triple therapy, 22% received autologous stem cell transplant (CDT) (Cyclophosphamide, Thalidomide, Dexamethasone), 7% RD (Lenalidomide, Dexamethasone), 3% CyBorD (Cyclophosphamide, Bortezomib, Dexamethasone), 3%RV (Lenalidomide, Bortezomib), 2% Thal-Dex (Thalidomide, Dexamethasone), 2% RT (local Radiotherapy), 2% Watchful Wait, 1% MP (Melphalan, Prednisone) and 3% refused for treatment and lost follow up.

Summary/Conclusions: Applying the RISS system to myeloma patients is a very effective and easy method to categorise myeloma patients, a significant number of patients in Kuwait are diagnosed as stage III, with median age of 56 years although the use of novel therapies shows excellent response to most of them.

PB1973
FEASIBILITY/PHASE II STUDY OF MYELOABLATIVE BEAM ALLOGENEIC TRANSPLANTATION FOLLOWED BY ORAL IXAZOMIB MAINTENANCE THERAPY IN PATIENTS WITH HIGH RISK MYELOMA
E. Scott1,2, R. Mazlur3, S. Dreumont1, C. Gasparetto2
1Hematology and Oncology, Oregon Health and Science University, Portland, 2Hematology and Oncology, Duke University, Durham, United States

Background: While the role of allo-HCT in MM remains controversial several studies have shown encouraging PFS and OS with this treatment even in patients with high-risk myeloma (HRM). HRM manifests with early relapses and refractoriness. Median OS is 2.5 years despite aggressive therapy with novel agents. Post auto-HCT maintenance with lenalidomide is considered standard of care, but post allo-HCT maintenance presents unique challenges and has not been well studied. Ixazomib (Ixa) is a new oral proteasome inhibitor with activity in bortezomib resistant patients, and is a promising agent in the maintenance setting.

Aims: Here we present preliminary results for this trial. The primary objective is safety defined as day 100 transplant related mortality (TRM), and safety of Ixa maintenance in incidence of grade III-IV GVHD and Ixa related toxicity. Other objective is inclusion define of efficacy (ORR, PFS, MRD for CR), the ability to start Ixa, and quality of life.

Methods: The protocol was approved by a local institutional review board and ethics committee. The study was conducted in accordance with the Declaration of Helsinki. All subjects provided written informed consent prior to treatment. Eligibility criteria include: age ≤65; relapsed/refractory multiple myeloma (MM) previously treated with autologous HCT, bortezomib and an immunomodulatory agent; one of the following high-risk factors: del17p, del17p+t(14;16), del17p+amp1q+del1p, 2% Thal-Dex (Thalidomide, Dexamethasone), 2% RT (local Radiotherapy), 2% RD (Lenalidomide, Dexamethasone), 3%CyBorD (Cyclophosphamide, Thalidomide, Dexamethasone), 3%RV (Lenalidomide, Bortezomib), 2% Thal-Dex (Thalidomide, Dexamethasone), 2% RT (local Radiotherapy), 2% Watchful Wait, 1% MP (Melphalan, Prednisone) and 3% refused for treatment and lost follow up.

PB1974
EPIDEMIOLOGY OF MULTIPLE MYELOMA. THE GRANADA MYELOMA REGISTRY
R. Ríos Tamayo1,2, D. Sánchez-Rodríguez2, J. Sainz Pérez2, J.J. Jiménez Molero4, M.J. Sánchez Pérez2, M. Jurado Chacón2
1Hematology, University Hospital Virgen de las Nieves, 2Hematology, FIBAO, 3Hematology, GENYO, 4Medicine Preventive, University of Granada, 5Cancer Registry, Andalusian School of Public Health, Granada, Spain

Background: The Granada Myeloma Registry is the second largest single-institution population-based registry (Rios-Tamayo et al, 2015) of multiple myeloma (MM) referenced to date. Here we update and point out the epidemiological variables of interest.

Aims: To highlight the importance of the epidemiological perspective in the knowledge and outcome of MM.

Methods: From January 1985 to February 2017 all consecutive patients diagnosed with MM at our institution have been registered, including clinical, biological and socio-demographic variables, as previously reported. A comprehensive approach to comorbidity was recorded as well as diagnostic and treatment delay. Overall survival (OS) was estimated by the Kaplan-Meier method.

Results: 700 patients have been included in the registry, 343 men (49%) and 357 women. All cases have their place of residence in the Granada province. The median age was 67 years (range: 12-93). The race was Caucasian in 98.9%. In relation to occupation, 18.4% were skilled or elementary agricultural workers. Only 9% had a previously documented precursor disease (solitary plasmacytoma, monoclonal gammopathy of undetermined significance, or smoldering MM), and 14 patients (2%) remain alive with smoldering MM without progression. The subtype of MM is IgG 55.6%, IgA 24.8%, Light Chain only 15.9%, Non-secretory 3%, IgD 0.6% and IgM 0.2%. The International Staging System was known in 378 patients (99.3%), 2 (2.5%), 4 (4.8%) and 30 (39.9%). Baseline performance status (ECOG) was: 0 (4.7%), 1 (41.1%), 2 (26.7%), 3 (21.7%), and 4 (5.9%). Comorbidity was assessed in 498 patients. 30.6% of patients were obese at the moment of diagnosis. 8.2% had other previously known or synchronous neoplasms. 150 patients (30.1%) had three or more comorbidities.

Median diagnosis delay was 4.1 months (0.1-80) and median treatment delay was 13 days. 44 patients (6.3%) were very unfit and they did not receive active treatment. Information about stem cell transplant is available in 606 cases: 151 of them (24.9%) received a first autologous transplant. Median OS for the whole cohort was 43.1 and 22.4 months for patients younger than 65 years or 65 years or older, respectively (p<0.001). For patients younger than 65 years or later, median OS is not reached for younger than 65 and 40.4 months for the elderly (p=0.001). Information about the main cause of death is available in 230 patients: 101 (43.9%) of them died by infection.

Summary/Conclusions: MM is a very heterogeneous disease from a clinical, biological and epidemiological perspective. The distribution by sex is identical. Farmer is the most frequent occupation. Almost one in three patients are obese, and one in ten had another prior or associated neoplasm. Information is the leading cause of death. Information derived from population-based registries may help to complement data from clinical trials.

PB1975
REAL WORLD USE OF IXAZOMIB WITH LENALIDOMIDE AND DEXAMETHASONE FOR PATIENTS WITH RELAPSED AND RELAPSED REFRACTORY MULTIPLE MYELOMA
M. Ziff1,*, S. Cheesman1, C. Kyriakou1, A. Mehta1, X. Papanikolaou1, N. Rabin1, R. Popat1
1University College London Hospitals NHS Foundation Trust, London, United Kingdom

Background: Ixazomib (Ixa) is a novel oral proteasome inhibitor (PI) approved in combination with lenalidomide and dexamethasone (IRD) for the treatment of relapsed/refractory multiple myeloma (MM). This was based on the TOUR-MALINE-MM1 trial which demonstrated a progression free survival benefit over HD. However real world use often differs to clinical trials due to heterogeneous patient selection, more flexibility with dosing intensity and country specific prescribing practices/funding restrictions.

Aims: To characterise real word use of IRD by demographics, response rate (RR) and progression free survival.

Methods: This was a retrospective review of patients sequentially treated with IRD at a large UK Haematology Centre. Patients received Ixa 4mg D1, 8, 15 with lenalidomide (dose as per label) days 1-21 and dexamethasone 40mg weekly or as tolerated every 28 days until disease progression or intolerance. In some cases, Ixa was added later to RD. RR and PFS were assessed according to IMWG criteria and haematological toxicities graded by CTCAE 4.0 criteria.

Results: Up to 31th October 2018, 30 patients were treated with the IRD schedule. Median age was 65 years (32-75), male (57%), ISS: stage I 18 (60%), stage II 4 (13%), stage III 8 (27%). 27% had median of 2 (2-5) prior lines of therapy. All patients had previous treatment with a proteasome inhibitor (PI) (29 bortezomib, 5 carfilzomib) and 8 (27%) were refractory to a PI. 3 (10%) had prior lenalidomide and all remained sensitive. 23 (77%) had a prior autol-
With successful salvage, contributing to the observed long duration of local therapy compared to national averages. Pomalidomide was highly effective at rescuing patients failing lenalidomide-based regimens and well tolerated.

PB1977
APPLICATION OF CONDITIONING REGIMEN WITH BUSULFAN AND CYCLOPHOSPHAMIDE IN AUTOLOGOUS HEMATOPOEITIC STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA Y. Xu1,2, C. Fu1,2, Y. Yao2, W. Yao2, S. Jia2, L. Yan2, J. Jiang2, X. Zhu2, A. Sun2, D. Wu1,2
1Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, 2The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, Suzhou, China

Background: Busulfan is the most commonly used drug in conditioning regimens for hematopoietic stem cell transplantation and high-dose melphalan (MEL) is the standard conditioning regimen in autologous stem cell transplantation (ASCT) for multiple myeloma. Studies have shown that in ASCT for multiple myeloma, conditioning regimens containing busulfan is even more effective as HDM.

Aims: Evaluate the safety and efficacy of BUCY (busulfan and cyclophosphamide)-conditioning regimen for autologous hematopoietic stem cell transplantation (ASCT) in patients with multiple myeloma (MM).

Methods: We retrospectively analyzed the clinical data of 72 MM patients who received transplantation in the Hematology Department of the First People’s Hospital of Soochow University from May 2012 to June 2015. Among them, 36 patients underwent BUCY regimen while the others received high dose melphalan. Those were compared between the two groups including the complication, hematopoietic reconstitution and the post-transplantation efficacy.

Results: There were no significant differences in age, stage, induction therapy, mobilization method between the two groups. The transplantation-related adverse events were similar in both groups but the incidence of pulmonary infection and bloodstream infection were slightly higher in BUCY group. The median time to neutrophil engraftment in the BUCY and HDM groups were 10(8-17) days versus 10(9-13) days, taking the same time on average (P=0.46). On the other hand, the median time to platelet engraftment was 10(8-18) versus 11(9-47) days accordingly (P=0.017). The TRM in both group was 2.7%. The SCR/CR rates after ASCT (47.2% and 50.0%) were higher than those before it (38.9% and 26.6%), in both groups. In the BUCY group, the median follow-up was 12.5 (0-26) months. Six patients (16.7%) underwent disease progression. The 2-year progression-free survival (PFS) rate was 68%. Correspondingly, in the HDM group, the median follow-up time was 23 (0-38) months. Fifteen patients (41.7%) developed disease progression and the 2-year PFS rate was 55%.

Summary/Conclusions: The BUCY regimen is a safe and effective therapy for ASCT in patients with multiple myeloma. Besides, BUCY regimen is not inferior to HDM regimen. In conclusion, BUCY regimen may replace HDM regimen as a standard conditioning regimen for ASCT in multiple myeloma.

PB1978
MULTIPLE MYELOMA WITH CENTRAL NERVOUS SYSTEM INVOLVEMENT, 12 CASES AND REVIEW OF THE LITERATURE G. Varga1,2, G. Mikála2, L. Gopcsa2, Z. Csukly2, P. Reményi2, G. Varga1,* G. Szombath1, L. Gopcsa1, Z. Csukly1, P. Reményi1,1
1Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, 2Department of Haematology and Cell Transplantation, St. István and St. László Hospital, 3Laboratory of Molecular Diagnostics, Hungarian National Blood Transfusion Service, 4Heart and Vascular Center, Division of Diagnostic Imaging, 51st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary

Background: Central nervous system (CNS) propagation is a rare event in multiple myeloma (MM), but may become more prevalent as newer treatment options allow patients to have a prolonged life expectancy and with this comes the selection of increasingly aggressive clones.

Aims: We reviewed 12 MM cases with CNS involvement treated in two hospitals. Methods: Statistical analyses were performed using the SPSS (version 20.0) software package.

Results: Between 2008 and 2015 twelve MM patient developed CNS involvement which presented in all cases at relapse. The median age at diagnosis and at CNS presentation were 55.5 and 57.4 years. At first presentation nine had ISS 3, one ISS 2 and two ISS 1 stage disease, two patient presented originally as plasma cell leukaemia. FISH showed 1q amplification in 4, 13q deletion in 4, 17p deletion in 4, translocation (4;14) in 1, 11q14 deletion in 17p deletion in 1, hyperdiploidy in 1 and complex karyotype in 2 cases. In 2 cases we demonstrated the development of new karyotypic abnormalities (one 1q amplification, one 17p deletion) at CNS progression. The median number of treatment lines prior CNS progression was 6, the most common used chemotherapeutics were cyclophosphamide and thalidomide in all but one cases, two patients had lenalidomide. Six patients had ASCT before the CNS progression from which one had a second ASCT and one a reduced intensity allogeneic transplantation. The median time from diagnosis to CNS progression was 12.5 (0-26) months. Six patients (16.7%) underwent disease progression.

Summary/Conclusions: CNS involvement is rare, but could become more prevalent in the future. In our study the median time to CNS progression was 12.5 months. Two patients underwent second ASCT and one a reduced intensity allogeneic transplantation.
progression was 23.9 (3-65) months. Eight patients presented with cerebral nerve palsies, 2 with paraesthesia, 1 with hemiparesis and 1 with headache. CSF cytospin or flow cytometry was positive in 7, MRI or CT supported the diagnosis in 4 patients. Treatment consisted of combination chemotherapy, intrathelial chemotherapy, cranio-caudal radiotherapy and imids with various success. The PFS and OS from CNS progression was 63 and 125 days. Two patients survived for over a year (427 and 776 days), both responded in terms of CNS symptoms to imid-based combination therapy and one had cranio-caudal radiotherapy (Figure 1).

Figure 1.

Summary/Conclusions: CNS progression in MM has a particularly poor prognosis as it represents a late stage of an aggressive relapse which often shows chemo-refractoriness. The differential diagnosis includes infection, autoimmune or vascular diseases of the CNS as well as paraneoplasia and drug toxicity. The CNS penetration of the effective myeloma drugs is poor except for the imids, and drugs with CNS availability are usually not very effective in refractory MM.

Methods: We outline the pathways integrated at MDT level; patient characteristics and adverse event profiles of the 15 myeloma patients we have treated with Daratumumab, in a standard service setting.

Results: Daratumumab affects certain pathology 1st so samples should be clearly identified. Relevant laboratory teams need to be aware of the methods used to process samples. Daratumumab binds to CD38 on Red Blood Cells, and therefore with Cross Match Compatibility testing and Antibody Screening. Obtaining RBC Products for patients receiving Darai will take longer, requiring up to 48 hours notice. Cross match samples taken prior to treatment provide the National Blood Service Laboratory with a baseline antigen profile to aid selection of suitable blood products. Darai is detected during Paraprotein Electrophoresis; Pre and Post baseline samples help to identify the Darzalex Band in the serum; our lab use a Sebia capillary 2 analyser to separate the Dara band for accurate reporting. Bone Marrow Testing: Daratumumab affects Immunophenotyping by masking the CD38 epitope used to identify plasma cells by flow cytometry; special kits are available using a different CD38 epitope thus dealing with this issue. Infusion Related Reactions (IRRs) have been reported in over half of patients receiving Daratumumab: 95% of these were seen at the first dose. Typically involving the upper respiratory tract and include rhinitis, cough, wheeze, bronchospasm, laryngospasm and chest pain. More rarely they include rash, fever, and nausea. Reactions can be grade 1-4 so it’s important that the patient is closely monitored where there is quick access to specialist staff, resuscitation equipment and respiratory support in a high dependency setting. Staff training is important and patients must aware that they report all new symptoms so the infusion is interrupted immediately and the IRRS treated and re-started at a lower rate when the symptoms have resolved. Premedication is given one hour prior to infusion and patients with a history of COPD receive extra support. Patient characteristics. Total:15. (Table 1).

OPTIMIZATION OF APPROACHES FOR STEM CELL MOBILIZATION FOR AUTOLOGOUS STEM CELL TRANSPLANT FOR MULTIPLE MYELOMA: PRACTICAL CONSIDERATIONS

O.-L. Lee1,2
1Haematology, Royal Adelaide Hospital; 2Haematology, SA Pathology, Adelaide, Australia

Background: Autologous stem cell transplant (ASCT) is a well-established treatment for myeloma. However, the optimal strategy for stem cell mobilization remains undefined. The goal of mobilization is to collect adequate stem cells for at least 2 ASCT (4x10^6/kg), with the minimum apheresis sessions and toxicities such as febrile neutropenia.

Aims: We aim to compare stem cell mobilization using granulocyte colony stem cell factor (GCSF) only (steady state), high dose cyclophosphamide (4 g/m2) with GCSF or low dose cyclophosphamide (2 g/m2) with GCSF.

Methods: We performed a retrospective analysis of 79 patients mobilized with GCSF only from mid-2014 to Aug 2016 with 32 patients mobilized using high dose cyclophosphamide and 23 patients with low dose cyclophosphamide during a similar period.

Results: Patients undergoing steady state collection required a median of 2 days for adequate collection, in comparison to 1 day for both high and low dose cyclophosphamide. Addition of plerixafor was required in 27.8% of patients on high dose cyclophosphamide. The mean yield of CD34+ x 10^6/kg was 4.56, 8.14 and 8.3 for steady state, high and low dose cyclophosphamide respectively. The mean yield of CD34 x 10^6/kg cells collected was 5.39, 9.14 and 8.5 for steady state, high and low dose respectively. There was no significant difference in time to engraftment despite a lower dose of CD34+ cells reinfused for the steady state cohort. Admission for febrile episodes was observed in 60.7% patients mobilized with high dose cyclophosphamide, as compared to 13% of patients on the lower dose regime and none in the steady state cohort. Patients mobilized with cyclophosphamide had a longer interval between stem cell collection and transplant (median of 20, 42 and 34 days respectively for steady state, high dose and low dose). However, we observed that 60.7% patients with steady state mobilization had increases in their myeloma markers during this period, in contrast to biochemical improvement in 50% of patients mobilized with high dose cyclophosphamide and 26% with low dose cyclophosphamide.

Summary/Conclusions: All 3 strategies for stem cell mobilization have their own merit. Steady state mobilization is safe and yields sufficient stem cells; however, patients require more apheresis sessions. Moreover, more than a quarter require additional therapy with plerixafor. Of concern, greater than half of these patients have increased myeloma markers during the interval between stopping chemotherapy and mobilization which may potentially affect outcomes. Mobilization with high dose cyclophosphamide yield more CD34+ cells but with increased toxicities- 50% of patients required admission for febrile episodes. Conversely, half of these patients had improvement in their myeloma markers. The use of low dose cyclophosphamide for mobilization resulted in lower admission rates (13%), however, plerixafor is required in a fraction. In light of these findings, we propose that patients who have not achieved at least VGPR should be mobilized with cyclophosphamide, the dosage dependent on their individual risks.

PB1982

MINIMAL RESIDUAL DISEASE MONITORING IN MULTIPLE MYELOMA PATIENTS BY FLOW CYTOMETRY: A SINGLE CENTER EXPERIENCE

S. Sizikova1, N. Pronkina1, E. Baturov1, G. Usakhova1, V. Sergeevicheva1, A. Gilevich1, I. Kruchkova1
1Hematology and bone marrow transplantation, 2Laboratory of immunology, 3Laboratory of cell immunotherapy, Research Institute for Fundamental and Clinical Immunology, Novosibirsk, Russian Federation

Background: Multiple myeloma (MM) is a malignant disease characterized by an increased number of clonal (abnormal) plasma cells in the bone marrow (BM). High-dose chemotherapy followed by autologous peripheral blood stem cell transplantation (SCT) is used for the treatment of young MM patients and produces a high rate of complete remissions (CR). Recent trials with novel agent combinations alone have also resulted in high CR rates, even among old patients, high-risk patients and relapse/refractory MM. Unfortunately, most patients have a recurrences of the disease. This is due to the persistence of residual tumor cells, known as minimal residual disease (MRD), responsible for tumor relapse.

Aims: BM samples from 51 MM patients who had achieved partial or complete response or were resistant after chemotherapy, including autologous SCT, were evaluated by multiparameter flow cytometry (MFC). The study was conducted to assess the quality of remission, the correlation between the number of abnormal plasma cells of BM and other signs of disease activity, readiness of patients for autologous SCT.

Methods: The study included 51 patients MM, average age - 54 years (36-70 years), who underwent assessment of MRD from November 2014 to February 2017. According to the classification Durie-Salmon the vast majority of patients (n=40) had III stage of disease, 8 patients – II and 2 patients – I. Response to treatment was assessed according to standard EBM criteria. The time of MRD assessment 20 patients were in CR, 8 had a partial response (PR) and 15 had a resistant disease; 5 patients had a primary MM, 3 patients were in the first transplantation. Most of the patients were under chemotherapy high-dose chemotherapy with autologous SCT (n=42). Re-evaluation of MRD after therapy was managed to hold in 36 patients at a mean of 3.1 months (1.9-5.7, min-max). Analysis was performed using a FACScantoll flow cytometer (BD) and FACSDiva software (BD). Instrument performance was checked daily by recording fluorescence intensity with calibrating beads (Cytometer Setup and Tracking from BD Biosciences). Whole BM was estimated using combination of surface and intra-cellular staining CD38/CD56/CD27/CD117/CD81/CD19/CD45/cyLucLambda/CD138/cyKappa. The sensitivity of our panel MRD is 0.01% (i.e. 10^-4).

Results: Among patients in CR (n=20) confirmed the absence of MRD in 6 patients, 14 CR patients were MRD positive. MRD was detected in all patients with PR and resistant disease (n=31). The relative content of abnormal plasma cells in CR patients with MRD positive (n=14) was significantly lower than that in PR/resistant patients (n=31): 0.095% (0.026-0.271%) versus 1.3% (0.203 -5.9%), pU=0.000092. PR patients (n=8) had a lower relative content of abnormal plasma cells (as expressed tendency), than patients with resistant disease (n=15): 0.286% (0.177-1.129%) versus 1.48% (0.90-8.0%), pU=0.053. Besides the relative content of abnormal plasma cells in PR/resistant patients (n=31) correlated with the serum M-gradient concentration (r=0.42, p=0.019) in low-dose cyclophosphamide patients (r=0.54, p=0.0017).

Summary/Conclusions: Currently, we can consider that MFC could be confirmed as the method of choice for MRD monitoring in MM. If the disease is measured, then, indeed, enough to evaluate only the M-gradient level of serum. If the M-gradient is not defined, it is necessary to assess the number of abnormal plasma cells in the BM and strive for the high-quality responses at the time of transplantation. And also it can help us to regulate duration of maintenance therapy.
Results: Overall we analyzed 36 pts: 21 males and 14 females (median age 66, range 65-70); 23 had IgG MM, 4 had IgA MM and 9 had light chain MM. Induction therapy was bortezomib-based (bortezomib in combination with dexamethasone, VD, in 7, or VD plus thalidomide in 26 pts) for a median of 4 cycles (range 3-6), 2 patients received thalidomide plus dexamethasone (6-12 cycles). PBSC were collected after high-dose cyclophosphamide (2 g/sqm in 2 pts, 3 g/sqm in 11 pts, 4 g/sqm in 22 pts) plus G-CSF, plerixafor was administered in 4 pts. Three pts also received lenalidomide and dexamethasone to improve the depth of response before ASCT. At the time of conditioning, among 34 evaluable pts, 8/34 pts were in complete response/stringent complete response (CR/sCR), 19/34 in very good partial response (VGPR), 5/34 in partial response (PR) and 2/34 in stable disease (SD). The conditioning regimen consisted of melphalan 140 mg/sqm in 11 pts or 200 mg/sqm in 24 pts. A median number of 4.1 ± 10^6 CD34+ cells/Kg was reinfused (range 2.09-10.44). The most frequent complication was fever (9 pts) with gram negative bacteremia documented in 3/9 and gram positive bacteremia in 1/9. Other complications were represented by 1 case of atrial fibrillation and 3 cases of pneumonia and 1 case of VZV reactivation. All 35 pts achieved neutrophils recovery recovery after a median of 12 days (range 8-25) and platelets recovery after a median of 13 days (range 8-45) after transplant. No grade 3-4 toxicities were recorded. No transplant-related mortality was recorded within 100 days post transplantation. Three months after ASCT, among 28 evaluable pts, 10/28 pts were in CR, 14/28 pts in VGPR and 4/28 pts in PR. Three pts underwent tandem ASCT. After a median follow-up of 32 months (range 3-96) among 33 evaluable pts, 21 experienced disease relapse and 7 deaths occurred. Median PFS and OS were 21 and 40 months.

Summary/Conclusions: Our data support the use of ASCT as an effective and safe first-line treatment approach also in elderly MM pts. A careful patient selection is needed to reduce the toxicity of the procedure.

PB1985
CHARACTERIZATION OF A SERIES OF PATIENTS WITH PLASMA CELL LEUKÉMIA
P. Betancourt Medeiros1,*, R. Berganini1, F. Trigo1, J.E. Guimarães1
1Servicio de Hematología Clínica, Centro Hospitalar de São João, EPE, Porto, Portugal

Background: Plasma cell leukemia (PCL) is a rare malignancy characterized by the proliferation of monoclonal plasma cells in the bone marrow and ≥2x10^9 or ≥20% plasma cells in the peripheral blood. It is an aggressive disease, with a median survival of 7 to 11 months. Due to its rarity, it is difficult to design prospective studies or randomized trials in PCL, so collecting and publishing data from the largest number of cases is essential for the understanding of PCL’s pathophysiology and outcome.

Aims: To characterize a series of PCL patients, in order to obtain data with the potential to be used as prognostic factors and to improve clinical outcomes.

Methods: Single-center, observational, retrospective study including all PCL cases admitted in our hospital between 2007 and 2016. Data regarding demography, clinical characteristics, laboratory results, treatment, follow-up and mortality were collected and analyzed using Statistical Package for Social Sciences (21st version), searching for significant associations (p<0.05) with overall survival (OS) and progression-free survival (PFS).

Results: 15 patients were included, with a median age of 58 years. Most patients were male (60%) and had PS ECOG 0-1 (93,3%) at presentation and primary PCL (80%). Median hemoglobin (Hb) and platelets values were 8.5 g/dl and 74x10^9/L, respectively. Median plasma cell percentage was 37.3% (peripheral blood) and 60% (bone marrow). IgG heavy chain was present in 33.3% and lambda light chains in 53.3% of cases. Most patients had total serum calcium ≥4.5mmol/L, ISS III (80%), R-ISS III (73.3%) and at least 1 cytogenetic abnormality associated with poor prognosis in multiple myeloma (86.7%). Ten (66.7%) patients received bortezomib-based chemotherapy and nine patients (58.3%) were treated with an IMiD. Among variegated β-2 microglobulin (93.3%), ISS III (80%), R-ISS III (73.3%) and at least 1 cytogenetic abnormality associated with poor prognosis in multiple myeloma (86.7%). Ten (66.7%) patients received bortezomib-based chemotherapy and nine patients (58.3%) were treated with an IMiD. Among these 10 patients, 9/10 were in CR, 9/10 were in VGPR and 6/9 were in PR. After ASCT and the achievement of, at least, VGPR after chemotherapy and ASCT the median OS was 13.1 months overall for Pomalidomide and low doses of dexamethasone in RRMM patients. Those results were better when a third drug was added (Poma-Dexa, Poma-Cyclophosphamide-dexa, and Poma-Bortezomib-dexa, ORR 38.9, 64.7 and 85%; PFS 4.4, 9.5, 10.7 months respectively).

Summary/Conclusions: This study’s retrospective design and the small sample size limit the strength of our data and our conclusions. Interesting results were obtained regarding pre-treatment prognostic characteristics and the association of improved OS and PFS with treatment response and ASCT execution. More studies are necessary to determine the clinical relevance of this findings and the best treatment strategies in PCL.

PB1986
OPTIMIZATION OF POMALIDOMIDE PLUS LOW DOSE DEXAMETHASONE IN REFRACTORY/RELAPSED MYELOMA MULTIPLE PATIENTS
D. Du Val1,*, A. Gill1, N. Goibano1, M. Diaz1, H. Guillet1, A. Vazquez1, B. Pinedo1
1Hematología, Hospital universitario de Guadalajara, Guadalajara, Spain

Background: MM-003 study has presented a median PFS of 4.0 months and median OS was 13.1 months overall for Pomalidomide and low doses of dexamethasone in RRMM patients. Those results were better when a third drug was added (Poma-Dexa, Poma-Cyclophosphamide-dexa, and Poma-Bortezomib-dexa, ORR 38.9, 64.7 and 85%; PFS 4.4, 9.5, 10.7 months respectively).

Aims: To evaluate the response at therapy with pomalidomide plus dexamethasone in RRMM, and to analyze the efficacy of another drug in high risk MM.

Methods: We reported the clinical experience of the 8 patients treated with pomalidomide and dexamethasone. In patients with high risk MM (cytogenetic, extramedullary myeloma or plasmatic cell leukemia) pomalidomide and dexamethasone have had poor response. In myeloma cells in the bone marrow and third drug (cyclophosphamide or Bortezomb) and we have obtained the best results.

Results: We have used pomalidomide and dexamethasone in 4 patients and poma-dexa-cyclophosphamide in 3 patients (extramedullary myeloma) and

Summary/Conclusions: The aging of population and the higher sensitivity of laboratory techniques for diagnosing of MG is reflected in the incidence of MGUS, which increased from 17.04 cases per 100,000 in 2003 to 35.00. MM incidence in our area did not increased in parallel.
Background: Most outcome data for multiple myeloma (MM) come from clinical trials which can not necessarily be extrapolated to real-world patients. More information is needed on patients treated in the ‘real world’ and in a wider range of settings.

Aims: To compare and contrast baseline characteristics, investigations, and initial therapies in different geographical regions, Australia/New Zealand (ANZ) and Austria, through first analysis of data from two established MM registries on behalf of the steering committees of the Australian and New Zealand Myeloma and Related Diseases Registry and the Austrian Myeloma Registry.

Methods: Analysis of data from newly diagnosed MM patients enrolled on the Austrian Myeloma Registry (AMR) and the ANZ Myeloma and Related Diseases Registry (MRDR) from 2002-2017.

Results: Available data from 250 and 691 patients from the AMR and ANZ MRDR, respectively, were included. DEMOGRAPHICS: The AMR cohort was younger (median age 63.5 years vs 65 years as per the AMR and MRDR, respectively). The proportion of female/female patients was similar between the AMR and MRDR (56% and 64%, respectively). PRESENTATION: Iqg myeloma was the most common sub-type of disease in both registries (64% vs 55% and 58%-58%, respectively) with more light chain only disease on the AMR (26% vs 20%; p=0.19). Presence of documented previous plasma cell dyscrasias was similar (21% 19% on the AMR and MRDR, respectively). INVESTIGATIONS: A higher proportion of patients underwent MRI (51% vs 25% and 27% and skeletal survey (78% vs 60%) on diagnosis on the AMR than the MRDR, respectively. Baseline laboratory investigations were similar, however, patients on the MRDR demonstrated higher median LDH (176-178 vs 187-186 units/L) and serum calcium (2.34-2.48 vs 2.41-2.45 mmol/L) but less serum albumin serum albumin (39.39 vs 35.35 g/L) when compared to the AMR. STAGE: ISS staging was similar on both registries with ISS stage 2 being most common in both cohorts (42% vs 40% on the AMR and MRDR, respectively) while ECOG performance status at diagnosis was lower in the MRDR cohort (ECOG 1: 43%-44% vs 81%-78% on the AMR and MRDR, respectively). FIRST LINE THERAPY: First line therapy was predominantly bortezomib (velcade - V) based on both registries (81% vs 85%). Vincristine (V) was the most common treatment on the MRDR (29%) followed by Vithalidomide/D (VTD) (25%) with a combination of either V or VTD respectively.漢語

Background: Plasmablastic (PB) feature of plasma cells in multiple myeloma (MM) has long been identified as poor prognosis. Interestingly it does not take part of International Revised Scoring System (R-ISS). Similarly, the prognostic impact in the era of novel agents and novel classes in MM is unknown. Finally, the percentage of PB in the bone marrow to which a poor prognosis develop is unclear.

Aims: To assess which modality of treatment of plasmablastic MM was associated with longer progression free survival (PFS) and overall survival (OS).

Methods: We have performed a retrospective analysis of all MM in our center from May 2005 to November 2016, and sought for MM with plasmablastic features, characterized by immature cells with high proliferative index rate. The PFS and OS were calculated since the first time the PB morphology was observed in the bone marrow aspiration, at the outset in newly diagnosed patients or in relapsed patients.

Results: 65 patients with PB were included. Adverse cytogenetic per IMWG criteria was reported in 6 patients, del17p x3, t(4;14) x3, and one with both. 33% were ISS 3, and 23,1% R-ISS 3. Extramedullary disease (EMD) was reported in 40%. 35 patients (53,8%) were in first-line therapy. The overall response rate with any triplet-based treatment containing always a proteasome inhibition and IMiDs or alkylators was 49,2%, with 29,2% VGPR and 4,6% CR. The median PFS and OS were 6,9 and 14,9 months as a whole, respectively. The median PFS with any triplet-based treatment containing always a proteasome inhibition and IMiDs or alkylator was 49,2%, with 29,2% VGPR and 4,6% CR. The median PFS and OS were calculated since the first time the PB morphology was observed in the bone marrow aspiration, at the outset in newly diagnosed patients or in relapsed patients.

Summary/Conclusions: This pilot study between the AMR and ANZ MRDR demonstrates many similarities but also highlights significant differences, particularly in first line therapy and depth of response. Future studies between the AMR and MRDR will provide a platform for ongoing international benchmarking.
weeks and every 3 months later (minimum follow-up: 6 months). EBR was defined as 25% on M-protein increase (any amount for patients on CRiSR) and/or ≥20mg/dl FLC increase, and/or 25% involved HLC increase with abnormal ratios. For urine, an increase >500mg/24 hrs of involved free-chain protein.

**Results:** Fifty-five patients were registered. Median follow-up 47 months. MF ratio: 29/26, mean age 59.5 y (33-71). Immunoglobulin subtype: IgG: 41.8%, IgA: 23.6%, IgG-IgA: 61.2%, IgA: 16.4%, (9). IgA-λ: 7.3% (4). Bence-Jones-IgA: 3.6% (2). Bence-Jones-Lambda: 7.3% (4). Durie-Salmon Stage: IA: 13.5% (7), II-A: 32.7% (17), III-A: 44.2% (23), III-B: 9.6% (5), missing-data 3 case. All patients received Bortezomib based therapy and MEL200 as ASCT conditioning. Status pre-ASCT: minimal response: 12%, Partial Response (PR): 50.0%, very-good-PR (VGPR): 28.0%, complete response (CR): 6% and string response (SR): 4.0%. After ASCT, evaluation reveals that 13.0% achieved SR, 30.4% VGPR and 39.1% PR. During follow-up, 34/50 (68) patients who achieved at least PR after ASCT, had a clinical relapse/progress, median PFS 41 months (31.5-50.5). EBR were detected in 28 patients, of them 22/34 (64.7%) clinically relapsed patients at median time 8.0 (2-22) months before symptomatic relapse. The EBR were detected by FLCr (36.7%), HLCr (22.7%), FLC+SPE (4.5%), FLC+IFX (9.1%), FLC+HLC+SPE (13.6%), FLC+HLC+SPE+UPE (13.6%).

**Summary/Conclusions:** Both FLC and HLC are useful tools to detect EBR in more than 50% of patients in our cohort ahead other techniques.

**PB1990**

**EARLY MORTALITY (<6 M) IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS: COMPREHENSIVE INTERVENTION**

V. Martínez-Rubíes1,2, B. Ballina1, S. Cerda1, N. de las Heras1, M. Fuentes1, L. Villada1, M. Rodríguez-Cigala1, F. Ramuñ3, F. Escalante1, L. Villada1, M. Rodríguez-Cigala1, F. Ramuñ3, F. Escalante1

**Background:** Early mortality in the first 6 to 12 months from diagnosis is well recognized in newly diagnosed multiple myeloma (NDMM) patients, with rates in the real-world setting of around 20-30%.

**Aims:** In a retrospective analysis of the causes of death performed by the end of 2012 we identify 2 different causes in the 2 consecutive periods analyzed. In the first period (1998-2006) the main cause was MM progression and in the second (2006-12) was secondary to infectious complications. Additional analysis were done after it an is can identify a patient and a infectious profiles. Main risk factors from the patient were: age (over 75), suboptimal treatment and renal failure (calculated ClCr<50 ml/min). The infectious occurred mainly in the first 3 months from diagnosis and principally polymicrobial and multiresistant infections.

**Methods:** After this analysis several measures were taken to reduce this high early mortality: 1) To promote the ambulatory regime both in diagnosis and for the rapid assessment of complications to avoid or shorten income and to reduce these nosocomial-behaviour infection complications. 2) Early initiation of ‘optimal’ anti-myeloma treatment. 3) Get infectious prophylaxis in patients over 75 and/or renal failure with Septrin®.

**Results:** 343 pac NDMM were treated between 1998 and 2015 (127 in the 1st period, 115 in the 2nd: 242 pts before 2013; and 101 in the 3rd period: 2013-15). The median age at dx was 74 years (39-100). The number of patients died <6m was 77. 60 died before 6 months: 55 before 2013 (29 in the 1st period (22.8%) and 26 in the 2nd (22.6) and 5 after 2013 (5.0%). Of these, 60, 37 had a severe infectious complication. The main cause of mortality before 2013 was infectious complications, (14 of 28 early death in the first period and 22 of 26 in the second). Severe pneumococcal infections were infrequent (11%) In the 3rd period, mortality <6m was reduced by 77% (22% vs 5%) (p=0.001); There was only 1 severe infection (OS) in this period (CMV reactivation, probably Pneumocystis pneumonia infection, E. Coli bactoperiemia and an intestinal necrosis after an atrial fiblation embolism) Figure 1 (upper corner). Improvement in early mortality increases significantly overall survival: 32.5 monts vs not reached pre and post-2013 (p=0.0034).

**Summary/Conclusions:** Infectious complications and progression of MM have been the main cause of early mortality in patients with NDMM. Identifying potential “modifiable” variables and acting on them improves the short-term prognosis of patients with NDMM like: Supportive treatment to prevent infectious complications (avoid unnecessary hospitalization, antibioretical prophylaxis) and rapid access to optimal antiMM treatments. These improvements of short-term

**PB1991**

**FIRST LINE USE OF NOVEL AGENTS BEFORE AUTOLOGOUS SCT HAS A POSITIVE IMPACT ON TIME TO SECOND PROGRESSION AND SURVIVAL IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA UNDER 70 YEARS**

S. Gassiot1,2, C. Mottöl3, M. Morgades1, Y. Gonzalez4, M. García-caro1, J.-M. Ribera1,4, A. Crigi1,2

1Hematology, Hospital Germans Trias i Pujol - ICO, Badalona, 2Universitat Autónoma de Barcelona, Cerdanyola del Vallés, 3Universitat Autònoma de Barcelona, Badalona, 4Hematology, Hospital Dr Josep Trueta, Girona, Spain

**Background:** Most clinical trials for multiple myeloma (MM) patients using novel agent-based regimens before autologous stem cell transplantation have shown improvement in response rates and progression-free survival, however they have failed to identify a significant overall survival (OS) benefit.

**Aims:** Our aim is to analyze the potential impact of initial induction in the feasibility of second responses that also contributed to longer PFS periods. After a median follow-up of 6.97 years, clear differences in OS were observed (7.97 years for NA compared to 3.35 years in CC, P=0.001). Despite the fact that better risk patients in the NA group were more likely to remain in first or second response, relapsed and refractory patients in this group still presented longer survivals beyond second relapse than patients in the CC group (Figure 1).

**Results:** The overall response rate after completing first line treatment for all the 154 eligible patients was 85%, 79% in CC compared to 94% in NA (P=0.012). Very good partial response or better for NA was significantly higher than for CC (39% vs 29%, P=0.012). Patients in NA demonstrated not only a superior median progression-free survival (2.8 years vs 1.6 years, P=0.03) but also superior median progression-free survival from diagnosis to second progression – PFS2 (5.2 years vs 2.7 years, P=0.003). In both cohorts PFS1 and PFS2 represented more than 50% and 80% of life expectancy respectively. It could be hypothesized that CC patients would obtain more benefit than NA patients of second-line therapy, as they would be naïve to the novel agents used at relapse, but this is not the case. The use of thalidomide and/or bortezomib induction did not reduce the efficacy of these same agents second line. Indeed, these patients also had the best second responses that also contributed to longer PFS2 periods. After a median follow-up of 6.97 years, clear differences in OS were observed (7.97 years for NA compared to 3.35 years in CC, P=0.001).

**Summary/Conclusions:** New agent based first line induction treatments in newly diagnosed MM patients provide benefits beyond first progression free survival that contribute to a significant improvement in OS.
Background: Multiple Myeloma (MM) is mainly a disease of the elderly and the very elderly patients (80 years of age or more) comprise one third of all MM patients. This subset of patients suffer from concomitant disabilities and/or comorbidities and require a different and a more individualized therapeutic approach, including the novel agents.

Aims: The aim of our study is to verify safety and efficacy of novel agents with the reliability to maintain a good quality of life and obtain a maximal disease control.

Methods: Patients from 8 Hematology Centers of the “Rete Ematologica Pugliese (REP)” were included in this study. Between January 2011 and December 2016, 71 patients (M/F: 42/29) with a median age of 82 years (range 80-91) were diagnosed as newly symptomatic MM. Of the entire study population, 40 (56%) patients showed an ECOG score lower than 2. According to immunoglobulin heavy and light chain isotypes, patients had IgG-k (n=23), IgG-l (n=16), IgG-k (n=14), IgA (n=6), micromolecular kappa (n=8) and lambda (n=4) chains. On the basis of ISS, patients were classified as I (n=4) score, II (n=23) and III (n=44) score, respectively. When CRAB features were considered, bone lesions represented the most frequent (n=43, 60.6%) clinical manifestations, while a hypercalcemia and renal failure were found in 35 (49.3%) and 2 (2.8%) patients, respectively. Majority of patients (n=49, 69%) showed at least 1 comorbidity requiring specific treatments, and 11 patients (15.5%) showed more than 3 comorbidities. Patients were treated according to Bortezomib-based regimens (VMP, VCD and VD) (n=45; 63.4%), Lenalidomide-based regimen (RD) (n=11; 16.2%) and Pomalidomide-based regimen (MPT) (n=5; 7%). Only 13 patients (18.3%) did not receive any novel agent.

Results: Based on IMWG criteria, 15 patients (21.1%) achieved a CR, 15 patients (21.1%) a VGPR and 15 patients (21.1%) a PR. Fourteen patients (19.7%) and 12 (17%) patients experienced a SD and a PD, respectively. As second line of treatment, Bortezomib was used in 14 (33.3%) patients, Lenalidomide in 17 (40.5%) patients and Thalidomide in 3 (7.2%) patients. Height patients (19%) were treated with old drugs (Melphalan, Cyclophosphamide or Bendamustine). Pomalidomide was used as third line-therapy in 3 patients. After 72 months (median 32.5 months) of follow-up, 33 (46.5%) patients remained alive with a median survival of 17.8 months (25.2%) died. Last follow-up from 13 patients was unavailable. Hematological and extra-hematological toxicities were similarly distributed (13.3% and 18.3%, respectively) and usually weak/moderate. Neuropathy was the most common toxicity reported (n=5; 7%). Of patients treated with only novel agents (n=58), hematological and extra-hematological toxicity was observed in 14% and 16% patients, respectively.

Summary/Conclusions: We showed that all MM patients can be treated by novel agents independently of the age. Results from our study show that particularly very elderly and frail patients can benefit from these drugs by prolonging their life expectancy and maintaining a good quality of life.

PB1993
BORTEZOMIB-MELPHALAN-PREDNISONE VERSUS MP AS INITIAL TREATMENT FOR VERY ELDERLY PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA

1Institute of Medicine, Yeungnam University College of Medicine, Daegu, 2Samsung Medical Center, Sungkyunkwan University School of Medicine, 3University of Ulsan College of Medicine, Seoul, 4Kyungpook National University Hospital, Daegu, 5Seoul National University Hospital, 6Ewha Womans University Hospital, 7Hwasun Hospital, Hwasun, 8Hallym University Sacred Heart Hospital, Anyang, 9Catholic University College of Medicine of Daegu, 10Severance Hospital, 11Yonsei University College of Medicine, Seoul, 12Seoul National University Bundang Hospital, Seongnam, 13National Cancer Center Research Institute, Goyang, 14Busan Paik Hospital, 15Seoul National University Bundang Hospital, 16Seoul National University School of Medicine, Seoul, 17Seoul National University College of Medicine, Seoul, 18Ewha Womans University College of Medicine, Daegu, 19Ewha Womans University Hospital, Daegu, Korea, Republic Of

Background: Although bortezomib-melphalan-prednisone (VMP) therapy is a well-established standard treatment for patients with multiple myeloma (MM) who are ineligible for high-dose therapy, it is not clear whether very elderly patients should be treated with VMP in clinical practice, considering the toxicities.

Aims: The purpose of this case-control study was to compare the efficacy of VMP versus melphalan-prednisone or cyclophosphamide-prednisone (MP/CP) as initial therapy for elderly patients.

Methods: We retrospectively studied 233 patients aged 75 years or older with newly diagnosed multiple myeloma between March 2007 and February 2015. One-hundred thirty one patients received VMP and 102 patients received MP/CP regimen were enrolled from 15 institutions throughout Korea.

Results: Patient characteristics were comparable in these two groups. Overall response rate was 70.2% in VMP patients and 48.0% in MP/CP patients (P=0.001). Complete response rate was 22.9% in VMP patients and 7.8% in MP/CP patients (P=0.002). After a median follow-up for survivors of 28.5 months, progression-free survival (PFS) and overall survival (OS) were significantly different between the two groups (PFS: median 11.5 months in VMP and MP/CP group, respectively, P=0.108; OS, median 39.4 vs 22.8 months in VMP and MP/CP group, respectively, P=0.006). Nonetheless, for 61 patients who were aged ≥80 years, PFS and OS was not significantly different between the two groups (PFS, median 19.6 vs 13.2 months in VMP and MP/CP group, respectively, P=0.376; OS, median 27.8 vs 17.8 months in VMP and MP/CP group, respectively, P=0.443).

Summary/Conclusions: Although VMP therapy was associated with a significant improvement in overall survival among patients ≥75 years, there is no differences for patients aged 80 or older. Frailty and comprehensive geriatric assessment should be incorporated to guide treatment decisions for this population.
Summary/Conclusions: Multiple myeloma patients with concurrent HIV infection treated on HAART tolerate ASCT for treatment of myeloma as well as myeloma patients without HIV infection and have generally good outcomes.

PB1995
FEASIBILITY OF USING GLOBAL FDG UPTAKE IN BONE MARROW TO ASSESS TREATMENT RESPONSE IN MULTIPLE MYELOMA

M. Oestergaard1,2, W.Y. Raynolds1, M.Z. Zirakchian2, R. Taghvaei2, A. Nielsen3, J.T. Asmussen4, P. Holdgaard5, T. Plesner6, A. Alavi2, N. Abildgaard1, P.F. Høilund-Carlsen3

1Hematology, Odense University Hospital, Odense, Denmark, 2Radiology, Hospital of the University of Pennsylvania, Philadelphia, United States, 3Nuclear Medicine, Odense University Hospital, Odense, 4Nuclear Medicine, Vejle Hospital, Vejle, Denmark

Background: Multiple myeloma (MM) is characterized by plasma cell proliferation and expansion primarily in the bone marrow. Modern assessment of MM using FDG-PET has so far been limited to the analysis of focal lesions, requiring subjective interpretation to determine overall disease activity.

Aims: A novel method using CT segmentation to determine global bone marrow activity portrayed by FDG uptake was used to achieve a comprehensive understanding of disease burden in patients with MM before and after therapy.

Methods: Prospective FDG-PET/CT data of 23 MM patients between ages of 50 and 76 (mean=64.3, males=21, females=2) were collected from Odense University Hospital (NCT02187731) and included scans before initiation of treatment and at end of treatment (EOT) two months after high dose chemotherapy with stem cell support. All scans were conducted 60 min after intravenous injection of 4-6 MBq per kg of FDG. Images were analyzed using an iterative thresholding algorithm that delineates a continuous region based on Hounsfield units from the CT data (OsisiX software; Pixmeo SARL; Bernex, Switzerland), allowing for segmentation of the total skeleton on a fused PET/CT image. This enabled the quantification of FDG uptake representing the entire skeleton, providing a global SUVmean that considers all bone marrow involvement. Global SUVmean scores were compared before and at EOT using a two-tailed paired t test.

Results: A decrease in marrow FDG uptake was observed at EOT compared to baseline in most patients. The calculated global SUV/mean uptake decreased after initiation of treatment in 17 (73.9%) of the cases and increased in 6 (26.1%) of the cases. Changes in SUVmean were analyzed using a paired t test. Global SUVmean scores were compared before and at EOT using a two-tailed paired t test.

Summary/Conclusions: We assessed the effects of treatment in MM patients using a novel technique for global quantification of FDG uptake in the bone marrow and skeleton and found lower global uptake at EOT. However, a limitation of our approach is the absence of evidence suggesting that FDG uptake is a meaningful discriminant of response. Global assessment rather than focal analysis of discrete lesions represents a robust and straightforward method of determining total disease activity that potentially will be of value in treatment evaluation, disease monitoring and prognosis in multiple myeloma.

VALUE OF MYELOMA PROGNOSTIC INDICES IN ERA OF NOVEL DRUGS IN TRANSPLANT SETTING

V. Zatezalo1, A. Hanček1, N. Gredelj-Simec1, V. Milunović1, M. Bogošelj-Patekar1, M. Lukić1, B. Jelić-Puškavec2, A. Štrikč3, D. Radić-Krstić1,4, S. Ostojić Konjoli5,6

1Department of Haematology, 2Department of Cytology, 3Department of Pathology, Clinical Hospital Merkur, Zagreb, 4School of Medicine, Osijek, 5School of Medicine, Zagreb, Croatia

Background: Despite the era of emerging novel agents, autologous peripheral blood stem cell transplantation remains backbone of myeloma treatment.

Aims: The main aim of our study was to evaluate the role of tandem transplantation in myeloma treatment as well as prognostic indices in era of novel drug therapy.

Methods: We consecutively included all patients transplanted due to myeloma at our center from 2012 to the end of 2016. Patients were treated with either VAD or bortezomib based therapy. After induction therapy, all patients proceeded to mobilization therapy cyclophosphamide 3g/m² and received pegfilgrastim. Preparative regimen was either MEL 200 for fit patients or MEL 140 for frail and those with severe renal function impairment. Patients treated with VAD who had poor response after autologous transplantation were subsequently treated with bortezomib based therapy. We examined following baseline characteristics: age, proportion of plasma cells in bone marrow biopsy or aspirate, FISH and lactate dehydrogenase (LDH). Additionally, for each patient International Staging System (ISS), Revised International Staging System (ISS-R) and Durie Salmon staging were calculated. Patients with other malignant diseases and infections were diagnosed by the observed statistical difference of the dependent means before and after treatment (P=0.0053).

Results: From January 2012 to December 2016 hundred and one patient with MM (49 male, 52 female), median age 55 (range 22-71), were transplanted. Bortezomib based induction therapy was used in 55 (54.5%) and VAD induction was used in 46 (45.5%) patients. Median OS of all treated patients was 73 months; median OS of VAD group was 73 months while in bortezomib group median OS was not reached, but this difference was not statistically significant (P=0.19). TNT was significantly longer in bortezomib group than in VAD one (27.8 vs 17.5 months respectively; p=0.02). Interestingly prognostic indices could not discriminate patient groups according to OS (p=0.1), but could discriminate them due to TNT (p=0.008), possibly due to cross-over to bortezomib treatment after treatment failure. TNT had a significant correlation with levels of LDH (p=0.04) and no significant correlation with number of plasma cells in bone marrow. OS was significantly longer in those with longer duration of time to next treatment (p=0.0004). There was no difference in OS or TNT in patients treated with tandem transplant vs single transplant (p=0.68 and p=0.57 respectively), possibly due to heterogeneity of tandem group.

Summary/Conclusions: Even if novel drug therapy seems to converge risk groups to lower ones, prognostic indices remain relevant. Due to heterogeneity of patients and myriad of known prognostic factors further studies are needed so they may be translated into risk adapted therapy approach.

PB1997
WHICH ORGAN SHOULD WE BIOPSY TO DIAGNOSE AL AMYLOIDOSIS?

1Hematology, 2Anatomical Pathology, 3Cardiology, Hospital Universitario Puerta de Hierro de Majadahonda, 4Cardiovascular Proteomics, Centro Nacional de Investigaciones Cardiovasculares Carlos III, Majadahonda, Spain

Background: Light chain (AL) amyloidosis is a deposition disease with can affect many organs and with a variable but usually bad, prognosis. Therapy requires a quick and correct diagnosis. Accurate identification of amyloid deposition and of the amyloid subtype in tissue biopsies is thus, mandatory. Random biopsies of easily accessible tissues such as subcutaneous fat, gingivae or rectum are usually recommended but sensitivity of this approach is low.

Aims: To present our experience with tissue biopsies performed in 62 consecutive patients diagnosed of AL amyloidosis in our center.

Methods: We reviewed all tissue biopsies performed during the study period (2004-2017) in 62 consecutive patients diagnosed of AL amyloidosis at the same center. A bone marrow (BM) biopsy was performed per protocol in all cases. Decisions on biopsies were taken considering organ involvement and accessibility: skin, lymph nodes, lung or tongue biopsies were performed when lesions were seen on clinical or X-ray examinations, cardiac biopsies in the presence of increased NT-proBNP (N-terminal natriuretic peptide) levels and typical echocardiographic findings, kidney biopsies in patients with nephrotic syndromes. Biopsies were stained with Congo Red and read under polarized light with a Texas filter. Subtyping of the amyloid was done using anti- kappa, anti- lambda, anti-TTR and anti-A antibodies. If any biopsy was positive for AL amyloid, no further biopsies were performed unless necessary for therapeutic decisions.

Results: A total of 152 biopsies were performed during the study period: see Table 1.

Summary/Conclusions: Prognosis in AL amyloidosis is slowly improving with the use of new anti-myeloma drugs and may improve further with new monoclonal antibodies. Therapy requires an early and accurate diagnosis. We do not perform random biopsies of tissues such as fat or gingivae due to low sensitivity. Our hands biopsy protocols that are based on accessibility: skin, lymph nodes, lung or tongue biopsies were performed when lesions were seen on clinical or X-ray examinations, cardiac biopsies in the presence of increased NT-proBNP (N-terminal natriuretic peptide) levels and typical echocardiographic findings, kidney biopsies in patients with nephrotic syndromes. Biopsies were stained with Congo Red and read under polarized light with a Texas filter. Subtyping of the amyloid was done using anti- kappa, anti- lambda, anti-TTR and anti-A antibodies. If any biopsy was positive for AL amyloid, no further biopsies were performed unless necessary for therapeutic decisions.

Results: A total of 152 biopsies were performed during the study period: see Table 1.
A COMPARISON OF CYCLOPHOSPHAMIDE-GLUCOCORTICOIDS AND LENALIDOMIDE-DEXAMETHASONE AS TREATMENT FOR MULTIPLE MYELOMA IN FIRST RELAPSE AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION

R. Sterrett1,2, A. Figueiredo2, R. Mallick3, N. Kekre1,2, H. Atkins1,2, A. McCurdy1,2
1Department of Medicine, University of Ottawa, 2Ottawa Hospital Research Institute, 3School of Epidemiology, Public Health and Preventive Medicine, University of Ottawa, 4Clinical Epidemiology Program, Ottawa Hospital Research Institute, 5Division of Hematology, The Ottawa Hospital, Ottawa, Canada

Background: The optimal management of relapsed Multiple Myeloma (MM) with respect to therapeutic combinations and sequence remains controversial and is actively evolving. Many commonly used regimens have not been directly compared. These agents vary widely in cost, and knowledge of their relative efficacy is of particular importance in regions where cancer medicines are publicly funded.

Aims: We sought to compare the efficacy and safety of two commonly used regimens for relapsed MM using historical cohorts from a single transplant center.

Methods: A retrospective observational study was performed between January 1991 and November 2016 to compare the efficacy of cyclophosphamide and dexamethasone/prednisone (Cyclo), or lenalidomide and dexamethasone (Len-Dex) for relapsed MM post autologous stem cell transplant (auto SCT). The primary outcome was Time to Next Treatment 2 (TTNT2), defined as time from first relapse requiring therapy after auto SCT to second relapse requiring therapy. The secondary outcome was overall survival, defined as time of diagnosis to death from any cause. Outcomes were assessed by Kaplan Meier methods and overall differences determined by log rank test. Hazard ratios were calculated for individual treatment groups and compared by univariate and multivariate logistic regression.

Results: A total of 243 patients underwent treatment for MM at first relapse post autologous transplant. Of these, 139 were included in this analysis: 88 Cyclo and 51 Len-Dex. Patient demographics and disease characteristics were similar between each group for age, sex, subtype of MM and ISS Stage (p>0.05). Vincristine, Doxorubicin and Dexamethasone (VAD) was the most common treatment at diagnosis for the Cyclo group (68%), whereas bortezomib-based therapy was the most common for the Len-dex group (76%) (p=0.0001). No differences were observed in overall response rate or depth of response based on induction therapy between both groups. Median time to first relapse requiring treatment after auto SCT was longer in the Cyclo group, 36 months vs 25 months (p=0.0008). The median TTNT2 was similar for the two groups: 12.2 months (IQR, 4.56-27.96) for Cyclo and 12.1 months (IQR, 4.80-29.16) for Len-Dex (p=0.52). However, after adjusting for standard patient and disease related factors in a multivariate model, TTNT2 was shorter for Cyclo compared to Len-dex (HR 2.29; 95% CI, 1.17 – 4.51; p=0.016). The median overall survival was 84 months for Cyclo and 75.6 months for Len-dex (p=0.31). In the multivariate analysis, overall survival was not different for Cyclo compared to Len-dex (HR 0.99; CI 0.42 – 2.34; p=0.99). There was no significant difference in rates of hospitalization, infection, or grade 3 adverse events between the two groups (Figure 1).

Figure 1. Survival curves.

Summary/Conclusions: In this observational study of patients with relapsed multiple myeloma post autologous stem cell transplantation, Lenalidomide-dexamethasone was associated with longer TTNT2 compared with Cyclophosphamide-glucocorticoids. However, there was no difference in overall survival. Cyclophosphamide is considerably less expensive than the novel agents. In an era when fiscally sustainable care for MM remains a challenge, further prospective studies are required to compare cyclophosphamide with novel agents in the management of relapsed multiple myeloma.

PB1999

CLINICAL IMPACT OF THE PLASMA LENALIDOMIDE CONCENTRATION AND THE ANALYSIS OF ANTI-TUMOR IMMUNE RESPONSE IN NEWLY DIAGNOSED MULTIPLE MYELOMA TREATED WITH LENALIDOMIDE AND DEXAMETHASONE THERAPY

T. Kobayashi1,2, M. Miura2, T. Nioka2, Y. Fujioka1,3, M. Abumya2, S. Ikeda1, T. Yoshioka1, Y. Kameoka1, H. Nishikawa4, N. Takahashi1
1Hematology, Nephrology and Rheumatology, Akita University Graduate School of Medicine, 2Pharmacy, Akita University Hospital, Akita, 3Division of Cancer Immunology, Exploratory Oncology Research and Clinical Trial Center, National Cancer Center, Chiba, Japan

Background: Lenalidomide (Len) and dexamethasone (DEX) combination therapy (Ld) is now the standard treatment of multiple myeloma (MM). Len has both a direct effect on MM cells and an immunomodulatory effect and recently many drugs are combined with Ld therapy to expect the synergistic anti-tumor immune response. However, adverse events (AEs) make continuation of Ld therapy difficult for some patients especially for elderly patients.

Aims: To investigate the safe and effective plasma concentration of Len and the anti-tumor immune response change in MM patients treated by Ld therapy.

Methods: Forty patients (18 men and 22 women) were enrolled in this study. Median age was 75.5 years old (range 61-86). Len was administered on days 1–25 of a 28-day cycle, and DEX, on days 1, 8, 15, and 22. The plasma concentrations of Len just before oral administration and 1, 2, and 4 hr thereafter were analyzed by using liquid chromatography-tandem mass spectrometry. Before and after Ld therapy, Peripheral blood mononuclear cells (PBMCs) of MM patients were isolated from whole blood by Ficoll-Hypaque density-gradient centrifugation. PBMCs were stained with the fluorescent dye-conjugated antibodies against surface antigens and intracellular antigens and evaluated by flow cytometry. Intracellular cytokine production of IFN-γ, TNF-α, IL-2 and CD107a molecule was detected after stimulation with PMA/ionomycin for 5 hours in the presence of protein transport inhibitor Golgi stop (BD Bioscience). Analysis was performed using LSR Fortessa (BD Bioscience) and Flowjo version 10.2 software (TreeStar). This study protocol was approved by the Ethics Committee of Akita University Hospital, and all recipients gave written informed consent.

Results: 21 patients showed renal impairment (RI) necessary to adjust initial Len dosage. Adverse cytogenetics of del17p and t(4;14), detected by using fluorescence in situ hybridization, were found in 2 and 4 patients, respectively. The median initial dosage of Len was 15 mg and DEX 20 mg. The overall response rates were 68.6% and the 2-year progression-free survival was 70.8% at a median follow-up of 26.5 months. Grade 3 to 4 nonhematologic AEs were observed only in 8 patients. We estimated the AUC0-24 of Len by using formula as we previously reported (Ther Drug Monit 2014) and the cut-off value of the hematologic AEs was 2531.5 mg/hr/ml (sensitivity 81.3%, specificity 80%) and non-hematologic AEs 3023.5 mg/hr/ml (sensitivity 78.9%, specificity 62.5%). After Ld therapy, naïve subset of CD4 and CD8 T cells and monocytic MDSC reduced significantly. On the other hand, effector memory subset and intracellular cytokine productions of IFN-γ, TNF-α, IL-2, and CD107a of CD4 and CD8 T cells increased significantly (Figure 1).

Summary/Conclusions: Len can be administrated safely even in elderly patients with RI by using the estimated AUC0-24 of Len as a prediction marker of AEs. Enhanced cytokine production and increased memory subset of T cells were observed after Ld treatment.

PB2000

THE ROLE OF EXPRESSION CD56 ON BONE MarROW PLASMA CELLS AND EXTRAMEDULLARY PLASMA CELLS IN PATIENTS WITH MULTIPLE MYELOMA

M. Firsova1, L. Mendeleva1, A. Kovrigina2, M. Soloviev1, O. Pokrovskaya1, M. Nareko1, L. Kuzmina2, V. Sevchenko1
1Department of High-Dose Chemotherapy of Paraproteinemic Hemoblastosis, 2Pathology department, 3Bone Marrow Transplantation Department, 4National Research Center for Hematology, Moscow, Russian Federation
Background: The myeloma cells interact with the bone marrow microenvironment through several adhesion molecules. One of them is CD56 (neural cell-adhesion molecule N-CAM) – a membrane glycoprotein, a member of the immunoglobulin superfamily, expressed on the surface of malignant plasma cells of patients with multiple myeloma (MM). Decreased expression of CD56 is considered as one of the possible factors, that help tumor cells to spread outside the bone marrow.

Aims: To evaluate the impact of CD56 expression on the rate of overall survival (OS) in MM patients with extramedullary disease (EMD).

Methods: The study included 32 patients with primary MM (17 males, 15 females) 23-77 years old (median value: 52 years old). The disease was diagnosed in accordance with the IMWG criteria (2014). 17 patients had EMD including 14 patients with soft-tissue plasmacytomas associated with bone and 3 patients with extramedullary foci in the neck area, in the stomach, in the liver. In all cases a tumour biopsy and bone marrow trephine biopsy were performed, that confirmed the presence of malignant plasma cell infiltration. Paraffin block slices from trephine biopsy material and tumour biopsy material were used to perform an immunohistochemistry (IHC) analysis with an antibody to CD56. Kaplan-Meier survival curves were generated, statistical analysis was done using the program «Statistica» ver.10.

Results: In patients with plasmacytomas the IHC analysis of trephine biopsy material showed CD56+ in 59% cases vs 73.4% in patients without EMD. Five-year OS in patients with CD56+ in the bone marrow was 90%, which was significantly higher (p=0.04) than that of the patients with CD56 - 0% with follow-up of 5 to 61 months (median 20 months, Figure 1). Expression of CD56 on the surface of extramedullary MM cells was found in 76.5% patients. OS in the group of patients with CD56+ in extramedullary MM cells and in bone marrow cells (n=9) was 67% which was significantly higher (p=0.04) than that in the group of patients (n=4) with CD56+ in extramedullary MM cells and CD56- in bone marrow cells – 50%. Simultaneous lack of CD56 in extramedullary MM cells and in bone marrow cells (n=0) was 27% which was significantly higher (p=0.04) than that in the group of patients (n=4) with CD56+ in extramedullary MM cells and CD56+ in bone marrow cells – 50%. Simultaneous lack of CD56 in extramedullary MM cells and in bone marrow cells was observed in 3 patients with 2 of them died of progression in 31 and 51 months. However simultaneous expression of CD56 in extramedullary MM cells and in bone marrow cells was observed in 9 patients with median follow-up of 40 months and 1 patient died of progression after 47 months.

Summary/Conclusions: CD56 expression in bone marrow plasma cells significantly increases the OS rate in MM patients regardless the presence or absence of plasmacytomas. Double CD56 negativity both in extramedullary and bone marrow MM cells is a poor prognostic factor with high risk of early relapse and death.

PB2001

BENDAMUSTINE-BORTEZOMIB-DESAMETASONE IN THE MANAGEMENT OF RELAPSED AND REFRACTORY MULTIPLE MYELOMA C. Cerchione1,*, L. Catalano1, A. E. Pareto1, S. Basile1, L. Marano1, I. Peluso1, and bone marrow MM cells is a poor prognostic factor with high risk of early relapse and death. Double CD56 negativity both in extramedullary and bone marrow MM cells is a poor prognostic factor with high risk of early relapse and death.

Aims: To evaluate the impact of CD56 expression on the rate of overall survival (OS) in MM patients with extramedullary disease (EMD).

Methods: The study included 32 patients with primary MM (17 males, 15 females) 23-77 years old (median value: 52 years old). The disease was diagnosed in accordance with the IMWG criteria (2014). 17 patients had EMD including 14 patients with soft-tissue plasmacytomas associated with bone and 3 patients with extramedullary foci in the neck area, in the stomach, in the liver. In all cases a tumour biopsy and bone marrow trephine biopsy were performed, that confirmed the presence of malignant plasma cell infiltration. Paraffin block slices from trephine biopsy material and tumour biopsy material were used to perform an immunohistochemistry (IHC) analysis with an antibody to CD56. Kaplan-Meier survival curves were generated, statistical analysis was done using the program «Statistica» ver.10.

Results: In patients with plasmacytomas the IHC analysis of trephine biopsy material showed CD56+ in 59% cases vs 73.4% in patients without EMD. Five-year OS in patients with CD56+ in the bone marrow was 90%, which was significantly higher (p=0.04) than that of the patients with CD56 - 0% with follow-up of 5 to 61 months (median 20 months, Figure 1). Expression of CD56 on the surface of extramedullary MM cells was found in 76.5% patients. OS in the group of patients with CD56+ in extramedullary MM cells and in bone marrow cells (n=9) was 67% which was significantly higher (p=0.04) than that in the group of patients (n=4) with CD56+ in extramedullary MM cells and CD56- in bone marrow cells – 50%. Simultaneous lack of CD56 in extramedullary MM cells and in bone marrow cells was observed in 3 patients with 2 of them died of progression in 31 and 51 months. However simultaneous expression of CD56 in extramedullary MM cells and in bone marrow cells was observed in 9 patients with median follow-up of 40 months and 1 patient died of progression after 47 months.

Summary/Conclusions: CD56 expression in bone marrow plasma cells significantly increases the OS rate in MM patients regardless the presence or absence of plasmacytomas. Double CD56 negativity both in extramedullary and bone marrow MM cells is a poor prognostic factor with high risk of early relapse and death.
enrolled in the study. Diagnosis and staging of multiple myeloma were defined by current clinical practice guidelines. To be achieving remission chemotherapy with bortezomib, thalidomide, dexamethasone, cyclophosphamide, melphalan, and anthracyclines was used accordingly contemporary clinical guidelines. All subjects were at complete or partial remission at baseline. Observation period was up to 12 months. ELISA method for measurements of circulating level of VE-cadherin was used.

Results: Medians of circulating levels of VE-cadherin in subjects without progression of multiple myeloma (n=89) and subjects with progression (n=23) during 12 months were 0.92 ng/ml (95% confidence interval [CI]=0.66-1.19 ng/ml) and 1.77 ng/ml (95% CI=1.47-2.07 ng/ml) (p=0.0002). The best VE-cadherin cutoff value for progression-free survival was 1.13 ng/ml, with AUC value 0.838 (p=0.0001), the sensitivity and specificity were 77.8% and 61.5% respectively.

The presence of high levels of serum VE-cadherin was significantly correlated to a shorter progression-free survival (PFS). In a multivariate analysis along with clinical and biologic prognostic parameters, high serum VE-cadherin level (>1.31 ng/ml) was an independent adverse prognostic variable for PFS (median PFS 9.93 (IC=8.16-11.71) months vs 7.35 (IC=5.75-9.85) months (p=0.02).

Summary/Conclusions: The serum VE-cadherin level is a valuable biomarker for predicting treatment response and an independent prognostic factor for progression-free survival for patients with multiple myeloma.

PB2003 THE UTILITY OF FACS PURIFICATION OF PLASMA CELLS FOR FISH ANALYSIS IN MONOCLONAL GAMMOPATHIES

M. Pereira1,2,*, G. Marques3, J. Lima3, R. Reis3, A. Coelho3, L. Jorge3, S. Pedroso3, L. Ribeiro3, A. Paiva4, F. Rodrigues3

1Clinical Department, Coimbra Hospitality Centre, 2Faculty of Medicine, University of Coimbra, 3Clinical Pathology Department, 4Flow Cytometry Unit, Coimbra University Hospital Centre, Coimbra, Portugal

Background: Despite the prognostic value of chromosomal aberrations, conventional metaphase karyotyping in monoclonal gammopathies (MG) is often uninformative due to the inherent difficulty of obtaining proliferating plasma cells (PC). Interphase fluorescence in situ hybridization (FISH) is a simple, quick and effective technique for the detection of cytogenetic aberrations that can overcome this limitation. However, the signal of interest is frequently diluted by the noise of the mixed cellularity of the sample, originating both false negatives and false positives. Fluorescence-activated cell sorting (FACS) of the target cells enables a focused application of FISH on pathologically significant cells – such as the PC in MG – reducing the confounding noise. This is particularly relevant when the percentage of pathologic cells in the sample is low, such as in monoclonal gammopathy of undetermined significance (MGUS) where, by definition, there are less than 10% PC in the bone marrow.

Aims: This study aims to analyze the utility and effectiveness of FACS purification of PC for the cytogenetic workup of MG by FISH.

Methods: We analyzed all FISH studies performed in our laboratory, in individual patients, on clonal interphase FACS-separated bone marrow PC, between the 1st June 2015 and the 15th September 2016. The probes used in our standard MG panel were del(1p32), amp(1q21), t(4;14) and del(17p13.1) (TP53 gene) and, starting in April 2016, t(14;16). We had previously established 20 variables and false negatives. Fluorescence-activated cell sorting (FACS) of the target cells enables a focused application of FISH on pathologically significant cells – such as the PC in MG – reducing the confounding noise. This is particularly relevant when the percentage of pathologic cells in the sample is low, such as in monoclonal gammopathy of undetermined significance (MGUS) where, by definition, there are less than 10% PC in the bone marrow.

Results: In both groups, males were predominant. IgG MG was most common (53.8%) in our cohort. PPN appeared to be mainly sensory regardless of heavy chain or light chain. Compared to PPN patients, CIDP patients were associated with motor symptoms manifesting as motor weakness (50.0% versus 91.2%, P=0.001) and ataxia (44.4% versus 61.8%, P=0.043) (Table 1). There were equal number of axonal type neuropathy and demyelinating type neuropathy in patients with PPN, and there were no differences in type of neuropathy between various immunoglobulin subclasses. However, demyelinating type PPN was associated with more severe clinical presentations, including more dysesthesia, pain and sensory symptoms. During median follow-up of 49 months, 2 PPN patients developed overt hematologic malignancies: 1 case of Waldenstrom macroglobulinemia and 1 case of AL amyloidosis, both of them showed malignant transformation within 8 months of neuropathy development, and were associated with worsening neuropathic symptom at the diagnosis of hematologic malignancy. There were no differences between the two groups with regards to overall survival.

Table 1. Clinical characteristics of all enrolled patients.

Background: Paraproteinemic neuropathy (PPN) refers to a disorder of the peripheral nervous system associated with a monoclonal gammopathy (MG). It is known that about 10% of idiopathic peripheral neuropathies are of this type. Unfortunately, PPN is often underdiagnosed or confused with chronic inflammatory demyelinating polyneuropathy (CIDP), subsequently leading to inappropriate management. Since progression of neuropathy is associated with possible malignant conversion of underlying monoclonal gammopathy, it is important to recognize underlying hematological conditions.

Aims: We aimed to determine whether the clinical characteristics and course differed in patients with PPN compared to those with CIDP in order to identify factors useful for differential diagnosis.

Methods: This study was carried out at Seoul National University Hospital, which is a tertiary academic center. During the period between January 2005 and December 2016, patients with 1) monoclonal gammopathy of undetermined significance (MGUS), and 2) CIDP were identified. Those with previous history of cancer or autoimmune disease requiring treatment with immunomodulatory agents were excluded from analyses. In the end, a total of 18 MGUS patients and 34 CIDP patients, with complete set of data including clinical physical examinations, electrodagnostic studies, and laboratory test results, were enrolled.

Results: In both groups, males were predominant. IgG MG was most common (53.8%) in our cohort. PPN appeared to be mainly sensory regardless of heavy chain or light chain. Compared to PPN patients, CIDP patients were associated with motor symptoms manifesting as motor weakness (50.0% versus 91.2%, P=0.001) and ataxia (44.4% versus 61.8%, P=0.043) (Table 1). There were equal number of axonal type neuropathy and demyelinating type neuropathy in patients with PPN, and there were no differences in type of neuropathy between various immunoglobulin subclasses. However, demyelinating type PPN was associated with more severe clinical presentations, including more dysesthesia, pain and sensory symptoms. During median follow-up of 49 months, 2 PPN patients developed overt hematologic malignancies: 1 case of Waldenstrom macroglobulinemia and 1 case of AL amyloidosis, both of them showed malignant transformation within 8 months of neuropathy development, and were associated with worsening neuropathic symptom at the diagnosis of hematologic malignancy. There were no differences between the two groups with regards to overall survival.

Table 1. Clinical characteristics of all enrolled patients.
Summary/Conclusions: Although both PPN and CIDP patients suffer from sensorimotor symptoms, CIDP patients were more often associated with superimposed motor symptoms. Among PPN patients, demyelinating type neuropathy seems to be associated with more severe clinical presentations. Worsening of neuropathic symptoms in PPN patients warrants a high level of suspicion of malignant transformation of underlying disease.

PB2005

MOLECULAR GENETIC CRITERIA PREDICTING THE EFFICIENCY OF PERIPHERAL BLOOD HEMATOPOIETIC STEM CELLS TRANSPLANTATION IN PATIENTS WITH MULTIPLE MYELOMA

Z. Minchenko1, Z. Misharin2a, O. Dmytryenko1, T. Liubarets3,3-1, I. Dmytryenko1, V. Khomonko2
1Immune Genetic Laboratory, National Research Center for Radiation Medicine of National Academy of Medical Science of Ukraine, 2O.O. Bogomolets National Medical University, 3Hematology and Transplantation Department, National Research Center for Radiation Medicine of National Academy of Medical Science of Ukraine, 4Kyiv Bone Marrow Transplantation Center, Kyiv, Ukraine

Background: Global gains in treatment of MM using auto-PBHSCT testify to heterogeneity of long-term outcomes of transplantation - different term of the achievement and duration of complete remission, progression-free survival (PFS), overall survival (OS). These facts determine individual approach to the approach and better outcomes of PBHSCT.

Aims: Finding molecular genetic criteria of predicting the effectiveness of autologous peripheral blood hematopoietic stem cell transplantation (auto-PBHSCT) for improving of algorithm of multiple myeloma (MM) patients cure at various stages of treatment.

Methods: The study involved 61 patients with MM and relapse and primary therapy resistant patients. Molecular cytogentic, immunogenetic, hematological and statistical methods were used.

Results: Since appearance of genetic abnormalities in the malignant plasma cells is one of the pathogenic mechanisms of the disease, genetic support of patients is essential. It was determined that the carriage of the allele HLA-DQB1*03:02 in MM patients is associated with a high risk of high-dose chemotherapy resistance (F=4.83, p=0.028, OR=1.75, p=0.038), and achieving remission after auto-PBHSCT is associated with carriage of haplotype HLA-C*06 - HLA-DQA1*01:01 (F=4.87, p=0.028, OR=7.34, p=0.05), Abnormalities of chromosomes 6, 11, 13, 14, 15 and 17 were determined to be patients with complicated disease course and minimal therapy response. Significant alterations were revealed in the presence of two or more abnormal clones (23 patients (37.7%), Ro Spirman=0.42, p < 0.05), deletion of chromosomes 17 (17 patients (27.9%), Ro Spirman=0.41, p < 0.05), deletion/monosomy of chromosome 13 (10 of 15 patients surveyed, Ro Spirman=0.33, p < 0.05), the translocation t(6;14) (4 patients (6.6%), Ro Spirman=0.50, p < 0.02).

Summary/Conclusions: The results indicate the necessity of introducing the molecular genetic support into protocol of examination MM patients on various stages of treatment with auto-PBHSCT.

PB2006

THE INFLUENCE OF MINIMAL RESIDUAL DISEASE AND TUMOR LOAD ON THE PROGRESSION FREE IMPROVEMENT ON THE PROGRESSION FREE SURVIVAL IN MULTIPLE MYELOMA PATIENTS

A. Ganfinlin1, S. Voloshin1, A. Kuvsinov1, Z. Chubukina1, A. Schmidt1, S. Bessmel’sev1, A. Chechetkin1
1Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Use of modern drugs and their combinations in the complex antymyeloma therapy (induction, high-dose therapy (HDT) with autologous stem cells transplantation (ASCT), consolidation and maintenance therapy) to improve efficacy of treatment and duration of responses. Despite the achievement of complete response (CR) many patients has a relapse which is caused by activation of residual clonal plasma cells.

Aims: To define influence of induction therapy regimens, HDT with ASCT to the frequency of Minimal Residual Disease (MRD) negative status and estimate a role MRD in duration of Progression Free Survival (PFS) in multiple myeloma (MM) patients.

Methods: We analyzed 52 patients with MM (median age 55 years, male/female = 2.1:1). The induction therapy with Bortezomib-based regimens (Vd, Dvd, Vmp, Pad) was used in 38/52 (62%) patients, Immunomodulator-based regimens (Thal+D, Rd, Vrd, PomD) – in 14/52 (27%), chemotherapy – in 2/52 (4%). ASCT is carried out 31 (59.6%) patients. Primary tumor cells phenotype and MRD were detected by 5-color flow cytometry. Clonal plasmatic cells were detected by markers: CD38, CD138, CD45, CD19, CD20, CD27, CD38, CD56, CD193 in 2017. MRD-negative status considered in identifying less than 1 tumor cell in 10000 (0.01%).

Results: MRD-negative CR was reached in 23.8% (10/42) patients after 4-6 cycles of therapy. The frequency of MRD-negative status in the “Bortezomib group” was 31% (8/26), in the “Immunomodulator group” – 7.7% (1/13) (Chi-square =0.1; p > 0.05). The general frequency of MRD-negative CR after HDT with ASCT was 33.3% (7/21). The carrying out HTD with ASCT allowed to MRD eradication in 36.4% (4/11) patients. One patient with a “light chain” myeloma lost MRD-negative CR after HTD with ASCT that led to development of a clinical relapse after 6 months. Carrying out a maintenance therapy with bortezomib or lenalidomide didn’t allow to achieve MRD-negative status in patients with MRD-positive response. On the contrary, achieve ment MRD-negative status promoted to increase of PFS. The PFS median in MRD-positive group of patients (n=36: 21 CR, 6 VGPR, 9 PR) was 21 months, in the MRD-negative group (n=16) – 66 months (p<0.005). The PFS median patients with CR was higher in the MRD-negative group than in the MRD-positive group (66 and 48 months, respectively, p=0.0045). The tumor load is also a strong prognostic factor like MRD status. Patients who attained low-level MRD had better benefit in the duration of PFS: <0.01% - 66 months, 0.01%-0.1% - 48 months at, 0.1%-1% - 22 months, >1% - 10 months (p=0.0009) (Figure 1).

Summary/Conclusions: The frequency of achievement MRD-negative doesn’t depend from program of induction therapy, HDT with ASCT and maintenance therapy. Negative prognostic role of MRD status independent from clinical response. Presence of MRD after treatment to associated with decrease of PFS and early relapse. Control of MRD allows to increase of PFS and can be done by means of modern drugs and its combinations. HDT with ASCT and maintenance therapy. Impact of MRD requires further studies, especially after HDT with ASCT.

PB2007

QUALITY OF RESPONSE AS PREDICTOR OF SURVIVAL AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION IN REAL LIFE MULTIPLE MYELOMA PATIENTS IN A SINGLE INSTITUTION

A. Pinto1, A. Roque1, E. Cortesio1,2, A. Espadana1, A. B. Sarmento1,2, C. Geraldes1,2, M. L. Ribeiro1
1Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra, 2Faculty of Medicine and Cimago, University of Coimbra, Coimbra, Portugal

Background: High dose chemotherapy (HDC) followed by autologous stem cell transplantation (ASCT) is the standard treatment approach for younger patients with multiple myeloma (MM). Since the introduction of proteasome inhibitors and immunomodulatory drugs in MM treatment more patients achieve deep and durable responses and better disease control before ASCT.

Aims: To evaluate the association between the depth of response before ASCT and survival outcomes in a cohort of patients with MM.

Methods: Retrospective analysis of patients with MM treated with HDC and ASCT between 2007 and 2016 in a single institution. All patients received a high dose stem cell support after conditioning with high dose melphalan (200 mg/m² and 140mg/m² for patients with renal insufficiency). Response was assessed 100 days after ASCT according to the International Myeloma Working Group response criteria. The Kaplan-Meier method was used to estimate progression free survival (PFS) and overall survival (OS) and comparison between risk groups was performed by using the log-rank test. The prognostic factors of survival were analyzed by Cox regression univariate and multivariate analysis.

Results: We included 195 MM patients, mainly males (57.9%) with a median age at ASCT of 61 years (28-71). The most prevalent subtype was IgG κ (44%). The median number of previous therapeutic lines was 1 (1-4) and the majority of patients (61%) received bortezomib as part of first-line regimen. Patients undergone ASCT within a median of 10 months after diagnosis. With a median follow-up time from ASCT of 28.55 months (2.8-121.4), OS at 2 and
Five (29.4%) patients presented with leptomeningeal infiltration; in three of them it was diagnosed at the time of the diagnosis of PCL. All the patients had neurological features. Thirteen (76.4%) patients were able to start a curative treatment: VD in 7 (53.8%) patients, VTD in 2 (15.4%), VAD in 1 (7.7%), D-PACE in 1, MXT-ARAC in 1 patient and RD in the remaining one. Three patients received intrathecal treatment. The intention-to-treat response was: 2 (15.4%) CR, 2 PR, 7 (53.8%) refractory disease or progression and 2 no evaluable. Only 2 (15.4%) patients achieved enough response (2 CR) to undergo an autologous stem cell transplant (ACST) and only 1 to undergo an allogeneic-SCT. With a median follow up of 4 months for all the patients included, median of PFS was 3 (CI 95% 0.47-4.76) months and median of OS was 4 (IC 95% 0.47-7.53) months.

Summary/Conclusions: Prospective multicenter studies are required to provide a better understanding of the pathogenesis of PCL. Staging procedures should include lumbar puncture or magnetic resonance at diagnosis when extramedullary involvement is suspected. Intrathecal prophylaxis with cytarabine, metotrexate and dexamethasone is not today a standard of care for patients with PCL.

PB2009
MANAGEMENT AND OUTCOMES OF PATIENTS WITH MULTIPLE MYELOMA IN REAL-WORLD SETTINGS IN BULGARIA, CROATIA AND SLOVAKIA
G. Mihaylov1, K. Sostojkovic2, Z. Stefani kova3, L. Fink4, M. Hemetsberger5, K. Bjorklof6, K. Szabolcs Toka6, F. Gatta6, D. Niepel7
1Clinic for Hematology, University Hospital Sofia, Sofia, Bulgaria, 2School of Medicine, Merkur University Hospital, Zagreb, Croatia, 3Department of Hematology, Transfusiology, University Hospital, Bratislava, 4Kantar Health, Paris, France, 5Hemetsberger medical services, Vienna, Austria, 6Amgen (Europe) GmbH, Zug, Switzerland, 7Amgen (Europe) GmbH, Vienna, Austria
Background: The multiple myeloma (MM) treatment (Tx) landscape is rapidly evolving, with varying Tx practice patterns and access schemes across countries. However real-world (RW) data describing patient (pt) management, MM Tx use and outcomes in some Eastern European Countries are limited.
Aims: To understand the characteristics, management, Tx patterns and outcomes of pts with symptomatic MM in a RW setting in Bulgaria (BG), Croatia (HR) and Slovakia (SK).
Methods: Data were collected within a cross-sectional (X) and retrospective (R) phase of a chart review in 6 countries between June/15 and June/16 by onc-hematologists who managed at least 15 pts with MM per month (mo)
Results: In the X-phase, data included characteristics and current Tx by line of therapy for all pts with MM seen during a 3-week observation period, regardless of pts’ Tx status and strategy. In the R-phase, data included pt and disease characteristics at diagnosis, Tx response, comorbidities and outcomes by Tx line. Pts were selected in reverse chronological order and those who had completed specific lines of active Tx within the past 3 mo were included as follows: 3 pts in first line (1L), 4 pts in second-line (2L) and 7 pts in third or higher lines. Analyses were descriptive.
Results: In the X-phase, 7 physicians from BG, 6 from HR and 5 from SK participated. In BG, 95, 54 and 91 pts were included. In HR, 73, 69 and 89 pts were included. In SK, 69, 69 and 91 pts were included. In the R-phase, data included 121, 120 and 124 pts respectively. The proportion of pts that had received SCT at any point increased from 1L to 2L (3% to 19%, 7% to 35% and 9% to 54% in BG, HR and SK respectively). 82% of pts in BG, and 70% both in HR and SK were currently receiving Tx (Table 1), while 17%, 30% and 25% of pts respectively, were treated previously. Only 4 pts (1 in BG and 3 in SK) had never been treated. In the R-phase, 6 physicians from each line of therapy were included. Survival curves were estimated using the Kaplan-Meier method and compared using the Log-Rank test.
Summary/Conclusions: These findings suggest a high unmet need for access to more effective and innovative Tx options with manageable safety profiles in these countries. In particular, in BG where bortezomib- and chemotherapy-based regimens are the only treatments used, pts might be re-treated with the same agents, which may explain why most do not achieve ≥vGR from 2L. In HR and SK, sustained or increased rates of ≥vGR in 2L may be due to the use of newer or different agents from those used in 1L and to the fact that most pts had previously received a SCT. These RW data provide useful input for economic evaluations of new MM agents to include in earlier Tx lines in these countries.
**PB2010**

**SINGLE SHOT MEDIUM DOSE MELPHALAN IN RELAPSED MM PATIENTS: A RETROSPECTIVE, SINGLE CENTER EXPERIENCE**

C. Clissa1, A. Isidori1, F. Loscocco1, E. Gabucci1, L. Malerba1, B. Guiducci1, G. Visani1

1Hematology, AORMN Pesaro, Pesaro, Italy

**Background:** Multiple myeloma (MM) patients refractory to proteasome inhibitors, IMiDs or both, have an extremely poor prognosis. Moreover, they frequently fail to respond to further therapies, and represent a major challenge in everyday clinical practice.

**Aims:** With this in mind, we treated 12 patient with relapsed MM with a single shot of medium dose melphalan (60 mg/m²) between October 2010 and January 2016.

**Methods:** The median age was 72 years (range, 62 – 79) and the median time from initial diagnosis to melphalan treatment was 51 months (range, 24 – 144). Patients were heavily pretreated with a median number of 3 prior lines of therapy. All patients were refractory to the previous therapeutic regimens and had failed to respond or were refractory to regimens containing bortezomib.

Seven patients (74%) had previously received at least one IMiD, 8 (67%) autologous stem cell transplantation (ASCT) and 1 allogeneic stem cell transplantation. The patients included in the series were not eligible for any clinical trial available at the institution. All patients gave informed consent.

**Results:** All patients had cytopenia (anemia, neutropenia and thrombocytopenia). We observed 3 cases of gastrointestinal toxicity (1 bleeding, 1 subocclusion, 1 mucositis), 1 WHO, 3 cases of clinically documented infection (1 Escherichia coli bacteremia, 1 fever of unknown origin, 1 erysipela) and 2 deep vein thrombosis. Response was assessed between six and eight weeks after melphalan therapy. Overall, 10 out of 12 patients had a response (1 complete response, 3 very good partial response, 2 partial response and 4 stable disease); only 2 had progressive disease. Median overall survival was 11 months (range, 2 - 37). 10 of 12 patients relapsed after a median time of 5 months (range: 2-12). Concerning two patients not relapsed, 1 patient died in partial response 8 months after therapy of other causes; 1 patient is still alive, in complete remission 18 months after melphalan. He underwent ASCT and maintenance with lenalidomide.

**Summary/Conclusions:** Many patients refractory to proteasome inhibitors and IMiDs are probably still sensitive to alkylating agents and could be rescued in complete remission 18 months after melphalan. He underwent ASCT and 1 allogeneic stem cell transplantation in complete response, 3 very good partial response, 2 partial response and 4 stable disease, after melphalan therapy. Overall, 10 out of 12 patients had a response (1 complete response, 3 very good partial response, 2 partial response and 4 stable disease). A total of 10 of 12 patients relapsed after a median time of 5 months (range: 2-12). Concerning two patients not relapsed, 1 patient died in partial response 8 months after therapy of other causes; 1 patient is still alive, in complete remission 18 months after melphalan. He underwent ASCT and maintenance with lenalidomide.

**PB2011**

**LENALIDOMIDE AT THE DOSE OF TWENTY-FIVE MG EVERY OTHER DAY IN PATIENTS AFFECTED BY MULTIPLE MYELOMA AND RENAL FAILURE: A REAL-LIFE EXPERIENCE**

C. Cerchione1, L. Catalano1, A.E. Pareto1, D. Nappi1, I. Peluso1, K. Ferrara1, M. Di Perma1, I. Zacheo1, F. Fane1

1Hematology, Ematologia e Epatologia/ ************************************************************************** federico ii, Naples, Italy

**Background:** Lenalidomide, available as oral compound, is an IMiD with both antiproliferative and immunomodulatory activity which is largely used in the management of newly diagnosed, relapsed or refractory MM and as maintenance therapy after autologous stem-cell transplantation. Due to its renal route of excretion, it is mandatory to adjust lenalidomide dose in patients with RI, guided by Creatinine Clearance (ClCr), in order to impede a systemic prolonged exposure that could boost myelosuppression. With normal renal function, lenalidomide reaches its maximal plasma concentration after a median time of 0.6-1.5 h, and it shows a linear relation with ClCr. To our knowledge, lenalidomide dosing has been poorly investigated in patients with renal insufficiency.

**Aims:** In this study, we present our clinical experience of lenalidomide administration of lenalidomide 25 mg every other day for patients with MM and RI.

**Methods:** From March 2014 to February 2016, 19 consecutive patients, 11 female and 8 male, with a median age of 63.3 years (range: 49-81) affected by advanced, resistant and progressive MM (median number of previous treatment lines: 3, range : 1-5, all including bortezomib) with concomitant renal failure not in dialytic support (median calculated ClCr: 36.4 ml/min, range : 18-66) were treated, after informed consent, with weekly 21-day courses of 25 mg lenalidomide every other day and dexamethasone (20-40 mg on days 1-8-15-22, every 28 days).

**Results:** Disappearance of urinary light chain and reduction of serum creatinine (complete response) were detected in 7 patients (36.8%); 3 patients (15.7%) had a very good partial response, 3 (15.7%) had a partial response, 4 of them (21.0%) were in stable disease, whereas 2 patients (10.5%) had signs of progressive disease. Overall response ratio was 68.2%. More than half of the patients (11/19, 57.8%) had a renal response (median calculated ClCr 51.5ml/min, range: 20-148). Median progression free survival for patients with RI (range 3-18 months). No patient experienced grade 4 myelotoxicity; four patients required red cell transfusions for grade 3 anemia. No SAE occurred during treatment.

**Summary/Conclusions:** Dose adjustment RI-related of Lenalidomide is recom-
RESULTS: From March to December 2016 we admitted 57 pts with RI and monoclonal component (29 F, 28 M, 41-83 yrs range), 20 are known MM pts and 37 de novo pts. We diagnosed 11 de novo MM, 13 known MM with a de novo RI, 12 diabetes related RI, 3 amyloidosis, 16 other causes.

SUMMARY/CONCLUSIONS: The implementation of the International Myeloma Working Group Recommendations in a routine clinical practice confirmed its feasibility and utility in the optimal workout of MM pts. We obtained diagnosis of RI within 4 days, both in known and de novo MM pts, with a positive impact on reduced hospitalization, unnecessary dyalisis and steroids overtreatment.

Summary/Conclusions: The proteosome inhibitors and immunomodulatory drugs which are used in MM treatment enhance the risk of infection by several mechanisms. Nocardial infections are rare in Turkey.

Aims: Here, we present three relapsed myeloma cases which developed nocardia pneumonia.

Methods: Case-1: 66 year old man, who has a history of autologous SCT 4 years ago and lenalidomide usage because of IgG kappa type myeloma, has been presented to our clinic as a case of possible infection with Nocardia. The patient was admitted to the hospital because of the production of sputum for more than 2 days. Blood cultures showed no growth. Bronchoscopy showed multiple nodules and bronchioalveolar lavage showed acid-fast bacillus. A typical morphological appearance was defined as Nocardia.
Aims: To identify demographics and clinical characteristics of patients with hematology/transplant referral center in Kuala Lumpur, Malaysia, which is accessible only by airplane. Hence, treatment of patients with multiple myeloma in this part of the state is a big challenge due to its geographical constraint.

Methods: We included in this retrospective and observational study at University Hospital of Vall d’Hebron, all patients with newly MM and PET/CT before to start a first line treatment and a second PET/CT when completing treatment. PET/CT were analyzed by the department of Nuclear Medicine with experience to grade the lesions in MM, were evaluated and categorized into positive or negative according to the criteria proposed by Zamagni, et al. The biochemical response was defined according to the standard IMWG response criteria.

Results: Eighteen patients (8 males and 10 females) with untreated MM entered, seven patients were classified with ISS III, fifteen had a good performance status, none presented renal lesion, only 16% had hypercalcemia and 66% showed immunoreparus. Ten patients were IgG isotype, six were classified as light chains myeloma and two patients were oligosecretors. Seventeen patients had bone marrow infiltration with a median of 42% plasmatic cells. Two patients had a extramedullary plasmocytoma and nine had an anormal ratio of light chains. Seventeen patients were treated with bortezomib-based regimens, (median 5.5 cycles) included VTD, MPV, VLD and VD. After treatment, two of fourteen patients achieved complete response, two partial response and two had progressive disease. PET/CT was positive in all patients pretreatment, 15 focal lesions, 2 diffuse bone marrow involvement plus focal lesions and 1 involvement of bone marrow alone. Twelve patients had more than 3 focal lesions and two had extramedullary disease. At the end of first line treatment, PET/CT was negative in eight patients (44%) and fourteen had complete biochemical response (78%). 62% of the patients with negative PET/CT showed negative flow minimal residual disease (MRD) and biochemical complete response. Two patients had PET/CT with progression disease and corresponded to a biochemical progression.

Summary/Conclusions: The correlation between PET/CT and biochemical response obtained after treatment was positive in patients with complete response. We found discordant data in two patients with oligosecretory myeloma. No correlation was shown between PET/CT and flow MRD.

PB2016
MULTIPLE MYELOMA IN BORNEO SARAWAK: A DEVELOPING WORLD’S EXPERIENCE
T.S. Leong1,*, L.P. Chew1
1Hematology Unit, Medical Department, Sarawak General Hospital, Kuching, Malaysia

Background: Sarawak, is the largest state of Malaysia situated on the island of Borneo. Sarawak General Hospital is the tertiary referral center of Sarawak (serving a population about 1 million people). It is 980 km away from its main hematolgy/transplant referral center in Kuala Lumpur, Malaysia, which is accessible only by airplane. Hence, treatment of patients with multiple myeloma in this part of the state is a big challenge due to its geographical constraint.

Aims: To identify demographics and clinical characteristics of patients with multiple myeloma; To establish treatment and outcome of patients with multiple myeloma.

Methods: This is a retrospective study examining basic characteristics and clinical outcomes of patients diagnosed with multiple myeloma between 2010 and 2016 in Sarawak General Hospital. Patients’ case notes were traced and the relevant information was entered into a pre-designed data collection form. Data was analysed and interpreted via IBM SPSS Statistics version 24.0.

Results: There were a total of 63 patients with the male to female ratio of 3:2. The median age for patient was 61 years old (range 31 to 86 years old). Majority of them were local natives of Iban or Bidayuh descendants (n=32, 50.8%) followed by Chinese (n=20, 31.7%) and Malays (n=11, 17.5%). Most common type of multiple myeloma is of IgG variant (n=27, 42.9%). The most common myeloma related organ or tissue impairment (ROT) are anaemia (n=54, 85.7%) followed by bone lesion (n=48, 77.8%), renal impairment (n=27, 42.9%) and hypercalcemia (n=18, 28.6%). More than half presented late with Dure Salmon stage III disease (n=34, 54%). Majority of patients were treated with dexamethasone/thalidomide (n=25, 39.7%). Sixteen patients (25%) received bortezomib based treatment. Three patients (n=3, 4.8%) undergone bone marrow transplant. Thirty five patients died (n=35, 55.6%). Median survival time was 21 months (95% CI: 16.26). One year, two years and five years survival rate was 67.4%, 43.6%, 31.6%. Patients who were 60 years old and above have lower median overall survival (20 months) compare to patients who were 60 years and below (36 months) even though they are not statistically significant (p=0.565).

Summary/Conclusions: Baseline characteristics of patients with multiple myeloma in Borneo Sarawak are similar to the rest of Asia. However, our median overall survival was comparatively lower to our counterparts. Limitation wise, due to logistic and economic reasons, we do not have good access to cytogenetic and genetic profiling that enables us to prognosticate patients accordingly.

PB2015
STUDY USE OF 18-F FDG PET / CT SCANNING INTO THE FIRST FOLLOW UP OF PATIENTS WITH MULTIPLE MYELOMA AND ASSOCIATION WITH BIOCHEMICAL RESPONSE
K. Vallejo Luna1, M. Simó1, J. Montoro3, C. Palacio3, M. Junquera4, M. Gironella Mesa1,2,4
1Hematology, Vall d’Hebron Institute of Oncology, 2Department of Nuclear Medicine, 3Department of Clinical Diagnostic, 4Department of Hematology, Hospital Universitario de Vall d’ Hebron, Barcelona, Spain

Background: Positron computed tomography (PET / CT) with 18F fluoro-deoxyglucose-labeled glucose (FDG) is a reliable technique with high sensitivity and specificity for assessing skeletal involvement and recent studies propose it as a method for predicting treatment response in multiple myeloma. Conventionally, the response is measurable by the monoclonal component in both serum and urine and Minimal residual disease (MRD) by flow cytomtery has been established as a mandatory tool. The studies are aimed at combining the measurement of paraprotein with imaging tests that help to promptly define response or failure to the treatment.

Aims: The primary endpoint was the correlation of the biochemical response with the FDG PET/CT in a second evaluation after first line treatment. The secondary endpoint was the correlation between MRD and second FDF PET/CT.

Methods: We included in this retrospective and observational study at University Hospital of Vall d’Hebron, all patients with newly MM and PET/CT before to start a first line treatment and a second PET/CT when completing treatment. PET/CT were analyzed by the department of Nuclear Medicine with experience to grade the lesions in MM, were evaluated and categorized into positive or negative according to the criteria proposed by Zamagni, et al. The biochemical response was defined according to the standard IMWG response criteria.

Results: Seventeen patients (8 males and 10 females) with untreated MM entered; seven patients were classified with ISS III, fifteen had a good performance status, none presented renal lesion, only 16% had hypercalcemia and 66% showed immunoreparus. Ten patients were IgG isotype, six were classified as light chains myeloma and two patients were oligosecretors. Seventeen patients had bone marrow infiltration with a median of 42% plasmatic cells. Two patients had a extramedullary plasmocytoma and nine had an anormal ratio of light chains. Seventeen patients were treated with bortezomib-based regimens, (median 5.5 cycles) included VTD, MPV, VLD and VD. After treatment, two of fourteen patients achieved complete response, two partial response and two had progressive disease. PET/CT was positive in all patients pretreatment, 15 focal lesions, 2 diffuse bone marrow involvement plus focal lesions and 1 involvement of bone marrow alone. Twelve patients had more than 3 focal lesions and two had extramedullary disease. At the end of first line treatment, PET/CT was negative in eight patients (44%) and fourteen had complete biochemical response (78%). 62% of the patients with negative PET/CT showed negative flow minimal residual disease (MRD) and biochemical complete response. Two patients had PET/CT with progression disease and corresponded to a biochemical progression.

Summary/Conclusions: The correlation between PET/CT and biochemical response obtained after treatment was positive in patients with complete response. We found discordant data in two patients with oligosecretory myeloma. No correlation was shown between PET/CT and flow MRD.

Are necessary more long term studies that include greater number of patients to confirm the results of this study. PET/CT in a second evaluation after first line treatment is a feasible method for predicting treatment response in multiple myeloma.

Summary/Conclusions: The updated NICE guidelines for diagnosis and management of myeloma (2016) suggests whole-body MRI as first-line imaging for people with suspected myeloma and consideration of MRI/CT/PET in newly diagnosed myelomas to assess for bone disease or EM plasmacytoma.

Aims: Our aims were to ascertain; 1) Our current practice regarding radiological investigation for myeloma (2) Whether additional diagnostic information was gained using CT/MRI imaging (3) Since its release, is the trust compliant with the NICE guidance (4) The estimated cost of meeting the current NICE guidance (5) Whether the NICE guidance (2016) suggests whole-body MRI as first-line imaging for people with suspected myeloma and consideration of MRI/CT/PET in newly diagnosed myelomas to assess for bone disease or EM plasmacytoma.

Methods: This retrospective and prospective audit included all patients having a skeletal survey performed for suspected multiple myeloma within the Alt-nagelvin Area Hospital (AAH). Retrospectively from 10/2/15 until 9/2/16 data was collected using the advanced search feature of the Sectra IDST PACS system. The ‘Reason for examination’ for each study was then analysed and those ordered for reasons other than suspected myeloma were excluded. Each case was analysed individually and any follow up MRI/CT/NMB imaging performed in the 6 month period following the skeletal survey were included in the data collection. The same information was gathered prospectively from 10/2/16-30/5/16 following the NICE guidance. 54 skeletal surveys where performed for suspected/prospective staging myeloma pre guidance.

Results: The indications for requesting imaging is shown in Table 1A. No WB MRI/CT was performed in this period. 26% patients had new lytic lesions on skeletal survey. 23 patients had further imaging in the form of MRI or CT following skeletal surveys. All the positive MRI findings offered additional diagnostic information - including examples of missed multiple spinal deposits. The results of imaging are summarised in Table 1B. The false negative rate for skeletal surveys was 39% and the false positive rate was 22%. Following NICE guidance publication 23 patients had skeletal surveys performed for suspicion of myeloma between 10/2/16 and 30/5/16. The indications are summarised in Table 1C. No WB imaging was performed. 5 patients had positive skeletal surveys. 6 patients had subsequent CT/ MRI imaging. A skeletal survey was reported normal with a subsequent MRI showing multiple spinal deposits. The imaging results are summarised in Table 1D.

Table 1.
economic model for imaging with WB MRI. In addition it reviews evidence which links time to diagnosis to survival and myeloma related complications. The NICE guidance offers clear evidence that WB-MRI should be the investigation modality of choice for suspected myelomatous disease. It offers a diagnostic and cost-effective strategy that will ensure health improvements for myeloma patients. This audit offers further evidence of the diagnostic accuracy of MRI imaging. At present failure to comply with NICE guidance will lead to delayed diagnosis of myeloma in certain patients and potential patient harm. Therefore I offer a business and health improvement case for the Western Trust to instigate WB-MRI imaging for all suspected myelomatous bony disease.

TONI DEBRE FANCONI SYNDROME DURING MYELOMA, ABOUT 8 CASES

R. Cherif1*, B. Salah Eddine1
1Hematology, Hospital Card. G. Panico, Tricase (LE), 2Haematology and TMO, Hospital Card. G. Panico, Tricase (LE), 2Haematology and TMO, Policlinico di Bari, Bari, Italy

Background: The cast nephropathy with cylinders is the most frequent renal complication of the myeloma, which results from a catabolism of the light chains by the tubular cells and can lead a tubular chronic suffering showing itself by a syndrome of acquired Toni-Debré-Fanconi marked by a glycosuria, a phosphatura, an aminoaciduria, a sometimes severe and sometimes revealing hypokalemia.

Aims: We reporting some observations informed by Multiple Myeloma complicated with a Fanconi syndrome.

Methods: From January 2000 till December 2010: 78 cases of Multiple Myeloma were brought together, whose circumstance of discovery 22 cases with renal failure, it's was a evolutes complications in 12 cases; and in 10 cases it's discovered at diagnosis. The renal achievement is dominated by Tubule disease in 11 cases, Randall syndrome 8 cases, and Nephrotic syndrome in 3 cases. The tubule disease of Fanconi is suspected at only 8 patients: in front of the presence of a glycosuria without (associated diabetes) and a frank proteinuria in the majority of the cases, with a hypophosphatemia and a sickle hypokalemia.

Results: The clinico-epidemiological and immuno-biological characters of these 8 patients are the following ones: - The median age is of 64 years (39-76), sex ratio 3. The osseous pains and the muscular cramps dominate the clinical presentation with constant diffuse de mineralisation in the radiology. - The patients were classified (according to the Salmon-Durie classification): IIIB (3 cases) and IIIB (5 cases). ISS 3 in majority of the cases. - The mononclonal immunoglobulin observed: IgG kappa: 4cases, IgA kappa: 2cases, light chain kappa: 2cases. With a Bence Jones proteinuria isotype kappa and a glycosuria in the majority of the cases. - The gravity of the renal failure, based on the clearance of the creatinine: with an average clearance of 16.19 ml/min (4-37): several in 5cases, terminal in 3cases. - We note more of hypocalcaemia while the hypercalcemia is noted in a single case, the hypophosphatemia is found in half of the cases. The therapeutic approaches was double: - Symptomatic: alkaline hydration, correction of the metabolic disorders and sometimes the renal extra purge (indicated in 3cases). - Specific: chemotherapy VAD cases, a patient died by cardio-vascular complication. Under treatment the recovery of the renal function is obtained in 3 cases, to the rest of the patients persists a stable renal failure.

Summary/Conclusions: The Syndrome of Fanconi is a frequent and often formidable complication during Myeloma, observed to 30-40% of the patients in an autopsique series. It is necessary to think to it in front of any renal achievement in myeloma of kappa light chain with renal glycosuria, a generalized aminoaciduria and a hypophosphatemia resulting respectively from a defect of the transport of the glucose, from amino acids and from phosphates by the renal proximal tubule. To improve the osseous and renal appearances, it is necessary to realize a calcic supplementation, phosphorous and by the vitamin D active, as well as the correction of the acidoise and a specific treatment reducing the excretion renal of the light chains.

DEPP RESPONSES WITH CARFLIZOMIB-LENALIDOMIDE-DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENTS: A REAL LIFE EXPERIENCE

V. Federico1, B. Rossini1, D. Carlino1, A. Mele1, P. Curci2, A. Giordano2, S. Citro1, G. Specchia1, V. Pavone1.
1Haematology and TMO, Hospital Card. G. Panico, Tricase (LE), 2Haematology and TMO, Policlinico di Bari, Bari, Italy

Background: Carfilzomib is a new proteasome inibitor with in contrast to the reversible binding of bortezomib, binds irreversibly and selectively to its target: the chymotrypsin-like activity of the 20S proteasome. The phase IB/II PX-171-006 study was the first study in which carfilzomib was combined with lenalidomide and dexamethasone. In the phase I dose-escalation part the maximum tolerated dose was established as well tolerated and in the phase II part the study focused the efficacy and toxicity in the subgroup treated with maximum planned dose. The ASPIRE trial showed superior response rates and progression free survival for carfilzomib-lenalidomide-dexamethasone compared with lenalidomide-dexamethasone in relapsed/refractory Multiple Myeloma patients.

Aims: The aims is explorer the efficacy and tolerability of carfilzomib-lenalidomide-dexamethasone in relapsed/refractory Multiple Myeloma patients in real life.

Methods: All patients received carfilzomib 20/27 mg/m2 days 1,2,8,9,15 and 16; lenalidomide 25 mg days 1-21 and dexamethasone 20 mg days 1,2,8,9,15,16, 22 and 23, according to post approval access protocol. After 2, 4, 6 cycles the responses, disease progression and toxicity were assessed using the International Myeloma Working Group Uniform Response Criteria and WHO score respectively.

Results: From January 2016 to February 2017 in hematology “Cardinale G. Panico Hospital” and “Bari Policlinico”, treated 15 relapsed/refractory Multiple Myeloma patients with carfilzomib-lenalidomide-dexamethasone. Six patients male (40%), 9 female (90%), mean of age 62 years (range 38-79); 10 (66%) and 5 (34%) relapsed/refractory multiple myeloma respectively. Median time from diagnosis to carfilzomib-lenalidomide-dexamethasone was 46 months (range 12-92); median of prior therapy was 3 (range 1-4); 9 (60%) received autologous transplantation while 1 (6%) allogeneic; 15 (73%) prior therapy with lenalidomide; 15 (100%) prior therapy with bortezomib; 2 (14%) prior therapy with pomalidomide (Table 1). Eleven (73%) patients achieved after 2 cycles a response rate ≥PR, of these 3 VGPR. After 4 cycles, 5 (33%) and 1 (7%) have obtained at least a VGPR and CR respectively (Figure 1). Three patients were not evaluated for treatment discontinuation because of rapid progression disease and died during first cycle with a median of 5 prior lines therapy. Most grade 3-4 adverse events were haematological and well manageable, 10 (80%) trombocitopenia and 5 (35%) neutropenia grado 3-4. Dyspnea, fatigue and pyrexia were higher but were mostly grades 1 and 2. Only 2 patients developed respiratory failure and pneumonia while cardiac failure, ischemic heart disease and hypertension not were detected.

Figure 1.
Background: Carfilzomib is an epoxysketone proteasome inhibitor of second generation, proved to be effective in relapsed and refractory Multiple Myeloma (rrMM).

Aims: In this retrospective observational trial, it has been evaluated efficacy and tolerance of Carfilzomib, in combination with lenalidomide-dexamethasone (KRD) as salvage regimen in patients with relapsed and refractory MM (rrMM), whose prognosis is particularly severe.

Methods: 21 patients (12 M/9 F, Table 1), with rrMM, median age at diagnosis 62 years (r. 47-75), median age at start of treatment 65 years (r. 53-81) treated with several lines of treatments (median 3, r. 2-10), included 2 patients refractory to Bortezomib, underwent to KRD regimen (ASPIRE trial schedule: Carfilzomib starting dose 20 mg/sgm on days 1,2 of cycle 1, target dose 27 mg/sgm thereafter; Lenalidomide 25 mg on days 1 through 21; Dexamethasone 40 mg on days 1,8,15 and 22, every 28 days) for a median treatment cycles of 2 (r. 1-6). ISS was equally distributed, and cytogenetic was evaluable in 8 patients, and in particular one del13q14 1qgain, one del 13q14 and one t(11;14). 86% of patients had previously been treated with schedule containing bortezomib and IMIDs, and 33% had also received radiotherapy. 57% of them had undergone at least to a single autSCT.

Results: Carfilzomib was well tolerated, with grade 2 anemia in 28% of patients, without necessity blood transfusions; 5% grade 1 and 9.5% grade 3 neutropenia (no ospedalization was required, no septic shocks were observed); 33% grade 2, 19% grade 3 and 5% grade 4 thrombocytopenia, without hemorrhagic events and necessity of transfusions. Concerning severe extrahematologic toxicity, it was observed grade 1 pneumonia in 47% of patients, treated by common antibiotic drugs; grade 2 Hypertension in 24% of patients; grade 3 arrhythmias in 5% of patients; grade 2 dyspnea in 5% of patients; grade 1 fatigue in 9.5% of patients. According to IMWG criteria, after a median follow-up of 3 months (r.1-13), ORR was 66.7% (14/21 : 8 VGPR, 6 PR) with 3 progressive diseases and 2 patients in stable disease, which can be considered as an impressive result in this subset of rrMM patients. In particular, for 1 patient, KRD was, after having achieved at least a PR, a bridge to second autSCT. Median time to response was 2 months (r.1-4), median OS from diagnosis was 47 months (9-170 range), median OS from start of Carfilzomib was 3 months (range 1-13).

Table 1.

Summary/Conclusions: KRD has shown significant efficacy in a particularly selected setting of patients, relapsed and refractory to all available therapeutic resources, and, in particular cases, it could be considered as a bridge to a second autologous or allogenic SCT.
Background: The treatment of patients with multiple myeloma (MM) has dramatically changed over the past decade due in part to the development of new agents and myeloma-specific targets. Nowadays, new effective treatments exist for patients with RRMM not responding to bortezomib and lenalidomide. Poma-lidomide alone has shown limited efficacy in patients with RRMM, but synergistic effects have been noted when combined with dexamethasone.

Aims: To show our experience with the use of 28-day cycles of pomalidomide (4 mg/day on days 1–21, orally) plus low-dose dexamethasone (40 mg/day weekly, orally) (Pom/dex) in RRMM.

Methods: This is a retrospective study performed between May 2014 and January 2017 in the Hospital of Guadalajara (Spain). Eight patients (3M, 5F), with a median age of 67 years (range, 40-81), diagnosed with MM were included. Four were classified as high-risk myeloma (Patients 1–4). Patient 1 (P1) had plasma cell leukemia and received Pom/dex plus bortezomib; Patient 2 (P2) presented complex karyotype and received Pom/dex after three previous regimens and an autologous transplantation; Patient 3 and Patient 4 (P3 and P4) had extramedullary plasmacytoma and received Pom/dex/local radiotherapy. The eight patients of this study had failed to bortezomib and lenalidomide-based therapy, and received Pom/dex until disease progression or unacceptable toxicity. Pom/dex was associated with ciclophosphamide in two patients, and with bortezomib in another two patients. The primary endpoint was progression-free survival (PFS).

Results: The median number of prior regimens was 2 (range, 1-4) and five of eight patients (62.5%) had previously received autologous transplantation. Median time from diagnosis to Pom/dex was 51.5 months (range, 28-155). Patients received a median of 6 cycles of Pom/dex (range, 2-16). In the whole series, the median follow-up was 60.5 months (IQR: 56.0-80.25), and median PFS was 11 months; 75% of patients had not progressed after 5 months, and 50% of patients after 11 months. The overall response rate was 87.5% (1 patient discontinued therapy for non-response). In standard-risk MM patients, median follow-up was 61 months (IQR: 46.25-140.25), and median PFS was 13 months; 75% of patients had not progressed after 2 months, and 50% of patients after 13 months. Regarding the high-risk group of patients, P1 achieved complete response after 6 cycles of Pom/dex/bortezomib; P2 achieved PFS of 11 months; P3 achieved plasmacytoma resolution after 6 cycles of Pom/dex plus local radiotherapy; P4 abandoned Pom/dex after 3 cycles because of severe neutropenia and sepsis. In this group median follow-up was 60.5 months (IQR: 56.3-79.8), and median PFS was 6 months; 75% of patients had not progressed after 5 months, 50% of patients after 6 months, and 25% of patients after 11 months. Regarding adverse events, they were present in two patients: one had neutropenia, and the second one pneumonia plus pulmonary venous thromboembolism. Both of them died (Figure 1).

Summary/Conclusions: In our experience, Pom/dex regimen has prolonged PFS of patients with RRMM, with an improvement of health-related quality of life. This regimen has been even valuable in high-risk patients who received Pom/dex after ≥2 treatment regimens. Pomalidomide plus low-dose dexamethasone, an oral regimen, could be considered a new treatment option as a standard of care for patients with RRMM who have poor prognosis and a high need for effective treatments.

Myeloproliferative neoplasms - Biology

ROUTINE SCREENING FOR KIT M541L IS NOT WARRANTED IN THE DIAGNOSTIC WORK UP OF PATIENTS WITH HYPEREOSINOPHILIA

N. Cross1,2, Y. Hoode1, O. Metzgeroth1, J. Schwab2, A. Reiter2

1University of Southampton, Southampton, United Kingdom, 2Universitätsmedizin Mannheim, Mannheim, Germany

Background: The role of the KIT M541L variant in patients with hypereosinophilic (HE) is controversial. On the one hand, this variant is a recognised single nucleotide polymorphism (c.1621 A>C; rs3822214) with a minor allele frequency of 0.08 in the ExAC database and classified as benign/likely benign on ClinVar. On the other hand, it has been suggested that KIT M541L increases the sensitivity of the KIT receptor to stem cell factor (Foster R et al., Br J Dermatol. 2008;159:1160-9) and may be specifically acquired in in patients with hypereosinophilic syndrome (CEL-NOS) (Schröck 2016). The role of KIT M541L in patients with hypereosinophilic syndrome (HE and HES) is controversial. On the one hand, this variant is a recognised single nucleotide polymorphism (c.1621 A>C; rs3822214) with a minor allele frequency of 0.08 in the ExAC database and classified as benign/likely benign on ClinVar. On the other hand, it has been suggested that KIT M541L increases the sensitivity of the KIT receptor to stem cell factor. Consequently it has been suggested that HE patients should be screened for KIT M541L, as positive cases may benefit from imatinib treatment.

Aims: We aimed to (i) compare the KIT M541L allele frequency between patients referred for investigation of HE and normal healthy controls (ii) investigate the variant allele frequency (vaf) to determine if KIT M541L mutations may be acquired somatically and (iii) investigate the KIT M541L status in cases negative for PDGFRAβ abnormalities who responded to imatinib.

Methods: We screened healthy controls (n=214) and patients referred for investigation of PDGFRAβ abnormalities (n=220) for KIT M541L using an amplification refractory mutation system (ARMS) PCR designed to amplify allele specific products of different sizes, and able to detect KIT M541L down to 5% vaf. Fishers exact two tailed test was used to compare the allele frequency between the two groups. Digital droplet PCR (ddPCR) was used for patients heterozygous for KIT M541L by the ARMS assay to determine whether the KIT M541L mutation burden was close to 50% (consistent with a constitutional polymorphism) or <50% (suggestive of a somatic mutation). We also studied pre-treatment DNA from 3 patients with hypereosinophilic syndrome who were treated with imatinib (400 mg/day) and showed normalization of eosinophil counts at a median of 0.8 months (0.4-5.0) after treatment for a duration of 13.6 months (range, 3.7-44.8).

Results: Forty two (19%) of HE cases tested positive for KIT M541 compared to 38 (18%) of healthy controls. The KIT M541L allele frequency was no different between controls and cases (0.095 versus 0.098; P=0.91). Of the 42 KIT M541L heterozygous HE cases, 40 had sufficient DNA for analysis by ddPCR. The mean allele burden was 50.4% (range 48.3%-56.0%), consistent with all heterozygous HE cases, 40 had sufficient DNA for analysis by ddPCR. The mean allele burden was 50.4% (range 48.3%-56.0%), consistent with all heterozygous HE cases.

Summary/Conclusions: Whilst we cannot exclude the possibility that KIT M541L may be acquired somatically in very rare cases, we conclude that there is no clinical value in screening for this variant on a routine basis for patients with HE or HES.

MUTATIONS OF THE JAK2 GENE AND CYTOGENETIC ABNORMALITIES ARE PREDICTIVE OF PROGRESSION TO HEMATOLOGICAL NEOPLASMS IN PATIENTS WITH IDIOPATHIC LEUKOCYTOYSIS

N. Mori1,2, K. Yoshina3, M. Ohwashi-Miyazaki3, M. Shiseki4, H. Sakura4, J. Tanaka3

1Hematology, Tokyo Women’s Medical University, 2Internal Medicine, Tokyo Women’s Medical University Medical Center East, 3Hematology, Tokyo Women’s Medical University, 4Internal Medicine, Tokyo Women’s Medical University Medical Center East, Tokyo, Japan

Background: Idiopathic leukocytosis and erythrocytosis are hematological disorders without specific causes. Frequent V617F mutations on the JAK2 gene have been reported in patients with polycythemia vera (PV), essential thrombocytopenia, and primary myelofibrosis. We also found JAK2 V617F mutations in one of 11 patients with idiopathic erythrocytosis. Mutations of the CSF3R, JAK2, PDGFRα/β and ETNK1 genes have been found in chronic neutrophilic leukemia and atypical chronic myeloid leukemia (CML). Furthermore an autosomal mutation was found in the CSF3R gene in a family with chronic neutrophilia. However, little is known about mutations associated with idiopathic leukocytosis.

Methods: We previously analyzed the JAK2, CSF3R, CALR, SETBP1, and ETNK1 genes in 10 patients with idiopathic leukocytosis (EHA20). To elucidate the relevance of genetic alterations, we extended the analysis with 17 genes known to be involved in hematological neoplasms in 16 patients with idiopathic leukocytosis. We also found JAK2 V617F mutations in one of 11 patients with idiopathic erythrocytosis. Mutations of the CSF3R, JAK2, PDGFRα/β and ETNK1 genes have been found in chronic neutrophilic leukemia and atypical chronic myeloid leukemia (CML). Furthermore an autosomal mutation was found in the CSF3R gene in a family with chronic neutrophilia. However, little is known about mutations associated with idiopathic leukocytosis.

Methods: We aimed to (i) compare the KIT M541L allele frequency between patients referred for investigation of HE and normal healthy controls (ii) investigate the variant allele frequency (vaf) to determine if KIT M541L mutations may be acquired somatically and (iii) investigate the KIT M541L status in cases negative for PDGFRAβ abnormalities who responded to imatinib.

Methods: We screened healthy controls (n=214) and patients referred for investigation of PDGFRAβ abnormalities (n=220) for KIT M541L using an amplification refractory mutation system (ARMS) PCR designed to amplify allele specific products of different sizes, and able to detect KIT M541L down to 5% vaf. Fishers exact two tailed test was used to compare the allele frequency between the two groups. Digital droplet PCR (ddPCR) was used for patients heterozygous for KIT M541L by the ARMS assay to determine whether the KIT M541L mutation burden was close to 50% (consistent with a constitutio
of time. The period of observation was 1 year or longer in most patients. Sixteen patients with idiopathic leukaemia were analyzed in the study. Neutrophils or mononuclear cells were collected after obtaining written informed consent from the 16 patients. Neutrophils from peripheral blood were purified by dextran sedimentation followed by hypotonic lysis and centrifugation with Ficoll-Conray. Mononuclear cells were isolated from bone marrow by Ficoll-Conray gradient centrifugation. DNA was extracted using the QIAamp DNA blood mini kit (Qiagen, Valencia, CA, USA). Mutations within hot spots of the CSF3R, JAK2, CALR, SETBP1, ETNK1, CBL, TET2, ASXL1, EZH2, IDH1/IDH2, DNMT3A, U2AF1, and CEBPA genes were analyzed by direct sequencing in both directions using a 3730XL DNA Analyzer (Life technologies, Carlsbad, CA, USA) and/or allele specific polymerase chain reaction. Total RNA extraction and reverse transcriptase polymerase chain reaction (RT-PCR) were performed between the ETV6 and ABL1 genes in 10 patients. BCR/ABL1 gene was analyzed by RT-PCR or fluorescence in situ hybridization in 8 patients. The current study was conducted within the guidelines and with the approval of an institutional ethics committee.

Results: JAK2 V617F mutations were found in one of the 16 patients with idiopathic leukaemia. No mutations were found in the other genes in the 16 idiopathic leukaemia patients. ETV6-ABL1 fusion gene was detected in one of the 10 patients. No BCR/ABL1 fusion gene was detected in the 8 patients. One patient with idiopathic leukaemia has JK2 V617F mutation has developed PV. Another patient with sustained leukaemia for 20 years showed cytogenetic abnormalities during observation and has developed Philadelphia chromosome negative CML (Ph-CML). ETV6-ABL1 fusion gene was detected in this patient. Another patient with normal karyotype progressed to blast crisis of Ph-positive CML (Ph-AML) as a consequence of cytogenetic abnormalities. Of the remaining 13 patients with idiopathic leukaemia, one resolved the disease and twelve had a stable disease.

Summary/Conclusions: Idiopathic leukaemia comprises heterogeneous conditions. JAK2 mutations and cytogenetic abnormalities are predictive of progression to hematological neoplasms.

Background: Myelofibrosis is a hematological disease inserted in the group of myeloproliferative neoplasias. It has as main characteristic fibrosis of the bone marrow, consequence of a variety of histological changes presented in the medullary microenvironment. The development of the disease is related to the clonal expansion of myeloid stem cells, abnormal expression of cytokines, hypercellularity of myeloid lines and also extramedullary hematopoiesis. The pathophysiology of myelofibrosis involves the activation of signal transduction pathways, which may occur due to genetic rearrangements and mutations that alter the structure of protein tyrosine kinases, making hematopoietic progenitor cells independent or hypersensitive to cytokines, generating anomalous cellular behavior. Myelofibrosis is a hematological disease inserted in the group of myeloproliferative neoplasias. It has as main characteristic fibrosis of the bone marrow, consequence of a variety of histological changes presented in the medullary microenvironment. The development of the disease is related to the clonal expansion of myeloid stem cells, abnormal expression of cytokines, hypercellularity of myeloid lines and also extramedullary hematopoiesis. The pathophysiology of myelofibrosis involves the activation of signal transduction pathways, which may occur due to genetic rearrangements and mutations that alter the structure of protein tyrosine kinases, making hematopoietic progenitor cells independent or hypersensitive to cytokines, generating anomalous cellular behavior.

Aims: Recent studies have shown that microvesicles produced by cells of the organism may be associated with the cellular communication process due to their structure and content that microRNAs in this compartment are able to regulate diverse cellular processes. The expression of some microRNAs is associated with hematopoietic processes such as the transformation of myeloid, erythroid and megakaryocytic progenitors. These can regulate the hematopoiesis of normal stem cells and also of compromised progenitors, having an impact on the hematopoietic pathogenesis of diseases. The development of this research is related to the clonal expansion of myeloid stem cells, abnormal expression of cytokines, hypercellularity of myeloid lines and also extramedullary hematopoiesis. The target of this study was to investigate the presence of specific miRNAs in microvesicles excreted in peripheral blood plasma of patients with myelofibrosis, which may be related to cellular communication.

Methods: Microvesicles were isolated from the plasma by ultracentrifugation methods and their content was analyzed by biology techniques. miRNAs were park in their presence. Assays by qPCR were performed to evaluate the presence of specific miRNAs.

Results: We used the miRNAs described in the literature as influential in the process of hematological disorders. They are: miR-146b, miR-150, miR-29a and miR-29b. A total of 20 patients from the study group were evaluated. Total RNA was extracted using the Qiagen DNA blood mini kit (Qiagen, Valencia, CA, USA). Mutations within hot spots of the CSF3R, JAK2, CALR, SETBP1, ETNK1, CBL, TET2, ASXL1, EZH2, IDH1/IDH2, DNMT3A, U2AF1, and CEBPA genes were analyzed by direct sequencing in both directions using a 3730XL DNA Analyzer (Life technologies, Carlsbad, CA, USA) and/or allele specific polymerase chain reaction. Total RNA extraction and reverse transcriptase polymerase chain reaction (RT-PCR) were performed between the ETV6 and ABL1 genes in 10 patients. BCR/ABL1 gene was analyzed by RT-PCR or fluorescence in situ hybridization in 8 patients. The current study was conducted within the guidelines and with the approval of an institutional ethics committee.
Background: Myeloproliferative neoplasms (MPNs) are a group of chronic myeloid cancers characterized by overproduction of mature hematopoietic cells. Mutations in one of three genes; Janus kinase 2 (JAK 2), myeloproliferative leukemia virus oncogene (MLP), and calreticulin (CALR), have been observed in and in most patients with BCR-ABL negative MPNs. JAK2 mutations are present virtually all cases of Polycythemia Vera and 50-60% of pmf and Essential Thrombocythemia (ET). Recently, mutations in CALR gene were found in 50-80% of JAK2 and MPL mutation negative ET and pmf patients. Aims: To evaluate immunohistochemical results of CALR gene mutation in the bone marrow samples of the JAK2V617F mutated and JAK2V617F wild type Primary Myelofibrosis (pmf) patients. Methods: Material: Bone marrow biopsy samples from 32 patients previously diagnosed as primary myelofibrosis with known JAK V617F mutation status were evaluated from archives of Marmara University Pathology Laboratory. Bone marrow samples of two patients were already known as CALR mutated by PCR analysis. Bone marrow samples of three JAK2 wild type and CALR mutated ET, two JAK2 wild type, CALR mutated pmf patients and two CALR wild type ET patients were used as positive and negative control tissues for CALR immunohistochemistry. Immunohistochemistry: 4-µm unstained sections of each bone marrow biopsy specimens were cut onto electrostatically charged glass slides. Immunohistochemistry was performed on an automated immunostainer (Ventana Benchmark Ultra; Ventana Medical Systems, Inc). CALR antibody (clone CAL2, Dianova, Germany) staining used a 1:100 dilution. Any cytoplasmic staining of the cells with CAL2 antibody was considered positive immunostaining.

Results: We studied 32 bone marrow specimens of primary myelofibrosis with 15 (47%) of them having JAK2 V617F mutation and 17 (53%) of them lacking JAK2 V617Fmutation. CALR immunoreactivity was seen in 8 (25%) of all pmf patients. CALR immunoactivity was seen in 8 (47%) of patients with PMF myelofibrosis who are negative for JAK2V617F mutation. CALR immunoreactivity was not seen in patients with PMF myelofibrosis who are positive for JAK2V617F mutation. CALR immunoreactivity was seen in 3 (100%) of patients with ET and 2 (100%) of patients with known CALR mutation. CALR immunoreactivity was seen in patients with CALR wild type ET patients. We observed that CAL2 immunostaining was seen mainly in the cytoplasm of the small and large megakaryocytes, and atypical megakaryocytes as found in fibrotic PrMF. Pale immunostaining was seen in myeloid and erytroid cell precursors. This immunostain also stained some small cells appearing as micromegakaryocytes. Summary and Conclusions: An immunohistochemical stain easily detects the CALR mutation by staining of megakaryocytes in formalin-fixed bone marrow biopsy specimens. This method would be a easy, rapid, and cost effective way to detect CALR mutations in daily routine hematopathology biopsy evaluation of the myeloproliferative patients.

PB2028

THE HIF1A/2A MRNA INDEX HAS A SIMILAR TREND AS THE CHANGES OF EXPRESSION MRNA CALR AND MDR1 GENES IN WHOLE BLOOD SPECIMENS OF PATIENTS WITH JAK2 V617F POSITIVE MPN

A. Gorbenko1, M. Stolyar2,*, M. Mikhalev3, E. Vasiliev1,4, V. Khorzhevskyi5, I. Okhrymskyi2,6
1Department of Health, Krasnoyarsk branch of the Federal State budgetary Institution «Hematology Research Center», 2Siberian Federal University, 3Krasnoyarsk city Clinical Hospital № 7, 4Krasnoyarsk regional hospital, 5Krasnoyarsk State Regional Bureau of Pathology, 6Krasnoyarsk Scientific Center SB RAS, Krasnoyarsk, Russian Federation

Background: Various groups have reported that isoforms of hypoxia-inducible transcription factor 1α (HIF-1α) and 2α (HIF-2α) can regulate both overlapping and distinct target genes. HIF-1α and HIF-2α have been shown to play opposite roles in the regulation of macrophage function [Takeda N. e.a., 2010]. HIF-index incorporated as a strong prognostic biomarker of renal cell cancer [Szendrői A. e.a., 2016]. New data have shown exclusive role of HIF-2α in regulates the proliferation and distinct target genes. HIF-1a and HIF-2a have been shown to play opposite roles in the regulation of macrophage function [Takeda N. e.a., 2010]. HIF-index incorporated as a strong prognostic biomarker of renal cell cancer [Szendrői A. e.a., 2016]. HIF-index more clearly showed a correlation with the fall of MDR1 and CALR mRNAs (r=-0.6) in control and r=-0.7 in MPN group, p<0.05, CALR gene unlike MDR1 gene is not known among the target HIF regulation, but their unidirectional change indicates the possible metabolic links.

Methods: Real-time PCR was performed to detect HIF1α, HIF2α, MDR1 and CALR mRNA transcribes levels in white blood cells 14 healthy volunteers (median age 22 years, range 21-58 years, 57% males) and 11 (median age 44 years, range 20-77 years, 45% males) patients with JAK2 V617F-positive MPN, median of allelic burden is 36%, range 9-87%. Venous blood were collected in tube with RNase inhibitor. Total RNA was isolated using "RIBO-zol-ol" (Aplisens) and were transcribed using "Reverta-L" (Aplisens). PCR was optimized for the thermocycler CFX96 (Bio-Rad). The results were calculated using the delta Ct method in the software package of “R”. The threshold cycles (Ct) genes and housekeeping genes (TBP, GUS, ABL) determined using Cq0 method. The results was normalization with this reference genes. Mann-Whitney U test was used to evaluate significant difference between the groups, the degree of correlation (r) was assessing used Spearman test.

Results: We observed a lower mRNA expression MDR1 and CALR in whole blood samples of patients with MPN compared with a group of healthy volunteers (Figure 1). The expression level of mRNA HIF2α not changed and for HIF1α it should be noted a tendency for statistical significance. It found no correlation between allelic burden and mRNA expression level. Index HIF 1a2a more clearly showed a correlation with the fall of MDR1 and CALR mRNAs (r=-0.6) in control and r=-0.7 in MPN group, p<0.05, CALR gene unlike MDR1 gene is not known among the target HIF regulation, but their unidirectional change indicates the possible metabolic links.

Figure 1.

Summary/Conclusions: We assume that the studied gene expression changes reflect the metabolic processes in the bone marrow progenitor cells. Probably JAK2 V617F mutation leads to more favorable microenvironment and reduced willingness to autophagy, causing the index shift HIF1a2a. We found reduced of mRNA CALR expression in blood cells at MPN and this fact require further investigation.

PB2029

CD177 EXPRESSION IN PERIPHERAL BLOOD NEUTROPHILS IN HEALTH AND DISEASE STATES

A. Arafat1, S. Rizk1, R. Samy1, N. Al-Hussein2, R. El-Hawary1
1Clinical and chemical pathology, 2Internal medicine, Cairo university, Cairo, Egypt

Background: Objective and specific assays are required in the identification of both chronic myeloproliferative disorders and myelodysplastic syndromes. Aims: Exploration of the possibility of using the CD177 expression in the peripheral blood neutrophils for the diagnosis of either entity. Methods: The 213 subjects were organized into 4 main groups; benign neutrophil leukocytosis group, secondary erythrocytosis group and clonal myeloid neoplasms group together with a haematologically normal group as controls. All cases were subjected to clinical assessment as well as the flow cytometry determination of the percentage (%) and mean fluorescent intensity (MFI) of peripheral blood neutrophils expressing CD177.

Results: Skewed high peripheral blood neutrophil CD177 MFI was significantly associated with Philadelphia-negative cMPDs patients (2.9-37.4; median 14.1) compared to controls (0.8-20.5; median 8.8). The MDS patients did not show a significant difference in either CD177% or MFI compared to the controls. Polycythermia Vera (PV) patients had similar results of CD177 expression (% and MFI) compared to Essential Thrombocytosis (ET) patients. However, they had higher CD177 MFI levels compared to the secondary erythrocytosis patients and controls (4.8-37.4; median 16.5, 1.58-25.7; median 5.81, 0.85-20.5; median 8.8 respectively). CD177 MFI showed statistically significant higher values in ET patients compared to the haematologically normal control group (2.9-34.5; median 13.4 versus 0.85-20.5; median 8.8 respectively). No correlation between CD177 expression and JAK2 V617F allele burden could be detected in either PV or ET patients. With a 0.25 p.d.u cutoff, the specificity of neutrophil CD177 MFI in Philadelphia-negative cMPDs patients’ diagnosis and differentiation of PV from secondary erythrocytosis was 93% and 85% respectively. The CD177% had a low accuracy of in the diagnosis of MDS patients. The CD177 patterns observed were one positive peak and bimodal pattern (Figure 1).

Summary/Conclusions: The CD177 expression is highly associated with Philadelphia-negative cMPDs. It could reliably represent a useful potential marker in detecting those disorders and differentiating them from reactive cases.
DETECTION OF THE MUTATIONS IN GENES JAK2 AND MPL IN THE DIAGNOSIS OF CHRONIC MYELOPROLIFERATIVE DISORDERS

K. Boboev1, K. Karimov1, A. Mohammad1
1Institute of hematology and blood transfusion, tashkent, Uzbekistan

Background: Chronic myeloproliferative diseases is a group of clonal Ph-negative hematological diseases, which include erythema (polycythemia Vera, PI), chronic megakaryocytic leukemia (essential thrombocythemia, ET) and subleukemic myelosclerosis (primary myelofibrosis, PMF, chronic idiopathic myelofibrosis). The origin of these diseases is linked to transformation of hematopoietic stem cells, the result is the excessive production of mature cells of erythroid, granulocytic and megakaryocyte shoots with relatively long course of the disease. The frequency of occurrence of mutation V617F of gene JAK2 exon 12 and MPL gene varies in different literature.

Aims: Determination of the frequency of occurrence of mutations in genes JAK2 and MPL and identifying the importance of the verification of these diseases.

Methods: The study included 350 patients with chronic myeloproliferative diseases — with polycythemia Vera 150 patients, with essential thrombocythemia 78, with chronic idiopathic myelofibrosis 55 and 67 patients were examined with the purpose of differential diagnosis with Ph(-) Chronic myeloproliferative diseases. The age of patients ranged from 20 to 70 years, median age was 54 years. Isolation DNA of patients was carried out using a set of reagents "Ampiprep Ribo-prep" (OOO Interalservice, Russia). The concentration and purity of isolated DNA was determined by Nano Drop 2000 instrument (USA). Detection of gene mutation JAK2/V617F and MPL gene was carried out by standard polymerase chain reaction on a thermal cycler 2720 "Applied Biosystems" (USA), using a set of "Litech" (Moscow).

Results: The result of the research showed that the incidence of the V617F mutation in JAK2 was varying in patients depending on the type of disease. In polycythemia Vera the mutation V617F in the JAK2 gene was identified in 147 patients (98,3%), with essential thrombocythemia in 42 patients of the 78 (54.2%), with chronic idiopathic myelofibrosis in 27 patients of 55 (49,1%). In 67 patients with no hematological profile, with examined with the purpose of differential diagnosis with Ph(-) chronic myeloproliferative diseases, V617F in JAK2 was detected in 6 (8,6%), which allowed to confirm Ph(-) Chronic myeloproliferative diseases. A mutation in exon 12 of the JAK2 gene was detected in 2 of 33 (2,9%) of those surveyed V617F JAK2-negative patients exclusively diagnosed with polycythemia Vera. The MPL V615L mutation gene was detected in polycythemia Vera and chronic idiopathic myelofibrosis 2,2% (1 of 41) and 2% (1 of 52) of patients.

Summary/Conclusions: Thus established, our data confirm that mutations in the genes JAK2 and MPL are highly specific diagnostic markers in patients with Ph-negative chronic myeloproliferative diseases.

ASSOCIATION OF MYELOPROLIFERATIVE NEoplASM AND LYMPHOPROLIFERATIVE DISORDER IN 3 PATIENTS

B. Pouche1, M. Dudez2, M. Daniel2, S. Girard2, C. Froelich2, F. Mestrallet2, I. Tigaud3,  S. Hayette4, A. Belhabri5, M.P. Pages2, L. Vila6,7
1Laboratoire, Hôpital d’instruction des armées Desgenettes, 2Laboratoire, Groupement Hospitalier EST, 3laboratoire, Groupement hospitalier Sud, 4department of cytogenetics and molecular biology, Groupement Hospitalier EST, 5department of oncology and hematology, Centre Leon Berard, 6laboratoire, Groupement Hospitalier EST, 7laboratoire, Centre Léon Bérard, Lyon, France

Background: Lymphoproliferative disorders (LPD) and myeloproliferative neoplasms (MPN) are two very different sets of hematological pathologies. However, several studies have shown that the risk for LPD onset in patients with MPN is higher than in the general population (1)(2). No single LPD seems to be more at cause and all MPN are likely to present the onset of an associated LPD.

Aims: We present 3 cases diagnosed in the Department of Hematology, "Groupement Hospitalier Est", Lyon, France, of patients bearing an association of MPN and LPD: an essential thrombocythemia (ET) with myeloma, ET with marginal zone lymphoma and a chronic myeloid leukemia with chronic lymphoid leukemia.

Methods: Diagnosis have been made thanks to cytology of peripheral blood, bone marrow aspirate and biopsy and confirmed by cytogenetic and molecular biology techniques.

Results: Case number 1. A 68 year old woman known to have essential thrombocythemia as a MPN, with V617F mutation of the JAK2 protein kinase. After 19 years of treatment by Hydrea, she developed a splenomegaly, anaemia and slight lymphocytosis of 4.77 G/L. The blood smear, the bone marrow aspirate and biopsy examination revealed myelofibrosis evolution and an infiltration by 30% of a small sized clonal lymphoid population CD20+, CD5- Medullar karyotype was normal: 46, XX[10]. In conclusion the ET has evolved into myelofibrosis and is associated with a lymphoproliferative syndrome, possibly marginal zone lymphoma. No additional treatment has been implemented. Case number 2. A 64 year old woman know to have ET with V617F mutation of the JAK2 protein kinase treated by acetic salicylic acid. 5 years after, she presented with IgG kappa type monoclonal gammopathy up to 28 g/L, without any associated clinical manifestations nor cytopenia. Medullar blood was diluted but showed slightly atypical plasmocytes remaining under 10%. Myeloma was diagnosed anyway and the patient received 5 cures of Velcade-Melphalan-Prednisone which resulted in complete remission. The MPN remains stable to this day. Case number 3. A 62 year old man with chronic lymphoid leukemia, treated by six cycles of R-FC. While in remission since 2 years, hemogram shows hyperleucocytosis (WBC: 18.3 G/L) with thrombocythemia (platelets: 1886 G/L) without anaemia (Hb: 13.7 g/dL). Blood smear examination reveals 3% of myeloma and basophilia (3.66 G/L). BCR-ABL transcript is positive in 43% and karyotype points out a 9;22 translocation. (46, XY, t (9;22) (q34 ;q11)[1] nuc ist (BLX3, BCRX3, ABL con BCRX2)(48/100). Before starting Nilotinib, cytoreductive treatment by Hydrea was decided. Treatment is under way.

Summary/Conclusions: The three cases described highlight the diverse situations observed in cases of combined MPN/LPD pathologies. MPN with secondary onset of LPD are most frequently encountered, as was the case with patients 1 and 2. Cases of preexisting LPD and late onset MPN are rare (1), and cases of simultaneous discovery of both pathologies even more so (3). Several hypotheses have been formulated to explain the frequency of onset of these pathological associations: genomic instability due to JAK2 protein kinase activation, or due to BCR-ABL mutation, or exposure to cytotoxic chemotherapy or radiations (3).

CLINICAL AND ANALYTICAL DIFFERENCES BETWEEN CALR TYPE-1 AND CALR TYPE-2 MUTATION IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA AND PRIMARY MYELOFIBROSIS: A SINGLE CENTER STUDY

M. Sobas1, M. Olejniczak1, I. Andrasiak2, M. Krużewski3, B. Jazwiec1, J. Rybk1, T. Wrobel1, K. Kulczewski1
1Department of Hematology, Blood Neoplasms and Bone Marrow Transplantation, Wroclaw Medical University, 2WroMedica Research Center, 3Wroclaw Medical University, Wroclaw, Poland

Background: The JAK2V617F is a major molecular marker in myeloproliferative neoplasms (MPN) and is harbored in about 50-60% of essential thrombocythemia (ET) and primary myelofibrosis (PMF). Recently, CALR mutation was described in ET and PMF JAK2V617F negative patients. There are two main variants of CALR mutation: type 1 (a 52-bp deletion) and type 2 (a 5-bp insertion).

Aims: To compare clinical and analytical data of ET and PMF patients with CALR type-1 vs CALR type-2 mutation.

Methods: We performed a single center study on 471 patients: 87 PMF and 384 ET. The JAK2V617F mutation was analyzed in DNA from peripheral blood leukocytes by PCR ARMS method. In all JAK2V617F negative patients detection of CALR mutation was performed by fragment length analysis and the results were confirmed by sequencing. Statistical data analysis was performed using Statistica 12.5 software for Windows.

Results: From 384 ET patients 254 were JAK2V617F positive (66%), 80 were CALR positive (21%) and 51 were JAK2V617F and CALR negative (13%). From CALR positive patients: 36 (51%) had type-1, 34 (45%) type-2 mutation, and 10 (12%) type-3 mutation. From 87 PMF patients 56 were JAK2V617F positive (64%), 18 were CALR positive (21%) and 13 (15%) were JAK2V617F negative and CALR positive. From CALR positive groups: 13 (72%) had type-1 and 5 (28%) had type-2 mutation. Compared with ET carrying JAK2V617F mutation, patients ET CALR type-1 positive (type 1 plus type 2) had lower hemoglobin (13.3 vs 14.5 g/dL, p<0.001) and leukocyte (8.2 vs 9.7 G/L, p<0.001), higher platelet counts (967 vs 800 G/L, p=0.001) but with no significant differences in frequency of thrombosis. In ET, CALR mutation was associated with increased odds of myelofibrotic transformation (odds ratio [OR]=2.61; 95% CI: 1.28 - 5.34; p=0.009) comparing with JAK2V617F positive patients. Patients ET CALR type-1 had higher leukocyte counts than ET CALR type-2 mutation (9.6 vs 7.3 G/L, p=0.008), but we did not find significant differences in hemoglobin, platelet counts, frequency of thrombosis or myelofibrotic transformation. Within PMF, no significant differences were observed. Moreover in PMF, there was no significant differences between the JAK2V617F, CALR type-1 and type-2 mutation status respect to the International Prognostic Score System (IPSS).

Summary/Conclusions: This study highlights that, although ET has a very good prognosis, there is a significant percentage of patients that will need a change of treatment, either because of resistance or intolerance.

PB2034

THROMBOTIC AND BLEEDING RISK FACTORS IN ESSENTIAL THROMBOCYTHEMIA

A. Zhermakova1, I. Martynkevich1, V. Shuvueva1, L. Polushkina1, M. Fominykh1, V. Udal'eva1, I. Zotova1, D. Shichabaeva1, S. Voloshin1, A. Chechelnik1, K. Abdulkadyrov1
1Russian Research Institute of Hematology and Transfusionology, Saint-Petersburg, Russian Federation

Background: Thrombosis and hemorrhage are the main category of complications, that affects the overall survival (OS), quality of life and therapy option choice in essential thrombocythemia (ET). Molecular marker presence (JAK2V617F, MPL, CALR) or its absence (triple-negative status (TN)) in ET supposed to impact on the clinical course, thrombosis rate and ET prognosis.

Aims: The aim of this study was to investigate interactions between the presence of molecular marker, thrombosis/bleeding rates and the OS in ET.

Methods: Outpatient’s charts of 240 ET patients, who had been diagnosed with ET at our institution according to WHO 2008 criteria. The following data were assessed: complete blood count, bone marrow biopsy results, bone marrow cytogenetic, the restriction fragment length polymorphism (RFLP) results used for JAK2V617F detection, in case of JAK2V617F-negative status the PCR-RFLP (MPL detection) and the direct sequencing (CALR detection) results. Different thrombotic/bleeding complications rates were analyzed. The OS in ET patients was compared according to molecular markers revealed.

Results: According to their mutational status 182/240 (75.9%) patients (pts) were JAK2V617F positive (JAK2+), 30/240 (12.5%) – CALR-positive (CALR+), 17/240 (7.1%) – MPL-positive (MPL+). Only two pts were MPL-positive (MPL+) (0.8%), TN were 26/240 pts (10.8%). Among 240 pts 183 (76.3%) hadn’t any thrombotic complication or bleeding event (no complications/NC), 57/240 (23.7%) had complications: 49/57 (85.9%) NC and TN were 26/240 pts (10.8%). Thrombosis+ (arterial or/and venous thrombosis, stroke or heart failure) incidence in TN was 11/87 (13.9%). No significant differences were observed. Moreover in PMF, there was no significant differences between the JAK2V617F, CALR type-1 and type-2 mutation status respect to the International Prognostic Score System (IPSS).

Summary/Conclusions: This study highlights that, although ET has a very good prognosis, there is a significant percentage of patients that will need a change of treatment, either because of resistance or intolerance.

PB2033

ESSENTIAL THROMBOCYTHEMIA: STUDY OF TREATMENT LINES REQUIRED. EXPERIENCE OF A SINGLE CENTER

1Hematology, 2Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain, 3Internal Medicine, Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, Spain

Background: Essential thrombocythemia (ET) is a chronic myeloproliferative neoplasm that shows similar survival prognosis as general population, with a very low rate of transformation to myelofibrosis and acute leukemia. There are different treatments for these patients with optimal responses at first. For the first line, it is usually treated with hydroxyurea, although in young patients it is usually replaced by anagrelide / interferon. There are publications of hydroxyurea side effects, especially cutaneous, but there are not many studies about how many lines of treatment are needed to control the disease.

Aims: Study type and lines of treatment needed in patients with ET in a cohort of patients from January 1997 to January 2017.

Methods: We studied patients diagnosed of essential thrombocythemia in one area of the region of Murcia from January, 1997 to January, 2017. Those who started treatment and those who needed change were analyzed, either by resistance or by intolerance.

Results: In our area we have registered a total of 152 patients diagnosed with ET. Of these, 71 (10% patients) have required at least one treatment line. Table 1 shows the number of treatment lines required for the control of the disease. As it is shown in the Table, more than 20% of treated patients needed a second line and 6.5% required more than 2 lines. At last, Table 3 shows current treatment of ET patients.

Summary/Conclusions: This study highlights that, although ET has a very good prognosis, there is a significant percentage of patients that will need a change of treatment, either because of resistance or intolerance.
median platelet count as follows: 742×10⁹/l (thrombosis+) and 937×10⁹/l (hemorrhage+) (p=0.003). No significant statistical differences in median hemoglobin and leucocyte count (p=0.75 and p=0.47) were detected. There were more than a half pts older than 60 years in groups NC (51%) and thrombosis+ (59%) and in group hemorrhage+ only 36% (p<0.001). Cardiovascular risk factors were reported in 24% pts (NC), 69% pts (thrombosis+) and 36% pts (hemorrhage+) (p<0.001). There were no significant statistical differences in follow risk factors as thrombosis >100x10⁹/l and leucocytosis >11x10⁹/l (p=0.85 and p=0.72). No significant differences in OS among groups NC, thrombosis+ and hemorrhage+ (p=0.12) were found (Figure 1).

Figure 1.

Summary/Conclusions: Leukocytosis >11x10⁹/l and thrombocytosis >100x10⁹/l cannot be assessed as independent thrombosis risk factors in ET. JAK2V617F mutation was associated with increased risk of thrombotic complications in ET. CALR mutations were correlated with lower thrombosis risk and better OS rate, comparing to JAK2+ and TN status despite the fact of CALR+ patients had higher platelets level. Along with common thrombosis risk factors (age >60 and cardiovascular risk factors) mutational status may help to identify ET course and to optimize individual therapy option choice.

PB2035
DETECTION OF JAK2 exon 12 MUTATIONS BY HETERODUPLEX ANALYSIS AND PYROSEQUENCING
T. Subbotina1,2,*, E. Dunaeva3, K. Mironov3, A. Kharsekina1, E. Vasiyliev2,4, I. Olkhovskiy2,8, G. Shipulina1

1Department of Medical Biology, Siberian Federal University, 2Krasnoyarsk branch of the Federal State budgetary Institution «Hematology Research Center» Department of Health, Krasnoyarsk, 3Federal Budget Institute of Science «Central Research Institute for Epidemiology», Moscow, 4Krasnoyarsk regional hospital, 5Municipal Budget Health Service Institution «City Clinical Hospital № 7», 6Krasnoyarsk Territory Department of Health Regional state budget health facility «Krasnoyarsk interdistrict clinic №1», 7Krasnoyarsk State Regional Bureau of Pathology, 8Krasnoyask Scientific Center of the Siberian Branch of the Russian Academy of Sciences, Krasnoyarsk, Russian Federation

Background: Somatic mutations in codons 533-547 of JAK2 exon 12 are highly specific to confirm the diagnosis of polycythemia vera (PV). We have previously proposed techniques for the detection and quantification of JAK2 exon 12 allele burden using a pyrosequencing method (Subbotina T et al, Hematologya, 2014). However, due to the high cost of sequencing, developing a two-stage algorithm for detect mutations in JAK2 exon 12 using inexpensive screening is of immediately practical necessity.

Aims: The aim of this study was to demonstrate the feasibility of using heteroduplex analysis with screening by electrophoresis on non-denaturing PAGE as the preliminary screening test for detection of JAK2 exon 12 mutations.

Methods: 274 patients with PV or unclear erythrocytosis and with a low JAK2V617F allele burden or unmutated JAK2V617 (51 women, mean age 52.2±15.7 years and 223 men, mean age 43.6±15.6 years) were included in this study. The informed consents from these patients were obtained. The PCR with the additional stage of formation heteroduplexes was performed using the Real-time PCR kit (Syntol, Russia) and CFX 96 Real Time System (Biorad, USA). PCR products were analyzed by electrophoresis in 8% PAGE. The presence of the mutations was identified and confirmed by pyrosequencing method with PyroMark Q24 (Qiagen, Germany). To verify the presence of mutations, the DNA sequences extracted from the clinical samples were cloned into pGem-T vector using standard protocol («Promega», USA), and obtained clones were sequenced using reagents and equipment of the «Applied Biosystems» (USA). JAK2 exon 12 allele burden was calculated as a measure of relative changes in allele burden between the baseline and follow-up sample (Theocharides A et al, Haematologica, 2008).

Results: We detected JAK2 exon 12 mutation in five out 274 patients. The results of electrophoresis on non-denaturing PAGE are reported in Figure 1. The type of №1-5 patient mutations was determined by pyrosequencing: N542-E543del (c.1624_1629delGAAATG), I540-E543delinsKK (c.1619_1627 TCA-gAAATGK) (c.1622_1627delGAAATG) and p.H538_K539>L (c.1612_1616CACAATTT). These mutations have been already described. Main characteristics of 5 patients with JAK2 exon 12-mutated PV are reported in Table 1. The PV diagnosis of №1, 2, 3 and 5 patients was confirmed by bone marrow trephine biopsies histological examination. All 5 patients with JAK2 exon 12-mutated PV have an increased number of red blood cells, along with an accompanying increase in the concentration of hemoglobin and hematocrit level in the peripheral blood. Some of them had increase number of leukocytes and platelets in the disease dynamics. №1-4 patients was treated phlebotomy only and did not received any cytoreductive treatment to date. Patient №5 receives hydroxyurea (HU). Importantly, two out five patients with JAK2 exon 12-mutated PV also have a mutation JAK2V617F (<1%). JAK2 exon 12 allele burden in sample from №1 patient is significantly increased in the disease dynamics.

Figure 1.

Table 1.

Summary/Conclusions: The proposed variant of the heteroduplex analysis with separation of the PCR product by electrophoresis on non-denaturing PAGE can be recommended for use as the preliminary screening test which is carried out before the confirming pyrosequencing. The two-stage approach allows to optimize the algorithm of the JAK2 exon 12 mutation detection and to improve the efficiency of testing for patients suspected of having PV in whom a JAK2V617F mutation is not detected or detected in a low allele burden. In five out 274 patients we detected JAK2 exon 12 mutation and confirmed the diagnosis of PV.

PB2036
INTRODUCTION OF AN NGS GENE PANEL INTO CLINICAL SERVICE FOR MYELOPROLIFERATIVE NEOPLASMS
A. Skowronska1,*, J. Bryon1, S. Clokie1, Y. Wallis1, J. Mason1, K. Reay1, M. Griffiths1

1West Midlands Regional Genetics Laboratory, Birmingham Women’s and Children’s NHS Foundation Trust, Birmingham, United Kingdom

Background: In the West Midlands region of the UK, all patients with a suspected myeloproliferative neoplasm (MPN) have access to quantitative analysis...
of JAK2 V617F by droplet digital PCR as standard of care. The British Committee for Standards in Haematology recommends that suspected MPN cases have investigation of JAK2 exon 12, CALR and MPL genes if JAK2 V617F is negative.

Aims: The aim of the project was to improve the MPN service by substituting sequential analysis of individual target regions within the JAK2, CALR and MPL genes with a single assay, and to increase the number of genes available for analysis.

Methods: A commercial next generation sequencing (NGS) gene panel (Oxford Gene Technology, SureSeq Myeloid Panel), coupled with the Illumina MiSeq platform was validated and implemented. The gene panel utilizes hybridization based enrichment technology and consists of 25 MPN-related genes. During the validation stage the following were enriched and analysed: 29 positive control samples with 30 known pathogenic variants, 30 negative control samples without known pathogenic variants in the JAK2, CALR and MPL genes, and 24 MPN samples of unknown mutational status. Thus so far over 200 clinical samples have been analysed and reported since the service was introduced in October 2016.

Results: The panel has successfully identified: a large range of known pathogenic variants at high sensitivity (JAK2 V617F variant allele frequency 1%, CALR Type 1 frameshift variant allele frequency 3%), a potential alternative driver mutation in a known low level JAK2 V617F positive patient, a rare MPL exon 4 pathogenic variant and also the detection of low level CALR pathogenic variants, which would not have been detected by Sanger sequencing analysis. In one patient the panel identified the presence of two different JAK2 exon 14 pathogenic variants in cis (JAK2 V617F and JAK2 C618R). The JAK2 C618R prevented the hybridization of the probe binding site of the JAK2 V617F ddPCR assay which had to fail a negative result by ddPCR. The validation procedure also explored coverage and limits of sensitivity, potential chemistry specific artefacts and identified common polymorphisms for all 25 genes.

Summary/Conclusions: The panel has replaced the current sequential analysis of CALR, MPL and JAK2 exon 12 in JAK2 V617F negative patients and reduced turn-around-times with increased accuracy and sensitivity compared to Sanger sequencing and fragment analysis. Our current clinical service operates on a two tier system whereby clinicians can request analysis of the full 25 gene panel or a 4 gene subset (JAK2, CALR, MPL, CBL as an in silico analysis).

PB2037 IN JAK2V617F POSITIVE MYELOPROLIFERATIVE NEOPLASMS, BLEEDING RISK CORRELATES WITH ALLELE BURDEN I. Bertozzi1, E. Cosi1, C. Santarossa1, G. Bogioni1, F. Fabbris1, M.L. Randi1
1Dep. Internal Medicine - DIMED, University of Padova, Padova, Italy

Background: Myeloproliferative neoplasms (MPN) are characterized by the presence of JAK2V617F mutation that is almost invariably associated with polycthemia vera (PV), but also occurs in the majority of patients with essential thrombocythemia (ET) or primary myelofibrosis (PMF). JAK2V617F-positive patients display different laboratory and clinical features from JAK2 wild-type, but no clear correlation was found between the JAK2V617F allele burden and natural history of the disease. The most common causes of morbidity and mortality in MPN are thrombotic and hemorrhagic complications, albeit bleedings are less frequent than thrombosis and mostly represented by minor hemorrhagic lesions (epistaxis, menorrhagia and gingival hemorrhage). The impact of different allele burden on bleeding risk is uncertain.

Aims: Aim of our study is to explore whether there is an association between JAK2V617F allele burden and hemorrhagic complications in a large cohort of MPN diagnosed and followed in a single center.

Methods: We selected 253 MPN (121 ET; 47.8%, 124 PV=49% and 8 PMF=3.2%) carrying JAK2V617F mutation. The median follow-up of patients was 8.8 years (0.1 – 37.3 y). Complete medical history and anti-thrombotic drug use were recorded. Hemorrhagic complications were classified as “major” or “minor” in agreement with ISTH criteria. The patients were categorized into four quartiles according to the amount of JAK2 mutant allele (1st quartile 1-25%, 2nd quartile 26-50%, 3rd quartile 51-75% and 4th quartile 76-100%). Nominal variables were compared with X2 test or Fisher’s exact where indicated. Survival has been evaluated only for groups with different prevalence of events during follow-up and was calculated with the Kaplan Meier method and compared with log rank test.

Results: Three patients (1.2%) bled at diagnosis (1 major and 2 minor hemorrhages) while 27 (11.8%) suffered for hemorrhages during follow-up in 4th quartile compared to 1st (p=0.003) and to 3rd (p<0.001) quartiles. Hemorrhages-free survival was shorter in 4th quartile compared to 1st and 2nd (p=0.004) and to 1st (p<0.001). The incidence rate of hemorrhages are respectively 0.7/100 pats/y for 1st quartile, 0.65/100 pats/y for 2nd quartile, 1.26/100 pats/y for 3rd quartile and 3.23/100 pats/y for 4th quartile with a IRR of 5 and of 4.6 for the 4th quartile respectively versus 2nd and 1st one. No statistically significant difference was found in the use of anti-thrombotic drugs among patients of the different quartiles.

Summary/Conclusions: Risk factors for hemorrhage in MPN are not well defined, and there is no risk estimation model for this outcome. Acquired von Willebrand disease, entity of platelet increased count and aspirin use have been implicated in bleeding occurrence. Previous reports fail to demonstrate a correlation between JAK2 mutation and bleeding risk. In contrast, in our cohort we found a significantly higher incidence of bleeding manifestations during follow-up in patients with higher allele burden. Interestingly no differences were seen in administration of anti-thrombotic drugs among quartiles, suggesting an independent role of JAK2 allele burden in the different distribution of hemorrhagic events.

PB2038 JAK2 ALLELE BURDEN IN PATIENTS WITH PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS M. Napolitano1, S. Siragusa1, M. Santoro1, M.R. Lanza Cariccio1, M. Bono2, F. Di Piazza2, A. Russo2, V. Accurso1
1UO Ematologia, 2Laboratorio di genetica e oncologia molecolare, 3UO Oncologia, University Of Palermo, Palermo, Italy

Background: The JAK2V617F allele burden (JAK-AB) plays a central role in chronic myeloproliferative neoplasms (cMPNs): its presence has also been advocated in the differential diagnosis of cMPNs and as independent risk factor for venous thromboembolic complications. New treatment with Ruxolitinib may decrease JAK-AB but at the present, it is not clear the clinical advantage of this approach.

Aims: Primary aim of the current study was to evaluate at diagnosis the JAK-AB in patients with Philadelphia negative cMPNs, in order to evaluate any association with standard demographic, clinical and laboratory parameters with particular emphasis to thrombotic and hemorrhagic events.

Methods: Peripheral blood samples from patients with Ph-negative cMPNs were collected. DNA from leucocytes was analysed for JAK-2 (V617F) gene mutation with amplification-refractory mutation system (ARMS) PCR, subsequently a real-time quantitative polymerase chain reaction (qRT-PCR) for JAK2V617F allele burden measurement was applied. A multivariate analysis was then performed to evaluate any association of AB with demographic and clinical data.

Results: One hundred and twelve patients with Philadelphia negative cMPNs were investigated: 52 females with a median age at diagnosis of 69 years (age range: 18-85 years), 60 males with a median age of 68 years (age range: 18-82 years). Thirty-four patients had Essential Thrombocythemia (ET), fifty-two had Polycythemia Vera (PV) and twenty-six had primary myelofibrosis (PMF). JAK-2 AB of patients with an age <69 years and >69 years, was respectively evaluated. Patients older than 69 years showed a significantly higher JAK2-AB. JAK-AB was significantly reduced in ET, when compared to PV and PMF. No correlation was found between median values of allele burden and IPSS and DIPSS scores. In patients with PV (n=52), a significant correlation was observed between allele burden and WHO2008 scoring system. No significant correlation was found between allele burden and thrombotic risk according to IPSET-t and IPSET-ET for PV and ET, respectively. Patients with a previous history of thrombosis had the highest JAK2-AB. In PMF, a positive correlation between JAK-AB and grading of fibrosis was found only for the highest grades (PMFIII and IV). JAK-AB had a positive correlation with splenomegaly in PMF.

Summary/Conclusions: Our report cannot confirm any correlation between allele burden and thrombotic risk, according to currently adopted scoring systems. A previous history of thrombosis is however associated with the highest AB in all cases.

PB2039 COMPARISON OF CLINICAL AND LABORATORY DATA, INCLUDING JAK-2 46/1 HAPLOTYPE, BETWEEN PATIENTS WITH IDIOPATHIC ERYTHROCYTOSIS AND POLYCYTHEMIA VERA M. Napolitano1, S. Siragusa1, M. Santoro1, F. Di Piazza2, M. Bono2, S. Mancuso1, A. Russo2, V. Accurso1
1UO Ematologia, 2Laboratorio di genetica e oncologia molecolare, 3UO Oncologia, University Of Palermo, Palermo, Italy

Background: Idiopathic erythrocytosis (IE) is a relatively rare finding characterized by an increased red blood cell mass without an identifiable cause. Diagnosis of IE is based on the exclusion of primary and secondary erythrocytosis including JAK2-wild-type polycythemia Vera (PV).

Aims: In the current study, we report clinical features and laboratory data able to discriminate IE from PV, at diagnosis.

Methods: We have here analyzed clinical and laboratory parameters, including JAK-2 46/1 haplotype, from patients with a confirmed diagnosis of IE and PV, followed from January 2010 to December 2016. Data were statistically analyzed, nominal variables were compared with X2 test and continuous variables with the Mann-Whitney test.

Results: Overall, 40 patients with IE and 93 patients with PV were included in the current analysis (Table 1). Splenomegaly and Ithg were reported only in patients with IE. History of thrombosis and cardiovascular events was positive in one case with IE. JAK-2 (V617F) and exon 12 mutations were negative in all patients with IE, while JAK-2 46/1 haplotype was found at heterozygous state in 18 patients and at homzygous state in 2 patients with IE.

**Methods:**
Cytogenetic examination of bone marrow cells obtained from patients was performed by 24th culture method. R banding technical was used for karyotype analysis. PGDFRA and B gene rearrangement were detected by FISH using triple-color of 4q12 and dual color break-apart PDGFRB probes.

**Results:**
The fusion genes of rearrangements of PGDFRA and B genes were detected by RT-PCR. Immunophenotype analysis was carried out by flow cytometry. Most of all cases were treated with IM and followed up.

**Summary/Conclusions:**
In the current study, we highlight peculiar clinical and laboratory findings of IE, in comparison with Polycythemia Vera. As shown by available studies, Hb and HCT level do not easily discriminate between the two categories of patients while gene panels may be useful to improve diagnostic accuracy of IE. We have here first observed the presence of Jak-2 46/1 haplotype in approximately half patients with IE, even in absence of Jak-2 mutations; the homozygous status was statistically different among PV and IE patients. The role of such association deserves further specific studies.

PB2040
LABORATORY RESPONSIVENESS OF LOW-DOSE ASPIRIN IN PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA

| Background: 
| The essential thrombocytocemia (ET) is a myeloid neoplasm characterized by platelet hyperreactivity and thrombosis. The daily low-dose aspirin (ASA) is a cornerstone in the prevention of the thrombotic events. In the ET an accelerated platelet turnover translates in a renewal of the drug target shortening the duration of cyclooxygenase (COX-1) inhibition and may dictate new dosing strategies particularly in ASA “low-responders” patients. 

**Aims:**
Therefore, we evaluated platelet count, β-thromboglobulin (β-TG) and platelet factor 4 (PF4), as markers of platelet activation, the platelet function activity (PFA), as indicator of ASA platelet sensitivity.

**Methods:**
We studied 60 patients (20 men, 40 women; mean age 51 years, range 32-70) with ET according to WHO criteria. The mean duration of disease was 11 years. All patients were on ASA 100 mg once daily. Of the 60 patients, 45 were on aspiraglide hydrochloride (daily dose 1.5 mg) (10 men, 35 women), 15 were on hydroxyurea (daily dose 2 mg) (10 men 5 women). None had inherited or acquired thrombotic risk factors. Sixty subjects served as controls.

Platelets were measured by automated analyzer. β-TG and PF4 were determined by ELISA. ASA platelet sensitivity was measured by Platelet Function Analyzer (PFA-100).

**Results:**
The mean platelet count was 455±200×10⁹/L. All patients had normal β-TG and PF4 (12±5 IU/mL and 4±1 IU/mL) and prolonged C/EPI closure time (T, unit: s, n.v. 84-160 s) (240±40 s). 

**Summary/Conclusions:**
These findings suggest that in ET patients the daily low-dose ASA represents an optimal dosing strategy and that PFA test may be a useful tool to distinguish between the ASA “normal-responder” and “low-responder” ET patient.

PB2041
CLINICAL AND EXPERIMENTAL CHARACTERISTICS OF MYELOID/LYMPHOID NEOPLASMS DISPLAYING PDGFR-A OR PDGFR-B REARRANGEMENT

| L. Kou1, J. Pan1, H. Ou1,2, S. Chen1, D. Wu1,2 |
| The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, 1Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China |

**Background:**
According to the 2016 revision to the WHO classification of myeloid neoplasms and acute leukemia, the cases with rearrangement of tyrosine kinase (TK) genes PDGFR-A or PDGFR-B are classified in Myeloid/lymphoid neoplasms with eosinophilia and rearrangement of PDGFR-A, PDGFR-B, or FGFR1, or with PCM1-JAK2. It is a rare event that patients presented rearrangements of these genes. And in the past decade, the dose of TKI to cases with PDGFR-A and B abnormal was inconclusive.

**Aims:**
The goal of the study was to assess the clinical and experimental characteristics and observe the response of Imatinib(IM) therapy of Myeloid/lymphoid neoplasms with PDGFR-A or B abnormal.

**Methods:**
Cytogenetic examination of bone marrow cells obtained from patients was performed by 24th culture method. R banding technical was used for karyotype analysis. PGDFRA and B gene rearrangement were detected by FISH using triple-color of 4q12 and dual color break-apart PDGFRB probes.

**Results:**
The diagnoses included 27 cases of MPN, 1 case of AML-M2 and 1 case of non-hodgkin lymphoma. 21 cases were PGDF-RB rearrangement, the other 8 were PDGFRB abnormal. 7 of 8 were EP fuse gene, one of which concurrent with DEX-CAN fused gene, and the eighth had MYO18A-PDGFRB. 7 cases of the 8 PDGFRB rearrangement had a primary abnormality with t(5;12)(q33;p13) and the other one had a secondary abnormality of AML-M2. PGDFRA and B genes rearrangement detected by FISH and multiple-RT-PCR were positive. The immunophenotypical analysis showed myeloid or lymphoid.

**Summary/Conclusions:**
In summary, patients with significantly anemia and eosinophilia should be screened for the presence of PDGFR-A and B rearrangements. The dual-color FISH is a simple approach and should be added into the diagnostic work-up because these patients respond to imatinib therapy, and sustained responses have been observed. The OS of PDGFR-A and B abnormal was similar with a previous report in a western population and another Chinese hematology center.

PB2042
PLATELET AGGREGATION STUDY OF ESSENTIAL THROMBOCYTHEMIA TREATED WITH ANAGRELIDE

| Y. Hiramatsu1, K. Furukawa2, K. Mizuhashi3, T. Sakayori3, Y. Fujinara3, N. Mochizuki1, S. Kubonishi1, Y. Komiya3 |
| 1Department of Hematology and Oncology, 2Department of Pathology and Clinical Laboratory, Japanese Red Cross Society Himeji Hospital, Himeji, 3Hemostasis Product Engineering, Sysmex Corporation, Kobe, Japan |

**Background:**
Essential thrombocythemia (ET) is a myeloproliferative neoplasm characterized by thrombocytosis and abnormal megakaryocyte proliferation. Patients with elevated platelet count are considered to be a high-risk group for thromboembolic and/or hemorrhagic complications. In Japan, anagrelide treatment was recently approved for the 1st line as a cell reduction therapy on ET. Even now, there are few study whether the risk of thrombosis has decreased after anagrelide treatment. Moreover, the platelet count problem remains what is the best practice to follow when the platelet count in platelet-rich plasma (PRP) exceeds about 600 x10⁹/L, in the recent recommendation of the standard of light transmission aggregometry by the platelet physiology subcommittee of Scientific and Standardization Committee /International Society of Thrombosis and Hemostasis.

**Aims:**
The aim of this study was to characterize the platelet aggregation (PA) in patients with ET. We would also clarify whether there were any changes of hemostatic side effect and platelet aggregability before and after treatment with anagrelide.

**Methods:**
This study has been conducted with blood sample obtained from six healthy subjects, compared to 18 consecutive patients with ET. None of the patients was taking anticoagulants or cytoreductive agents. We also studied six anagrelide-treated patients with ET. Whole blood aggregometry (WBA) and LTA using PRP were performed; ADP-induced PR or collagen-induced PR used natural count PRP and platelet count adjusted PRP with platelet-poor plasma. Data were compared in the groups using the Tukey-Kramer test. This study was approved by the Ethical committee of our hospital. All study procedures were performed in accordance with the Declaration of Helsinki.

**Results:**
The result of WBA was not obtained, because the filter was obstructed by giant platelets. In the natural PRP, even over 900x10⁹/L, the platelet aggregability was markedly increased compared with the control (ADP-induced PA: p=0.023, collagen-induced PA: p=0.001), but, was not significantly different (ADP-induced PA: p=0.703, collagen-induced PA: p=0.986) in the count adjusted PR. These results were not confirmed in cases with platelet counts of less than 600x10⁹/L. There was no decrease in platelet aggregation before and after treatment with anagrelide (ADP-induced PA: p=0.3403, collagen-induced PA: p=0.514).

**Summary/Conclusions:**
In the ET patients with platelet counts more than 900x10⁹/L, the platelet aggregation by LTA with natural count PR was markedly accelerated and this data seemed to reflect the disease state. Although treatment with anagrelide showed cyto-reductive effect without any hemorrhagic complication in patients with ET, it did not fully reduce platelet aggregability.
one or more organs. KitD816V mutation and other Kit mutations play as driver mutations in the pathogenesis of disease. KitD816V mutation is positive in %80 of systemic mastocytosis patients. Recent studies show that high allele burden of KitD816V and high serum tryptase levels correlate with aggressive disease. Recently the importance of CD30 expression on neoplastic mast cells has been confirmed. CD30 is expressed abnormally on neoplastic mast cells in patients with primary systemic mastocytosis. Aims: In this study we aimed to present demographic data, clinical follow-up and treatment of patients with mastocytosis and identify the impact of KitD816V allele burden and expression of CD30 by mast cells in systemic mastocytosis.

Methods: We performed a retrospective study on 54 adult patients with mastocytosis (24 female, 30 male; mean age: 44±13) who fulfilled WHO criteria between 2006 and 2016. These patients comprise cutaneous mastocytosis (CM) (%10), indolent systemic mastocytosis (ISM) (%30), smoldering systemic mastocytosis (SSM) (%2), aggressive systemic mastocytosis (ASM) (%4), systemic mastocytosis associated with hematologic neoplasm (SM-AHN) (%3), mast cell leukemia (MCL) (%4) and mast cell activation syndrome (MCAS) (%1).

Results: At diagnosis, age of patients with advanced disease was higher than ISM and SSM group (p=0.001). Most frequent symptom of disease was skin lesion (urticaria pigmentosa) (%64). Skin lesions were significantly higher in patients with ISM and SSM than with advanced disease (p<0.009). But B symptoms were significantly higher in advanced disease variant (p=0.013). Anemia, trombocytopenia, elevation of ALP and GPT, hypoalbuminemia were significantly higher in advanced disease than in ISM and in SSM. Osteoporosis was higher in patients with ISM and SSM than with advanced disease, %56 and %18 respectively. KitD816V mutation was detectable in peripheral blood in 33 of 40 cases in patients who were positive for KitD816V with a median Ct value 36±4. Median Ct value was significantly lower in advanced SM (Ct: 32±5 ) than in SM and SSM (Ct: 36±4 ) (p=0.028) showing a significantly higher allele burden. Expression of CD30 on mast cells in bone marrow biopsies with immunohistochemistry in 20 of 32 systemic mastocytosis patients (%62). There was no significant difference expression of CD30 on mast cell between patients with ISM (%65) (13±20) and advanced SM (%78) (78) (p=0.371). There was no significant correlation between elevated serum tryptase level and CD30 expression (p=0.114).

Summary/Conclusions: The definition of disease subcategories in systemic mastocytosis is important for choosing the treatment modality (cytoreduction or allogeneic stem cell transplantation vs treatment of the mediator symptoms) for the individual patient. CD30 is a diagnostic marker and also a possible therapeutic target.

PB2045

COMPARISONS OF PATIENT MANAGEMENT IN MYELOPROLIFERATIVE NEOPLASM PATIENTS IN THE UK VS REST OF WORLD: ANALYSIS FROM THE INTERNATIONAL LANDMARK SURVEY

1Guy’s and St Thomas' NHS Foundation Trust, Guy's Hospital, London, 2Head of Campaigns and Advocacy, Leukaemia CARE, Worcester, 3Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, 4QMC Treatment Centre, Castle Hill Hospital, Cottingham, 5MPN Voice, London, 6Adelphi Real World, Bollington, 7Haematology Franchise, Novartis Pharmaceuticals, Camberley, United Kingdom

Background: Patient (Pts) with myeloproliferative neoplasms (MPNs), including myelofibrosis (MF), polycythaemia vera (PV), and essential thrombocythaemia (ET), experience a substantial disease burden. The international MPN LANDMARK survey evaluated the patient-reported impact of MPNs in pts across 6 countries and identified current treatment strategies in these pts.

Aims: To analyze differences in treatment strategies used by physicians and pts to manage their MPN between the UK and the Rest of Surveyed World (ROSW).

Methods: A cross-sectional survey was conducted in Australia, Canada, Germany, Italy, Japan, and the UK. The Internet-based survey was administered secondarily to MPN patients and treating physicians (the two samples were not linked). Observed differences between the UK and ROSW are described in terms of treatment patterns and patient physician communication.

Results: A total of 699 pts (UK, n=286; ROSW, n=413) and 219 physicians (UK, n=31; ROSW, n=188) completed the survey. UK physicians were more likely to report treatment rather than delay at diagnosis of PV or ET. A greater proportion of ROSW physicians reported they would observe >25% of patients at diagnosis (UK - 54% MF, 30% PV, 37% ET; ROSW - 51% MF, 48% PV, 50% ET). No difference was observed in the most commonly received treatments for each disease, but a greater proportion of UK patients reported receiving treatments than ROSW. This difference was greater in PV and ET than MF. For MF the most commonly received treatments were ruxolitinib (UK 55%, ROSW 50%), aspirin (UK 53%, ROSW 37%), hydroxyurea (HU) (UK 31%, ROSW 28%) and transfusion (UK 27%, ROSW 23%), for PV they were aspirin (UK 83%, ROSW 58%), phlebotomy (UK 76%, ROSW 67%) and HU (UK 63%, ROSW 36%) and for ET they were aspirin (UK 94%, ROSW 52%), HU (UK 62%, 30% ROSW) and anagrelide (UK 14%, ROSW 18%). Physician reported data on treatments prescribed demonstrated a similar pattern as a greater proportion of UK physicians reported using treatments than ROSW. UK physicians reported their patients were more likely to ‘often’ disagree with their primary treatment recommendation than ROSW (16% vs 7%) but despite this UK patients were more likely to be ‘completely’ satisfied with their physicians understanding and support of their treatment goals (UK, 51%; ROSW 35%). Patients rated who they thought should be the main decision maker on a scale of 1 (patients) to 7 (physician). UK patients were slightly more inclined than ROSW to be involved in treatment decisions (mean: UK, 6.25; ROSW, 7.01). UK physicians supported this as more ‘agreed strongly’ with the statement ‘I involve my MPN patients in treatment decisions’ (UK, 39%; ROSW 28%).

Summary/Conclusions: In comparison with ROSW, UK physicians were more likely to prescribe drug treatments for ET/PV. Interestingly, UK patients desired to be more involved in treatment decisions, and this was reflected in the physician’s perspective to involve their patient in treatment decisions more. UK patients were also more likely to disagree with their physician on primary treat-
ment recommendations. However, this had no impact on satisfaction suggesting that UK patients welcomed an open discussion on treatment options with their physician. These data highlight the importance of maximizing patient physician communication in order to improve patient satisfaction with treatment in the UK.

PB2046
ANALYSIS OF EMERGING MOLECULAR SIGNATURES AND ASSOCIATED CLINICAL FEATURES IN MPN
S. H Al Shemmari1,*, R. Rajan2
1Department of Medicine, Kuwait University, 2Bone Marrow and Stem Cell Transplant Lab, Kuwait Cancer Center, Kuwait, Kuwait

Background: Myeloproliferative neoplasms (MPNs) are a group of clonal hematological disorders that arise from transformation of a multipotent hematopoietic stem cell which includes polycythemia vera (PV), essential thrombocythemia (ET) and primary myelofibrosis (PMF). Driver mutation’s confers growth advantage on the cancer cell and most likely is selected in the tissue microenvironment within which the neoplastic cells arise. Three-quarters of these patients carry the unique JAK2V617F mutation, JAK2 exon 12 mutations are found in 5% of patients with PV, MEL, MDS and 10% of patients with ET. CALR mutations are found in 50-70% patients with ET and PMF.

Aims: In this study we investigated the prevalence of these so called carrier mutations in patients with MPN’s from January 2007 – January 2017 reported in our center.

Methods: We analyzed 3000 samples with suspected MPN for JAK2V617F mutation by ARMS-PCR and their alelle burdens were reported by QPCR. We have screened a cohort of 500 patients for JAK2/MPL/CALR mutations by a sequential molecular analysis which includes PCR, RT-PCR and fragment analysis.

Results: JAK2V617F mutation is present in 50% of patients with MPN. Among 600 cases submitted for sequential molecular analysis identified 372 cases with JAK2V617F mutation, 70 cases with CALR mutation, and 6 cases with MPL mutations. Allele burden study on JAK2V617F positive patients revealed that patients with ET has the lowest allele burden, those with PV an intermediate one and those with PMF showed the highest burden. Measurement of JAK2V617F allele burden by QPCR for a PMF case after allogenetic transplantaion reported that allele burden of 2.9% after 20 days of transplantation and a negative result after 60 days of transplant vs 13% before ASCT. CALR mutation is found in ET and PMF cases that are mutually exclusive with JAK2V617F and MEL exon 10 mutations in ET whereas 2 cases with PMF found to be positive for JAK2V617F and CALR mutations. We found 40 cases with a 52 bp deletion and 26 cases with a 53bp insertion. CALR variants reported in our cohort were 54% type 1 and 46% type 2 mutations. We found a tendency towards older age among type 2 carriers compared to type 1 carriers (median age at diagnosis: 57 years versus 52 years) or compared to non-type 2 carriers (median age at diagnosis: 57 years versus 54 years). Similarly, platelet count at diagnosis tended to be higher in the subgroup of type 2 mutation carriers than in patients with the type 1 mutation while hemoglobin levels and white blood cell count were lower compared to those with non-type 2 mutation. The mutual allele burden of JAK2V617F/CALR exon 10 indel mutations of two PMF patients found as 10%65% and 15%55% respectively. In our cohort, 10% of the patients with CALR mutation had anemia, 21% had splenomegaly, and 43% had megakaryocyte at time of diagnosis. Compared with JAK2 V617F-positive ET and PMF, CALR-mutant ET and PMF are clinically correlated with lower WBC, leukocyte and hemoglobin counts, higher platelet counts, and a reduced risk of thrombosis.

Summary/Conclusions: This study reconfirms and extends previous findings on the frequency of CALR mutations in our study had no effect on the number of PLT in ET, but have a value for this index in PMF. Type I mutations in ET accompanied higher WBC level and a lower level of Hb. The published studies have not shown the influence of the type of mutation in the Hb level and the number of WBC in ET. An important observation was the detection of the type of mutation on development fibrotic changes of the bone marrow (BM) in patients with type I CALR mutations (p <0.005). CALR mutation type had no influence on the distribution of patients with PMF, depending on the risk groups on the scale of IPSS and DIPSS.

THE UNIQUE CASE OF GERMLINE CEBPA MUTATION IN PATIENT WITH FIP1L1/PDGFRA ASSOCIATED MYELOID/LYMPHOID NEOPLASM WITH EOSINOPHILIA
N. Gabeeva1,*, E. Zvonkov1, E. Parovichnikova2, D. Koroleva1, O. Gavrilina1, S. Kusnetsova1, L. Grebenuk4, T. Obukhova4, A. Kovrigina5, L. Kuzmina6, V. Savenko3
1Scientific and clinical department of chemotherapy for lymphomas, 2Scientific and Clinical Department of Hemoblastosis Chemotherapy, Hemotopoietic Depression and Bone Marrow Transplantation, 3National Research Center for Hematology, Moscow, Russian Federation, 4cytogenetics department, 5Department of Hematooncology and Clinical Department of Hemoblastosis Chemotherapy, 6National Research Center for Hematology, Moscow, Russian Federation

Background: Myeloid/lymphoid neoplasms with eosinophilia (M/LE) associated with PDGFRA rearrangement are rare disorders. The most frequent Ph/PDGFRA abnormalities is FIP1L1/PDGFRA (F/P) fusion gene results from a cryptic interstitial deletion at 4q21 with constitutive activation of tyrosine kinase (TK) activity. Although known since 2003, many questions remain in understanding the biology, disease course and response to therapy. The F/P fusion gene may clinically present as chronic eosinophilic leukemia (CEL), T-cell lymphoblastic lymphoma or both concurrently. Acute myeloid leukaemia (AML) may also occur at presentation or during the course of the disease. While F/P is the driver mutation, to date there are few data about genetic variants of the disease that may contribute to clinical outcome. CCAAT/enhancer binding protein alpha (CEBPA) gene functions as key regulator of granulocytic differentiation. CEBPA mutations are characterized by cell cycle deregulation, proliferation and blocking differentiation of myeloid lineage in AML. Germline CEBPA mutations is a very rare and account about 1% in AML only.

Aims: We present the first case of detection of familial germlinal CEBPA muta-
tion in a patient with F/P MLNe who received related allogeneic transplantation from brother.

Methods: A 26-year-old male patient was presented with a 4-week history of fever, fatigue, difficulty in swallowing. Physical examination revealed generalized lymphadenopathy, splenomegaly, tonsillar enlargement, leukocytosis (20x10^9/L), with marked eosinophilia (4,0x10^9/L). A bone marrow aspirate showed 2% blasts, 21% eosinophils. Hematologically examination of an cubital lymph node biopsy showed diffuse proliferation of medium-sized lymphoblasts. Immunohistochemistry and flow cytometry showed that the lymphoblastic population expressed CD2, CD5, CD7, CD4, CD9, Td7 and CD1a. Polymerase chain reaction (PCR) analysis from samples of the lymph node and bone marrow failed to detect transcribed T-cell receptor rearrangement. A diagnosis of T-cell lymphoblastic lymphoma (T-LBL) associated with reactive eosinophilia was rendered. The patient began standard multigent chemotherapy in accordance with ALL-2009 protocol (ClinicalTrials.gov Identifier: NCT01199333) and achieved complete clinical remission. As he was planned to conduct autologous hematopoietic stem cell transplantation (HSCT), bone marrow aspirates and mononuclear cell cultures have been successfully harvested after stimulation of hematopoiesis. However, within 10 days after the discontinuation of G-CSF he developed leukocytosis (130x10^9/L) with 21% of eosinophils (absolute number 27,3x10^9/L) and cubital lymphadenopathy. Histological examination of lymph node showed T-LBL relapse. Bone marrow biopsy revealed the expansion of predominantly eosinophilic cells. The study was carried out to exclude second myeloproliferative disease. Molecular and cytogenetic examinations of bone marrow failed to reveal BCR-ABL, FLT3 and NPM1, but showed CEBPA (TAD2) mutation. FISH probe revealed deletion 4q12 (F/P rearrangement), confirmed by RT-PCR. Gene expression in mononuclear cell cultures showed a difference with 2008 WHO classification, he was diagnosed as «PDGFRα-associated MLNe». The patient was subsequently treated with imatinib mesylate at the dose 100mg daily and showed a good clinical response. After 4 months minimal residual disease still persisted in bone marrow (RT-PCR positive for F/P and PCR for CEBPA mutation) and he received an allogeneic HSCT from his brother. Routine testing of chimerism at 2 months after HSCT revealed the recipient DNA less than 5% and positive probe for F/P and CEBPA. We hypothesized the germlinal origin of CEBPA mutation.

Results: The same N-terminal (TAD2) CEBPA mutation was found in the patient's skin node and bone marrow, and in the patient's brother bone marrow samples. Unfortunately, no materials from parents were available for analysis at that time.

Summary/Conclusions: Germline CEBPA mutations is very rare event and have been identified as causative gene mutations in familial AML. For the first time to our knowledge this mutation was detected in patient with PDGFRα-associated MLNe. This observation is of particular interest because it will provide novel insight about the genetic basis and the additional events responsible for the course of the disease.

PB2051

COMPARISONS OF SYMPTOM BURDEN IN MYELOPROLIFERATIVE NEOPASMS IN THE UK VS REST OF WORLD: ANALYSIS FROM THE INTERNATIONAL LANDMARK SURVEY

1Guy’s and St Thomas’ NHS Foundation Trust, Guy’s Hospital, London, 2Head of Campaigns and Advocacy, Leukaemia CARE, Worcester, 3Queens Centre, Castle Hill Hospital, Cottingham, 4Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, 5MPN Voice, London, 6Adelphi Real World, Bollington, 7Haematology Franchise, Novartis Pharmaceuticals, Cambridge, Unitedby, 8Merck

Background: Patients with myeloproliferative neoplasms (MPNs), including myelofibrosis (MF), polycythemia vera (PV), and essential thrombocythemia (ET), experience a substantial disease burden. The international MPN LANDMARK survey evaluated patient-reported impact of MPNs across 6 countries. Aims: To analyze differences in disease and symptom burden of MPN patients between the UK and the Rest of Surveyed World (ROSW). Methods: A cross-sectional survey was conducted in Australia, Canada, Germany, Italy, Japan, and the UK. The internet-based survey was administered separately to MPN patients and treating physicians (the two samples were not linked). Observed differences between the UK and ROSW are described in terms of symptom burden.

Results: A total of 699 pts (UK, n=286; ROSW, n=413) and 219 physicians (UK, n=102; ROSW, n=117) completed the survey. UK patients reported more symptoms than those in ROSW (9.02 vs 9.95 respectively). A higher proportion of UK patients reported experiencing symptoms compared with ROSW (e.g. fatigue and tiredness UK - 87% MF and PV, 86% ET; ROSW – 64% MF, 39% PV, 45% ET). This pattern was observed for 28 of the 31 symptoms reported. A similar difference was seen when physicians were asked about frequency of patient-reported symptoms (e.g. fatigue and tiredness UK – 90% MF, 67% PV, 70%; ROSW – 71% MF, 55% PV, 48% ET). Patients rated symptom severity from 1 (not severe at all) to 10 (worst possible). The UK was higher than ROSW for the three most common symptoms: fatigue and tiredness (mean: UK 8.73, SD 1.56; ROSW 7.23, SD 1.61); pain (mean: UK 8.4, SD 1.6; ROSW 7.5, SD 1.5); and itching (mean: UK 8.2, SD 1.7; ROSW 6.7, SD 1.5). A difference was not observed when physicians were asked to rate symptom severity. An overall symptom burden was calculated as a function of all patient-reported symptoms. UK patients were disproportionately represented in the high symptom burden group (38% in ROSW, 16% in the UK) and had an average overall symptom burden score of 40.1 compared with 24.1 among ROSW patients. UK patients were also more likely to have been classified with a high risk score at diagnosis (UK 22% vs ROSW 9%). Despite the consistently greater symptom burden experienced by UK patients, little difference was observed in patient satisfaction with their health care (UK 83%, ROSW 84%) and disease management (UK 87%, ROSW 90%). However, UK patients were more likely to disagree with the statement ‘My doctor understands how much my condition impacts my life’ (UK 39% vs 22% ROSW). UK physicians had more MPN patients under their care than ROSW (mean patients under care in last 12 months: UK 50, ROSW 25; mean patients under care in last 3 months: UK 25, ROSW 15; mean patients under care in last 1 month: UK 15, ROSW 10). There was no significant difference between UK and ROSW.
Summary/Conclusions: UK patients perceive a higher symptom burden than ROSW in terms of frequency and severity. While UK physicians agree with regards to frequency, they didn’t perceive a greater symptom severity in their patients compared to ROSW physicians. Patient/physician disconnect was unlikely to be the cause as satisfaction was high and similar to that in ROSW. However, UK physicians not only have more patients under their care than their ROSW counterparts, they are also more likely to feel they don’t have enough time to discuss all symptoms. This is likely to be impacting on the ability of patients and physicians to communicate fully on symptoms and to agree on the best disease management plan.

PB2053

CONCLUSIONS: MPN10 score is directly affected by JAK2 and CALR positivity and can be used as a major predictor of survival in MPN patients. Triple negative ET patients in our cohort have significantly lower MPN10 score, show lower incidence of BM fibrosis and splenomegaly which may indicate a more indolent disease course.

JAK2/CALR/MPL mutants (p<0.001). After a median follow-up period of 36 months (6.6-102), progression free survival (PFS) and overall survival (OS) of the best disease management plan.

PB2052

MPN10 SCORE AND SURVIVAL OF MOLECULARLY ANNOTATED MYELOPROLIFERATIVE NEOPLASMS PATIENTS; A FIRST REPORT ON AN EGYPTIAN COHORT

Y. Elnahass1,*, H. Mahmoud1, M. Mattar2, O. Fahmy2, M. Abdelmoaty1, R. Abdelfattah1, F. Elrefaey1, W. Elmetenawy2

1Haematology, National Cancer Institute-Cairo University, 2Haematology, Faculty of Medicine- Cairo University, Cairo, Egypt

Background: The vast majority of myeloproliferative neoplasms (MPNs) patients are characterized by a molecular genetic background and by variable disease burden and correlating mutational status with symptom severity calculated by MPN10 score, degree of bone marrow (BM) fibrosis, clinical characteristics and survival in MPN patients.

Methods: MPN Symptom Assessment Form Total Symptom Score (MPN-SAF TSS) was assessed as mean/median of 10 items: fatigue, concentration, early satiety, inactivity, night sweats, itching, bone pains, abdominal discomfort, weight loss and fever. JAK2V617F and exon12 mutations were performed by allele-specific oligonucleotide polymerase chain reaction (ASO-PCR) while CALR and myeloproliferative leukemia virus oncogene (MPL) on disease burden and correlating mutational status with symptom severity calculated by MPN10 score, degree of bone marrow (BM) fibrosis, clinical characteristics and survival in MPN patients.

Results: 93 MPNs patients (48 males and 45 females): 18 polycythemia vera (PV), 41 essential thrombocythemia (ET), 24 primary myelofibrosis (PMF), 10 Post-ET/PV-myoelofibrosis (post-ET/PV-MF) were included. Median age at diagnosis was 55 years (17-75) and was lower in ET than PV and PMF patients; 44 (19-75) vs 56 (34-70) years and 56 (20-75) years, respectively (p<0.01). JAK2 mutation was positive 53/93 (57%); 16 (90%) PV patients, 44 (19-75) years vs 62% (52) PMF patients, 8(80%) post-ET/PV-MF patients (p<0.01). CALR mutation was positive in 14/13 (11%); 10 (24%) ET patients, 4 (17%) PMF patients, zero (0%) post-ET/PV-MF patients. 23/93 (25%) patients were triple negative; 15 ET, 2 PV, 4 PMF and 2 post ET-MF. Median MPN10 score was 21 (4-45) in ET versus 37.5 (25-56) in PV, 54 (15-80) in PMF and 59 (45-75) in post-ET/PV-MF (p<0.01). From 31 patients with BM fibrosis, 6 (15%) were triple negative vs 33 (85%) mutant patients (p=0.007). Among 52 patients with splenomegaly, 7 (13.5%) patients were triple negative vs 45 (87%) patients with a positive mutational status (p<0.001). Median MPN10 score was 48 (5-76) in JAK2 positive patients vs 25 (4-80) in JAK2 negative (p<0.001) and was 22.5 (4-65) in CALR mutants vs 35 (5-80) in CALR negatiive (p<0.05). Median MPN10 score was 21 (10-48) in triple negative patients vs 40 (4-80) in MPNs JAK2/CALR/MPL mutants (p=0.001).After a median follow-up period of 36 months (6.6-102), progression free survival (PFS) and overall survival (OS) of the whole cohort was 85% and 95%, respectively. PFS of JAK2 positive vs negative patients was 62% vs 0% (p=0.001). PFS of CALR positive vs negative patients was 100% vs 78% (p=0.067). PFS of triple negative vs mutant patients was 100% vs 75% (p=0.004). OS of JAK2 positive vs negative patients was 85% vs 100% (p=0.011). OS of CALR positive vs negative patients was 100% vs 92% (p=0.197). OS of triple negative vs mutant patients was 100% vs 90% (p=0.015). (Figure 1).

Summary/Conclusions: UK patients perceive a higher symptom burden than ROSW in terms of frequency and severity. While UK physicians agree with regards to frequency, they didn’t perceive a greater symptom severity in their patients compared to ROSW physicians. Patient/physician disconnect was unlikely to be the cause as satisfaction was high and similar to that in ROSW. However, UK physicians not only have more patients under their care than their ROSW counterparts, they are also more likely to feel they don’t have enough time to discuss all symptoms. This is likely to be impacting on the ability of patients and physicians to communicate fully on symptoms and to agree on the best disease management plan.

Background: Inferferon-alpha (IFNa) based therapies have been successfully used in myeloproliferative neoplasms for over thirty years. A known burden for long-term therapy applying IFNa in otherwise fit outpatients is the necessity of frequent hospital visits for product administration. Roquefergonfer alfa-2b (AOP2014) is a novel long-acting monopentafy (IFNa allowing initially bi-weekly and, in long-term maintenance, monthly administration. To further improve on convenience and compliance, a pre-filled, dose-adjustable pen was developed for patient self-administration at home.

Methods: The study was performed in 18 sites in 8 European countries. Patients were eligible who completed the AOP2014-arm in the PRouD-PV study (12 months of treatment). A total of 7 visits was scheduled within 3 months (1 week, 3 weeks, 6 weeks, 3 months, 6 months and 12 months). This was followed by a final assessment visit at study site.

Results: A total of 36 patients were enrolled and received the AOP2014 pen for self-administration. The mean age was 58.5 years (range 37 to 77 years), 23/36 (63.9%) were male patients and a large proportion of patients (15/36 (41.2%)) achieved a complete response by the end of the study. Progression free survival (PFS) and overall survival (OS) of the best disease management plan.

Figure 1.
Summary/Conclusions: The AOP2014 pen was well accepted and no major difficulties were reported. The study drug performed as expected and there were no safety concerns arising from the administration of AOP2014 using the pen device. The AOP2014 pen allows for individual dosing and a patient-convenient mode of self-administration of ropeginterferon alfa-2b at home and is expected to support adherence and compliance in the long-term treatment of PV patients.

PB2054

JAK2, CALR AND MPL MUTATIONS: CORRELATION WITH PHENOTYPE DISEASE AND HISTOPATHOLOGICAL FEATURES OF BONE BIOPSY

H. J. Campo Palacio1, J.M. Ramirez Sanchez1, A.M. Rodriguez Fernandez2, L. Hermosin Ramos3, B. Bellosillo Paricio3, E. Camilo Cruz1

1Haematology, 2Pathology, Jerez de la Frontera Hospital, Jerez de la Frontera, 3Pathology, Hospital del Mar, Barcelona, 4Haematology, Hospital Virgen del Rocio, Seville, Spain

Background: Drivers mutations JAK2, CALR and MPL are mutually exclusive in Essentials thrombocythemia (ET) and these are included in the diagnostic criteria of myeloproliferative neoplasms (MPNs). Consistent with known literature, the molecular characterisation have implications in the phenotipo disease and it might be interesting to study if these are associated with the histopathological characteristics of bone marrow biopsy

Aims: The purpose of this work is analyse the correlations between clinical-biological and histological characteristics of bone marrow biopsy and the mutational status (JAK2, CALR, MPL).

Methods: The study included 76 patients with ET diagnosed according to WHO criteria at the Haematology Department from Hospital de Jerez from January 2005 to December 2015. We examined the prevalence, and clinical and laboratory correlations of JAK2/CALR/MPL mutations. To evaluated the histology, one pathologist with expertise in haematopathology review the bone marrow biopsies corresponding to 44 patients with ET. We included only bone marrow biopsies of at least 10 mm in length and/or minimum 8 inter-trabecular areas. The pathologist only had access to age and gender data. Mutations JAK, CALR and MPL were analysed by PCR real time and sanger sequencing.

Results: There where 55 (72%) patients JAK2, 12 (15.5%) patients CALR, one patient MPL and 9 (11.8%) patients triple-negative (TN). The main clinical and laboratory features of the patients are show in Table 1A. As can be seen, a 75% of patients belonged a high risk group, 18 (23%) patients presented thrombotic events before diagnosis and only 4 (5.3%) during the evolution. Clinical and molecular characteristics of patients as age, sex, hemoglobin level and stratification of risk were statistically significant. (Table 1A). Thromboembolic events seemed to be more frequent in patients with JAK2 mutation, although statistical significance was not achieved. The correlation between histopathological characteristics and mutational status are shown in Table 1B. We observed differences between the presence of laxes groups of megagranulocytes according with the mutational status and there were more frequently in patients with CALR mutation (p = 0.01). With a median of follow up of 4 years (ranger 0.3-11 años) a total of 6 patients had died. Two patients evolved to overt, one of them to acute leukaemia and the other one to myelofibrosis at 66 and 44 months from ET diagnosis respectively.

Summary/Conclusions: In our study we can confirm that there are differences between clinical and laboratory finding according with mutational status, as shown in previous studies. The most consistent finding of this study was the presence of laxes groups of megagranulocytes significantly higher in those with CALR mutations. The major limitations of this study include a small number of patients and biopsies available to analysed, this might be the mayor causes for the lack of the data demonstrating clinical and histological relevance. But our results should not be underestimated because, to our knowledge, this is the second study thus has investigated this relation.

CLINICAL IMPLICATION OF QUANTITATIVE JAK2 V617F ANALYSIS WITH DROPLET DIGITAL PCR IN MYELOPROLIFERATIVE NEOPLASMS

E. Lee1, K. J. Lee2, H. Park2, J. Y. Chung2, M. N. Lee3, M. H. Chang4, J. Yoo5, H. Lee1, S. -Y. Kong6, H. -S. Eom1

1Hematology, 2National Cancer Center, Goyang, 3Green Cross Laboratories, Yongin, 4Oncology-Hematology, 5Laboratory Medicine, National Health Insurance Service Ilsan Hospital, 6Laboratory Medicine, National Cancer Center, Goyang, Korea, Republic Of

Background: JAK2 V617F is the most common genetic mutation in myeloproliferative neoplasms (MPN) and included in the major diagnostic criteria. Beyond the description of existence, quantification of mutational load is proposed as a useful information to classify subgroups of MPN and to predict prognosis. Droplet digital PCR (ddPCR) is a novel assay which has an advantage in accurate and reproducible quantitative analysis.

Aims: This study was planned to verify the correlation of ddPCR with pyrosequencing in diagnosis of MPN and to investigate clinical implication of the mutation burden in disease course.

Methods: Between 2012 and 2016, peripheral blood or bone marrow samples were obtained from 56 patients at diagnosis and every 3 months after enrollment. Inclusion criteria were 1) older than 20 years, 2) who were newly diagnosed with MPN and 3) diagnosed with MPN before, not met the indication of JAK2 inhibitor treatment yet. JAK2 V617F mutation was detected by pyrosequencing as diagnostic work-up. The ddPCR was performed using the same samples with pyrosequencing to prove correlations between assays and to establish a detection sensitivity cutoff. Clinical aspects and hematologic profiles of enrolled patients were reviewed.

Results: The lowest value of measured JAK2 V617F allele by ddPCR except negative samples in our study was 0.01%, which was approximately 0.07 copies/μL of mutant allele. Some discrepancies were observed from 0.0001% to 0.01% concentration between the expected and measured values in ddPCR detection sensitivity assay. 0.1% was determined as the cutoff. Forty-two patients (75%) were positive for JAK2 V617F by pyrosequencing and 46 (82.1%) were positive by ddPCR. The mean mutated allele at diagnosis was 37.5%±30.08%. With ddPCR, the mean was 40.7%±31.2%. Pyrosequencing and ddPCR were highly correlated (r=0.9712, P<0.001). JAK2 V617F burden measured with ddPCR was significantly different by subgroups (P=0.001). In comparison of one disorder with another, polycythemia vera (PV) had more amount of mutant allele than essential thrombocytosis (ET) (P=0.001), however, differences between PV-myelofibrosis (MF) and ET-MF were not statistically significant. Follow-up samples were available in 12 patients and 8 were JAK2 V617F positive. Among them, reduction of mutant burden after treatment was observed in 6 patients (75%). JAK2 V617F burden showed initial reduction in a MF patient treated with JAK2 inhibitor, however, after dose reduction for toxicities, the JAK2 V617F mutation increment with hematologic aggravation was discovered. Mutation burden decrease showed a tendency consistent with hematologic improvement. Hematologic characteristics and JAK2 V617F load at the initial diagnosis and follow-up after treatment (Table 1, Figure 1).

Figure 1.
Background: JAK2 (V617F) gene mutation is found in approximately 60% of patients with Essential Thrombocythemia (ET), while 5-10% of JAK2 (V617F) negative patients carry MPL gene mutations involving codon 515. Recently, mutations at the exon 9 of calreticulin (CALR) gene have been identified in approximately 50% of patients with ET, unmutated for Jak2 and MPL.

Methods: A cohort of consecutive patients with a diagnosis of ET followed between January 2013 and June 2016 were considered. JAK2 (V617F) gene mutation was detected by PCR testing; MPL and CALR mutations were analyzed by direct sequencing methods. Thrombotic risk score was calculated according to the European Leukemia Net recommendations. Data were statistically analyzed.

Results: Overall, 148 patients were included: 107 (72.30%) had JAK2 (V617F) gene mutation (JAK2+), 12 (8.10%) carried a mutation at exon 9 of CALR gene (CALR+), 3 (2.30%) carried a mutation at codon 515 of MPL gene, 26 (17.58%) patients were not mutated for JAK2, CALR and MPL genes (triple negative). JAK2+ subjects, compared to JAK2+ patients, had a younger age at diagnosis: median age 48 years (25-92) in CALR+ patients vs 72 years (18-93, respectively). Patients with MPL mutation had a median age of 82 years while triple negative patients carry a median age of 59 years (23-89). The thrombotic risk score was 0 in CALR+ patients and 1 in JAK2+ MPL+ and triple negative patients. The distribution of International Prognostic Score for Essential Thrombocythemia (IPSET) categories was also statistically significantly different (p=0.003) for the three groups. The percentage of high-risk patients was 0% in CALR+, 28% (9/26) in JAK2+ group, and 19, 30% (5/26) in the triple negative group. The IPSET1 model also stratified patients with statistically significant difference (p=0.001) among the three groups: the percentage of high-risk patients was 16, 66 (2/12) in the CALR+ group, 82, 35% (88/107) in the JAK2+ group, and 33, 33(9/29) in triple negative group. CALR+ patients belonged more frequently to the low intermediate risk group than JAK2+ patients (80 vs 17.5%, p=0.05). The incidence of thrombotic events at diagnosis of ET was 0 in the CALR+ group, 28, 30% (30/107) in the JAK2+ group and 23, 07% (6 /26) in the triple negative group. The median overall survival was not reached in any group.

Conclusions: CALR+ patients with ET are phenotypically distinct from JAK2+ and triple negative patients. We can speculate a potential protective role of CALR mutation given the absence of thrombosis in IPSS and IPSET1 high-risk patients.

PB2085 MONITORING OF TRANSIENT MYELOPROLIFERATIVE DISORDER AND LEUKEMIA IN DOWN’S SYNDROME: A SINGLE UNIVERSITY HOSPITAL STUDY

Background: Children with Down syndrome (DS) have a 10- to 20-fold increased risk of developing leukemia. But some patients don’t suffer leukemia or myeloproliferative diseases. In DS, myeloproliferative disorders (MPDs) are derived from the condition called Transient myeloproliferative disorder (TMD), and it is a disease entity unique to DS newborns and is defined as the morphologic detection of blasts in DS less than three months of age.

Aims: This study gathered DS patients to find some difference between leukemia and TMD, to determine the percentage of DS patients with blast in three months of life.

Methods: We collect 317 patient’s blood lab results in 433 DS patients. 102 patients has leukocytosis, and in 18 case found blast cells in their peripheral blood.

Results: 12 patients have found blast in three months of life, 11 of them finally diagnosed as TMD, and only 1 patient progress to Acute Myeloid Leukemia (AML) in 98 days of his life. Other 6 patients have blast in their blood after three months of life, and underwent chemotherapy due to hematologic malignancy. All patients with leukemia has anemia at diagnosis, which is not found in TMD patients (p=0.018). In 7 leukemia patients, 3 was acute Lymphoblastic Leukemia (ALL) and 4 was AML. ALL patients had a median age of 2 years at diagnosis, while AML patients have a median age of 4.5 years at diagnosis.

Conclusions: DS Patient who has blast in their peripheral blood before 3 months of life need closely follow up their Complete Blood Count and Chromosome analysis to find whether TMD progresses to leukemia.

PB2058 INFECTIONOUS EVENTS IN A COHORT OF PATIENTS WITH MYELOFIBROSIS UNDER TREATMENT COMPARING RUXOLITINIB WITH CONVENTIONAL THERAPY, A MONOCENTRIC EXPERIENCE OF 22 PATIENTS RETROSPECTIVELY ANALYSED

Background: Infectious events are more frequent in patients with myelofibrosis (MF) treated with ruxolitinib than in patients treated with conventional therapy (CCT). However, there is a lack of well-defined data on specific infections in this population.

Aims: To assess specific infections (SI) in a single-center cohort of MF treated with ruxolitinib or with CCT.

Methods: A retrospective analysis of patient records was performed in a single center between January 2013 and June 2016. SI incidence and infective characteristics were compared in the ruxolitinib-treated group (20 patients) and CCT group (2 patients) using Fisher’s exact test and the t-test.

Results: A total of 22 infectious events were recorded in 18 patients: 11 SI in the ruxolitinib group (55.5%) and 1 SI in the CCT group (50%). The most common SI were respiratory tract infections (6 SI in the ruxolitinib group vs 1 SI in the CCT group) and urinary tract infections (4 SI in the ruxolitinib group vs 0 SI in the CCT group).

Conclusions: This study suggests that MF patients treated with ruxolitinib have a higher incidence of specific infections compared to those treated with CCT. Further studies are needed to confirm these findings.
Background: Treatment with the Janus-activated kinase (JAK) 1 and 2 inhibitor ruxolitinib decreases constitutional symptoms and spleen size in myelofibrosis. However accumulating evidences suggest that the drug also exerts substantial immunosuppressive activity. The impressive clinical activity of ruxolitinib is predominantly mediated by its profound anti-inflammatory effects modulating dendritic cell (DC) function resulting in impaired CD4+ and CD8+ activity. Several studies have shown that Ruxolitinib affects different cytokines (IL-1, IL-6 and TNFa) and other immune processes and has been linked to increased incidence of opportunistic and no opportunistic infections. Herein we report our experience at our Centre.

Aims: In our retrospective study we analysed myelofibrosis patients treated with Ruxolitinib and cytotherapy treatment with Hydroxyurea and supportive therapy followed in our Department from 2012 to 2016 to evaluate rate of infections developed.

Methods: We reviewed 22 patients presenting myelofibrosis (median age 72, range 60-86) describing clinical and biological features (Table 1). Our aim was description of documented infections identified with conventional treatment and with Ruxolitinib. They were 11 treated with JAK inhibitors and 11 with Hydroxyurea taken orally, similar for age and clinical features.

Results: A total of 22 patients consecutively diagnosed were included in this analysis. There were 15 primary and 7 secondary myelofibrosis patients. According to the Dynamic International Prognostic Scoring System (DIPSS) 8 were low risk, 10 were intermediate risk and 4 were high. A total of 5 documented infections were identified throughout the evaluation period, 4 were grade 1 and one grade 2. They are various including oral herpes simplex reactivation, pneumonia, recurrent viral flu syndromes, esophagitis fungal and urinary infections. All of them were present in the subgroup of patients undergoing therapy with Ruxolitinib (45%) after a medium time of 8 months from beginning of therapy (range 3-10). No patients received any anti-infective prophylaxis. Median total daily dose of ruxolitinib was 10 mg (range 5-20). All of this infections were transiently resolved after antimicrobial therapy and did not require hospitalization. None of patients were treated with concomitant immunosuppressive therapy. 3 of this patients presented renal impairment (median creatinine clearance of 46 ml/min).

| Summary/Conclusions:                        | These data in our small series of patients suggest a higher incidence of ruxolitinib associated infections observed in clinical practice compared to traditional treatment. Immunosuppressive effect of Ruxolitinib is reported and the use of this drug in the transplant setting with beneficial effects on alloreactivity and on graft versus host disease is becoming more common. These patients might benefit from receiving prophylactic therapy with antiviral drugs or antibiotics or antifungal therapy or in alternative by careful monitoring. Finally nowadays physicians and patients should be aware of potential risks of using ruxolitinib including the risk of infections. In summary, infections can occur in patients treated with ruxolitinib but are generally mild. Generally infections were non-life threatening and managed with appropriate supportive care. Special care probably should be taken for patients older (more than 75 years old), treated with corticosteroid therapy and with renal impairment. However larger studies are needed to confirm these observations.

PB2060
THE JAK2V617F MUTATION AND LEUKOCYTOSIS AS RISK FACTORS FOR INCIDENCE OF THROMBOTIC COMPLICATIONS IN PATIENTS WITH POLYCYTHEMIA VERA AND ESSENTIAL THROMBOCYTHEMA

E. Simonovic1,2, V. Colic1
1Internal Medicine, General Hospital Leskovac, Leskovac, Serbia
2Internal Medicine, Clinic of Hematology, Niš, Serbia

Background: Polycythemia vera (PV) is a clonal, chronic, progressive myeloproliferative disease, caused by transformation of pluripotent hematopoietic stem cell. It is a malignant hematological disease that leads to excessive proliferation of erythroid, myeloid and megakaryocytic elements in the bone marrow. Essential thrombocythemia (ET) is a clonal disorder of unknown etiology that affects multipotent hematopoietic stem cell, and it is characterized by enhanced formation of megakaryocytes in the bone marrow and for no apparent cause, by markedly increased platelet counts in peripheral blood. PV and ET belong to a group of Philadelphia chromosome negative myeloproliferative neoplasms. Thrombotic and hemorrhagic complications are the most common causes of morbidity and mortality in patients with PV and ET. It is thought that the mechanisms that lead to thrombosis in MPN are the following: increased blood cell mass, abnormal platelet function and the phenomenon of spontaneous aggregation. The contribution to the incidence of thrombosis: increased level of products that are formed in the activation of platelets (thromboxane, p-selectin); increased production of microparticles that are parts of various cell membrane structures of platelet origin; JAK2V617F mutation. In patients with MPN there is increased activity of the coagulation system due to the resistance to the anticoagulant function of thrombomodulin.

Aims: The aim of this study is to monitor JAK2V617F mutations and leukocytoses as potential risk factors for the development of thrombotic complications in patients with polycythemia vera and essential thrombocytoma.

Methods: During the five-year period we monitored the occurrence of thrombotic complications in 56 patients (of both sexes, aged between 30 and 78 years), being diagnosed with PV and 22 patients (of both sexes, aged between 38 and 79 years) being diagnosed with ET. We used methods of clinical, laboratory, ultrasound and CT scans. With regard to the risk factors we followed the presence of JAK2V617F mutations and leukocytoses.

Results: Leucocyte count ranged from 5,2-27,1 x 1 109/L. The highest leucocyte count was recorded in the group of patients with PV (p=0,01). JAK2V617F mutation was also statistically more significantly present in patients with PV. The highest percentage of thrombotic complications (arterial and venous) was found in the group of patients with ET, which was statistically more significant relative to PV. Thrombotic complications in those groups were more frequent in patients with JAK2V617F mutation, but statistical significance was present only in the group with PV. Thrombotic complications were in both groups more frequent in percentage with JAK2V617F positive patients, but without statistical significance. It is believed that activated neutrophils bind to platelets by influencing the increased expression of tissue factor activity, as well as the activation and damage of the endothelial cells, especially with JAK2V617F positive patients.

Summary/Conclusions: Leukocytosis and JAK2V617F may be considered as potential risk factors for the incidence of thrombosis in patients with PV and ET. Further follow-up of those patients, as well as a larger number of subjects are needed.

PB2061
RISK FACTORS FOR INCIDENCE OF HEMORRHAGIC COMPLICATIONS IN PATIENTS WITH PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

E. Simonovic1,2, L. Macukanovic-Golubović2
1Internal Medicine, General Hospital Leskovac, Leskovac, 2Internal Medicine, Clinic of Hematology, Niš, Serbia

Background: Myeloproliferative neoplasms (MPN) are the group of clonal, malignant hematopoietic stem cell disorders, characterized by the proliferation of one or more blood lines with normal or nearly normal maturing in the bone marrow and in extramedullar hematopoietic organs. Hemorrhagic syndrome is a complication that occurs in about a quarter of patients with PV and even 60% of patients with ET. Patients may also develop the clinical course of the IMF. It is manifested in the form of petechiae and ecchymoses, or may be life-threatening as uncontrolled esophageal bleeding. Bleeding occurs due to ineffective megakaryocytopenia, retention of platelets in the large spleen, qualitative
platelet disorders, acquired deficiency of factors V and vWF, disseminated intravascular coagulation (DIC).

Aims: The aim of this study is to monitor the count of erythrocytes, leukocytes and platelets, as well as hemoglobin and hematocrit values as potential risk factors for the incidence of hemorrhagic complications in patients with chronic myeloproliferative neoplasms.

Methods: During the three-year period we monitored the occurrence of hemorrhagic complications in 139 patients of both sexes, aged between 30 and 87 years, being diagnosed with Ph-myeloproliferative neoplasm. Patients were classified into the following groups: 1. Group with polycythemia vera (PV) (61); 2. Group with essential thrombocytopenia (ET) (28); 3. Group with idiopathic myelofibrosis (IMF); 4. Group with unclassified myeloproliferative neoplasms (MPNs) (25). The following possible risk factors were monitored: counts of erythrocytes, leukocytes and platelets, as well as hemoglobin and hematocrit values. We used methods of clinical, laboratory, endoscopy, ultrasound and CT scans.

Results: The highest percentage of hemorrhagic complications were in the group of patients with ET and IMF (p<0.01), followed by the group with MPNs (p<0.05). In all three groups, the incidence of hemorrhagic complications in patients older than 65 years of age was higher (p<0.001). The erythrocyte count ranged from 6.45-8.89 x 10^12/L, leukocyte count 1.27-21.1 x 10^9/L and the platelet count ranged from 10.2-1986.6 x 10^9/L. Hemoglobin values ranged from 176-210 g/L, and hematocrit from 0.58 to 0.83 L/L. The highest erythrocyte count, the highest hemoglobin and hematocrit values, as well as the highest leukocyte count was recorded in the group of patients with PV and MPNs (p<0.001) and the lowest in the group of patients with IMF (p<0.01). Among the group of patients with MPNs, 45% of them had statistically significant differences in those parameters. In the group of patients with PV and MPNs hemorrhagic complications were more frequent in percentage in patients with leukocytosis and erythrocytosis, but without statistical significance. The highest platelet count was found in the group of patients with ET and MPNs (p<0.001), and the lowest in the group of patients with IMF (p<0.01). Among the group of patients with PV and MPNs there was no statistically significant difference with regard to platelet count. Hemorrhagic complications were more frequent both in patients with platelet count below 10x10^9/L (p<0.05) and in patients with platelet count over 1000x10^9/L (p<0.01). The increase in platelet count influences the adsorption of larger von Willebrand multimers on the platelet membrane, thus having an effect on their elimination from circulation and degradation.

Summary/Conclusions: The platelet count can be considered a significant parameter for monitoring the risk of hemorrhagic complications in patients with myeloproliferative neoplasms, particularly with ET and IMF. Deviation from the count of leukocytes, erythrocytes, hemoglobin and hematocrit values may be considered as a potential risk factor for bleeding in patients with myeloproliferative neoplasms, but further follow-up and a larger number of subjects are needed. The age of the patient can also be considered as a risk factor for the incidence of hemorrhagic syndrome in those patients. The follow-up of patients with unclassified myeloproliferative neoplasms has been particularly important, which showed a high prevalence of hemorrhagic complications, and with the purpose of their further differentiation.

PB2062

CLINICAL RELEVANCE OF JAK2V617F MUTATIONAL LOAD IN PATIENTS WITH PHILADELPHIA NEGATIVE MYELOPROLIFERATIVE NEOPLASMS FROM REPUBLIC OF MACEDONIA (SINGLE-CENTER EXPERIENCE)

M. Popova-Labachevska1,*, L. Cevreska1, M. Ivanovski1, D. Dukovski1, B. Kocoski1, A. Eftimov1, I. Panovska-Stavridis1

1Division of Hematology, A.O. “Policlinico-Vittorio Emanuele”, University of Catania, Via Citelli 6, 95124 Catania, Italy, Catania, Italy

Background: Chronic neutrophilic leukemia (CNL) is a rare BCR-ABL1–neg- ative myeloproliferative neoplasm (MPN) with only 200 patients reported to date according to the WHO criteria. These cases are characterized by a high number of mature neutrophils in peripheral blood (PB), a hypercellular bone marrow due to neutral granulocyte proliferation and hepatosplenomegaly. None standard of care exist for CNL; most patients are palliated with hydroxyurea, interferons, splenectomy or splenectomy.

In the past years CNL has been reclassified as chronic myeloid leukemia (CML), atypical CML (aCML) or chronic myelomonocytic leukemia (CMML), however, this diagnosis has been more defined since the oncogenic mutations in the granulocyte colony-stimulating factor (CSF3R) gene were identified in approximately 83% of WHO-defined CNL patients. CSF3R T618I mutation is a rare CNL-specific mutation that is sensitive to in vitro and in vivo inhibition by currently approved protein kinase inhibitors.

Aims: here we report a case of a 76-years old man with diagnosis of chronic neutrophilic leukemia, according to WHO criteria, successfully treated with ruxolitinib.

Methods: On May 2015 a 76 aged male patient presented at our Institution with fatigue, night sweats, neutrophilic leukocytosis (neutrophils 42.080/mm, immature granulocytes <5%), and symptomatic splenomegaly (277x127x200 mm). Marrow biopsy was hypercellular (100%) with myeloid hyperplasia, immature granulocytes <5%), and symptomatic splenomegaly (277x127x200 mm). Marrow biopsy was hypercellular (100%) with myeloid hyperplasia, mild myeloid dysplasia and profound erythropoietic hypoplasia; reticulocyte fibrosis was minimally present. Molecular profiling demonstrated no mutations of JAK2 or CALR and polymerase chain reaction (PCR) studies for (t;9;22) and BCR-ABL fusion, was negative.

The patient was initially treated with hydroxyurea with a provisional diagnosis of prefibrotic phase of primary myelofibrosis (PMF), but symptoms worsened and the therapy was interrupted after 9 months for progressive anemia (Hb 9.9 g/dL) and thrombocytopenia (82.000/mm); meanwhile polymerase chain reaction (PCR) studies revealed the presence of CSF3R T618I mutation, suggesting diagnosis of CNL. By taking into account the activity of ruxolitinib in overt PMF, we decided to start this drug. The initial dose was 5 mg twice daily with a gradual increase in the dose to 20 mg twice daily when platelet count became normal.

Results: on a follow-up of 6 months after initiation of ruxolitinib therapy, symp- toms resolved, hemoglobin and platelet levels improved (PLT 186.000/mm), leukocytosis persisted (WBC 24.600/mm), and the patient achieved a dramatic reduction in spleen size (209x119x74 mm).

Summary/Conclusions: Current data suggest that constitutively active JAK- STAT signaling plays a central role in the pathogenesis of BCR-ABL1–negative myeloproliferative neoplasms (MPNs); our experience suggests that ruxolitinib use in CNL patients can induce partial responses by improving marrow function (normalization of hemoglobin and platelet counts), splenomegaly and symptoms.

PERIPHERAL BLOOD CELL STUDY FROM PATIENTS WITH FOLLICULAR LYMPHOMA AND DIFFUSE LARGE B-CELL LYMPHOMA: WHAT SHOULD WE EXPECT?

D. Subirá1, H. Guillén1, C. Fernández Maqueda2, Á. Gil1, D. de Miguel1, N. Goibano1, F. Barriopedro1, M. Morales1, M. Díaz Morfa1, J. Arbeteta1, A. Vázquez1, S. Herrero1

1Haematology, Hospital Universitario de Guadalajara, Guadalajara, 2Haematology, Hospital Universitario Puerta de Hierro, Madrid, Spain

Background: Follicular lymphoma (FL) may evolve to diffuse large B-cell lymphoma (DLBCL) and interactions between neoplastic cells and immune tumour microenvironment have been involved in this process. However, the potential value of the peripheral blood study to identify FL patients at high risk of progression is less known.

Aims: To describe the peripheral blood findings of patients with FL and DLBCL at diagnosis, and to investigate whether a particular lymphoid distribution could be associated with aggressive disease.

Methods: The study (performed between September 2012 and January 2017) included 52 patients (50 female) with a median age of 70.5 years (71% >60 years). Patients were newly diagnosed in situ FL (n=1), Grade 1 FL (n=12), Grade 3 FL (n=11), and DLBCL not otherwise specified (n=28). In situ FL and Grade 1.2 FL were grouped as low-grade FL. Most patients with FL (11/13) and DLBCL (8/11; Grade 3 FL) had clinical stages III/IV. Patients with primary or secondary immunodeficiency and those who had already received corticosteroids or chemotherapy were excluded from this study. A whole blood sample was studied at diagnosis of lymphoma and prior to the start of therapy, using multicolour flow cytometry immunophenotyping and a standardised monoclonal antibody panel. A single monoclonal antibody panel including reagents against CD19, CD20, CD22, kappa, lambda, CD3, CD4, CD8, CD56 and CD45 was used, and a minimum of 300,000 events were acquired on the flow cytometer. Results were expressed as the absolute number/ ml of monocytic lymphocytes, T cells, CD4, CD8 and NK cells. Polyclonal and monoclonal B lymphocytes were also identified.

Results: No difference in the distribution by sex or age was found between patients with FL and DLBCL. A low cell count in at least one lymphocyte population was detected in 35/52 patients (67.3%); 100% of cases had a low number of polyclonal B cells (<100/ml). Comparison of low-grade FL, grade 3 FL and DLBCL did not show any statistically significant difference regarding monocytic lymphocytes, CD4, CD8 and total T cells. Low-grade FL and DLBCL showed the highest number of differences, involving lymphocytes (257±2439 versus 1495±671, p=0.001), NK cells (381±312 versus 204±167, p=0.03), the CD4:CD8 ratio (1.5±4.29 versus 2.06±1.44, p=0.002), and circulating monoclonal B cells, for both percentage (15.2±23.23 versus 1.94±23, p=0.001) and absolute number (869±1758 versus 18.75±46.47, p<0.001). Grade 3 FL and DLBCL also showed a different CD4:CD8 ratio (1.16±0.45 versus 2.06±1.44, p=0.001), with a trend toward significance regarding CD4 T cells (413±184 versus 685±457, p=0.077). Grade 3 FL (p=1) had a lower number of polyclonal B cells as compared to DLBCLs (664±41 versus 105±102, p=0.048). The degree of expression of monoclonal B cells was higher in low-grade FL than in grade 3 FL, in both percentage (15.22±23.23 versus 4.58±8.48, p=0.008) and number (869±1758 versus 43.36±69.91, p=0.002) of monoclonal B cells. The number of lymphocyte sub-populations versus with low-count was higher in grade 3 FL than in low-grade FL (p=0.03).

Summary/Conclusions: The peripheral lymphocyte profile in patients with FL and DLBCL is heterogeneous, but B-lymphopenia and CD4:CD8 ratio deviations are frequent findings. Regardless of clinical stage, low-grade FL had more circulating lymphoma cells and preserved lymphocyte populations than grade 3 FL. Further studies are warranted to confirm these exploratory findings and determine their clinical implications.

PB2065

THE ACQUISITION OF RESISTANCE TO BENDAMUSTINE HYDROCHLORIDE INDUCES MULTIDRUG RESISTANCE IN A NOVEL MANTLE CELL LYMPHOMA-DERIVED CELL LINE KUPM-YP1

T. Takimoto1,*, H. Nagoshi1, S. Maegawa1, T. Tsukamoto1, Y. Shimura1, Y. Oinuma-Sugitani1, T. Kobayashi1, T. Tak1, S. Horii1, M. Taniwaki1, J. Kuroda1

1Kyoto prefectural university of medicine, kyoto, Japan

Background: Bendamustine hydrochloride (BH) has been one of the most promising cytotoxic moieties for mantle cell lymphoma (MCL), however, its mechanisms of action and the mechanisms for the acquisition of resistance to BH have not been fully clarified.

Aims: We tried to identify the underlying mechanisms for BH resistance to develop the strategy to overcome BH resistance.

Methods: This study was conducted in accordance with the Declaration of Helsinki and with the approval of the Institutional Review Board. Patient’s sample was obtained along with the written informed consent. We firstly established a novel MCL-derived cell line, KUPM-YY1, from circulating lymphoma cells of a 77-year-old male patient with MCL. A BH-resistant subline of KUPM-YY1 (KUPM-YY1R) was established by continuous exposure to BH with gradual escalation of its concentration from 5 μM up to 50 μM for about 8 months. Cyto-genetic analysis was performed by double color-fluorescence in situ hybridization and spectral karyotyping (SKY). The comparative gene expression profile (GEP) and the ingenuity canonical signal pathway analyses between of KUPM-YY1 and KUPM-YY1R were performed to identify the differential gene expression pattern along with the acquisition of BH resistance. Cell viability was evaluated by a modified MTT assay.

Results: SKY analysis revealed that both primary tumor cells and KUPM-YY1 had complex karyotype including three-way translocation (8;14;11) (q24;q32;q13). (Involving of cytogenetic abnormality, IC50 of BH to KUPM-YY1R was increased by about 10 fold compared to KUPM-YY1R). Furthermore, BH treatment for 48 hours resulted in the dose-dependent inhibition of cell proliferation in all four MCL cell lines (IC50 0.9–2.5 μM), and this inhibitory effect of BH was more profound in MCL cell lines compared with three DLBCL cell lines (IC50 3.7–17.0 μM) and a BL cell line (IC50 2.9 μM). In addition, the flow cytometric analysis revealed that the growth inhibition of MCL cells by BH in vitro blockade with BH at 912 was at least partly mediated through the induction of apoptosis. As the molecular sequelae, BH treatment of KUPM-ANTK, an AKT activator or CON1 expression was unaltered by BH treatment in MCL cells. By gene knock-down of BH by RNA interference using three different short hairpin RNAs, we further validated that the reduction of PDK1 protein caused the inactivation of RSK2 and the growth inhibition in MCL cell lines. Finally, when combined with BH, RSK2-active agents such as doxurubicin, etoposide, fludarabine, bortezomib, or ABT263, BH showed additive/synergistic growth inhibitory effects in MCL cell lines.

Background: Mantle cell lymphoma (MCL) has been one of the most promising cytotoxic moieties for mantle cell lymphoma (MCL), however, its mechanisms of action and the mechanisms for the acquisition of resistance to BH have not been fully clarified.

Aims: We tried to identify the underlying mechanisms for BH resistance to develop the strategy to overcome BH resistance.

Methods: This study was conducted in accordance with the Declaration of Helsinki and with the approval of the Institutional Review Board. Patient’s sample was obtained along with the written informed consent. We firstly established a novel MCL-derived cell line, KUPM-YY1, from circulating lymphoma cells of a 77-year-old male patient with MCL. A BH-resistant subline of KUPM-YY1 (KUPM-YY1R) was established by continuous exposure to BH with gradual escalation of its concentration from 5 μM up to 50 μM for about 8 months. Cyto-genetic analysis was performed by double color-fluorescence in situ hybridization and spectral karyotyping (SKY). Results: SKY analysis revealed that both primary tumor cells and KUPM-YY1 had complex karyotype including three-way translocation (8;14;11) (q24;q32;q13). (Involving of cytogenetic abnormality, IC50 of BH to KUPM-YY1R was increased by about 10 fold compared to KUPM-YY1R). Furthermore, BH treatment for 48 hours resulted in the dose-dependent inhibition of cell proliferation in all four MCL cell lines (IC50 0.9–2.5 μM), and this inhibitory effect of BH was more profound in MCL cell lines compared with three DLBCL cell lines (IC50 3.7–17.0 μM) and a BL cell line (IC50 2.9 μM). In addition, the flow cytometric analysis revealed that the growth inhibition of MCL cells by BH in vitro blockade with BH at 912 was at least partly mediated through the induction of apoptosis. As the molecular sequelae, BH treatment of KUPM-ANTK, an AKT activator or CON1 expression was unaltered by BH treatment in MCL cells. By gene knock-down of BH by RNA interference using three different short hairpin RNAs, we further validated that the reduction of PDK1 protein caused the inactivation of RSK2 and the growth inhibition in MCL cell lines. Finally, when combined with BH, RSK2-active agents such as doxurubicin, etoposide, fludarabine, bortezomib, or ABT263, BH showed additive/synergistic growth inhibitory effects in MCL cell lines.

Summary/Conclusions: Collectively, our study suggested that PDK1/RSK2 signaling axis is the potential therapeutic target in MCL.
gested that KPUM-YY1R cells harbored the distinct gene expression patterns in MCL, a gene for p-glycoprotein (P-gp), of drug transporter molecule, MGST1, a member of glutathione S-transferase (GST) families, and argininosuccinate synthetase 1 (ASS1), a rate-limiting enzyme for arginine biosynthesis. The upregulation of MDR1 (P-gp) and MGST1 were confirmed by Western blot or RT-PCR analysis in KPUM-YY1R compared with KPUM-YY1. Importantly, the addition of Pgp inhibitor a, such as aminocycltanide, at least partially restored the sensitivity to BH in KPUM-YY1R cells, indicating the functional significance of the upregulation of MDR1 and MGST1 in the development of BH resistance in MCL. In addition, BH-resistance cells were also found to express decreased mRNA level of ASS1 whose over expression plays tumor suppressor roles and its loss has been associated with clinical aggressiveness in various cancers.

Summary/Conclusions: This study revealed that the multiple molecular mechanisms overflappingly underlie the development of BH resistance, therefore, the acquisition of BH resistance potentially leads multidrug resistance in MCL cells. These findings have potentially developed KPUM-YY1 cells and KPUM-YY1R cells deserve the identification of multiplex mechanisms underlying BH activity/resistance and the future development of strategy which overcomes the treatment refractoriness in MCL.

Background: Bone marrow (BM) biopsy with or without aspiration is usually included in the staging workup for patients with non-Hodgkin's lymphoma (NHL). According to the National Comprehensive Cancer Network guidelines, BM aspiration is mandatory for lymphoma, but aspiration is optional. Moreover, the role of BM aspiration is controversial. Other studies have shown that BM aspiration morphologically or flow cytometry is often inconsistent with biopsy and is less likely to detect lymphoma than biopsy. There are no clear guidelines regarding BM aspiration results that are positive in BM aspiration and negative in biopsy.

Aims: The aim of this study was to establish guidelines through a comparison of the overall survival (OS) of patients with NHL using morphological method.

Methods: We performed a retrospective analysis of BM involvement in patients with newly diagnosed NHL in the Korea University Hospital from January 1991 to December 2016. OS was compared according to the BM groups, which were divided into three groups: the group without BM involvement in both BM aspiration and biopsy, the group with atypical lymphocytes only in BM aspiration, and the group with BM involvement in biopsy regardless of BM aspiration results. Atypical lymphocytes were identified as positive in BM aspiration if they displayed clumped nuclei, vacuolation, and aggregation including lymphoid aggregates, lymphoid presentation of mature B-cell neoplasm, and lymphoma associated hemophagocytic lymphohistiocytosis. Reactive changes, or relative lymphocytosis were excluded. OS was assessed using the Kaplan-Meier method, and the log-rank test was used for comparison between the groups. Multivariate analysis were performed using Cox proportional hazards model.

Results: In total, the data of 1,773 patients, of which 391 patients had indolent NHL and 1,382 patients had aggressive NHL, were reviewed. Of the 1,773 patients, 1,148 (64.7%) yielded negative results on both BM aspiration and biopsy, 30 (1.7%) yielded positive results with atypical lymphocytes only in BM aspiration, and 190 (10.7%) yielded positive results on biopsy. Remaining 405 patients were excluded owing to inadequate results in BM aspiration and/or biopsy. Median follow-up duration was 37.62 months (range, 0–288). At the time of Kaplan-Meier survival analysis, OS was significantly worse for patients with BM involvement in biopsy compared with those with no BM involvement, vacuolation, and aggregation including lymphoid aggregates, lymphoid presentation of mature B-cell neoplasm, and lymphoma associated hemophagocytic lymphohistiocytosis. Reactive changes, or relative lymphocytosis were excluded. OS was assessed using the Kaplan-Meier method, and the log-rank test was used for comparison between the groups. Multivariate analysis were performed using Cox proportional hazards model.

Discussion: Diffuse large B-cell lymphoma (DLBCL) is the most common B-cell non-Hodgkin’s lymphoma (NHL) throughout the world, comprising 30–35% of all NHLs, with approximately 71,000 new cases and 19,000 deaths estimated for 2014. Currently, R-CHOP, a combination of immunotherapy (Rituximab, targeting the cell surface protein CD20 expressed by B cell lymphoma) and chemotherapy (Cyclophosphamide, doxorubicin, vincristine and prednisone), remains the most commonly used regimens for newly diagnosed advanced DLBCLs. However, as it is a biologically aggressive disease, up to one-third of patients will ultimately become refractory to initial therapy or relapse after treatment and display poor survival outcome, underlying the need for novel therapeutic approaches based upon selective molecular targets. We are combining in vivo luminescent/fluorescent DLBCL xenograft models with mass spectrometry imaging (MSI) analysis to study the tumors characteristics during R-CHOP treatment and relapse. The in vivo imaging approach allows us to precisely quantify tumoral development and response to therapy, as well as to study the differences between patients with NHL. On the other hand, MSI technique provides information regarding analyte composition at an almost cellular level. Therefore, we can identify, localize the molecules, proteins, drugs or metabolites. 2 types of analysis are performed: i) comparison between primary untreated tumors and tumors relapsing from R-CHOP therapy. We are also studying the therapy resistant and sensitive areas of each tumor. Aims: Our aim is to investigate and analyze the various chemical composition of DLBCL xenografts during tumoral development and R-CHOP treatment relapse, in order to identify yet uncharacterized targets that could become alternative targets for therapy.

Methods: 10 millions cells of a U2932 lymphoma cell line were xenografted into 60 athymic nude immuno-deficient mice. Tumoral growth was repeatedly quantified in a non-invasive manner based on tumors’ luminescent signal using the in vivo imaging system (IVIS) Lumina II. R-CHOP treatment was applied to mice after primary tumoral growth. 2 types of samples are generated: i) comparison between untreated tumors and tumors relapsing from R-CHOP therapy. ii) comparison between therapy resistant and sensitive areas of each tumor. Mass spectrometry imaging is then used to analyze and compare the chemical and biological profiles of DLBCL xenografts at these stages of tumoral growth. Results: In vivo imaging allows us not only to precisely assess primary tumor

Summary/Conclusions: This study suggests that the detection of morphologically atypical lymphocytes only in BM aspiration, but not in biopsy, is not sufficient for predicting OS. Therefore, even if atypical lymphocytes are detected during BM aspiration in patients with NHL, it may not be sufficient to judge the BM involvement and predict the OS of these patients.

THE PROGNOSTIC ROLE OF INDOLEAMINE 2,3-DIOXYGENASE EXPRESSION IN HODGKIN’S LYMPHOMA.
T. Skrylyuk1,*, O. Novosad1, N. Svergun2, O. Skachkova2, O. Gorbach2, V. Solovev3, N. Khranovskaya2, I. Kryachok1
1Oncohematology, 2Experimental Oncology, National Cancer Institute, 3Thoracic surgery, Clinical Hospital No18, Kiev, Ukraine
Background: Indoleamine 2,3-dioxygenase (IDO) is an inducible enzyme that catalyzes the initial and rate-limiting step in tryptophan along the kynurenine pathway. IDO is a key factor maintaining immune tolerance and expression and it correlates with poor clinical outcome in different types of cancer and hematological malignancies. It also plays a role in a lot of pathophysiological processes, such as anitumor and antimicrobial defense. IDO causes immune-suppression in the tumor microenvironment by tryptophan breakdown. Although, only several reviews have been made to evaluate IDO expression value and its expression value in hematological malignancies.
Aims: The aim of the study was to assess the impact of the IDO expression on clinical outcome of patients with Hodgkin’s lymphoma (HL).
Methods: A total number of 35 patients with HL were included in the group (10 males and 25 females; median age: 17-60 years; range: 38.5 years). Early stages (I-II) and advanced stages (III-IV) were diagnosed in 48.5% (17/35) and 51.4% (18/35) of patients, respectively. B-symptoms had 37.1% (13/35) of patients at the time of diagnosis. Patients were treated with ABVD or BEACOPP (14/esc) and radiation therapy. The mRNA expression level of IDO was measured in pre-treatment tumor tissue specimens from HL patients using real-time qPCR analysis.
Results: For 35 patients with HL, the overall response rate after the first-line therapy was 88.6% (31/35). Progression of the disease during the therapy was observed in 11.4% of patients (4/35). Among the patients, who achieved a remission, 9 had relapses. In our study, only 20% (7/35) of HL patients were IDO-positive (IDO+), while the majority of cases in the group (80%, 28/35) were IDO-negative (IDO−). There were no significant differences in IDO expression between histological subtypes of HL. We also did not find any association between stage of disease and IDO expression in our study. Patients with the absence of IDO expression tended to have a better response to the 1st line chemotherapy comparing to patients with positive IDO expression. The overall response rate was achieved in 71.4% (5/7) of IDO+ cases and in 92.9% (28/28) of IDO− cases. The relapse rate of patients was more frequently, found in HL cases with IDO+ compared to IDO− expression (28.5% (2/7) versus 7.1% (2/28), respectively, p<0.05). We did not register any death of patients in IDO+ group, while one patient in IDO+ group died during the follow-up period (median duration – 37 months; range: 1-137 months). H.L. Julhakyan1,*, B. Background: Splenic lymphomas (SLs) are rare chronic lymphoproliferative neoplasms with a very elegant clinical course and a non-characteristic phenotype and karyotypic pattern. As a main diagnostic method of SMZL, the use of the immunophenotype is the only way to differentiate the other cell lymphoma and characterized by a peculiar morphology with micronodular pattern of infiltration, biphasic cytology, and the almost constant presence of marginal zone differentiation. Splenic diffuse red pulp lymphoma been introduced as a provisional entity but differential diagnosis with other SLs is needed to be performed. The aim of this study was to describe the clinical, morphological and immunophenotypic features of the patients diagnosed as SMZL or SDRP.
Aims: The aim of our study to determine the immunoglobulin variable heavy (IgVH) gene usage and somatic mutation patterns in a series of SMZL and SDRP patients.
Methods: We studied 24 patients with SMZL, 40 patients with HCL and 10 patients with SDRPL. Diagnosis was based on standard WHO criteria. In all patients, the diagnosis was based on peripheral blood and BM findings. The baseline clinical and laboratory features as well as follow-up and outcome were recorded for every patient. Unmutated IgVH genes were amplified essentially in reactions that contained only one of the 5 leader region primers for the indicated VH family. VH family configuration, whereas in 20 cases (83.3%), IgVH genes were somatically mutated. We have shown no differences in clinical and laboratory characteristics, immunophenotype, outcome or overall survival between unmutated and mutated cases of SMZL. A comparison of the VH genes to reported germline sequences in SDRPL revealed that five cases used the VH3 family VH 823 gene segments and five the VH4 family, one of case with unmutaited IgVH genes.
Results: A comparison of the VH genes to reported germline sequences in SMZL revealed that five cases used the VH4 family VH 823 gene segments and five the VH3 family VH 823 gene segments and five the VH4 family, one of case with unmutaited IgVH genes.
Summary/Conclusions: Our analysis also showed the selective use of VH1 gene segments in SMZL cases. A 3 cases of SMZL and SDRP cases were performed using appropriate positive and negative controls. The rearranged VH genes identified for each case seemed to represent functional rearrangements because no stop codons or crippled mutations were identified.
Aims: We aim to analyze the impact of secondary chromosomal abnormalities on treatment outcome in pediatric Burkitt leukemia.
Methods: Patients with BL presenting to Children Cancer Hospital in Egypt-57357 (CCHE) from July 2007 till end of December 2015, were reviewed for karyotyping, cMYC status by FISH using break apart probes, and secondary chromosomal abnormalities. These results were correlated with survival analysis.
Results: Twenty-seven BL patients were diagnosed and treated during the study period according to the FAB/LMB 96 protocol. Majority were males (77.3%) and above 10 years of age at presentation (42%). Associated central nervous system involvement was diagnosed in 32.9% of the patients. LDH more than 2 times the upper limit was seen in 79.5%, and 52.3% of the patients suffered from tumor lysis syndrome at presentation. Information for karyotyping was available in 20 all abnormal, half of the patients (54%) had demonstrated translocation of the MYC and IGH genes in 54 patients (86%) while translocation of the IGK and IGL were found in 2 (3%) and 7 (11%), respectively. Secondary chromosomal abnormalities were detected in 40 (60%) patients, with 5 or more abnormalities in 4 patients, 3 chromosomal abnormal- ities in 14 patients, and 2 in 12 patients. All abnormal cases were karyotypes. The most common secondary common chromosomal abnormality was duplication of chromosome 1q which was found in 16 patients. Other secondary chromosomal abnormalities included structural abnormality of chromosome 14q other than MYC transloca- tion (6 patients), chromosome 6q deletion (4 patients), chromosome 13d deletion (3 patients), marker chromosome (3 patients), loss of chromosome 17 (2 patients), isochromosome 9q (2 patients), translocation of chromosome 13, trisomy 13 and trisomy 9 in one patients each. Relapse or tumor progression on chemotherapy was seen in 16% of the whole group of patients. The 5 year OS was 57.7%, while 5 year EFS was 51.6%. When comparing incidence of relapse in relation to complex karyotype, we found that nine out of 16 (56.2%) patients having complex karyotype experienced relapse whereas relapse occurred in only 6 (12.5%) patients having non-complex karyotype (p-value= 0.005)
Summary/Conclusions: The frequency of secondary chromosomal abnor- malities in our series is in concordance with other publications with duplication 1q being the most common, followed by deletion 6q, 13q, and 17p. Complex karyotype was significantly associated with higher incidence of relapse and poor outcome.

SECONDARY CHROMOSOMAL ABNORMALITIES AND THEIR IMPACT ON TREATMENT OUTCOME IN PEDIATRIC BURKITT LEUKAEMIA.
S.I. Salem1,*, H. Abdelrahman3, M. Tantawy2, S. Talaat2, R. Hamdy4
1Clinical Pathology, Pediatric Oncology, NCI, Cairo University and Children Cancer Hospital Egypt-CCHE, 2Clinical Pathology, 3Research Department, Children Cancer Hospital Egypt, 57357, Cairo, Egypt
Background: Burkitt leukemia (BL) constitutes around 13.5% of pediatric malignancies in Egypt which is a high proportion comparing to the immunoglobulin genes to one of the immunoglobulin genes. The clinical significa- nce of secondary chromosomal abnormalities associated with this char-acteristic translocation remains unknown.
Aims: We aim to analyze the impact of secondary chromosomal abnormalities on treatment outcome in pediatric Burkitt leukemia.
Methods: Patients with BL presenting to Children Cancer Hospital in Egypt-57357 (CCHE) from July 2007 till end of December 2015, were reviewed for karyotyping, cMYC status by FISH using break apart probes, and secondary chromosomal abnormalities. These results were correlated with survival analysis.

CELL OF ORIGIN ASSIGNMENT USING IMMUNOHISTOCHEMISTRY IS INFLUENCED BY BCL-2 EXPRESSION IN DLBCL PATIENTS TREATED WITH CHEMOTHERAPY

R. Yassin1, S. Shieban2, T. Pasha1, G. Gmati1, H. Salama3, K. Abuelgasim3, M. Al-Zahrani1, A. Hejazi3, A. Ahmed3,4, M. Damlaj1,4,*

Background: Diffuse Large B-cell Lymphoma (DLBCL) is a heterogenous disease with variable clinical and pathologic presentations. Using gene expression profiling or Lymph2Cx assay, DLBCL can be assigned as germinal center (GCB) or non-germinal center (Non-GCB) subtype. However such assays remain cumbersome or unavailable for routine clinical care. Immunohistochemical (IHC) algorithms, such as the one proposed by Hans et al., are easy to use tools but demonstrated variable concordance to gene expression profiling. Importantly, cell of origin (COO) assignment appears to influence overall survival (OS) but not progression free survival (PFS). Furthermore, anti-apoptotic BCL-2 oncogene expression confers prognostic significance in GCB DLBCL but its significance in Non-GCB is unknown.

Aims: To examine the prognostic impact of cell of origin (COO) assignment in conjunction with BCL-2 expression in a cohort of DLBCL patients.

Methods: After due IRB approval, adult patients diagnosed with DLBCL and treated at our institution between 2010 – 2015 were identified. Clinical and pathologic variables were retrospectively abstracted. IHC expression was deemed positive if >30% of stained was observed. Cell of origin analysis was determined by the Hans criteria. All patients were treated with combinational chemotherapy containing rituximab. Patients who died prior to receiving therapy were excluded. Categorical and continuous variables were compared using Chi-squared and Wilcoxon tests, respectively. Time to end point analysis was computed using the method of Kaplan and Meier with log ranks. Relapse, progression or death was considered an event for PFS estimation. Analysis was computed using JMP software, version 11.

Results: A total of 122 patients were identified and analyzed. Median follow up of the cohort was 21.8 (1.47 – 107) months, during which OS was 73.5% and PFS was 59.9%. Stratified by IPI, 2-year OS was 85%, 76.3%, 72% and 49.5% for low, intermediate, high-intermediate and high risk patients, respectively (p=0.006). After stratifying patients to GCB and Non-GCB, baseline characteristics between the strata with regards to gender, age, stage, extranodal disease, lactate dehydrogenase (LDH), International Prognostic Index (IPI) and BCL-2 expression were not significantly different. At 2-years, PFS was significantly higher for GCB vs Non-GCB at 72.5% vs 64.7% respectively (p=0.008). After stratifying patients to GCB and Non-GCB, base-line characteristics between the strata with regards to gender, age, stage, extranodal disease, lactate dehydrogenase (LDH), International Prognostic Index (IPI) and BCL-2 expression were not significantly different. At 2-years, PFS was significantly higher for patients with BCL-2 expression to 75% vs Non-GCB at 56.2% respectively (p=0.02).

Summary/Conclusions: COO assignment using IHC demonstrated superior PFS for GCB over non-GCB however this was mitigated by BCL-2 expression. This raises questions regarding the currently presumed pathogenesis of the different subtypes and how to utilize the currently available targeted therapies including BCL-2 inhibitors. These observations warrant further study.

ARE DIFFERENCES BETWEEN PEDIATRIC EBV-ASSOCIATED LYMPHOMAS AND CARRIERS REGARDING LATENCY PROFILE AND MICROENVIRONMENT COMPOSITION INVOLVED IN LYMPHOMAGENESIS?

A. Vistarop1, M. Cohen1, O. Jimenez1, F. Huaman2, E. De Matteo3, M.V. Preciado1, P. Chabay1,*

Background: Epstein–Barr virus (EBV) infects more than 90% of the population worldwide. The virus has evolved to persist-long in B-lymphocytes of infected individuals, but disruption of this tightly regulated B-cell infection could result in EBV-associated B cell lymphomas. In Argentina, primary infection is mostly subclinical and 90% of patients are seropositive by 3 years old. However, EBV presence is statistically associated with Hodgkin lymphoma (HL) and Diffuse Large B cell lymphoma (DLBCL) in patients younger than 10 years, suggesting a relationship between low age of EBV infection and B-cell lymphoma development in children from Argentina.

Aims: Given that viral latent proteins and microenvironment composition play a key role in tumorogenesis or control of viral infection, our aim was to compare this scenario in pediatric EBV-associated lymphomas derived from the germinal center (GC) and post-GC subtypes, to investigate whether an alteration of microenvironment could be related to lymphomagenesis.

Methods: Formalin fixed paraffin embedded (FFPE) pediatric biopsy samples from 26 DLBCL, 55 HL and 41 tonsils from EBV carriers were analyzed. Immunohistochemistry for LMP1, EBNA2, CD4, CD8, FoxP3 and GrB was performed, together with EBERs in situ hybridization, and positive cells were counted in the EBV+ milieu.

Results: Latency II pattern (LMP1+ EBNA2-) was predominant in HL (100%), DLBCL (55%), as well as in EBV+ CG in pediatric carriers (90%). CD4+ cell count displayed no differences between EBV+ and EBV- lymphomas, except in EBV+ GC in pediatric carriers, to investigate whether an alteration of microenvironment could be related to lymphomagenesis.

Discussion: Our observations suggest that there is a significant alteration of the EBV latency profile in pediatric EBV-associated lymphomas compared to EBV+ CG in pediatric carriers. This pattern could be more frequent in EBV+ GC in pediatric carriers, and might be associated with the transformation of EBV+ lymphomas. Further studies are needed to confirm these findings.
real-time polymerase chain reaction (qRT-PCR) was used to confirm the results of six upregulated and two downregulated IncRNAs. Bioinformatic analysis (gene ontology analysis, pathway analysis and network analysis) was performed to predict the biological functions and potential mechanisms of the differentially expressed IncRNAs in GCB DLBCL.

**Results:** We demonstrated that 21,539 IncRNAs were expressed in all samples analyzed, of which 1,548 IncRNAs were upregulated and 2,671 IncRNAs were downregulated in GCB DLBCL cell lines (OCI-Ly1 and OCI-Ly9) (≥2.0-fold, P<0.05). Pathway analysis indicated that 64 pathways corresponded to upregulated transcripts, and 62 pathways corresponded to downregulated transcripts (P<0.05). In addition, an IncRNA-mRNA co-expression network was constructed to identify potential target genes related to the 3 upregulated and 2 downregulated IncRNAs.

**Summary/Conclusions:** Our data suggested that IncRNAs may play an important role in the pathogenesis of GCB DLBCL, and profile of IncRNAs may be used as a potential biomarker in the diagnosis of DLBCL and predicting its clinical outcome.

FLOW CYTOMETRY IN EVALUATION OF EXTRANODAL LYMPHOMA PRESENTING AT UNUSUAL LOCATIONS COMPARED TO NODAL LYMPHOMAS

P. Prakhar1, M. Choudhury2, S. Sharma2  
1Pathology, Lady Hardinge Medical College, New Delhi, India, 2Pathology, Lady Hardinge Medical College, New Delhi, India

**Background:** Immunophenotyping is a fundamental step in the diagnosis of hematolymphoid malignancies at extranodal sites. Flow cytometry presents significant diagnostic challenges due to their morphological diversity. In recent years flow cytometry (FCM) has proven useful in the evaluation of nodal and extranodal lymphoproliferative disorders on samples obtained by surgical specimens or fine needle aspiration cytology (FNAC). For years FNAC has been used for initial evaluation of suspected hematolymphoid neoplasms. Flow cytometry can additionally help in identifying B or T cell nature of neoplastic cells, clonality in case of B-cell neoplasms and aberrant phenotype. The possibility of detecting CD20 status can help in initiating targeted therapy without undergoing tissue biopsy to do so. FNA cytology with Flow cytometry can serve as a replacement for open biopsy and may help in eliminating the need for more invasive procedures. In this study FCM analysis on cytological specimens, including nodal and extranodal mass from GIT, Thyroid, Kidney, Breast, Tonsil, cerebrospinal fluid and ascitic fluid, was performed.

**Aims:** The aim of our study was to evaluate the efficacy of flow cytometer for the evaluation of extranodal and nodal lymphomas on 40 patients.

**Methods:** The current study was prospectively conducted on 40 patients with a clinical suspicion of hematolymphoid neoplasms. Samples for flowcytometric immunophenotyping (FCI) were obtained by fine needle aspiration (FNA) or by tissue scraping along with samples for cytomorphological, histological and immunohistochemical analysis. Samples collected in isotone were submitted for FCI on 5-color Beckman Coulter FC-500, using a set of mature and immature antigens markers for lymphoid cells. Results of FCI on cytological specimens along with cytological findings were compared with histological and IHC diagnosis.

**Results:** Flowcytometric immunophenotyping conducted on extranodal sites included total 10/40 (25%) cases out of which most common site was GIT (4 cases) followed by CNS (3 cases), Kidney (1 case), Thyroid (1 case), Breast (1 case), and Tonsil (1 case). Definite diagnosis using only FCI could be obtained in 25/40 (62.5%) cases in which 6/10 (60%) cases was conducted on extranodal and 19/30 (63%) cases on nodal tissue samples. The remaining 15 cases which could not be categorized by FCI included Hodgkin lymphoma (6 cases), inadequate cellularity (5 cases), Tuberculosis (2 cases), ALCL (1 case), Mantle cell lymphoma (1 case) and Ewing’s/PNET (1 case). Combining FCI with cytological findings definite diagnosis could be found in 33/40 (82%) cases compared to 30/40 (75%) cases. Immunophenotyping of lymphoblastic leukemia/lymphoma by FCM on cytological specimens was found to be in 100% concordance with FCI on peripheral blood/bone marrow aspirates.

**Summary/Conclusions:** Flowcytometric immunophenotyping along with fine needle aspiration cytology offer a rapid, simple and minimally invasive procedure for the detection of hematolymphoid neoplastic cells in solid tissue especially at extranodal sites. Flow cytometry alone may not consistently provides a definite diagnosis of lymphoma subtypes but can be very helpful in diagnosing extranodal lymphoma and nodal lymphoblastic leukemia/lymphoma.

**KEYWORDS:** Flow cytometry, extranodal lymphoma

POSSIBLE ROLE OF FLOW CYTOMETRY TO CHARACTERIZE INFILTRATING CD4 CELLS IN THE MICRO ENVIRONMENT OF LYMPHOMA TISSUE SAMPLES

R. Di Gaetano1, D. Belvini1, B. Callegari1, M.A. De Benedetto1, E. Pilotto1, R. Sartori1, L. Vassallo2, A. Scapinelló3, T. Giuseppe1  
1Haematology Castelfranco Veneto, 2Pathology Castelfranco Veneto, Azienda ULSS 2 Marca Trevigiana, Castelfranco Veneto (TV), Italy

**Background:** In our previous work (Di Gaetano et al, Ann Haematol, 2014) we analyzed by flow cytometry (FC) the rich infiltrated characterizing the microenvironment of Hodgkin lymphoma (HL), mainly comprised of CD4 T lymphocytes. We confirmed that the majority of these CD4 T expressing the activation marker (CD38) and the CD26 and CD39 lymphocytes of the subset CD4+CD26-CD38+ to identify the non-neoplastic cellular pattern in HL. A subset connectable to regulatory T (Treg) cells, because the low expression of CD26 (DPP4) added to the presence of CD39 (NTPDase) may be responsible for the generation of adenosine, which plays a major role in T-regulated immune suppression.

**Aims:** We wanted to test if this subset may also characterize T infiltrating lymphocytes the lymph nodes of Non-Hodgkin’s lymphomas (NHL) and to verify the expressions of the two enzymatic markers (CD26 and CD39) in microenvironments of HL and NHL analyzed by FC.

**Methods:** In 2016 we analyze by FC in lymph nodes of 6 HL and in 32 NHL (12 DLBCL, 10 FL, 5 SLL, 3 MZL, 2 MCL) the CD4 T subset expressing the expression of CD26, CD38, CD39.

**Results:** In CD4 T HL, CD39 is expressed in 44% of the subset and the increased presence (50%) of CD4+CD26-CD38+ cells is confirmed. Compared with HL the cells of DLBCL are not statistically different (Student test) different: CD38 (64 vs 55; P=0.39), CD26-CD38+ (50 vs 46; P=0.66), CD39 (44 vs 59; P=0.15). While HL and FL cells are significantly different: CD38 (64 vs 23; P<0.05), CD39 (CD26-CD38+ (50 vs 18; P<0.05), CD39 (44 vs 23; P<0.05). The other three types of NHL, few in number, show a tendency to a significant difference compared with DLBCL.

**Summary/Conclusions:** The our data show the phenotypic variations in the microenvironments of different types of lymphoma emphasizing of DLBCL the similarity with HL and the difference with FL and other NHL. They also suggest a link between activated environment (CD38+) and a high CD39, which, in addition to a low CD26, could enhance the generation of adenosine and, therefore, an increased immune suppressive activity. The profile by FC T infiltrating can characterize lymphomas in its environment indicating also signals and biological mechanisms representative of possible therapeutic target

**PB2077**

TREG CD4 PHENOTYPE IN THE PERIPHERAL BLOOD OF LYMPHOMAS

R. Di Gaetano1, D. Belvini1, E. Pilotto1, B. Callegari1, M.A. De Benedetto1, R. Sartori1, G. Tagariello1  
1Haematology Castelfranco Veneto, Azienda ULSS 2 Marca Trevigiana, Castelfranco Veneto (TV), Italy

**Background:** The T regulatory (Treg) cells down-regulate antigen responses by several distinct mechanisms. One is the adenosinergic pathway which, through ectonucleotidases, sequentially converts ATP to AMP and generates adenosine. Several studies have demonstrated in humans the overexpression of CD39 (NTPDase) and low adenosine deaminase (ADA) levels, the enzyme responsible for adenosine breakdown, and of CD26, a surface-bound ADA associated glycoprotein. In our previous work (Di Gaetano et al, Ann Haematol, 2014) we analysed by flow cytometry (FC) the CD T lymphocytes of solid biopsies, the surrounding neoplastic cells in Hodgkin lymphoma (HL) and in non-Hodgkin’s lymphoma (NHL). We also measured the expressions of the two enzymatic markers (CD26 and CD39) in microenvironments of HL and NHL analyzed by FC.

**Aims:** By using the same FC technique we wanted to explore if, as in the lymph node samples, the characteristic profile in HL and NHL of the TCD4+CD26-CD38+ CD39 subset and high levels of CD39 might characterize the peripheral blood (PB) of HL at diagnosis and possibly to distinguish them from those of B Non-Hodgkin lymphomas (B-NHL).

**Methods:** We have analysed by FC the PB of 16 healthy controls (HC), 10 HL and 22 NHL testing within T CD4 cells the expression of CD26, CD38 and CD39.

**Results:** In HC CD26-CD38+ cells were 2.6% of all CD4 and 5.5% expressed CD39. Compared with HC, the subset CD4+CD26-CD38+ of HL was statistically different (2.6 vs 17; P<0.05) as well as B-NHL (2.6 vs 12.9; P<0.05). The expression of CD39 between HC and HL was not different (5 vs 9.8; P=0.1), while it was statistically significant between HC and NHL (5 vs 19.5; P<0.05).

**Summary/Conclusions:** Our results may suggest that T CD4 profile in the PB can characterize the patients with HL and B-NHL and this could be probably variable according to the type of neoplasm. The significant presence of CD39 in HL and B-NHL would seem to suggest that the low expression/reduction of CD26 of ADA activity may indicate the T-regulated immunosuppression. Interestingly is the diversity of NHL showing increased CD39 expression on T CD4 lymphocytes probably connected with...
the clone of B lymphocytes involved in cancer. This may support that leukemic cells may contribute to create and to characterize an immune-subversive envi-
ronment and to facilitate immune escape mechanisms. FC analysis of CD26 and CD39, markers likely connected with the adenosinergic pathway, in PB
Aims: We aimed to find distinct histologic or immunohistochemical findings to further differentiate PMLBCL and CHL of the mediastinum.
Methods: A total of 32 cases of mediastinal B-cell lymphomas consisting of PMLBCL (N=16), CHL (N=13), and gray zone lymphoma (N=3) were collected from 6 university hospitals from Korea. Immunohistochemistry (IHC) for various cell lineage markers and EBV in situ hybridization were performed to confirm the diagnosis, and additionally, expression of P63, GATA3 and cyclinE was investigated.
Results: Most clinical features were overlapped between PMLBCL and CHL except more frequent disease progression and mortality in PMLBCL (p<0.05). In pathologic review, presence of epithelioid granuloma favored CHL (p=0.078), whereas fine reticulated fibrosis was unique for PMLBCL (p=0.001). By IHC, P63 was predominantly positive in PMLBCL (15/16) than CHL (2/11) with the highest diagnostic power (p<0.001). GATA3 was expressed in the majority of CHL (9/12) compared with PMLBCL (0/16) (p<0.001). Expression of cyclinE was rarely found in a minor population of PMLBCL.
Summary/Conclusions: Expression of P63 in the tumor cells, even focal, is the most helpful feature to distinguish PMLBCL from mediastinal CHL. Additional diagnostic markers include GATA3 in CHL and reticular fibrosis in PMLBCL.

PB2080
CASTLEMAN’S DISEASE: HISTOLOGICAL SUBTYPES AND MICROVESSEL DENSITY
A. Mikhailov 1,*, V. Baykov 2, S.S. Bessmeltsev 3, G. Raskin 4, V. Rugal 5, N.Y. Semenova 3
1Department of hospital therapy and cardiology, North-Western state medical university n.a. I.I.Mechnikov, 2Department of pathology, First St.-Petersburg state medical university n.a. I.P.Pavlov, 3Russian research institute hematology and transfusiology, 4Department of pathology, Russian National scientific centre of Radiology and surgical technologies, 5Department of pathology, Russian research institute hematology and transfusiology, Saint-Petersburg, Russian Federation
Background: Castleman’s disease (CD) is a rare non-clonal lymphoprolifer-
average disorder. Most of the cases are characterized by increased vascularity in the affected tissue. The disease falls into two major histological variants: plasma cell type and hyaline vascular type. However, the correlation between microves-
sel density and the subtype of the disease has not been established yet.
Methods: Twenty-eight lymph nodes from patients diagnosed with CD were used for the study. The age of the patients ranged from 24 to 65 years, 14 were male and 14 were female. Three nodes without evidence of metastasis were used for the study. The diagnosis of CD was performed by various histologic markers: GATA3 and cyclinE. Microvascular density (MVD) was measured using the panoramic scan procedure. Percentage of blood vessel area (vessel density index) was calculated using Panoramic Viewer software, statistical analysis was conducted with Student’s-t test.
Results: The plasma cell variant of CD was diagnosed in 8 patients, the hyaline vascular variant – in 20 patients. In control group vessels occupied 10.1±1.4% of the area. In patients with plasma cell variant, percentage of blood vessel area was increased to 15.1±1.4% (p<0.05). Patients with hyaline vascular CD were divided into 2 groups depending on the vessel density index. In 15 patients (75%) percentage of vessel area was 6.8±2.3%, which was somewhat lower than in patients with plasma cell variant (not statistically significant). In 5 patients (25%) with hyaline vascular CD, the percentage of vessel area was higher - 12.3±1.5% (p<0.05) and did not differ from levels in patients with plasma cell variant.
Summary/Conclusions: The highest index of vessel density in the lymph nodes from patients with hyaline vascular variant of CD was observed. In hyaline vascular variant, the index was characterized by significant variability, which could reflect the heterogeneity of this type of the disease. Increased density of blood vessels in the lymphoid tissue may be considered as a possible target for angiogenesis inhibitors, especially in patients with progressive disease.

PB2078
BCL-2 AND KI-67 AS INDEPENDENT PREDICTORS OF POOR-RISK IPI
GROUP OF PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA
1High Dose Therapy Department, Clinical Center of Sarajevo, Hema-
logy Clinic, 2Institute of Pathology, Medical Faculty University of Sarajevo, 3Clinical Center University of Sarajevo, Hematology Clinic, 4Clinical Center University of Sarajevo, Pathology, Citology and Human Genetics Department, Sarajevo, Bosnia and Herzegovina
Background: Diffuse large B cell lymphoma (DLBCL) is heterogeneous dis-
ease in terms of clinical behaviour, morphology, phenotype and genetics. Gene expression profiling has made a distinction between two entities germinal center B-phenotype (GCB), activated B-center phenotype (ABC). Use of immunohistochemical algorithms for identification of these phenotypes has been translated into clinically feasible approach defining groups as GCB, non-
GCB. These algorithms do not provide completely accurate prognostic infor-
mation so the International Prognostic Index (IPI) which identifies poor-
good risk patients with diffuse large B cell lymphoma (DLBCL) is still part of all current diagnostic guidelines; however, the majority of patients have an inter-
mediate IPI, with an uncertain prognosis.
Aims: In this study, we investigated the impact of bcl-2, bcl-6, CD10, MUM1 and Ki-67 on IPI as well as impact of GCB and non-GCB subclassification according to Hans and Muris algorithm on IPI risk stratification.
Methods: We have analyzed 50 patients with DLBCL for the expression of bcl-2, bcl-6, CD10, MUM1 and Ki-67. Patients were divided into two groups, the non-GCB, GCB group or favorable group 1 and unfavorable group 2, according to Hans’s algorithm and Muris’s algorithm. Clinical-pathological, bio-
chemical parameters of disease have been correlated with subgroups of DLB-
CL. Use of CL and biomarkers individually. The impact of the expression of bcl-2, bcl-6, CD10, MUM1 and Ki67 on IPI-highest score in multiple regression analysis, afterwards in regression equation and variance analyse.
Results: Group with GCB phenotype (defined by expression of bcl-2, bcl-6, CD10, MUM1) according to Hans’s and Muris’s algorithm showed positive correlation with good-risk patients identified by IPI. Multiple regression anal-
ysis proved impact of biomarkers on IPI. Following this analysis, bcl2 and Ki67 are independent predictors of poor-risk IPI group of patients, (bcl-2: p 0.0107, Ki67: 0.0377). The value of F-ratio 2.9845 proves that there is a linear connection between models including all variables bcl-2, bcl-6, CD10, MUM1 and variables depended on the value (IPI) (p 0.0210). The mutual impact of bcl-2, bcl-6, MUM1, Ki67 is significantly related to poor-risk IPI patients.
Summary/Conclusions: Multiple regression analysis proved impact of bio-
markers on IPI. Ki67 and bcl-2 are independent predictors of poor-risk IPI group of patients. Sequential addition of bcl-2 expression, Ki67 and GCB phenotype into the IPI significantly improves risk stratification in DLBCL. These finding can be part of treatment strategies that should be considered in future trials.

PB2079
COMPARATIVE PATHOLOGIC ANALYSIS OF MEDIASTINAL B-CELL LYMPHOMAS: EXPRESSION OF P63 BEST DIFFERENTIATES PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA FROM CLASSICAL HODGKIN LYMPHOMA
1Pathology, Sanggye Paik Hospital, Inje University college of medicine, 2Pathologist, Seoul National University Boramae Hospital, 3Department of hospital therapy and cardiology, North-Western state medical university n.a. I.I.Mechnikov, 4Department of pathology, First St.-Petersburg state medical university n.a. I.P.Pavlov
Background: Castleman’s disease (CD) is a rare non-clonal lymphoprolifer-
average disorder. Most of the cases are characterized by increased vascularity in the affected tissue. The disease falls into two major histological variants: plasma cell type and hyaline vascular type. However, the correlation between microves-
sel density and the subtype of the disease has not been established yet.
Methods: Twenty-eight lymph nodes from patients diagnosed with CD were used for the study. The age of the patients ranged from 24 to 65 years, 14 were male and 14 were female. Three nodes without evidence of metastasis were used for the study. The diagnosis of hyaline vascular CD was based on overall preserved immunohistoarchitecture with typical angio-follicular hyperplasia, circular arrangement of mantle cells around hyalin-
ized germinal centers (“onion skin” pattern). The plasma cell type of CD was confirmed by presence of perifollicular sheets of CD138+ plasma cells. Vessels were studied with CD34 and factor XIIIa. Slides were scanned by the whole slide digital Pananonic scanner. Percentage of blood vessel area (vessel density index) was calculated using Panoramic Viewer software, statistical analysis was conducted with Student’s-t test.
Results: The plasma cell variant of CD was diagnosed in 8 patients, the hyaline vascular variant – in 20 patients. In control group vessels occupied 10.1±1.4% of the area. In patients with plasma cell variant percentage of blood vessel area was increased to 15.1±1.4% (p<0.05). Patients with hyaline vascular CD were divided into 2 groups depending on the vessel density index. In 15 patients (75%) percentage of vessel area was 6.8±2.3%, which was somewhat lower than in patients with plasma cell variant (not statistically significant). In 5 patients (25%) with hyaline vascular CD, the percentage of vessel area was higher - 12.3±1.5% (p<0.05) and did not differ from levels in patients with plasma cell variant.
Summary/Conclusions: The highest index of vessel density in the lymph nodes from patients with hyaline vascular variant of CD was observed. In hyaline vascular variant, the index was characterized by significant variability, which could reflect the heterogeneity of this type of the disease. Increased density of blood vessels in the lymphoid tissue may be considered as a possible target for angiogenesis inhibitors, especially in patients with progressive disease.

PROGNOSTIC SIGNIFICANCE OF IMMUNOHISTOCHEMICAL MARKERS IN R-CHOP TREATED DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS
A.-M. Picleanu1,*, S. Patrascu2, L. Mogoanța3
1Hematology, Filantropia Hospital Craiova, 2Surgery, Emergency Hospital Craiova, 3Histology, University of Medicine and Pharmacy of Craiova, Craiova, Romania
Background: Despite its clinical, morphological and molecular heterogeneity, diffuse large B-cell lymphoma (DLBCL) is the most frequent lymphoid malig-
nancy in adults. The role of immunophenotype variability for the therapeutic outcome has long been the cornerstone for DLBCL management strategy.

**Aims:** To evaluate the immunophenotypic characteristics of DLBCL and the prognostic significance of specific biomarkers such as bcl2, bcl6, CD 10 and MUM1, in a population-based cohort of patients treated with R-CHOP.

**Methods:** We performed a retrospective assessment of all cases of DLBCL diagnosed at our institution between 2005-2013. The immunohistochemical expression patterns of all DLBCL patients were analyzed and correlated with the therapeutic response to R-CHOP regimen.

**Results:** The study included 101 patients diagnosed with DLBCL, with a median age at diagnosis of 57.1 years (19-90 years) and male/female ratio of 1.3/1. Ninety-one patients were eligible for R-CHOP treatment. The median follow-up was 41 months. Out of the 90 cases analyzed by immunohistochemistry CD 10, BCL2, BCL6 and MUM1 expression was found in 17.6%, 50.5%, 72.7% and 81.8% of cases, respectively. Negative expression for CD10, as well as positive expression of BCL2, were adverse prognostic factors for 3-years overall survival (OS) and disease free survival (DFS) (OS for bcl2: 72.3 vs 89.7, p<0.05, OS for CD10: 84.1 vs 75.1, p<0.05). BCL6 and MUM1 expressions, however, did influence neither OS nor DFS.

**Summary/Conclusions:** This study confirms the prognostic value of a multi-marker assessment which includes bcl2, bcl6, CD 10 and MUM1 expression for patients R-CHOP therapy.

---

**LYMPHOID NEOPLASMS: A REALLY IMPORTANT TRIGGER IN HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS**

V. Martínez Robles1,*, S. Calleja2, B. Ballina1, S. Cerdá1, S. Fernández-Ferrero1, F. Escalante1, F. Ramos1, J.A. Rodríguez-García1

1Hematology and Hemotherapy, 2Immunology, Complejo Asistencial Universitario de León (CAULE), León, Spain

**Background:** Triggered by several conditions Hemophagocytic lymphohistiocytosis (HLH) is an unusual, aggressive and life-threatening dysfunction caused by an excessive immune activation. It has become more recognized over the past decade. HLH was first described in 1939 by Scott and Robb-Smith, next case was reported in 1952 by Farquhar and Claireaux describing two infant siblings with progressive and lethal cytopenias, hepatosplenomegaly, and fevers with autopsy showing hemophagocytosis. A lengthy and unstoppable activation of antigen-presenting cells (macrophages, histiocytes) and CD8+ T and NK cells is characteristic. This condition leads to an important hyperinflammatory situation and organ damage including splenomegaly, fever, cytopenia, hypertrigliceridemia and/or coagulopathy. Histiocyte Society (HS) criteria have been applied for diagnosing HLH, however not all of them are usually showed at the presentation. This disease can be described in two different scenarios: primary (usually in children, genetic, and known as familial form) and secondary (acquired). It can be triggered by a large variety of events that disrupt immune homeostasis. When we talk about triggers, we can divide them in two broad categories, those that cause immune activation and those that lead to immune deficiency. Lymphoid neoplasms can be both.

**Aims:** Due to the lack of publications about HLH secondary to Lymphoid Neoplasms (LN), we would like to analyze the casuistry of our hospital and making a comparison with the current literature.

**Methods:** We conducted a retrospective analysis through medical files of all patients with suspected diagnosis of HLH between 1994 and 2017 in our inpatient ward. Clinical features, age, diagnostic criteria proposed by the HS, etiology, treatment and evolution were analyzed. In our study 18 out of 50 patients met the requested criteria for HLH diagnosis.

**Results:** We report 10 LN secondary cases (4 males, 6 females). The median age at diagnosis was 60.5 years, ranged between 46 and 80 years. In all of them, but in one, who presented long-term pancytopenia, symptoms were developed very fast. The most frequent causes of consultation were cytopenia and general syndrome. In two of them HLH was diagnosed with LN relapse, in one patient during a transformation from a low-grade B-cell lymphoma to DLBCL (Diffuse large B-cell lymphoma), in 6 of them we diagnosed LN and HLH concomitantly, and in the last one coinciding with a Richter Syndrome. Four of 10 were secondary to T-cell neoplasm. All patients met 5 o more HS diagnostic criteria. In only 3 of them HLH was healed. One patient is still in remission. Nine died, 7 of them due to HLH complications. Treatment was chemotherapy (depending on their LN) in almost all of them. Fluctuations were detected among activity HLH parameters due to LN response. Detailed characteristics of patients are shown in Table 1.

**Table 1.**

---
Summary/Conclusions: HLH triggered by LN is diagnosed in older patients than other causes secondary HLH (46-60 vs 4-8 y/o in our center), we think this is because in our experience there are not children or Young adult in HLH due to LN group. We would like to highlight that although LN is a very common HLH trigger there are a few works describing them in the literature, that is why we would like to spread our experience. We would like to emphasize in the importance of an early diagnosis. Despite heagrinosis disease, is it still underdiagnosed, reaching the diagnosis most of the times after seeing hemophagocytic phenomena in bone marrow biopsy. Agreeing with literature, main consulting reasons are similar to our series. Correlation between neoplastic activity and immune activation, as well as test and facts which could predict evolution should be more studied. Finally we would like to address the necessity of considering this possibility in the face of a patient with fever which does not respond to antibiotics and has not clarified citopenia, as well as the importance of conducting cheap and very profitable test such as ferritin or tryptophan level when symptoms or clinical features of lymphoid neoplasms are not concordant with the expected evolution.

PB2083 MARAH, A NATIONAL NETWORK FOR RARE IMMUNOHematological Disorders

Background: Health networks focused on rare diseases were created following health networks focused on rare diseases were created following: MaRiH is involved in organizing annual events, one for patients and another one for professionals. Moreover, MaRiH supports successfully the application of several of its members for European reference networks (Figure 1).

Figure 1.

Summary/Conclusions: The creation of these new networks allows strengthening the links between the various actors involved in the field to improve care and answer transversal questions. In this way, MaRiH pilot concerted actions to all its members around immunohematological rare diseases by: 1- increasing the visibility of the actors on the web or during events. The MaRiH website includes all the informations of the members as well as recommendations and events (www.marih.fr), 2- communication and training. MaRiH organizes two annual events, one for patients and another one for professionals. Moreover, MaRiH organizes two annual events, one for patients and another one for professionals. Moreover, MaRiH sends clinical cases by email to professionals and produce an annual webcast. 3- pushing forward research development and epidemiological surveillance. Thanks to his research project manager, MaRiH facilitates the submission of its members for European reference networks (Figure 1).

PB2084 CLINICAL FEATURES AND THERAPY OF PATIENTS WITH THROMBOTIC MICROANGIOPATHIES

Ü. Ergene1*, C. Özlü1

1hematologie, saglik bilimleri university, izmir, Turkey

Background: Thrombotic microangiopathy (TMA) is a heterogeneous group of disease that has a fatal pattern of endothelial damage. TMA can be found in association with diverse clinical conditions such as carcinoma metastasis, malignant hypertension, infections, and TTP (thrombotic thrombocytopenic purpura). TTP is a rare, life-threatening multisystem disease, characterized by microangiopathic hemolytic anemia, thrombocytopenia, fever, renal dysfunction, and neurological disorders.

Methods: The purpose of this study is to evaluate the etiology associated with TMA. Results: First patient presented with cachexia, thrombocytopenia, and TMA. He did not respond to plasmapheresis and corticosteroid treatment. We diagnosed carcinoma metastasis and liver metastasis, respectively, through bone marrow biopsy and PET (positron emission tomography). We thus ascertained that TMA was due to carcinoma unknown primary. The second patient presented with general neurological findings like Guillain-Barre Syndrome and paraplegia with renal failure, thrombocytopenia, and TMA. After PLEX and corticosteroid treatment, laboratory and neurological clinical recovery were observed after one month. The third patient had chronic obstructive pulmonary disease and pneumonia in anamnesis, who presented with anaemia, thrombocytopenia, fever and pneumonia findings. We conducted PLEX therapy. On the 8th day of PLEX, the patient had anaphylaxis, we performed cardio pulmonary resuscitation. The fourth patient January 30th 2016 in Paris to inform on the update status of research on their disease as well as to help patients in daily common problems (sport, psychological, transusion…). Pushing forward research development and epidemiological surveillance: the network has appointed a research project manager for its scientific and strategic committee to support, provide stability for and add value to research centre activities. The research project manager watch out for calls for tenders, set-up of new registers and continually monitor the regulations for retrospective and prospective studies, both in France and at the international level. Furthermore, MaRiH supported successfully the application of several of its members for European reference networks (Figure 1).
presented with acute renal failure with malignant hypertension. We performed hemodialysis together with PLEX treatment. Because his diagnosis was acute renal failure, malignant hypertension, and TMA. The fifth patient presented with epis-taxis and sepsis. He had chronic TTP diagnosis for two years ago. We diag-nosed the patient as relapse TTP. Early treatment against infection and PLEX increased his platelet counts as early as the second day of treatment. The sixth patient was diagnosed with a fever that had been going on for five days. We treated the patient with PLEX together with the corticosteroid. Because his ADAMTS13 level was very low and he had 35% schistocytes.

Table 1.

Summary/Conclusions: We diagnosed our first patient with carcinoma unknown primary, who did not respond to PLEX and corticosteroid treatment. The results we received for that patient indicate that PLEX with corticosteroid treatment alone, remain ineffective in cancer-related TMA patients. Etiology of our second patients TMA was idiopathic. His clinical and laboratory findings improved rapidly in response to PLEX and pulsed corticosteroid treatment. One viral infection induced TMA patient had anaphylactic reaction receiving his 8th PLEX. Allergic reactions should always be kept in mind when administering PLEX. One patient with TMA and malignant hypertension-induced renal failure was successfully treated with PLEX, hemodialysis and antihypertensive treat-ment. We successfully treated our bacterial infection and sepsis-induced TMA patients with PLEX and antibiotic administration. In second TMA patient, we coupled PLEX with high dosage corticosteroid treatment even though he had an infection. For he had high schistocyte count and atypical neurological find-ings. ADAMTS 13 activity may only be a guide for diagnosis of TTP, but it is unreliable for a definitive one. In conclusion, diagnosis of TTP and other TMA is difficult. Etiology, clinical features, laboratory findings should all be taken into account when diagnosing TMA. While it is established that ADAM TS13 defi-ciency is the major cause in acquired TTP, finding the etiology of other TMA's is determinant for a successful treatment of the latter.

PB2085

HAEMOYSIS AS SCREENING TEST IN lysosomal STORAGE DISEASES

L. López De Frutos1,2, J.J. Cebolla1,3,4, P. Irún1,2, P. Giraldo1,2,3
1Unidad de Investigación Traslacional. Hospital Universitario Miguel Servet, Fundación Española para el Estudio y Terapéutica de la Enfermedad de Gaucher y Otras Lisosomas (FEETEG), 2Unidad de Investigación Traslacional. Hospital Universitario Miguel Servet, Centro de Investigación Biomédica en Red En Enfermedades Raras (CIBERER), 3Departamento de Bioquímica, Biología Molecular y Celular, Universidad de Zaragoza, Zaragoza, Spain

Background: Lysosomal storage disorders (LSDs) are a group of rare inherited metabolic diseases, whose clinical hallmark is organomegaly among others, due to progressive accumulation of several non-catalyzed products inside the lysosomes. This storage leads to intracellular oxidative stress status triggering oxidized metabolites production as oxysterols, which are related to apoptosis and cellular erosis, as well as haemolysis dysregulation.

Aims: To evaluate the link between LSDS and haemolysis and if it could be used as a screening test in LSDs.

Methods: The osmotic resistance test (ORT) was evaluated in 150 samples including controls, LSDs carriers (LSDs-C) and LSDs patients (LSDs-P). Briefly, the blood was mixed with different concentrations of sodium chloride solution (NaCl) and the haemoglobin released was quantified by spectrophotometry. The raw data was normalized using isotonic solution (0.9% NaCl). The statistical analysis (non-parametric tests and ROC curves), was computed by IBM SPSS statistics v22 software and all statistical tests will be considered and taken as bilateral significance level α = 0.05.

Results: The analysis showed that haemolysis at 0.48% of NaCl allow us to sort out controls vs LSDs-C/LSDs-P (AUC 0.729) whereas no significant diff-erences were observed between LSDs-C and LSDs-P (p-value > 0.05).

Summary/Conclusions: According to our results the ORT test is an useful screening test in LSDs.

CLINICAL SIGNIFICANCE OF ELEVATED SERUM COBALAMIN (VITAMIN B12) LEVELS

M. Tekin Bajini1, E. Sabancan2, S. Akyan2, S. Aylaci1, M. Çetin1, F. Gümrük1
1Pediatric Hematology, 2Pediatrics, Hacettepe University, Ankara, Turkey

Background: Hypercobalaminemia is a frequent but underestimated abnor-mality. Elevated serum cobalamine levels may be a sign of a wide range of dis-eases like solid neoplasms, haematological disorders like myelodysplastic syn-dromes, chronic myelogeneous leukemia, promyelocytic leukemia, poly-cythemia vera, hyperesoinophilic syndrome as well as liver and kidney dis-eases.

Aims: We aimed to evaluate the underlying disorders of the patients with high cobalamin levels (>1000 pmol/l) between 01.02.2016- 01.02.2017 in Hacette-pe University Pediatric Hematology Department.

Methods: We investigated the patient records of the patients examined between 01.02.2016- 01.02.2017 in our department and included the patients with serum cobalamin levels higher than 1000 pmol/l. We excluded the patients who are taking Vitamin B12 supplement.

Results: There were 46 patients with serum cobalamin levels higher than 1000 pmol/l out of 14367 patients seen between 01.02.2016- 01.02.2017 in our department. The reason to check the cobalamin levels were anemia, neu-tropenia and thrombocytopenia in most of the patients. Only 2 patients were referred to our department because of hypercobalaminemia. The underlying disorders were found to be leukemia in 3 patient (Acute lymphoblastic leukemia (ALL) n:1, acute myeloblastic leukemia (AML) n:1, large granular lymphocytic leukemia (LGLL) n:1), myelodysplastic syndrome (MDS) in 2 patients, isolated thrombocytopenia in 4 patients, isolated neutropenia in 7 patients, bicytopenia in 4 patients and aplastic anemia in 2 patients, cobalamin metabolism defects in 10 patients, hypereosinophilia in 2 patients, polisitemia in 1 patient, cystic fibrosis in 1 patient, HIV in 1 patient, FMF (familial mediterrenian fever) in 1 patient, chronic kidney failure in 2 patients, sickle cell anemia in 1 patient, factor V Leiden in 1 patient, thrombosis in 1 patient, diphtheria in 1 patient and epistaxis in 1 patient.

Summary/Conclusions: An observed elevation of cobalamin merits the a full diagnostic work up to assess the presence of an early diagnostic marker of these diseases. When we look at the patients except hematological neoplasm and cytopenias, most of the underlying reasons is associated with inflammation and infection, cobalamin was found to be elevated as an acute fase reactant. A certain approach is needed whether to determine the potential indications to search for high serum cobalamin levels and to determine the practical clinical strategy when elevated cobalamin levels discovered.

PB2087

THE HEMATOLOGIC FINDINGS OF INHERITED METABOLIC DISEASE; THEY ARE MORE THAN EXPECTED

I. Yenicesu1, A.E. Sai2, I. Oktu2, Z. Kaya1, F.S. Ezgu2, U. Kocak1, L. Tumer2
1Pediatric Hematology, 2Gazi University, Faculty of Medicine, Ankara, Turkey

Background: Inherited metabolic diseases are pathological conditions that generally develop as a result of impairment of the production or breakdown of protein, carbohydrate and fatty acids. Hematological problems are some of the most frequently observed findings of inherited metabolic diseases. These may be seen together with other systemic findings or sometimes as the first and only diagnostic clues. The etiology of hematological findings has a positive effect on the prognosis of metabolic diseases.

Aims: The aim of this study is to evaluate the incidence of hematological findings in inherited metabolic diseases since there are a few studies about the true incidence in literature.

Methods: Three hundred eighteen patients who were being followed-up within the previous 6 months at Gazi University Department of Pediatric Nutrition and Metabolism, Turkey, were included in the study. Patients’ hematomal findings were taken from Department of Pediatric Nutrition and Metabolism and hospital data-processing records. Since patients were in different age groups, hematol-ogical findings were compared with normal values for each patient’s age group. The hematological findings were classified under seven main groups; anemia of chronic disease, iron deficiency anemia, vitamin B12 deficiency anemia, hemochromatosis, leukocytosis and thrombocytosis. Metabolic diseases were classified according to the textbook of Inborn Metabolic Diseases: Diagnosis and Treatment.

Results: Nine hundred twenty-two hematological examinations of the 318 patients were included to the study, and 282 hematological findings were deter-mined, 127 anemia of chronic disease, 80 iron deficiency anemia, 56 cytopenia and four vitamin B12 deficiency anemia. Leukocytosis (n=1), thrombocytosis (n=5) and hemochromatosis (n=9) were also observed.

Summary/Conclusions: It was determined that although anemia of chronic disease and nutritional anemia are the most common hematological findings, these may be diagnosed late, while neutropenia, thrombocytopenia, pancy-topenia and hemostasis may be diagnosed earlier. Metabolic dis-eases must be considered in the evaluation of cytopenias, particularly in cases with an atypical cause that are resistant to treatment and have additional accompanying findings. Our study is the most comprehensive one in the literature.
Hematoxic effects of generic triazole fungicides

Background: Pesticides are extensively used in agriculture today. Fungicides based on derivatives of triazole are the most widespread all over the world. Tebuconazole (TB) is one of the most frequently used substance of this group. Literature review confirms that fungicides have the ability to cause different hematoxic effects.

Aims: Since 2007-2016 years we have investigated 10 test-substances of generic tebuconazole (purity up to 97%) from different manufacturers with purpose to assess their hematoxic action on males Wistar Han rats peripheral blood in the subchronic 90-days oral toxicity study (according to SOP and OECD 408 recommendations in compliance with GLP).

Methods: The Wistar Han males were randomly allotted to four groups. The input controls of peripheral blood parameters were conducted after a period of animals acclimatization. The goal was to evaluate the physiological state of the Wistar Han rat and the blood picture in case of treatment. Dosimetry 100, 200, 400, and 500 mg/kg bw/day were defined and were the same in all studies. Blood samples for hematological measurements were examined at 4, 9, 13 weeks after TB exposure in the same groups of animals throughout the experiment. Hemoglobin (HGB) concentration, hematocrit (HCT), total amount of erythrocytes (RBC), white blood cells (WBC) and platelets (PLT), mean corpuscular hemoglobin (MCH) were evaluated.

Results: As a result, all generic TBs on high toxic doses level (200 mg/kg/bw/day) had shown the tendencies for quantitative hematological changes. TBs mainly provoked the significant decrease of HGB concentration and RBC count on 4th and 9th weeks of exposure. Morphological changes of RBC (anisocytosis) were seen too. It means that generic TBs had anemic effect. In general, changes of hematological parameters were not principally significant and did not differ from control values at 13th weeks of experiments, except two TBs, which had shown significant decrease of HGB. Also some of generic TBs on high toxic doses level (leukocytosis) or low WBC count in peripheral blood. In case of generic pesticides, the presence of impurities can demonstrate various hematoxic action. Also the adverse effects on peripheral blood of males Wistar Han rats were observed at a dose of 50 mg/kg/bw/day and demonstrated the lesions of red blood. But abovementioned changes were not clearly expressed. Any adverse hematoxic effects at 10 mg/kg/bw/day dose were not observed in all studies.

Summary/Conclusions: As a conclusion, due to our results the triazole fungicides generic tebuconazole have hematoxic action. They induce anemia in Wistar Han rats and quantitative white blood cells changes. Today it is very important to investigate the hazardous effects of pesticides on the blood system.
Summary/Conclusions: Immunosuppressive therapy including cyclosporine with or without steroid has been reported as the most effective treatment to primary acquired PRCA. Consistently, we had a dramatic response to immuno-suppressive therapy in our patient.

PB2091

APLASTIC ANEMIA IN CHILDHOOD: A TEN YEARS’ SINGLE CENTER EXPERIENCE

A. Apsemidou1,2, T.-S. Tsioila1, A. Tragiannidi1, E. Chatzipanteli1, M. Papageorgiou1, L. Damianidou1, T. Papageorgiou1, T. Koleta2,3, A. Giannopoulos3

1Pediatrics-Pediatric Hematology/Oncology, 2Pathology, 3Pediatrics-Pediatric Cardiology, AHEPA University Hospital, Thessaloniki, Greece

Background: Aplastic anemia in childhood is a rare, life-threatening disorder, characterized by peripheral blood pancytopenia and a hypocellular bone marrow without signs of dysplasia or fibrosis. Acquired aplastic anemia needs to be distinguished from inherited bone marrow failure syndromes or myelodysplastic syndromes.

Aims: The aim of this study is to assess the clinical and laboratory findings at the time of diagnosis, the treatment approach and the outcome of children with aplastic anemia treated in our department during the past decade.

Methods: This retrospective study evaluated 9 children with aplastic anemia, who were treated and followed up in the Pediatric Department of AHEPA, during the period 2006–2016.

Results: We identified 9 children with aplastic anemia. The patients’ population included 6 (66.7%) males and the mean age at admission was 9.7 years. At the time of diagnosis, the average neutrophil count was 750/mm3, the Hb count was 8.4mg/dl and platelets count was 8770/mm3. In all of our cases aplastic anemia was acquired, expect one case of Fanconi anemia. Predisposing risk factors (including drugs exposure, viral infections, chemicals) were identified in 4 patients. Among the 9 studied patients, 3 (33.3%) had bone marrow failure; severe 2 (22.2%) and severe 4 (44.5%) had very severe aplastic anemia. All of the patients received immunosuppressive therapy (consisting of antithymocyte globulin, cyclosporine A and steroids). 2 remained transfusion independent, 4 underwent bone marrow transplantation. In 4 patients, a matched related donor and 2 from a matched unrelated donor. One patient with refractory disease received, as an alternative first line therapy, etromobopag. Complete response was achieved in 22.2%, partial response was achieved in 22.2%, relapse occurred in 11.1% and 44.5% of the patients had refractory disease. The overall survival was 77.8%.

Summary/Conclusions: A remarkable progress has been made during the past decades in the understanding of pathogenesis and management of children with aplastic anemia. Bone marrow transplantation from a matched related donor is the recommended first line therapy resulting in an excellent survival rate that exceeds 90%. In the future the development of targeted strategies for patients who have failed allo-HSCT will further improve outcome and diminish the disease’s late complications.

PB2092

CAUSES OF IRON DEFICIENCY ANEMIA IN THE HEMATOLOGY CLINIC – SINGLE CENTER EXPERIENCE

M. Ionita1,2,3, L. Ionita1,2,3, I. Ionita1,2,3, D. Calamar1, D. Oro1, V. Todorescu1, C. Ionita1,2,3, C. Sorica1, H. Ionita1,2,3

1Hematology, University of Medicine and Pharmacy Victor Babes Timisoara, Timisoara, Romania

Background: Iron deficiency anemia (IDA) is the common nutritional deficiency worldwide. The studies concerning various causes of IDA in adult men are rare, although it is assumed that chronic gastrointestinal blood accounts for the majority.

Aims: Of the study is to evaluate retrospectively adult men with IDA that were hospitalized in our Hematology Clinic.

Methods: Two hundred fifteen male with IDA were enlisted at this study from January 2005 to December 2015. Anemia was defined as Hg <13g/dL using the WHO criteria. IDA was considered present if serum ferritin was 15 ng/mL combined with serum iron concentration <30ug/dL with a transferrin saturation of <10%. Complete physical examination, the history of the disease and fecal occult blood test (FOBT) of three spontaneously passed stools was done in all patients. All patients had complete blood count, serum and total iron binding capacity, and a serum ferritin level. Most patients underwent esophagogastroduodenoscopy (EGD). Colonoscopy was performed if lesion that caused IDA was not found, and/or FOBT was positive. The abdominal CT scan were performed according to clinician’s recomandation together with other tests related with blood lost.

Results: The median age was 62 (range 32 to 89) years old. 168 of 215 (78.13%) men with IDA had symptoms such as fatigue, dizziness, or digestive complaints. The history of prior gastrectomy, hemorrhoid, that probably had caused IDA were reported in 32 (14.88%), 43 (20.0%), patients, respectively. FOBT was positive in only 65 (30.23%) subjects. 170 (79.08%) patients underwent EGD. The most common findings from EGD were gastritis (48 patients) and peptic ulcer (39 patients). Seventy eight (36.27%) patients were found to have upper gastrointestinal disorders (20 patients with erosive gastritis, 19 gastric ulcer, 16 duodenal ulcer, 23 gastric cancer. Eighty-nine (41.39%) patients underwent colonoscopy. That showed 44 clinically important lesions that probably caused IDA; colon cancer in 17 (7.90%) patients, colon polyp in 10 (4.65%) patients and hemorrhoid in 17 (7.90%) patients. Concerning malignant lesions which are responsible for IDA, the malignant lesions were found more frequent in patients older than 50 years accounting for 20.45% (27/132 patients) and patients younger than 50 years 17.80% (13/73 patients).

Summary/Conclusions: This study demonstrated that gastrointestinal blood loss is the main cause of IDA in adult men, and that there is a high rate of malignancy in men older than 50 years.

PB2093

IMPACTS OF CLINICAL AND BIOCHEMICAL PARAMETERS ON KEY HEMATOLOGICAL INDICES IN ADULTS: A COHORT STUDY

C.-C. Chen1,*, M.-H. Lin2, Y.-H. Yang3, C.-E. Huang1, H.-Y. Tsou1, C.-C. Hsu1, Y.-Y. Wu1

1Department of Medicine, 2Center of Excellence for Chang Gung Research DataLink, 3Department of Traditional Chinese Medicine, Chang-Gung Memorial Hospital, Chiayi, Chiayi, Taiwan, Republic of China

Background: Studies in Caucasians have shown that values of hematological parameters could be affected by a wide variety of factors, most notably age and gender. However, parallel work in different ethnic populations, especially from Asia-Pacific region, is lacking. Importantly, it remains largely unknown whether some fundamental variables such as nutritional status, lipid profile, and hepatitis infection (either HBV or HCV) also affect the variation of values in hemogram.

Aims: Therefore, we conceptualize this study to explore through several key parameters regarding their potential impacts on the changes of hemogram.

Methods: Adult individuals aged 18 or older from several adjacent villages in Yun-Lin County, located in the central part of western Taiwan, who came to our hospital for annual health exams were screened for the current study. The work, retrospective in nature, was approved by institutional IRB. Information on age, gender, hemogram, levels of total cholesterol (TC), triglyceride (TG), apolipoprotein B (Apo B) as well as albumin, and results of serological testing for hepatitis B and C infection were obtained from a centralized digital data base. All the clinical data, after given a coding number for each case, were encrypted and provided to the investigators without identifiable personal information. We analyzed the impacts of various parameters on several key hematological indices.

Results: Overall, 26,497 individuals were included in the current analysis after excluding those with hemogram data fell outside of normal range. Carriers of either hepatitis B (HBV) or C (HCV) who had abnormal liver function (defined by elevated levels of aspartate transaminase or alanine transaminase) were excluded as well. Age, gender, and serum levels of TC, Apo B, and albumin all significantly impacted most key hematological profiles. As the levels of TC and Apo B correlated well with each other (correlation coefficient r=0.82211, p<0.0001, Pearson’s correlation), we did not incorporate TC in our multi-variate analysis. Several key variables were found to influence some hematological indices in the multi-variable regression model. Increasing age and male gender negatively affected the platelet count, whereas higher Apo B level was associated with elevated platelet count. Surprisingly, hepatitis C carriers with normal hepatic function had slightly higher platelet number than non-HCV carriers. Gender and serum albumin level were the major determinants of variation in hemoglobin. Total white cell count increased with male gender and elevating Apo B level but was inversely correlated with change in age and serum albumin level (Table 1).

Table 1.

Summary/Conclusions: The hematological indices are influenced by a wide variety of factors, especially age, gender, and serum level of Apo B. As age, gender, and serum levels of TC, Apo B, and albumin all significantly impacted most key hematological profiles. As the levels of TC and Apo B correlated well with each other (correlation coefficient r=0.82211, p<0.0001, Pearson’s correlation), we did not incorporate TC in our multi-variate analysis. Several key variables were found to influence some hematological indices in the multi-variable regression model. Increasing age and male gender negatively affected the platelet count, whereas higher Apo B level was associated with elevated platelet count. Surprisingly, hepatitis C carriers with normal hepatic function had slightly higher platelet number than non-HCV carriers. Gender and serum albumin level were the major determinants of variation in hemoglobin. Total white cell count increased with male gender and elevating Apo B level but was inversely correlated with change in age and serum albumin level (Table 1).
Background: Primary immune thrombocytopenia (ITP) is a rare hematological disease with unknown etiology. It is characterized by heterogeneity of the laboratory parameters as well as the features of clinical manifestation. DNA polymorphism of several cytokine genes has been suggested to modulate the risk of ITP development and/or treatment response in distinct population groups. There is no data on the prevalence of cytokine gene polymorphisms in ITP patients from the North-Western region of Russia (NWR).

Aims: To establish the features of genotypes distribution for several cytokine promoter gene polymorphisms in ITP patients from NWR.

Methods: A total of 68 patients (59 women and 9 men) with chronic primary ITP were involved in the study. The median age of the group was 57 years (range: 24-77). The mean duration of ITP was 7 years (2-48). In 19 (32.2%) women, ITP was diagnosed before 30 years old; 26 (38.2%) patients (5 men and 21 women) were diagnosed at age 30-50 years; 23 (33.8%) patients (9 men and 19 women) developed ITP after 50 years old. The control group consisted of 240 healthy persons originated from NWR. Nucleotide variations in the genes coding for interleukin (IL)-1b (-31/T/C), IL-6 (-174/G/C), IL-10 (-592G/A) and tumor-necrosis factor alpha (TNFA -308 G/A) were discriminated by PCR and subsequent restriction analysis (PCR-RFLP). Intergroup differences in genotype frequencies were assessed by Fisher’s exact method. Odds ratios (OR), their 95% confidence intervals (CI) and p-values were calculated by using the GraphPad Prism 5.0 software.

Results: The frequency of the IL-10 -592CC genotype was slightly increased in the ITP group when compared to controls (65.7% vs 54.0% respectively; OR=1.6, 95% CI: 0.9-3.1, p=0.15). Interestingly, this variant of the IL-10 gene was more prevalent among women than men with ITP (71.2% vs 25.0% respectively; OR=7.4, 95% CI: 1.4-40.5, p=0.016). When compared to controls, the IL-10 -592CC genotype was significantly overrepresented in the group of women with ITP (71.2% vs 54.0%; OR=2.1, 95% CI: 1.1-4.2, p=0.044). On the contrary, in the group of affected men we observed the increase of persons who had IL-10 -592A allele (75.0% vs 46.0% in control group; OR=3.5, 95% CI: 0.7-18.3, p=0.15). Genotype frequencies for other studied genes were similar between the patients and control group as well as between women and men with ITP. We have also found almost 2-fold increase of the IL-1b -31CC frequency in women diagnosed before 30 years old compared to other patients (15.8% vs 8.2% respectively; OR=2.1, 95% CI: 0.4-10.5, p=0.39). The presence of the TNFA -308A allele was more often seen in patients diagnosed before 50 years old (26.7% vs 8.7% in other ITP patients; OR=3.8, 95% CI: 0.8-18.8, p=0.12).

Summary/Conclusions: We suggest that the IL-10 -592CC genotype is associated with increased risk of ITP from women in NWR. On the other hand, the IL-10 -592A allele could be involved in pathogenesis of ITP in men. Further studies are needed to clarify the significance of TNFA and IL-1b gene polymorphism in ITP development.

Platelets disorders

COMBINED TREATMENT OF AZATHIOPRINE AND ROMIPLOSTIM IN PATIENTS ITP REFRACTORY TO STEROIDS OR THROMBOPOIETIN ANALOGS

M. E. Mingot-Castellano1, I. Sánchez-Bazán1, J. Díez-Pastor1

1Hematology, Regional University Hospital of Málaga, Málaga, Spain

Background: More than 70% of patients with Immune Primary Thrombocyto -penia (ITP) respond to steroids, but 40 to 70% relapse in the first year fol low-up. The use of romiplostim in this group is effective, although 8% failure has been described. In recent literature, there are clinical cases and small series describing the potentiating effect of combined treatment with throm bopoietin analogues and immunosuppressive drugs such as steroids, cyclophosphamide and rituximab. We have not found references to the combined use of azathioprine (AZA) and romiplostim (ROM).

Aims: To describe our experience in the combined use of azathioprine and romiplostim as a rescue treatment in patients with acute or newly diagnosed ITP refractory to corticosteroids or corticosteroid-dependence and refractory to maximal doses of romiplostim monotherapy.

Methods: We analyzed patients with newly diagnosed or persistent ITP, with corticosteroid-dependence or refractory to steroids or refractory to romi -plostim, both in monotherapy. We have considered refractoriness to steroids not reaching platelets higher than 30x109/L. Corticosteroid-dependence as the need for ongoing or repeated doses administration of corticosteroids for at least 2 months to maintain a platelet count at or above 30 x109/L and/or to avoid transient bleeding episodes. We considered refractoriness to romiplostim not getting platelets greater than 30x109/L with 10mg/kg/week for at least 3 consecutive weeks. All patients have been diagnosed in a single center with the same physician responsible for the treatment and follow-up. The initial doses of AZA was 100mg/days (2mg/kg/day) and ROM 10mcg/kg/week. Patients have been evaluated every week until platelets were higher than 30x109/L for to consecutive weeks, after this they were reviewed monthly.

Results: We treated 4 patients (75% female) with a median age at diagnosis of ITP of 53 years old (IQR, 20-61 years). Treatments received prior to the use of the combination of AZA and ROM were polyclonal immunoglobulins ( Ig), corticosteroids, methotrexate and cyclophosphamide. We have not found references to the combined use of azathioprine and romiplostim in monotherapy were: • Median dexamethasone cycles (40mg/days x 4 days) was 2.5 (2-4 cycles, IQR). The initial dose of prednisone was 1-2mg/kg/days with a median treatment day of 31.5 days (28-60 days, IQR). The type of response to steroids was PR with corticosteroid-pendence in one patient, 3 patients NR. • Median time from ITP diagnosis and romiplostim indication was 9.5 weeks (7-48 weeks, IQR). Median platelets count at the start of romiplostim was 6x109/L (2-13x109/L, IQR). The median platelet count achieved at maximal doses of romiplostim for at least 2 consecutive weeks was 10x109/L (3-19x109/L, IQR). Once established the refractoriness to romiplostim, we maintained ROM 10mcg/kg/week and AZA was initiated at 100mg/day. The median time from romiplostim indication to the association with azathioprine was 9.8 weeks (5.5 to 15 weeks, IQR). The median time to response after initiation of combination of AZA and ROM was 21 days (15-35 days, IQR). The type of response were: • One patient did not respond after 60 days of maintenance of 1 patient with RC of 7 months in the absence of active treatment. The combined was necessary during 6 months. • 2 CRs still undergoing combined dose reduction (current dose romiplostim 2mcg/kg/week and azathioprine 50mg id). Median platelets from onset of dose reduction 169x109/L (128-176x109/L, IQR). Duration of RC, 7 and 14 months. Non adverse events have been described in combination treatment.

Summary/Conclusions: The use of azathioprine and romiplostim in combination could be a safe and effective alternative in subjects refractory to steroids or corticosteroid-dependence and thrombopoietin analogs alone. More studies are needed to clarify the mechanism of complementation between the two drugs.

UNUSUAL DISTRIBUTION OF INTERLEUKIN-10 C-592A GENE POLYMORPHISM IN PATIENTS WITH PRIMARY IMMUNE THROMBOCYTOPENIA FROM NORTH-WESTERN RUSSIA

S. Kapustin1, I. Zotova2, S. Gritsaeva2, I. Sidorova1, L. Pavlova3, A. Pavlova3, S. Bessmeltsev2

1Laboratory of Biochemistry, 2Russian Research Institute Of Haematology And Transfusiology, Saint-Petersburg, Russian Federation, 3Laboratory of Immuno -hematology, Russian Research Institute Of Haematology And Transfusiology, Saint-Petersburg, Russian Federation

Apo B, white cell count, and platelet count all impose risk of thromboembolism, further work exploring the determinants and impacts of these parameters on the development of cardiovascular diseases should be mandatory.
Aims: Our objective was to assess a possible correlation between bleeding and platelet function in thrombocytopenic hematopoietic- oncological patients.

Methods: Inclusion was possible for admitted hematopoietic- oncology patients aged 18 years and above following written informed consent. Furthermore, an expected need for platelet transfusions was necessary. Bleeding was graded according to the WHO bleeding scale. Platelet reactivity to stimulation by either adenosine diphosphate (ADP), crosslinked-collagen-related peptide (CRP-XL), PAR-1- or PAR4-activating peptide (AP) was measured using flow cytometry.

Results: A total of 114 evaluations were available from 21 consecutive patients. Platelet reactivity in response to stimulation by all four studied agonists was inversely correlated with significant bleeding. Odds Ratio’s (OR) for bleeding were 0.23 for every unit increase in median fluorescence intensity (MFI) [95% Confidence interval (CI) 0.11-0.73] for ADP; 0.59 [0.40-0.87] for CRP-XL; 0.59 [0.37-0.94] for PAR1-AP and 0.43 [0.23-0.79] for PAR4-AP. The platelet count was not correlated with bleeding (OR 0.99 [0.96-1.02]).

Summary/Conclusions: The examind-induced platelet reactivity was significantly correlated to bleeding. Platelet function testing could provide a basis for a personal- ized transfusion regimen, in which platelet transfusions are limited to those at risk of bleeding.

PB2097

TUMOR NECROSIS FACTOR-A AND TUMOR NECROSIS FACTOR-B SINGLE NUCLEOTIDE POLYMORPHISM AND CHRONICITY IN EGYPTIAN PEDIATRIC PATIENTS WITH IMMUNE THROMBOCYTOPENIA

N. El-Gharbawi1, G. Shahin1, A. Eid1, N. Diaa1, M. El-Ghamrawy2,4

1Clinical and Chemical Pathology, 2Pediatrics, Faculty of Medicine, Cairo University, Cairo, Egypt

Background: Although the etiology of immune thrombocypenic purpura (ITP) remains unclear, both genetic and environmental factors may contribute to the development of disease. Tumor necrosis factor alpha & beta (TNF-a and TNF-β) are inflammatory cytokines that play a role in regulation of cell differentiation, proliferation and death, as well as in inflammation, innate and adaptive immune responses, and have been implicated in a wide variety of human diseases. We hypothesized that inflammatory cytokine genes polymorphisms (TNF-α and TNF-β) in ITP pediatric patients may play a fundamental role in pathogenesis of the disease or even of the development of the disease (p=0.001) compared with newly diagnosed/persistent group (57% vs 21% and 79% vs 9%, respectively). Recent history of infection was found mainly in newly diagnosed/persistent group (70% vs 21%, p=0.03). Platelet count below 10 x 109/L at diagnosis was found more frequently in newly diagnosed/persistent group (79% vs 36%, p=0.01). Similar, but not statistically significant difference, was found with mucosal bleedings (70% vs 50%, p=0.81). Children with newly diagnosed/persis- tent disease had less frequently impaired immunological markers (12% vs 65%, p=0.008 respectively). We received more than intravenous gamma globulin and/or cortico- costeroids (p<0.05). None of the children exhibited severe spontaneous bleeding.

Summary/Conclusions: Even though ITP in children is usually a self-limited disease, with rare serious bleeding complications, the newly diagnosed/persis- tent and the chronic form of the disease are characterized by different pre- dictive parameters that can be used in clinical practice.

PROGNOSTIC FACTORS IN PRIMARY IMMUNE THROMBOCYTOPENIA OF CHILDHOOD

A. Gkoutsias1, T. Palianopoulos1, E. Papae1, E. Papapetrou2, C. Tsoupi3, N. Chaliassos1, A. Makis1,2

1Department of Pediatrics, 2Department of Internal Medicine, 3Hematology Laboratory, University Hospital of Ioannina, Greece, Ioannina, Greece

Background: Primary immune thrombocytopenia (ITP) is an immune disorder with varied course. According the duration of the disease, it is distinguished in newly diagnosed (<3 months), persistent (3-12 months) and chronic (>12 months). International studies have highlighted prognostic factors for each form of ITP, but similar studies have yet to be performed in Greece.

Aims: The evaluation of clinical and laboratory parameters and the identification of prognostic markers for the three forms of the disease in children with ITP from an academic reference center in Greece.

Methods: This retrospective study included 57 children with ITP in the past 13 years, aged 1-16 years (median age 5.2). The following data were recorded: age, gender, preceding infection, bleeding type, duration of symptoms and platelet count at the diagnosis, treatment, disease course and immunological markers and comparison was made among the three types of ITP.

Results: 39 children had newly diagnosed, 4 had persistent and 14 had chronic disease. Due to the small number of children with persistent form they were incor- porated in the group of children with newly diagnosed ITP. In chronic ITP children are more likely to be above 10 years of age (p<0.015) and to have gradual initiation of the disease (p=0.001) compared with newly diagnosed/persistent group (57% vs 21% and 79% vs 9%, respectively). Recent history of infection was found mainly in newly diagnosed/persistent group (70% vs 21%, p=0.03). Platelet count below 10 x 109/L at diagnosis was found more frequently in newly diagnosed/persistent group (79% vs 36%, p=0.01). Similar, but not statistically significant difference, was found with mucosal bleedings (70% vs 50%, p=0.81). Children with newly diagnosed/persis- tent disease had less frequently impaired immunological markers (12% vs 65%, p=0.008 respectively). We received more than intravenous gamma globulin and/or cortico- costeroids (p<0.05). None of the children exhibited severe spontaneous bleeding.

Summary/Conclusions: Even though ITP in children is usually a self-limited disease, with rare serious bleeding complications, the newly diagnosed/pres- ent and the chronic form of the disease are characterized by different pre- dictive parameters that can be used in clinical practice.
Background: Sepsis is a relatively common diagnosis in the neonatal period. Apart from blood cultures which are the gold standard, C-reactive protein (CRP), total white blood cell count (WBC) and the ratio of immature to mature neutrophils (I:T) are considered to be useful markers of sepsis in the neonatal period. There are a few studies that show that mean platelet volume (MPV) is elevated in infectious disease processes.

Aims: The aim of this study was to investigate whether mean platelet volume is increased in neonates with sepsis.

Methods: Only term neonates were included in the study. Exclusion criteria included: (a) Any neonate born with a genetic defect, (b) Any neonate with suspected immunodeficiency, (c) Any neonate requiring surgery in the post-natal period, (d) Neonates admitted to NICU for hyperbilirubinemia, (e) Neonates requiring extensive resuscitation at birth resulting in documented Hypoxic Ischemic Encephalopathy or requiring transfer to a Regional Perinatal Center. Medical records were reviewed from March 2015 to June 2016 and a total of 114 eligible neonates were included in the study and they were divided into 2 groups: Control (neonatal sepsis) and case (defined by either culture positivity and/or clinical features plus treatment with antibiotics exceeding 48 hours) and 75 healthy controls (as defined by neonates in whom antibiotics were never started or discontinued when cultures were negative for 48 hours and the absence of clinical features of sepsis). Total white blood cell count, C-reactive protein, immature to total neutrophil count and mean platelet volume drawn on two occasions (first within 24 hours and the second between 24 to 48 hours after delivery) were compared between the two groups.

Results: There was no statistically significant difference in the mean platelet volume between the study group and the control group (p value 0.9 in the first 24 hours and p value 0.49 in the 24-48 hour sample). There was however, a statistically significant difference between immature to total neutrophil count and C-reactive protein on both samples (p value <0.0001) (Table 1).

Table 1.

Summary/Conclusions: In our study there was no statistically significant difference in the mean platelet volume values between neonates with sepsis and healthy controls. C-reactive protein and immature to total neutrophil count continue to be reliable markers of neonatal sepsis.

LONG-TERM EFFICACY AND SAFETY OF THROMBOPOIETIN AGONISTS IN ADULT REFRACTORY CHRONIC IMMUNE THROMBOCYTOPENIA
M. Kalliou1,*, E. Gaviilaki1,2, G. Papaioannou1, Z. Bousiou1, M. Iskas1, C. Vakidolou1, C. Lalayanis1, A. Anthanasadou1, R. Saloumi1, A. Anagnostopoulou1
1Hematology Department - BMT Unit, 2G. Papacolaoou Hospital, Thessaloniki, Greece

Background: Management of chronic immune thrombocytopenia (cITP) aims not only to increase and maintain platelet counts in safe levels, but also to improve quality of life. Thrombopoietin agonists eltrombopag and romiplostim have been approved in refractory ITP. The lack of randomized studies allows only for real-world data comparison on the two agents.

Aims: In the present study we evaluate and compare long-term efficacy and safety of eltrombopag and romiplostim in clinical practice and assess the switching feasibility between the two agonists.

Methods: Treatment with thrombopoietin agonists was initiated in 20 adult patients (pts) with refractory cITP between June 2011-2016. Patients resistant or intolerant to the first agonist switched to the second one. Complete response (CR) was defined as a platelet count of ≥100x10^9/L.

Results: Eltrombopag was administered in 15 pts, 6 male:9 female with a median age of 46 years (19-76 yrs) for 13 months (1.4-54 mo). Patients had received a median of 1 previous treatment (range 1-7); corticosteroids (15/15), intravenous immunoglobulin (5/15), rituximab (2/15), vincristine (1/15), cyclophosphamide (2/15), romiplostim (2/15), danazol (1/15) and splenectomy (1/15). Before eltrombopag treatment, the majority (8/15) showed grade 4 (WHO) thrombocytopenia. Initial dose was 50 mg and increased to 75 mg daily in 3/15 pts and in combination with corticosteroids that were gradually tapered by the 5th week in 12/15. Median platelets value by the 2nd week of administration was 140x10^9/L (5-450x10^9/L); whereas, by the 4th week increased to 158x10^9/L (16-500x10^9/L). At the end of follow-up, all patients but one achieved CR with median platelets of 145x10^9/L (60-400x10^9/L). Regarding adverse events, 1/15 pt presented hemolytic anemia, 1/15 pt hepatotoxicity grade 2 with episodes of thrombocytopenia grade 4 and 1/15 pt pulmonary embolism during the second month of treatment. The latter 2 pts switched to romiplostim. Romiplostim was administered in 9 pts, 4 male:5 female with a median age of 46 years (33-76 yrs, 4-73 mo). They had received a median of 3 previous treatments (range 1-8); corticosteroids (9/9), intravenous immunoglobulin (6/9), rituximab (6/9), vincristine (2/9), cyclophosphamide (2/9), eltrombopag (2/9), danazol (1/9) and splenectomy (2/9). The majority (5/9) presented thrombocytopenia grade 4 before romiplostim. Median platelets number by the 2nd week of administration was 50x10^9/L (9-140x10^9/L); whereas, by the 4th week increased to 115x10^9/L (20-400x10^9/L). At the end of follow-up, 6/9 pts achieved CR with median platelets at 145x10^9/L (110-400x10^9/L). All patients received concomitant steroid treatment that was gradually tapered and stopped in 6/9 pts. 2/9 pts switched to eltrombopag due to thrombocytopenia grade 3 and 1/9 pt to danazol and low-dose steroids achieving CR. No adverse events associated with romiplostim treatment were reported. No significant differences were found between the 2 treatment groups. All 4 patients that switched to the other agonist achieved CR without adverse events.

Summary/Conclusions: Our real-world data suggest that both eltrombopag and romiplostim are safe, well tolerated and highly effective in refractory cITP and furthermore, switching to another agonist is safe and effective. Future studies will determine predisposing factors for adverse events and more accurate classification of patients that will allow for better treatment guidance.
Background: Chronic idiopathic thrombocytopenic purpura (ITP) is an acquired disease characterized by a low platelet count caused by an immunological peripheral platelet destruction or a decreased platelet production. Several studies have shown increased reactive oxygen species (ROS) levels in chronic ITP and also a possible association between Helicobacter pylori (H. pylori) infection and immunological peripheral platelet destruction. Aim: To evaluate if patients with chronic ITP and H. pylori infection exhibit higher ROS levels compared to patients with chronic ITP and no H. pylori infection and whether there are statistically significant differences between the two groups.

Methods: We studied 29 patients with chronic ITP (median age 39 years) hospitalised in the Clinic of Hematology, Filantropia City Hospital, Craiova, Romania, between 2014 and 2016 (informed consent obtained). All patients were diagnosed with ITP, other causes of thrombocytopenia having been ruled out by bone marrow aspiration. The patients were divided in two groups: patients with ITP and H. pylori infection (group A) and patients with chronic ITP without H. pylori infection (group B). Two blood samples were used to identify the presence of a H. pylori infection and reactive oxygen species were evaluated by FORT (Free Oxygen Radicals testing) test from a single drop of capillary blood, at the time of diagnosis, before the administration of any drug (the normal value of FORT is considered less than 2.3 mmol/l H₂O₂), using a CR3000 analyzer (Callegari SpA, Parma, Italy). The differences between the two groups were assessed using the Student T-test and a p-value of less than 0.05 was considered statistically significant.

Results: Group A consisted of 11 patients positive for H. pylori, whereas group B included 18 patients with no H. pylori infection. ROS levels, measured by the FORT, were elevated in both groups (between 2.8 – 3.6 mmol/l H₂O₂). However, statistically significant differences were found in favour of group A, with higher ROS values than group B. The A group also associated lower platelet counts and more patients pertaining to this group relapsed in comparison to group B.

Summary/Conclusions: In chronic ITP, increased levels of ROS are associated with elevated autoantibody production. Autoantibodies are involved in platelet destruction via a highly immunogenic activity. On the other hand, association of H. pylori infection, via chronic inflammation, led to a supplementary association of H. pylori infection, via chronic inflammation, led to a supplementary

IDIOPATHIC THROMBOCYTOPENIC PURPURA AND HELICOBACTER PYLORI INFECTION VERSUS CHRONIC ITP WITHOUT HELICOBACTER PYLORI INFECTION

M.-A. Gaman1,*, A. M. Gaman2,3

Summary/Conclusions: In chronic ITP, increased levels of ROS are associated with elevated autoantibody production. Autoantibodies are involved in platelet destruction via a highly immunogenic activity. On the other hand, association of H. pylori infection, via chronic inflammation, led to a supplementary association of H. pylori infection, via chronic inflammation, led to a supplementary

IMMUNE THROMBOCYTOPENIA AND PREGNANCY: A SPANISH CASE SERIES OF 270 PREGNANCIES IN PRIMARY ITP

1Department of Hematology, Hospital Universitario de Burgos, Burgos, 2Department of Hematology, Hospital Universitario de Salamanca, Salamanca, 3Department of Hematology, Hospital Valle de Hebron, Barcelona, 4Department of Hematology, Hospital La Fe, Valencia, 5Department of Hematology, Hospital la Plana, Castellon, 6Department of Hematology, Hospital del Mar, Barcelona, 7Department of Hematology, Hospital Clinic San Carlos, 8Department of Hematology, Hospital General de Madrid, Madrid, 9Department of Hematology, Hospital Gregorio Marañón, Madrid, 10Department of Hematology, Hospital Universitario de Madrid, Madrid, 11Department of Hematology, Hospital Universitario La Paz, Madrid, 12Department of Hematology, Hospital de Valladolid, Valladolid, 13Department of Hematology, Hospital de Eche, Eche, 14Department of Hematology, Hospital de Cáceres, Cáceres, 15Department of Hematology, Hospital Universitario de Salamanca, Salamanca, 16Department of Hematology, Hospital de Segovia, Segovia, 17Department of Hematology, Hospital de Zamora, Zamora, 18Department of Hematology, Hospital Virgen del Puerto, Plasencia, 19Department of Hematology, Hospital Infantil-Leonor, Madrid, Spain.

Background: Effect of pregnancy on the course of primary immune thrombocytopenia (ITP) is not well known. Besides, due to the lack of clinical assays, it is difficult to establish a possible association of primary ITP and pregnancy. Thus, we aimed to evaluate the effect of pregnancy on the course of primary ITP and to evaluate the correlation between the platelet count and the severity of the pregnancy.

Aims: To evaluate the effect of pregnancy on the course of primary ITP and to evaluate the correlation between the platelet count and the severity of the pregnancy.

Methods: A retrospective case–control study was performed. Patients with a diagnosis of primary ITP were included in the study. Patients were divided into two groups: group A, patients with primary ITP who had at least one pregnancy after ITP onset were included in this registry, and group B, patients with primary ITP who had at least one pregnancy after ITP onset who were not included in this registry.

Results: We included 270 primary ITP pregnancies from 184 women. At pregnancy diagnosis, we observed a majority of chronic ITP cases (71.4%). At ITP diagnosis, median age of our case-series was 23 years (IQR, 19-29) and median time from ITP diagnosis to pregnancy was 167 months (IQR, 0-366). Median number of pregnancies prior to ITP diagnosis were 1 (IQR, 0-2) with 1 pregnancy (IQR, 1-2) after ITP diagnosis as a median.

Aims: To evaluate the effect of pregnancy on the course of primary ITP.

Methods: A retrospective case–control study was performed. Patients with a diagnosis of primary ITP were included in the study. Patients were divided into two groups: group A, patients with primary ITP who had at least one pregnancy after ITP onset were included in this registry, and group B, patients with primary ITP who had at least one pregnancy after ITP onset who were not included in this registry.

Results: We included 270 primary ITP pregnancies from 184 women. At pregnancy diagnosis, we observed a majority of chronic ITP cases (71.4%). At ITP diagnosis, median age of our case-series was 23 years (IQR, 19-29) and median time from ITP diagnosis to pregnancy was 167 months (IQR, 0-366). Median number of pregnancies prior to ITP diagnosis were 1 (IQR, 0-2) with 1 pregnancy (IQR, 1-2) after ITP diagnosis as a median.
50.8% of women received corticosteroids, immunoglobulins (IVIG) (16.9%), rituximab (8.6%) and splenectomy (8.4%) as ITP treatments between or before new pregnancies. On the other hand, 26.4% of women needed treatment for ITP during pregnancy, mainly steroids (13.5%) and IVIG (10.2%). The median platelet-count nadir during pregnancy was 74 x 10^9/l (IQR, 36-172). 127 (47%) pregnancies suffered from non-haematoma platelet levels (less than 50 x 10^9/l) with 73 (27.0%) women who achieved less than 30 x 10^9/l. 56 (20.7%) women exhibited hemorrhagic symptoms, being 30 (11.1%) of them severe bleedings.

Regarding type of delivery, this was vaginal in 63.4% of pregnancies and cesarean sections 30.5%. Median platelet count at delivery was 110 x 10^9/l (IQR, 70-181). 43 patients (23.4%) experienced 57 bleeding episodes. We only observed 48 cases (20.4%) of neonatal thrombocytopenia among 235 living newborns.

Summary/Conclusions: Our results are comparable to previously reported studies. No severe bleeding complications during pregnancy and/or delivery were observed in our case series. Rate of neonatal thrombocytopenia, and therefore, newborn bleeding is low.

1Haematology Department, University College London Hospital, 2Haemostasis Research Unit, University College London Hospital, London, United Kingdom

Background: When immune mediated Thrombotic Thrombocytopenic Purpura (TTP) has classically been suspected by the presence of a pentad of symptoms (microangiopathic haemolytic anaemia, fever, disturbed neurological function, renal failure, thrombocytopenia), the limitations of this have long been recognized and a wide variety of symptoms are seen on initial presentation.

Aims: A retrospective review of the significance of specific symptoms and their duration on mortality.

Methods: A retrospective review of all consecutive admissions to a single tertiary centre between 2009 and 2015. Only patients who required plasma exchange were included. Patients’ symptoms and their duration were reviewed in addition to presenting anti-ADAMTS13 IgG antibody levels and ADAMTS13 antigen levels, both of which have previously been found to have prognostic significance.

Results: 106 patients (68% female) were included with a median age of 48.58 years (median 48.58 years). 47% of patients had neurological symptoms on presentation, 24% reported a bleeding history and 12% a recent infection. The most common presenting symptoms were headache (27.4%), bleeding (24%) spontaneous bruising/petechial (19.8%), generalized weakness (16.4%), abdominal pain (15.1%) and dyspnoea (10.2%). The majority of patients had neurological symptoms on presentation, 24% reported a bleeding history and 12% a recent infection. The most common presenting symptoms were headache (27.4%), bleeding (24%) spontaneous bruising/peetechial (19.8%), generalized weakness (16.4%), abdominal pain (15.1%) and dyspnoea (10.2%). The majority of patients presented with hemorrhagic symptoms (70.9%). The main manifestations were cutaneous bleeding (64%), oral cavity bleeding (20.9%), epistaxis (8.9%), menorrhagia (7.8%) and gastrointestinal bleeding (5.5%). 430 patients (61.78%) had

Summary/Conclusions: Whilst there is little difference in the anti-ADAMTS13 IgG antibody and ADAMTS13 levels seen with different symptoms, there is a wide disparity in terms of mortality suggesting the effect of microangiopathic thrombosis differs by location. Abdominal pain, not previously recognized as a typical symptom in TTP, was found to be a poor prognostic indicator although this should be interpreted with caution given the sample size. Anti-ADAMTS13 IgG antibody level increases with symptom duration and this may lead to increased mortality.

CAN HISTOCHEMICAL C-MPL POSITIVITY IN BONE MARROW BE A PB2110 splenectomy decision.

Methods: Bone marrow specimens were taken from 24 patients who were diagnosed with ITP and who had splenectomy (15 female, 9 male, mean age 50±16) before splenectomy and 30 patients who were diagnosed with ITP but did not have splenectomy (15 female, 15 male, mean age 52±19). c-mpl staining was carried out retrospectively. Immunohistochemical (IHC) staining using Avidin-Biotin complex system (ABC) was conducted. For IHC, sections prepared from blocks were taken onto poly-L-lysine coated slides (MicroSlides Snowcoat X-tra, Surgipath, Richmond, IL, USA) and kept in an incubator at 37 °C overnight. Dissections were treated with IHC control (Santa Cruz/secret, B-515-3187) stain. Cytoplasmic and nuclear staining was observed in megakaryocytes using IHC c-MPL and vitamin D. Evaluation was made based on the intensity of the staining; i.e. negative (0), weak (1+), moderate (2+) and strong (3+) (1). All patients who had splenectomy were in chronic phase of the disease. The present study was supported as a Scientific Research Project by Adnan Menderes University (TFP-15027).

Results: c-mpl positivity was statistically significant in patient group who did not have splenectomy (Table 1). In patient group who had splenectomy, c-mpl was not associated with refractory status.

Table 1. c-mpl positivity in patient group who had and did not have splenectomy.

Summary/Conclusions: Status of c-mpl in ITP is ambiguous. Significant level of positivity in patient group who did not have splenectomy might be the useful for splenectomy indication.

PB2110

CLINICAL SIGNIFICANCE OF IMMATURE PLATELET FRACTION MEASUREMENT IN THROMBOCYTOPENIC DISORDERS DURING PREGNANCY

Methods: Pregnant women with thrombocytopenia were selected (2015-2016); a total of 25 patients (mean age: 33 yrs, range 19-43 yrs) were examined with platelet count <100,000 platelets/μL. Venous whole-blood samples were collected into Vacutainer EDTA-K2E tubes (Becton Dickinson and Company, Plymouth, UK). Complete blood counts and immature platelet fraction (%IPF) were immediately analyzed within 2 h of blood withdrawal by Sysmex XN20 system (Sysmex Corporation, Kobe, Japan). Novel PLT-F channel uses fluorescent light and stains platelets specifically with Oxazine Dye (Fluorescent Fluorocell). Measure of immature platelet fraction (IPF) has been suggested as a less invasive and early diagnostic test in the study of thrombocytopenic disorders. Immature platelet fraction can be currently measured by fully automated hematologist analyzers providing clinical utility for diagnosing and monitoring thrombocytopenia.

Aims: The aim of this is to know whether IPF can be a useful parameter in pregnant women with thrombocytopenia to predict the potential risk of bleeding.

Methods: Pregnant women with thrombocytopenia were selected (2015-2016); a total of 25 patients (mean age: 33 yrs, range 19-43 yrs) were examined with platelet count <100,000 platelets/μL. Venous whole-blood samples were collected into Vacutainer EDTA-K2E tubes (Becton Dickinson and Company, Plymouth, UK). Complete blood counts and immature platelet fraction (%IPF) were immediately analyzed within 2 h of blood withdrawal by Sysmex XN20 system (Sysmex Corporation, Kobe, Japan). Novel PLT-F channel uses fluorescent light and stains platelets specifically with Oxazine Dye (Fluorescent Fluorocell). Bcl-2 binding complication has been collected in order to know if there is related to%IPF.

Results: Mean platelet count was 73,000 platelets/μL (range of 69-91) and IPF mean was 11% (2.5-23.4). Lab test Hemoglobin shows a mean of 95.17 g/L (range of 45-132) (in no bleeding group was 105.8 g/L whereas in bleeding group was 86.14 g/L, p=0.076). IPF% was <10 in 11, which means a 44% of the patients. 14 patients bleed during or after labor, 56% among all the patients in this study. Related to this group, 11 patients had IPF <10%; 3 of bleeding patients showed an IPF >10%. All pregnant women with an IPF <10% (11/11) bleed as a complication. Pregnant women with thrombocytopenia and a IPF <10% has a higher risk of bleeding during and after labor compared with pregnant women with an IPF>10% (Fisher 12.41, P=0.001). 5 (20.83%) patients among all of them were under treatment (earlier or during labor); 3 (12.5%) with steroids and 2 (8.33%) with other methods.

Summary/Conclusions: Status of c-mpl in ITP is ambiguous. Significant level of positivity in patient group who did not have splenectomy might be the useful for splenectomy indication.
Summary/Conclusions: Thrombocytopenia is a potential risk of bleeding during the labor. A high IPF indicates either consumptive or recovering thrombocytopenic disorders, such as immune thrombocytopenic purpura, while low IPF is characteristic of bone marrow suppression states. Although not directly used in clinical decision making, the reference range is critical to the introduction of new parameters and the interpretation of laboratory results. Our results suggest that the platelet-specific activity parameter is the level <10% might be an independent bleeding factor which can be useful for detecting high risk pregnant patients. It should be corroborated in further studies.

Background: Chronic primary immune thrombocytopenia (ITP) is an acquired autoimmune disease characterized by enhanced clearance of platelets and impaired platelet production. Corticosteroid is the ministry line of treatment of ITP, patients who fail to respond to steroid (steroid resistant) or who relapse (steroid dependant) face the options of treatment with second line including anti CD-20 monoclonal antibody rituximab. Rituximab is a chimeric IgG1 monoclonal antibody (mAbs) that cause mechanism of action of rituximab is the antibody-dependent cellular cytotoxicity (ADCC). ADCC effectiveness is influenced by process of activation of effector cells via their immunoglobulin G fragment C receptors (FcRy). FcRy receptors show distinct affinity to bind to IgG subtype specificities. Differential response to rituximab has been reported to correlate with specific polymorphism of Fcγ genes. FcγRI (H131R) and FcγRIIa (V158F) in some diseases.

Background: Immune thrombocytopenia (ITP) is an acquired, immune-mediated disease that is characterized by increased destruction of platelets by autoantibodies. ITP is characterized by mucocutaneous bleeding. Rarely, life-threatening bleeding such as central nervous system bleeding can occur. Typically, patients have isolated thrombocytopenia. The diagnosis of ITP is one of exclusion. Corticosteroids are chosen as a first-line therapy for adult patients who require treatment. Responses to first line therapy with corticosteroids is about 80% with approximately 20% to 30% long term complete remission. Most patients finally relapse, requiring second-line therapy.

Aims: Our aim was to investigate potential effects of early platelet response to corticosteroid therapy on achieving long term complete remission.

Methods: We retrospectively evaluated 43 ITP patients who were followed-up at our institution. All patients' thrombocyte counts were below 30 x10^9/L at diagnosis. All patients received initial methylprednisolone (MP) 1 mg/kg/day. For patients who responded with platelet count ≥150 x10^9/L methylprednisolone was tapered over 3 months. Those who were unresponsive to MP or relapsed after a complete response, were treated with second line therapies that splenectomy or medical treatment agents. The platelet counts of the patients who achieved CR and achieved NR were compared in terms of second line therapy requirement or not. A platelet count of >30 x10^9/L on day 3 and >100 x10^9/L on day 7 were considered as a complete response.

Results: Baseline characteristics of the cohort of 43 patients with an initial diagnosis of ITP are shown in Table 1. The mean age at diagnosis was 51 years (18-84) with female/male : 25/18. All patients presented with severe thrombocytopenia (platelet counts below 30.0 x10^9/L). Most patients presented with mucocutaneous bleeding (n=39), only three patients had genitourinary or gastrointestinal bleeding and one patient had asymptomatic thrombocytopenia. Aspiration and biopsy was done in 14 (32.6%) patients due to various reasons mainly, failure to respond to MP treatment (7 patients) and advanced age (7 patients). On third and seventh day of MP therapy, median platelet counts were 30x10^9/L (2.0 x10^9/L - 150 x10^9/L) and 100 x10^9/L (1.0 x10^9/L - 347 x10^9/L), respectively. On third and seventh day, 20/100 patients (20%) achieved CR. Among the 50 patients who treated with Rituximab, 18 patients (36%) achieved CR, 19 patients (38%) achieved PR and 13 patients (26%) achieved NR. Out of the 18 patients who achieved CR, 8/18 patients (44.4%) carried FcγRIIa RR genotype and 7/18 patients (38.5%) carried FcγRIIa RH genotype compared to HR (38.5%) and HH (38.5%) genotypes. However it was not statistically significant. Among the 13 patients who achieved NR, lowest rate was patients carried FcγRIIa RR genotype (23.1%) compared to HR (38.5%) and HH (38.5%) genotypes. However it is not statistically significant. The mean value of platelet count at end of week 1, Week 2 and Week 3 of rituximab therapy show statistically significant differences (P value 0.001) being higher in patients who achieved CR than who achieved PR or NR.

Summary/Conclusions: The higher platelet count achieved early (end of week 1, 2, and 3) after rituximab is suggestive for a better response later (at end of M3). FcγRIIa RR genotype is predictive for better response to rituximab in ITP patients.

Background: The role of T cells in the pathophysiology of immune thrombocytopenia (ITP) is heterogeneous and complex. It has been studied in active and reactive ITP but not to same extend in chronic and persistent type.

Aims: In this study we review the demographic features of 150 immune thrombocytopenic Egyptian patients and for cases who were chronic and persistent with negative both autoimmune screen and virology for hepatitis B and C.

Methods: We measured IL-12, IL-35 and IL-17 cytokines in 100 chronic ITP patients; divided into two equal groups, first group received rituximab (375 mg/m2 per dose weekly for four doses) and the other group received non-mabthera second line therapy. A polymerase chain reaction-restriction fragment length polymorphism assay (PCR-RFLP) was used to detect FcγRIIa-131 R/H and FcγRIIIa-158 V/F polymorphism. Evaluation of platelets counts was assessed initially before starting second line therapy then weekly for 3 months. At the end of third month the response to second line therapy was considered according to the following criteria; complete response (CR) PLT >100×10^9/L., partial Response (R), PLT:30-100×10^9/L, no response (NR), PLT:<30×10^9/L.

Results: Regarding FcγRIIa polymorphism distribution in the 100 patients; 28 patients (28%) had wild HH genotype, 41 patients (41%) have heterozygote genotype (HR) and 31 patients (31%) have homozygote mutant genotype (RR). In our study, the 100 ITP patients included showed wild type of FcγRIIa (V158F) gene polymorphism. By the end of week 3 of the second line therapy, 50 patients achieved CR, 37/100 patients (37%) achieved NR, 20/100 patients (20%) achieved NR. Among the 50 patients who treated with Rituximab; 18 patients (36%) achieved CR, 19 patients (38%) achieved PR and 13 patients (26%) achieved NR.

Summary/Conclusions: The higher platelet count achieved early (end of week 1, 2, and 3) after rituximab is suggestive for a better response later (at end of M3). FcγRIIa RR genotype is predictive for better response to rituximab in ITP patients.

SWITCH OF TPO-MIMETICS IN PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA: FLORENCE MONOCENTRIC EXPERIENCE
C. Biagiotti1, V. Carrail2, F. Basiliani1, A. Bosi3
1Hematology, Careggi Hospital, Florence, Italy

Background: Primary immune thrombocytopenia (ITP) is an immune-mediated condition characterized by isolated thrombocytopenia, with peripheral blood platelet count <100,000/µl with no identifiable underlying cause of thrombocytopenia. Clinical studies in patients with ITP demonstrated that thrombopoietin (TPO) mimetics increase platelet production and can outpace platelet destruction.

Aims: We evaluated patients treated with both TPO-mimetics.

Methods: From November 2008 and February 2017, 65 patients were treated with TPO-mimetics with a median follow up of 29 months (1-96); 39 patients underwent therapy with Romiplostim and 26 to Eltrombopag. In our study we evaluated 18 patients who received both therapies; among patients treated at first with Romiplostim, 10 patients (9F; 1 M) switched to Eltrombopag and 8 patients (3 M; 5 F) switched from Eltrombopag to Romiplostim. In the group of 10 patients treated at first with Romiplostim, 5 patients started Eltrombopag because no responders, 3 for loss of response and 2 patients because of adverse events. In the group of 8 patients at first treated with Eltrombopag, 4 patients didn’t obtain any response with Eltrombopag and switched to Romiplostim, 1 patient underwent to Romiplostim for loss of response and 3 patients because of adverse events.

Results: Among patients switched from Romiplostim to Eltrombopag, 2 achieved complete response, 4 response and 4 were no responders; among patients switched from Eltrombopag to Romiplostim, 4 obtained complete response, 3 response, 1 no responder.

Summary/Conclusions: Romiplostim and Eltrombopag stimulate the TPO-R but have different mechanisms of action, therefore, in our limited experience switching from one thromboapoietic receptoragonist to the other could be beneficial in clinical practice for patients with severe chronic immune thrombocytopenia who failed to respond or experienced adverse events to the first treatment.

COEXISTENCE OF GLANZMANN’S THROMBASTHENIA AND MAPLE SYRUP URINE DISEASE: IMPLICATIONS FOR HEMOSTATIC MANAGEMENT
M. Elshinawy1, A. Alrawas2, Y. Wali2
1Pediatric Hematology, SOUH, Alexandria University, Muscat, Oman, Egypt;
2Pediatric Hematology, SULTAN QABOOS UNIVERSITY HOSPITAL, Muscat, Oman

Background: In Oman, autosomal recessive disorders are relatively commoner than western communities due to the high prevalence of inter-tribal marriage. Unfortunately, some patients have got more than one autosomal recessive genetic disorder, owing to complex consanguinity which might further complicate proper management plans.

Aims: To report a case of combined Glanzmann’s thrombasthenia and MSUD, and to review the existing data of platelet function disorders in Oman.

Methods: Case report and retrospective data analysis of all cases with confirmed or suspected platelet function disorders in Pediatric Hematology Unit, Sultan Qaboos University Hospital, Muscat, Oman from January 2006 till December 2016.

Results: A 2 years old girl who is a known case of MSUD. Her parents are double first cousins (from both maternal and paternal sides). At the age of 3 months, she required Gastrostomy tube (G-tube) insertion. Preoperatively, full blood count and coagulation screen were perfectly normal. Unfortunately, she developed profuse bleeding at the site of G-tube insertion, followed by massive hematemesis. The patient received multiple blood products, but bleeding didn’t stop. As an emergency measure, recombinant activated factor VII (rFVIIa) was given and resulted in cessation of bleeding. Platelet aggregation studies revealed defective aggregation with ADP, arachidonic acid, collagen and epinephrine which is consistent with Glanzmann’s thrombasthenia. The diagnosis was further confirmed by flow cytometry which showed no activity with CD41 and CD61, indicating absent GP IIb/IIIa complex. The patient experienced a severe bleeding phenotype, which is further complicated by multiple coexisting factors, including the recurrent episodes of metabolic crises which provoked worsening of platelet function, the development of platelet refractoriness at the age of 1 year, and the need for recurrent invasive procedures such as G-tube and central line insertion. Currently, the bleeding episodes are managed by rFVIIa at a dose of 120-180 µg /kg/dose. Excluding von Willebrand refractoriness at the age of 1 year, and the need for recurrent invasive procedures, we performed it to analyze whether hyper-responders to clopidogrel detected by VerifyNow® were also identified with PFA-100.

Results: The results of platelet function testing with three different methods are summarized in Table 1. None of the patients showed thrombocytopenia. Good response to aspirin was observed in 84.21%, 97.36% and 93.75% of the patients using VerifyNow®, Multiplate® and PFA-100 respectively. Good response to aspirin was detected in 86.84%, 38.88% and 62.5% of the patients using VerifyNow®, Multiplate® and PFA-100 respectively. VerifyNow® identified 6 (13.78%) aspirin-resistant patients. However, PFA-100 and Multiplate® didn’t show a significant aspirin-mediated platelet dysfunction in 5 of them. Low response to clopidogrel was detected by VerifyNow® in 5 (13.15%) patients consistent with Multiplate® results. VerifyNow® identified 10 patients with excessive response, but only 2 of these results were reproduced by Multiplate® or COL/ADP. Multiplate® detected 19 patients (50%) with suboptimal response to clopidogrel, although these results did not correlate with those obtained by VerifyNow®.

Table 1.

Summary/Conclusions: The effect of aspirin can be accurately measured by platelet aggregation and PFA-100 (with COL/EP1); however, VerifyNow® seems to identify a higher number of poor responders. Multiplate® assay using only
ADP is not good enough to detect clopidogrel-mediated platelet dysfunction since it is not specific for the P2Y12 receptor. The addition of PGE1 to the ADP test may increase its sensitivity. VerifyNow® assay seems to overestimate the effect of clopidogrel, since hyper-response data are not reproduced by other techniques. According to our results, a high interindividual variability in response to clopidogrel is observed.

Methods:

JAK2V617F mutation.

Aims:

To detect ROS levels, we studied 23 patients with ET admitted to the Clinic of Hematology, Filantropia City Hospital, Craiova, Romania, diagnosed with ET according to the 2008 revised WHO criteria (informed consent obtained). All analysis were performed after diagnosis and before the start of therapy. The JAK2/V617F mutation was detected by allele specific polymerase chain reaction (PCR) testing. ROS levels were detected by flow-cytometry using a Cy Flow Space Sysmex flow-cytometer and a DCFDA Cellular ROS Detection Assay Kit. Studied parameters were compared both to healthy controls and to each other. Exclusion criteria were pregnancy and any condition associated with an increased oxidative stress (chronic alcohol consumption, smoking, diabetes mellitus, hyperlipidemia, chronic renal failure, human immunodeficiency, cirrhosis, and active infection), use of antioxidants or iron supplementation. Data analysis was performed using Flow Max software. The differences between the two groups were assessed using the Student T-test and a p-value of less than 0.05 was considered statistically significant.

Results: The study group involved 12 females and 11 males, with a median age of 48 years. All patients had increased ROS levels at diagnosis compared to healthy controls. Eleven patients had JAK2/V617F mutation and twelve were JAK2/V617F mutation negative. Significantly higher ROS levels were found in JAK2V617F positive patients compared to JAK2 negative patients.

Summary/Conclusions: In our study, patients with ET had increased ROS levels. Cases with JAK2/V617F mutation associated higher ROS levels compared to those without JAK2/V617F mutation. In our future research, we will focus on the follow-up of these patients for a period of four years and we will try to observe if increased ROS levels enhanced genomic instability and transformation to acute myeloid leukemia.

PB2120

VARIATIONS IN PARAMETERS OF PLATELET COUNT AND PLATELET VOLUME ACCORDING TO GESTATIONAL AGE

S. Akarsu1,*, M. Aydin1, E. Taşkın2, M. M. Aydeniz3, 1Gastroenterology, Medical Faculty, Fatih University, Istanbul, Turkey 2Department of Pediatrics, Medical Faculty, Fatih University, Istanbul, Turkey

Background: Reference ranges of haematological parameters in preterm infants are limited.

Aims: In hematological evaluation not only platelet (PLT) counts but also important platelet volume parameters (mean platelet volume [MPV], platelet distribution width [PDW], plateletcrit [PCT]) are also taken into consideration.

Methods: Medical records were prospectively reviewed in preterm infants admitted to Fatih University Hospital from January 2001 to December 2007. Study group consisted of only one-hour-old newborns delivered in the clinics of Department of Gynecology, and Obstetrics of our hospital. The exclusion criteria included those with maternal history of antepartum haemorrhage, chorioamnionitis, fever, sepsis, preeclampsia and hypertension; and perinatal history of twin-to-twin transfusion syndrome, feto-maternal transfusion, infection and infection. A hundred and ninety-three newborns with apparent health problems were excluded from our study. Study group comprised 398 preterm infants born between 26-37 gestational weeks, and 63 healthy term (38 gestational weeks) infants. Blood smears and from all cases were obtained within the first hours after birth. Blood samples were placed into tubes with EDTA, and analyzed in ADVIA 120® (Japan) hematology analyzer using suitable kits. Data were expressed as mean±standard deviation. Platelet counts, and volume were indicated for each gestational week, and groups of 24-31, 32-36, 37, and 38 weeks. One-way analysis of variance (ANOVA) was used for statistical analysis, and p<0.05 was accepted as the level of statistical significance.

We established the reference ranges of platelet and platelet index in Turkish preterm and term infants. Platelet counts, and platelet volumes continually change as gestational age increases. Increases in platelet counts, and PCT, while decreases in MPV and PDW were detected. The gestational age-related changes in PLT patterns may reflect maturation of platelet regulation.

Results: Platelet counts increased beginning from the 26th up to 28th weeks. They did not change between 29th and 33rd weeks, while their levels raised again conspicuously between 34th and 37th weeks. At 38th week a dramatic increase occurred up to 40th week. MPV and PDW from all cases were obtained within the first hours after birth. Blood samples were placed into tubes with EDTA, and analyzed in ADVIA 120® (Japan) hematology analyzer using suitable kits. Data were expressed as mean±standard deviation. Platelet counts, and volume were indicated for each gestational week, and groups of 24-31, 32-36, 37, and 38 weeks. One-way analysis of variance (ANOVA) was used for statistical analysis, and p<0.05 was accepted as the level of statistical significance.

We established the reference ranges of platelet and platelet index in Turkish preterm and term infants. Platelet counts, and platelet volumes continually change as gestational age increases. Increases in platelet counts, and PCT, while decreases in MPV and PDW were detected. The gestational age-related changes in PLT patterns may reflect maturation of platelet regulation.

Summary/Conclusions: We established the reference ranges of platelet and platelet index in Turkish preterm and term infants. Platelet counts, and platelet volumes continually change as gestational age increases. Increases in platelet counts, and PCT, while decreases in MPV and PDW were detected. The gestational age-related changes in PLT patterns may reflect maturation of platelet regulation.

RISK OF LUPUS AFTER PRIMARY IMMUNE THROMBOCYTOPENIC PURPURA: A 14 YEAR SINGLE CENTER EXPERIENCE

M. Ayesh (Haj Yousef)1,*, K. Alawneh1, Y. Khader2, F. Maikawi3, 1Medicine, 2Public Health, Jordan University of Science and Technology, 3Department of Laboratory, Kng Abdullah University Hospital, Irbid, Jordan
Background: Primary immune thrombocytopenia (ITP) is an autoimmune disorder characterized by immune-mediated platelet destruction and suppressed platelet production. ITP may occur concurrently or precede the occurrence of SLE, which would have great diagnostic significance. ITP may also be the first early sign of the disease. Few studies have addressed the risk of systemic lupus erythematosus (SLE) after ITP. Aims: To estimate the risk of SLE after ITP in adult Jordanian patients. Methods: All patients diagnosed with ITP and with a platelet count \(<100 \times 10^9/\text{L}\) between September 2002 and January 2017 were included in the study. Results: This study included a total of 58 patients (43 females and 15 males) who were followed up for a period of 14 years. Their age at the baseline ranged from 16 to 65 years with a mean (SD) of 31.2 (13.3). ANA was positive in 11 (19.0%) patients. Over the period of follow up, 9 (15.5%) patients developed lupus. The incidence was 13.3% among males and 16.3% among females, with no significant difference (p-value=0.786). There was significant association between ANA and lupus in both genders. Only one patient with negative ANA and 81.8% of patients with positive ANA developed lupus (P<0.005).

Summary/Conclusions: SLE developed in patients with primary ITP with initial positive ANA titer at presentation. The results suggest that patients with initial positive ANA are at risk for development SLE. Thus, follow up after primary ITP diagnosis with positive ANA titer is of great importance as the risk of SLE is significant.

TREATMENT OF REFRACTORY IMMUNE THROMBOCYTOPENIA WITH THROMBOPOIETIN RECEPTOR AGONISTS: OUR EXPERIENCE IN CHILDHOOD

J. Zanabili-Al-Sibai1, T. Arias Fernández1, M.P. Palomo Moraleda1, L.R. Morais Bras1, C. Castañón Fernández1, T.F. Ávila Idrón1, A. Solé Magdalena1, S. González Muñiz1, M.A. Fernandez Rodriguez1

1Hematology, HUCA, Oviedo, Spain

Background: Immune thrombocytopenia (ITP) is an autoimmune disease in which antibodies develop against platelets (plts) and dysregulation of cellular immunity result in premature destruction of plts and impaired plt production. For most affected children, ITP is a self-limiting disease. Approximately, 10% of all ITP patients eventually develop refractory ITP (RITP). Thrombopoietin receptor agonists (TPO-RA) stimulate thrombopoiesis and are an alternative to corticoids, immune globulin A. Solé Magdalena1, S. González Muñiz1, M.Á. Fernandez Rodríguez1

Aims: To estimate the risk of SLE after ITP in adult Jordanian patients. Methods: All patients diagnosed with ITP and with a platelet count <100×10^9/L between September 2002 and January 2017 were included in the study. Results: This study included a total of 58 patients (43 females and 15 males) who were followed up for a period of 14 years. Their age at the baseline ranged from 16 to 65 years with a mean (SD) of 31.2 (13.3). ANA was positive in 11 (19.0%) patients. Over the period of follow up, 9 (15.5%) patients developed lupus. The incidence was 13.3% among males and 16.3% among females, with no significant difference (p-value=0.786). There was significant association between ANA and lupus in both genders. Only one patient with negative ANA and 81.8% of patients with positive ANA developed lupus (P<0.005).

Summary/Conclusions: SLE developed in patients with primary ITP with initial positive ANA titer at presentation. The results suggest that patients with initial positive ANA are at risk for development SLE. Thus, follow up after primary ITP diagnosis with positive ANA titer is of great importance as the risk of SLE is significant.

PB2123

INVESTIGATION OF PLATELET FUNCTIONS IN PSEUDOTHROMBOCYTOPENIA

B. Oneci1, S. Cesur2, K. Oneci3, E. Caliskan3, S. Cangur4

1Hematology, 2Internal Medicine, 3Medical Microbiology, 4Biostatistics, Duzce University Faculty Of Medicine, Duzce, Turkey

Background: Pseudothrombocytopenia (pseudTCP), is incorrectly detection of low platelet counts in automatic blood counter devices and is most frequently caused by ethylenediamine tetra-acetic acid (EDTA) induced platelet clumping and in vitro agglutination. Therefore, pseudTCP which accounts 15-30 of thrombocytopenic admissions, actually is not associated with a bleeding tendency. PseudTCP may be detected with a careful investigation of peripheral blood smears (PBS) by experienced clinicians but in centers which does not have these facilities; misleading of worried patients through advanced centers or even unnecessary treatments with steroids and platelet transfusions often occur.

Aims: In theory, formation of platelet clusters in the presence of EDTA requires functional adhesion molecules, so platelet adhesion and aggregation tests are expected to be in normal range. We aimed to investigate the capacity of simple platelet function analyzers for making the distinction between pseudo TCP and real thrombocytopenia.

Methods: Platelet functions were measured as collagen-ADP and collagen-epinephrine closure times (ColADP and ColEPI) by Platelet Function Analyzer (PFA-200™) for all patients who are referred to our clinic as thrombocytopenia (TCP, plt<150 x10^9/L) and value of this new method for determining pseu-
doTCP is compared with PBS which is accepted as the gold standard by using Receiver Operating Characteristic (ROC) curve analysis. PFA-200 system closure time is expected to be longer in true thrombocytopenia and normal in pseudTCP, but there is no study investigated this system for this purpose. Descriptive analyses were presented using means zstandard deviations for normally distributed variables or median and interquartile range (IQR) for nonparametric continuous variables. An overall p-value of less than 0.05 was considered to show a statistically significant result. This study is supported by Duzce University with project number of 2015.04.03.370 and these are pre-
liminary results.

Results: We included 59 patients who were referred to our clinic with throm-
boctopenia (TCP, plt<150 x10^9/L) and 11 healthy controls (plt>150 x103/L). Median age was 54 (IQR: 37-68) for thrombocytopenic subjects and 37 (%63) of them were female. Median plt count was 61 x103/L (IQR:30-90) in TCP group but WBC and HB were not different from control subjects. Subjects referred with TCP were grouped with PBS as pseudo-
TCP and real-TCP. There was no difference in terms of plt, MPV, PCT, WBC or HB between these groups but age was younger (median age 46 vs 62, p<0.05) and PDW was higher in pseudTCP group (med 17.6 vs 16.8, p<0.01). ColEPI and ColADP measures were significantly lower (med 125 vs 287 for ColEPI, med 84 vs 224 for ColADP, p<0.001 for both) at pseudTCP group. The capacity of CoEPI and ColADP values in predicting pseudTCP were analyzed using ROC curve analysis. We found that, when the manufacturer’s recommended cut-off value (150 s) was used, the sensi-
tivity and specificity were 84.7% and 62, with overall accuracy of 81.4% for ColEPI (AUC 0.813, %95CI: 0.694-0.933). Similarly sensitivity and specificity were 79.5%, and 95%, with overall accuracy of 84.7% for ColADP using manufacturer’s cut-off value of 100 s (AUC 0.878, SD:0.055, p<0.001, %95CI: 0.770-0.986).

Summary/Conclusions: We concluded that, running PFA tests for everybody with thrombocytopenic count, could be used for differentiating TCP and realTCP in centers which does not have conditions for proper BS. Especially long closure times excludes pseudTCP with a high specificity and could make clinicians quick decisions for further investigations.
PB2124
MANAGEMENT OF ADULT CHRONIC IMMUNE THROMBOCYTOPENIA.
SINGLE CENTER EXPERIENCE
C. Ionita1, I. Ionita1, D. Calamari-Popovici1, D. N. Oros1, M. Iordache1, M. Ionita1, I. Pascu1, M. Ifrose1, H. Ionita1
1UMF “Victor Babes” Timisoara, Timisoara, Romania

Background: The investigation and management of patients with Chronic immune thrombocytopenic purpura (ITP) varies widely. Although many treatments have been recommended for ITP, there are no evidence-based recommendations for when different treatments should be used, or when any treatment should be used rather than managing a patient by observation alone.

Aims: To evaluate the treatment of ITP patients in Department of Hematology, County Hospital, Timisoara.

Methods: A retrospective study for 350 ITP patients was performed. Patients demographics, medical history, current treatments and side effects, were abstracted from the patient’s medical charts for the 15 months prior to their most recent visit.

Results: The mean age was 45.6 years with 58% women and 42% men. Median time from the diagnosis of ITP to the start of the observational period was 23 months. Regardless of the presence of bleeding symptoms, for majority of patients we started treatment based on platelet count. Treatment was considered when platelet counts are less than 20x10^9/L in patients without bleeding, and less than 30x10^9/L in patients with bleeding. Prior to the observational period, 36% of patients had been splenectomized and the most reported treatment was corticosteroids. During the observational period, 72% of all patients were treated. The most frequent reasons given for treatment were platelet count (58%), followed by bleeding symptoms (42%). Corticosteroids represented 52% of treatments, followed by IVIg (20%), azathioprine (12%) rituximab and 8% others. Splenectomies (8% of patients) and platelet transfusions (27% of patients) were performed during the observational period. In the patient survey, 52% of participants were 60 years of age or older and the duration of disease was more than 10 years in 43% of patients. The minimum platelet counts were less than 10x10^9/L in 49% of patients. The most common symptoms of ITP was fatigue (45%). Approximately 60% of patients reported at least one side effect associated with ITP treatment. The side effects were most frequently associated with corticosteroid use (43%). Overall, 40% of patients required hospitalization. Mean duration of hospitalization was 13.5 days.

Summary/Conclusions: The retrospective study of 350 patients provides the results of treatment practices in our country. It showed that bleeding symptoms remained quite frequent among patients with chronic ITP. Corticosteroids were the most widely used treatment.

PB2125
IMMUNOLOGICAL THROMBOCYTOPENIC PURPURA AND PREGNANCY: A RETROSPECTIVE STUDY OF 89 PREGNANCIES IN 59 PATIENTS
H. Brahmi1, S. Tauxuss1, Z. Bouchetara1, K. Rekrouk1, M. T. Abad1
1Hematology, EHS ELCC CAC, Blida, Algeria

Background: Immunological thrombocytopenic purpura (ITP) occurs for about 1 case for 1000 pregnancies. The risk of onset, aggravation or relapse of ITP during pregnancy is not clearly established.

Aims: The aim is to describe the prevailing ITP progression profile in pregnant women and to evaluate the risk of neonatal thrombocytopenia in two situations, when ITP was known before pregnancy and when ITP was discovered for first time during pregnancy.

Methods: It is a retrospective study carried out in the hematology department of CAC Blida, Algeria, between 1993 and 2016. All patients (pts) who had a pre-pregnancy ITP or thrombocytopenia during pregnancy attached to an ITP were included.

Results: The development of 89 pregnancies (PG), including two twins, occurred in 59 women was analyzed. There were one PG in 40 pts, 2 PG: 13 pts, 3 PG: 5 cases, 4 PG: 1 case and 5 PG: 1 case. Of the 59 pts: in 42 cases it was a history of ITP before pregnancy (group 1: G1) with a history of splenectomy in 9 patients, and in 17 cases it was ITP discovered on the occasion of Pregnancy (group 2: G2). The average age at diagnosis=26.7 years (7-44) and that at delivery=30.4 years (19-44). The mean platelet count at diagnosis: G1: 34000 / µL, G2: 47000 / µL. In the first group (G1): At the beginning of pregnancy the ITP was chronic in 30 cases, newly diagnosed in 1 case, persistent in 2 cases and transient cured in 7 cases; treatments previously received were: corticosteroid therapy (n=34), splenectomy (n=9), Danazol (n=1), cyclosporine in 1 case and cyclophosphamide in 1 case, abstention in 7 pts, 2 of whom required corticosteroids during pregnancy. The status of the ITP at the beginning of each pregnancy was: out of treatment (n=8), corticosteroid dependence (n=5), non-response (n=7), PR (n=11), CR (n=24).In the second group (G2): the discovery of thrombocytopenia was in the first trimester (T) in 4 cases; a retrospective study was performed in the second T in 6 cases and in the third T in 7 cases: 17 pts had platelet counts <80000 / µL and were included due to the persistence or even worsening and / or necessity to resort to treatment of thrombocytopenia after delivery. In both groups: in 26 pts (G1:16; G2: 10 )variable dose and duration treatment were required during pregnancy; at delivery, 19 patients needed a treatment, out of them, a bolus of corticosteroids (n=11)+ transfusion of platelets (n=4), immunoglobulins in 4 cases and transfusion of platelets alone in 4 cases. At birth, thrombocytopenia was observed in 40 pregnancies (50.6%): platelets <30000 / µL (n=7), between 31000 and 50000 /µL (n=13), between 51000 and 100000/µl (n=20), between 100000 and 150000/µl in 2 cases. All pregnancies were completed: 14 by caesarean section, one for thrombocytopenia, with an average platelet count=95000 / µL and 75 by natural delivery with a mean platelet count=100000 / µL with 4 deaths born, one anencephaly and 88 newborns. No hemorrhagic syndrome was observed in pregnancy; two postpartum hemorrhages were seen in G2 group. Eleven newborns (5 in G1 and 6 in G2) were thrombocytopenic with platelet count <20000/µl in 4 cases; between 20000 and 50000/µL in 7 cases; neonatal thrombocytopenia occurred during the first 7 days. Only 4 newborns were treated, one by corticosteroid and 3 by immunoglobulins, with a good progression and only one of the untreated is always followed for thrombocytopenia.

Summary/Conclusions: The de novo ITP appearing during pregnancy is an etiological eventuality to be evoked in front of a thrombocytopenia of the pregnant woman after elimination of the other causes related to the pregnancy and in front of the non-resolution after the delivery. The pre-existing ITP does not necessarily.

QUALITY OF LIFE AND SYMPTOM BURDEN IN PATIENTS WITH MULTIPLE MYELOMA
B. Sidi Mohamed El Amine1,*, H. Asma1, O. Fouzia1, S.A. Najet1, C. Malka1, Z. Naima1, Z. Zahia1
1Hematology department, University hospital of Sidi Bel Abbès, Sidi Bel Abbès, Algeria

Background: Multiple myeloma (MM), the second most common hematological cancer, remains incurable. Its incidence is rising due to population ageing. Despite the impact of the disease and its treatment, not much is known about health-related quality of life (QoL) of patients with MM.

Aims: This study aimed to (1) Determine symptom prevalence in patients with MM on disease-modifying treatment, and identify the range and nature of these symptoms within the dimensions of physical, psychological, social well-being. (2) Measure the QoL of patients. (3) Compare the above-mentioned parameters to the general population.

Methods: Adults with multiple myeloma attending the hematology day unit in hematology department from November 2016 to January 2017 were eligible for inclusion in a cross-sectional. Consenting patients completed 2 validated questionnaires: 1) the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30) supplement ed by the myeloma-specific module (EORTC QLQ-MY20).

Results: Forty-seven patients were included for analysis: 51, 1% were male and 48.9% were female. Mean age was 64.7 years (range 42-82, standard deviation 11.5). The QoL scores were significantly lower than the general population (54.7 vs 71.2). The most commonly reported physical symptoms were pain (72%), fatigue (70%) and insomnia (66%). About 61% of the patients were burdened by financial worries. On multivariate analysis, a good performances status (PS≤1) and a response of the disease to therapy (at least a partial response) were associated with high scores of QoL (p=0.01, 3.86.0 respectively).

Summary/Conclusions: Patients with MM have a lower QoL than the general population and are symptomatic across physical, psychological and financial domains. They represent a polysymptomatic patient cohort with a complexity of need that merits a holistic multidisciplinary approach, and consideration of specialist symptomatic or palliative care review.

PB2127
QUALITY OF LIFE IN ANEMIC PATIENTS WITH HEMATOLOGICAL MALIGNANCIES
N. Romanenko1,*, S. Bessmeitsev1, A. Romanenko2, N. Potikhonova1, M. Zenina1
1Clinical Hematology, Russian Research Institute of Hematology and Transfusiology, 2Neurology, Children Hospital of St. Olga, Sankt-Peterburg, Russian Federation

Background: Anemia is a common complication of patients with hematological malignancies (HM), which may progress undergoing antitumor treatment significantly decreasing hemoglobin concentration and occur symptoms as fatigue, dizziness, palpitations, dyspnea markedly reduce patient activity, resulting in impaired Quality of Life (QoL).

Aims: To compare of QoL in HM’s patients with different grades of anemia.

Methods: In this study were included following patients (n=326) in the age of 19-82 (Me=65) years: myelodysplastic syndrome (n=37), acute myeloid leukemia (n=20), acute lymphoid leukemia (n=7), primary myelofibrosis (n=23), chronic myeloid leukemia in blast crisis (n=6), multiple myeloma in II and III stage (n=128), Non-Hodgkin’s lymphoma in III-I V stage (n=40) and chronic lymphocytic leukemia in B or C stage (n=67). Patients were examined: 1) clinical blood test (hemoglobin concentration) to assess anemia’s grade; 2) the Functional Assessment of Cancer Therapy-Anemia (FACT-An) scale to measure of QoL. The FACT-An questionnaire consists of a general questionnaire (FACT-G), measuring domains of physical well-being (PW), social/family well-being (S/FW), emotional well-being (EW), functional well-being (FW), an anemia-specific questionnaire – Anemia subscale (AnS), measuring fatigue-associated items – Fatigue subscale (FS) and non-fatigue-associated items – Non-Fatigue subscale (NFS). Patients were divided into six groups according to the Hb concentration: 1) the first group – Hb was 4.0-6.4 g/dl (Me=5.7 g/dl); 2) the second – Hb 6.5-7.9 g/dl (Me=7.2 g/dl); the third – Hb 8.0-9.4 g/dl (Me=8.6 g/dl); the forth – Hb 9.5-10.9 g/dl (Me=10.8 g/dl); the fifth – Hb 11.0-11.9 g/dl (Me=11.4 g/dl); the sixth – Hb 12.0-14.4 g/dl (Me=13.0 g/dl). The sixth group was control.

Results: In the first group of patients (n=34) with severe anemia grade 4 QoL was revealed too poor; number of points in the subscale of PW was 14.0±0.9, in S/FW – 14.2±0.7, in EW – 18.5±0.8, in FW – 27.8±1.3, in NFS – 13.4±0.6. In the second group of patients (n=53) with anemia grade 3 QoL was poor too; in PW – 13.3±0.8, in S/FW – 14.2±0.6, in EW – 9.9±1.7, in FW – 18.2±0.6, in NFS – 12.0±0.7. In the third group of patients (n=72) with anemia grade 2 QoL in the subscale of PW was 11.5±1.7, in S/FW – 14.0±0.5, in EW – 8.6±0.6, in FW – 16.9±0.5, in NFS – 11.6±0.6. In the fourth group of patients (n=70) with anemia grade 1 QoL in the subscale of PW was 11.3±0.7, in S/FW – 14.2±0.6, in EW – 8.4±0.8, in FW – 16.0±0.7, in NFS – 36.1±1.9, in S/FW – 25.5±1.4, NFS – 11.6±0.6. In the fifth group of patients (n=41) with anemia grade 0 QoL in PW was 11.1±0.9, in S/FW – 14.9±0.8, in EW – 7.6±0.6, in FW – 16.4±0.5, in NFS – 34.6±2.2, in S/FW – 23.7±1.6, in EW – 9.0±1.7. In the sixth group of patients (n=56) without anemia QoL in the subscale of PW was 7.5±0.9, in S/FW – 13.6±0.5, in EW – 6.4±0.5, in AnS – 14.8±0.7, in S/FW – 23.4±1.5, in FW – 14.9±1.0, in NFS – 5.4±0.6.

Summary/Conclusions: QoL was found too poor in patients with Hb <8.0 g/dl. QoL wasn’t satisfactory in patients with Hb 8.0-11.0 g/dl. But the QoL improvement were greater in patients with Hb levels >11.0-12.0 g/dl (p<0.05). These data suggest that early correct anemia with red blood cells transfusions and erythropoiesis-stimulating agents can improve QoL in a clinically meaningful way.

PB2128
AN ANALYSIS OF THE IMPACT OF LOCAL COSTS OF MEDICINES ON COST EFFECTIVENESS OF THE TREATMENT OF CANCER ASSOCIATED THROMBOSIS.
E. Reimer1,*, D.M.R. Lipp2, M. Gotfredsen1, M. Feuerbach3
1Thrombosis, LEO Pharma, Ballerup, Denmark, 2Haematology and Oncology, 3Health Economy, German Oncology, Hamburg, Germany

Background: New research has surfaced in relation to health care resource utilization and costs in Cancer Associated Thrombosis (CAT). The studies originate from the US and are difficult to transfer directly to other countries. A few studies in Europe focusing on the total cost of CAT seem to indicate that the cost data in the field of CAT varies greatly between regions. To examine the importance of region specific cost elements in relation to research related to CAT cost studies the cost driver in the newest and most relevant health economic research and compared it with the costs from 6 European countries as well as Canada.

Aims: To highlight the importance of localized or regionalized cost inputs as cost drivers when considering cost effectiveness in relation to CAT.

Methods: The cost driver is the medication in a recent analysis by Connell 2016 and thus the focus of our analysis. The American paper incorporates outcomes from 6 RCTs for treatment with LMWH in patients with CAT. The annual medication costs of LMWH for daily treatment in 365 days were 32,120 USD in wholesaler acquisition cost (WAC). For VKA the annual medication cost for 365 days was 44 USD. LMWH is the cost driver but is not cost effective due to the cost of it. The study finds that “The one-way sensitivity analysis shows that LMWH would become the preferred strategy once its annual cost was less than $7177.” In the present analysis, the daily cost acquisition cost Wholesaler Purchasing Price (WPP) (which corresponds to the American WAC) for a LMWH (prefilled treatment) was gathered in 7 large markets using a data retrieval from IHS global insights systems (Jan 2016). In addition to this, the role of the cost driver was also compared to other publications.

Results: Simply by applying the local unit cost for the treatment with LMWH for these countries, the conclusion becomes notably different. LMWH becomes the less cost effective alternative in the developed countries as well as in Canada with annual costs below 7177 USD. The price for VKA is comparable to that in the US, and does not change the cost effectiveness ratio. The data from the retrospective cost of CAT study that the cost of the hospitalization was 19% of the total cost of CAT and the CAT medication 11% of the total cost of CAT. This outlines hospitalization is a cost driver as well and not only the medication. Similar conclusions were reached in other studies. In summary, the role of the cost driver can change as a consequence of the localization of the costs. This outlines the great variation in costs in terms of CAT, and the caution it must be used with (Table 1).

Table 1.
Background: Mucositis is a frequent severe complication associated to aggressive therapies of hematological malignancies with chemotherapies and/or radiation therapy, conditioning therapy in stem cell transplants. It is self-limited within 2-4 weeks, but in this period the patient is vulnerable to systemic infections (bacterial and fungal). It could also compromise the optimal timing and dosage of the chemotherapy schedule, induce psychosocial distress, prolonged hospitalization and finally, higher costs.

Aims: Evaluating the efficacy of GelX® in chemotherapy induced mucositis.

Methods: A retrospective analysis of 77 adult patients: 17 with hematological treatments and 60 with alopecia stem cell transplantation. They were diagnosed and treated between January 2015 and December 2016 with various hematological malignancies (5 ALL, 2 ALL – 1 Ph positive, 2 blastic phases of CML, 3 AILH (CHOP/DA-EPOCH), 2 DLBCL, 1 FL (RCVP), 1 MM (radiotherapy), 1 Hodgkin disease (ABVD). Treatment regimens used for acute leukemias/blastic phases of CML were: 3+7 (3 cases), MEC (1 case), high doses ARA-C (1), GMALL protocol (1). HyperCVAD (1), Idarubicine and ARA-C(1)/HD-MTX(1). GelX® was applied as prophylactic treatment for eight patients, because the risk of mucositis was high (aggressive chemotherapy, bad oral condition, risk of prolonged neutropenia). Curative treatment of grade 3-4 mucositis was indicated for 10 patients (one was initially treated with curative intention and after that with prophylactic GelX®). In 60 patients alopecia stem cell transplantation, related to chemotherapy, un-related, 4 haplo and 21 sibling) GelX® was prescribed for treating grade 3-4 mucositis. For the 35 cases with unrelated allotransplant (21 AML, 4 ALL, 2 SA, 2ATLL, 2 MMA, 2 CML, 1 MDS, 1 BH), 16 cases of grade 3-4 mucositis has appeared. The conditioning regimen was myeloablative (14 cases) and reduced intensity (21 cases). There were 21 cases of sibling allografts (GAMIL, 3 ALL, 1 ATLL, 5 LMH, 1 CML, 2 SAA, 2 CML, 1 mycosis) with 10 cases of mucositis grade 3-4. The regimen used were 6 myeloablative and 15 nonmyeloablative. 3 from 4 cases of haplo transplant with nonmyeloablative conditioning (2MD5, 1 AHLL and 1 SAA) had grade 3 mucositis.

Results: GelX® reduced a reduction in the grading of mucositis (grad 1-2) and a shorter period of evolution (5 days) versus grade 3-4 mucositis and prolonged duration of oral lesions for those with curative treatment. From 60 patients allotransplanted, 30 patients experienced grade 3 and 4 mucositis with a medium duration of five days. All of them received GelX® as prophylactic treatment.

Summary/Conclusions: Prophylaxis is the key of successful evolution in mucositis (time to heal shorter than 10 days). Identifying candidates for mucositis is mandatory and the product should be applied starting with the chemotherapy (or in the first 24 hours on the onset of chemotherapy) in order to minimize the risk of mucositis appearance.
separately analyzed only those with young stroke (Age <45). In this cohort there were 420 patients. A total of 6 (1.4%) patients had potential PV based on the 2008 Hb criteria. On applying the 2016 revision; 37 (8.8%) patients fulfilled the Hb criteria. An exact McNemar’s test determined that there was a statistically significant difference in the proportion of polycythemia, p = 0.000. Separate analyses by gender was not significant in females, P=0.5; but significant in males P<0.005. The use of Elea Ema no. 6 was higher in males with the revised criteria for polycythemia. The impact of cost in influencing treatment decision from resource limited countries with predominant out of pocket health expenditure has been earlier reported (Phillip C et al, 2015). This revision promotes the routine use of BM and JAK-2. In our analysis we estimate this new criterion would add to the costs to each patient (~7000 per our centre estimate).

Summary/Conclusions: The present data shows that there exists a significant difference in the incidence of polycythemia in thrombosis (Ischaemic Stroke) on applying the revised criteria. The requirement to additionally investigate them with BM and molecular markers for PV has potential economic implications.

TH1006

DEPRESSION AS THE PRESENTING SYMPTOM OF CENTRAL NERVOUS SYSTEM LYMPHOMAS IN NORTHERN WESTERN TURKEY

E. G. Umit1,*, D. B. Esen1, M. Baysal1, A. M. Demir1

1Hematology, Trakya University Faculty of Medicine, Edirne, Turkey

Background: PCNSL represents approximately 4 percent of newly diagnosed primary central nervous system (CNS) tumors, with an age-adjusted incidence rate of four cases per million persons per year. Most cases of non-AIDS related PCNSL are diagnosed in patients between 45 and 65 years of age, with a median age at diagnosis in the fifth decade. The most notable risk factor for the development of PCNSL is immunodeficiency including HIV infection, iatrogenic immune suppression, and congenital immune deficiencies. Antecedent flu-like onset of CNS symptoms prior to presentation occurs in 9.7% of cases. PCNSL presenting with neuropsychiatric symptoms is underestimated due to the increased rates of depression and anxiety with antidepressant use. Diagnosis is based on imaging of the central nervous system (CNS), ideally with contrast-enhanced magnetic resonance imaging (MRI), cerebrospinal fluid (CSF) analysis, unless contraindicated due to elevated intracranial pressure. The radiographic lesion tends to be a solitary non-hemorrhagic mass, situated in the deep white matter adjacent to the ventricular surface.

Aims: We aimed to evaluate the presence of depression and antidepressant use before the diagnosis of CNS lymphoma and emphasize the duration between the diagnosis of depression and lymphoma.

Methods: Data of 40 patients with CNS lymphomas were evaluated in a retrospective manner. From their national health records, prescription for antidepressants and the duration of their use before the diagnosis of CNS lymphoma and the branch of the prescribing physician, presenting symptoms were documented. Neurophyschiatric symptoms like depression, apathy, psychosis, confusional state affecting the 50-59 years and 70-79 years age groups. 59.73% of patients had anemia at diagnosis and 40.27% of patients developed anemia during the evolution of NHL. The pathophysiological mechanisms involved in the development of anemia were: perturbations of iron metabolism and erythropoiesis caused by infiltration of malignant lymphomatous cells, cytopenias secondary to chemotherapy, immune peripheral destruction of red blood cells, iron and folate deficiency due to chronic bleeding.

Aims: To evaluate the prevalence of anemic syndrome in patients with non-Hodgkin’s lymphomas and the pathophysiological mechanisms involved in the development of anemia in this study group.

Methods: A retrospective study was conducted on 85 patients (informed consent obtained) with non-Hodgkin’s lymphoma, who were admitted to the Clinic of Hematology, Filantropia City Hospital, Craiova, Romania, in between 2013 and 2015, in order to evaluate the prevalence and pathophysiological mechanisms involved in the development of anemia in this study group.

Results: In our study group, the median age at diagnosis of non-Hodgkin’s lymphoma was 64 years, sex distribution was males:females=1:3, and the rural to urban area index=1:2. 85.88% of patients had B type H and 14.12% T type H. 20% of NHL were indolent lymphomas, aggressive lymphomas in 54% cases. EMA study on 26% NHL revealed on stage of disease: type I – 2.35%, type II – 18.81%, type III – 57.64%, and type IV – 21.16%. In our study group, 84% of patients enrolled had anemia, with the anemic syndrome affecting the 50-59 years and 70-79 years age groups. 59.73% of patients had anemia at diagnosis and 40.27% of patients developed anemia during the evolution of NHL. The pathophysiological mechanisms involved in the development of anemia were: perturbations of iron metabolism and erythropoiesis under pro-inflammatory cytokines and hepcidin action (47.25%), bone marrow failure induced by lymphomatous infiltrates (25%), anemia induced by chemotherapy (18.05%), and autoimmune hemolysis (9.7%). Five patients with anemia induced by chemotherapy and three patients with lymphomatous infiltration of the bone marrow also associated iron and/or folate deficiency.

Summary/Conclusions: In our study, anemia was present in 84% of NHL cases, more frequently found in patients that associated comorbidities and belonged to the 50-60 years and 70-80 years age groups. In half of the cases, anemia was moderately severe. 47.25% of patients had simple chronic anemia due to perturbations of the iron metabolism and of erythropoiesis, and 25% of patients presented anemia due to bone marrow failure. Chemotherapy led to an anemic syndrome in 18.05% of cases, whereas hemolysis of autoimmune causation was present in 9.7% of cases. Diagnosed as anemia, the management of anemia is extremely important in patients with NHL because it influences the administration of chemotherapy (dose intensity and density), prognosis and quality of life.
from their medical files, type and treatment of lymphoma and survival were recorded. OECD international statistics as well as Turkish Statistical Institute data for national antidepressant use were collected and interpreted.

Results: Of the 40 patients, 14 were male (35%) while 26 were female (65%). Mean age was 60.5 years (38-78). Seven patients were alive (17.5%). Method for diagnosis was radiological imaging (magnetic resonance imaging) in 27 patients (67.5%) while in 13 patients, diagnosis was supported with histopathological confirmation (32.5%). Mean survival was 8.6 months (2-24 months). As the complaint for medical help seeking, 4 patients presented with neuropsychiatric symptoms while 16 patients presented with headache (40%) and 20 patients (50%) presented with neurological defects. On the other hand, prior to lymphoma diagnosis, 7 patients were diagnosed as anxiety disorder and 13 as depression (total, 19 patients, 47.5%) and were prescribed antidepressant and anxiolytic medications. The mean duration between prescription of antidepressants and diagnosis of lymphoma was 2.6 months (0-10 months). Within the patients who were on antidepressants, 6 were female and 14 were male.

Summary/Conclusions: OECD Health at a Glance data revealed that in 2013, the defined dose per 1000 per day is 35, range of Europe is 21-88. According to our data of Ministry of Health, use of antidepressants in the general population is 10.52%, mostly in women. Within these patients, 42.37% were anxiety disorders and 22.99% were depression. In the last five years’ statistics, 30% of antidepressants was prescribed for an antidepressant. The major group of physicians prescribing these medications was family and general physicians (>4%). The most striking finding of our study was the majority of male patients receiving antidepressants before the diagnosis of CNS lymphoma with a mean delay of diagnosis as 2.6 months (0-10 months). Depression and anxiety disorders are the leading causes of disability and the importance of organic and underlying conditions should not be underestimated relying on the increasing need of antidepressants.

PB2135
IMPACT OF U.S. FDA APPROVAL OF LENALIDOMIDE MAINTENANCE THERAPY IN THE FIRST-LINE TREATMENT OF MULTIPLE MYELOMA AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANT ON TOTAL HEALTHCARE COSTS
K. Parikh1, J. Xie2, C. Chen3, C. Yang3, A. Farrukh5, P. Cockrum1, A.B. Agarwal1, S. Abouzaid1
1Celgene Corporation, Summit, NJ, 2Analysis Group, Inc, Los Angeles, CA, 3Analysis Group, Inc, Boston, 4Analysis Group, Inc, Boston, MA, 5Analysis Group, Inc., Los Angeles, CA, United States

Background: Lenalidomide maintenance therapy after autologous hematopoietic stem cell transplant (auto-HSCT) in the first-line treatment has been shown to improve progression-free survival (PFS) and overall survival (OS) in multiple myeloma (MM) patients.

Aims: This study assessed the budget impact of the United States (U.S.) Food and Drug Administration (FDA) approval of lenalidomide maintenance therapy on total healthcare costs of a U.S. health plan.

Methods: An economic model was developed to estimate the incremental (additional) total plan costs (in 2016 USD) of maintenance therapy in each year for the first 3 years after lenalidomide monotherapy (R) maintenance therapy approval. The number of post auto-HSCT adult MM pts eligible for initiating lenalidomide maintenance therapy was estimated from published epidemiological data and an analysis of Connect® MM Registry data. Clinical endpoints for R-maintenance, including time on treatment, PFS and OS, were obtained from a meta-analysis of published clinical trials (CALGB, IFM, and GIMEMA). The use of common off-label maintenance therapies was considered. Types of costs included in the model were drug, drug administration, adverse events (AE), AE monitoring, one-time progression and terminal care costs.

Results: In a hypothetical U.S. health plan with 1 million members, the number of adult MM pts eligible to initiate post-auto-HSCT maintenance therapy was estimated to be 28. Among them, 14.8 pts initiated R-maintenance in Year 1, 15.2 in Year 2, and 15.3 in Year 3, representing an incremental increase of 2.9%, 4.2% and 4.4% after R-maintenance therapy approval, respectively. After considering additional costs of maintenance, as well as potential offsets resulting from delayed progression the incremental total healthcare costs by year are listed in the Table 1. Results were consistent across all total plan, per patient per year, and per member per month costs. Deterministic sensitivity analysis showed that the model results were robust to the variations of key model inputs.

Table 1.

Summary/Conclusions: Approval of lenalidomide monotherapy for maintenance after auto-HSCT in the first-line treatment of MM has minimal impact on total plan costs, primarily due to the small incident population and the already common use of lenalidomide in post auto-HSCT maintenance.

PB2136
LAPAROSCOPIC APPROACH CAN EXTEND THE INDICATIONS OF SPLENECTOMY: ANALYSIS OF 31 CONSECUTIVE PATIENTS WITH MALIGNANT HEMOPATHIES
A. Salaroli1, B. Cadire 2, C. Spillebout1, M. Vercruyssen1, A. de Wind3, M. Maerevoet1, G. Dapri2, G. B. Cadire2, D. Bron1
1Department of Hematology, Institut Jules Bordet, ULB, 2Department of Digestive Surgery, Hôpital St Pierre, 3Department of Pathology, Institut Jules Bordet, ULB, Brussels, Belgium

Background: Surgical resection of large spleens may eliminate a significant amount of tumor, allow definite diagnosis of malignant disorder, ameliorate abdominal symptoms and resolve cytopenia. However, because of short term perioperative events (25%) and long term immunosuppression (increased risk of infections caused by encapsulated bacteria) physicians can be reluctant to choose splenectomy, especially in older patients or patients with comorbidities.

The role of laparoscopic splenectomy (LS) in patients with hematological malignancies is still unclear. Nevertheless, the ageing of the world’s population and the increased incidence of Non-Hodgkin’s Lymphoma are increasing the indications for splenectomy, requiring a well-tolerated and less invasive procedure.

Aims: The aim of this review is to analyze our single-center experience of LS performed for malignant Hemopathies. Results are compared with LS for benign splenomegaly and the risk of locoregional dissemination or inadequacy of fragmented histological sample were analyzed.

Methods: We retrospectively analyzed 50 patients who underwent LS between 2005 and 2016 at Saint-Pierre Hospital. Analysis was performed in 12 patients whereas in the remaining 38 cases, a semi-lateral position was chosen. All the patients received the triple vaccination (Streptococcus pneumoniae, type B Haemophilus influenzae, and Neisseria meningitidis). Patients characteristics, safety data such as early (<30 days) and late (>30 days) morbidities and mortality and efficacy (hematological recovery, accuracy of histological diagnosis) were analyzed.

Results: 19 patients underwent splenectomy for benign hemopathies (SBH) and 31 patients for malignant hemopathies (SMH). Non-Hodgkin’s lymphomas (12) and idiopathic myelofibrosis (10) were the most common causes of splenomegaly followed by chronic lymphocytic leukemia (7), hairy cell leukemia (1) and hodgkin’s lymphoma (1). Patients’ age (67 +/- 12, years) ranged from 36 to 87 in SMH, and from 11 to 71 in SBH), prior abdominal surgery (18/31) and spleen volume (1515 +/- 662 mL, ranging from 220 to 3000 mL in SMH, and from 90 to 1500 mL in SBH) were significantly higher in the SMH group (p <0.05). There was no significant difference in surgical time (150 vs 146 min, p=0.8), blood losses (243 vs 402 mL, p=0.26) and duration of hospitalization (5.4 vs 7.5 days, p=0.19) between SMH and SBH. No case of locoregional dissemination was experienced. The early morbidity of the SBH group was 10% and 13% for the SMH group (p=1). Late morbidity was 0% in the SBH group and 13% in the SMH group (p=0.26). This could be explained by a combination of underlying disease and immunosuppression (2 sepsis and 2 deep vein thrombosis). There was one conversion to open surgery and perioperative mortality in each group (p=1). There was no significant difference in efficacy of splenectomy, with respectively 83% and 79% (p=0.91) or quality of histological sample for pathological report (90% in the SBH and SMH group). Out of 31 patients received a pre-surgical corticosteroid treatment, with a pre-surgical platelets level of 156 +/- 108 x 10^9/L, white blood cell level of 15969 +/- 18950/mL and Hemoglobin level of 10.1 +/- 1.6 g/dL. Regarding the efficacy of LS in correcting hypersplenism in the SMH, a significant difference in term of platelets recovery after 1 month from the surgery was shown in patients efficiently Vs inefficiently operated (respectively 387 +/- 125 Vs 138 +/- 90 x 10^11/mL, p<0.05). The median follow up is 39 +/- 37 months and 80% achieved a hematological recovery.

Summary/Conclusions: LS is a safe and less-invasive procedure in patients affected by Malignant Hemopathies. This approach is also well tolerated in older patients (median 67yrs) and in patients with large spleen (1515 +/- 660 mL), extending the indication for laparoscopic SHM even in older patient and in patients with high volume spleen. Compared to historical data, LSy for Malignant Hemopathies shows better early and late morbidities. Our data shows however a trend for higher late morbidity in the SMH group, warranting a careful long term follow-up in this subset of patients.

PB2137
ARE WE AWARE OF ANXIETY AND DEPRESSION IN PATIENTS WITH NEWLY DIAGNOSED ACUTE LEUKEMIA?
M. H. Dogu1, R. Eren1, N. Nizam2, O. Yokus1, E. Suyan1
1Hematology, Internal Medicine, Istanbul Education Research Hospital, Istanbul, Turkey

Background: Acute leukemia poses a high risk of stress for the patient during the process of diagnosis. The process after the diagnosis is challenging for the
Results: 21 patients were included in the study. 13 of these patients (61.9%) were diagnosed with acute myeloid leukemia (AML) and 8 (38.1%) were diagnosed with acute lymphoblastic leukemia (ALL). Median age of the patients was 45 (range: 21-69). 11 patients (52.4%) were female and 10 (47.6%) were male. 5 patients (23.8%) had comorbidities while 16 (76.2%) had none. Anxiety evaluation revealed that 38.1% of all patients in the study experienced anxiety. The rate of anxiety was 38.5% in AML patients and similarly 37.5% in ALL patients. 45.5% of the female patients had anxiety while the rate was only 30% in male patients. The difference was not statistically significant (p >0.05). Depression evaluation revealed that 81% of all patients in the study. The rate of depression was 84.6% in AML patients and 75% in ALL patients. 81.8% of the female patients had depression while it was 80% in male patients. Neither anxiety nor depression had a significant correlation with comorbidities or gender (p >0.05). Correlation analysis revealed a positive correlation between anxiety and depression (r=0.846; p <0.01).

Summary/Conclusions: In conclusion, assessing anxiety and depression in patients with acute leukemia is an essential course of and adherence to treatment. In our study, depression was distinctively more common than anxiety and there was a positive correlation between depression and anxiety. We think that including a professional for psychological support in the medical team is important for the treatment of these patients.

Background: Three years ago, a unit for autologous bone marrow transplant for hematological patients has been established in Shaare Zedek Medical center. The patients meet with the doctors for the treatment plan usually following the diagnosis. From the point of view of a part of the patients, the process appears simple, short term, and promises cure. In reality, the process is long term, including aggressive chemotherapy prior to the transplant. The treatment is highly aggressive and toxic with many physical and mental side effects for the patient and his/her family. The transplant process requires hospital admission for about a month in an isolation room. No one is allowed in the room except for close relatives and the medical staff. The social worker, part of the caring staff, accompanies patients and families from the initial diagnosis through this taxing and stressful process. Most patients are young, average 45 years, in the middle of their careers, from a broad spectrum of occupations, education as well as social status, representing Israeli society.

Aims: 1. To accompany and empower patients by means of giving them tools to cope with the transplantation process which is a crisis situation in the midst of their lives. 2. To teach patients self-awareness. 3. Promote quality of life for the patients especially during the stay in the isolation room by way of creating a safe domain.

Methods: The following tools had been utilized: 1. The “Empowerment method”. An advanced view of the powers and experiences of patients that constitute resources in addressing crisis. 2. Work of hope- finding unique meaning in life crisis.

Results: This work is based on therapeutic conversations that took place inside the isolation room with about 30 patients, mostly men, average age was 50, during the past three years. With the understanding that a patient goes from the public sphere to a private one -the isolation room- my entrance into the room was based on the ability and willingness of the patients to go into a treatment dialogue at that point and time. From the narratives of the patients, a few themes were extracted that were repeatedly discussed by most patients. 1. Fear of death. 2. Post-traumatic issues. 3. Fear of isolation. 4. The issue of relationships. 5. Mind and body. 6. Children. 7. Faith. 8. Closure

As cited by S.A, a 49 year old man “I’m afraid to give in and die, help me to stay alive. And if I die, I want to know that I have left no unfinished business.”

Summary/Conclusions: From the therapy sessions it appears that the central issue for the patients during the private phase of the coping with it. The process of treatment helps patients to go from the private sphere back to the public one.

Recommendations: It seems essential for the patients in the isolation room, undergoing autologous bone marrow transplant, to have therapy sessions with a qualified social worker as part of the holistic care. ‘Having a room of his own’ in the process enables an opportunity to examine the inner self esteem and strengths of the patients thereby patients learn to contribute to themselves from themselves.
Sickle cell disease

**HYDROXYUREA INHIBITS MYELOID DIFFERENTIATION VIA NITRIC OXIDE SYNTHASE**

T. Subotički1,*, O. Mitrović Ajtić1, M. Diklić2, S. Vignjević Petrinović1, M. Budeč1, D. Djukić, J. Šakić3, V. Vukčič1,2,*, J. Vukoč1

1Laboratory of neuroendocrinology, 2Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, Belgrade, Serbia

**Background:** Hydroxyurea and nitric oxide (NO) inhibit erythroid differentiation, while hydroxyurea is NO-releasing agent used in therapy of sickle cell diseases in the USA, China, and Italy. The aim of our study was to determine whether hydroxyurea inhibits erythroid differentiation by examining NO synthase (NOS) dependence.

**Aims:** To study the mechanism of hydroxyurea inhibition of erythroid differentiation by exploring NO synthase (NOS) dependence.

**Methods:** The erythroid differentiation is studied by methylcellulose colony assay in mice, whereas presence and activation of endothelial NOS (eNOS) by immunocytochemistry and immunoblotting, respectively in K562 erythroblast cell line.

**Results:** In ex vivo experiments, mice exposed 7 days to hydroxyurea demonstrated significant decrease in the number of nucleated cells per femur, partially reversed by NOS inhibitor N-nitro L-arginine methyl ester hydrochloride (L-NAME). The same, but less prominent reduction has been observed with NO metabolites nitrite (NO2) and nitrate (NO3). Moreover, hydroxyurea demonstrated a large diminution in the number of bone marrow derived myeloid colony-forming unit-granulocyte/macrophage (CFU-GM), burst-forming units-erythroid (BFU-E) and colony-forming unit-erythroid (CFU-E) colonies in methylcellulose cultures. L-NAME attenuated hydroxyurea reduction of myeloid and erythroid colonies, while by itself increased CFU-E and CFU-GM colonies and slightly BFU-E colonies. NO metabolites NO2 and NO3 generally inhibited myeloid and erythroid colonies, but the reduction was more prominent by NO2 compound. Moreover, the hematological parameters and weight (before and after treatment) of mice did not show any significant difference among studied groups. Hydroxyurea increased NO production and the number of eNOS positive K562 erythroblast cell lines, while phosphorylation of eNOS and activation of AKT/MTOR signaling was not blocked by phosphatidylinositol 3-kinase inhibition.

**Summary/Conclusions:** NO produg hydroxyurea demonstrated NOS dependence in inhibition of myeloid / erythroid differentiation, not influencing the hematological parameters.

**PB2141**

**SLEEP DISORDERED BREATHING IN CHILDREN AND ADOLESCENT WITH SICKLE CELL DISEASE: IMPACT ON EXECUTIVE FUNCTION AND PROCESSING SPEED INDEX**

M. Koelbel1,*, J. Kawadler2, H. Stotesbury2, P. Balfour2, F. Kirkham1

1UCL Great Ormond Street Institute of Child Health https://www.ucl.ac.uk/ich, London, United Kingdom, 2Developmental Imaging & Biophysics, UCL Great Ormond Street Institute of Child Health https://www.ucl.ac.uk/ich, London, United Kingdom

**Background:** Studies in non-syndromic children have shown that sleep-disordered breathing (SDB) increases the risk of neurodevelopmental deficits and neuronal brain injury. Few authors have investigated the role in cognitive deficits of SDB and the associated hypoxia in children with sickle cell disease (SCD). Snoring and SDB is very common in children with SCD and may affect cognitive function in very young children. Previous data suggested that executive function was worse in older children with SCD and low mean overnight oxygen saturation.

**Aims:** We aim to investigate if SDB could be a potential factor contributing to developmental problems in cognition in children and adolescent with SCD.

**Methods:** We have followed up children and adolescents in the Sleep Asthma cohort who underwent Polysomnography at two different time points (1) 2006-2009 and (2) 2011-2014 and compared the sleep data with subsequent neuropsychological assessment.

**Results:** Worse performance was found for processing speed: PSI (p<0.01) and general intelligence (p<0.05) compared to controls. SDB, measured as apnea and hypoxia index (i.e. AHI >3%) Apneas and hypoapneas with more than 3% of breaths (p<0.05) was found to impact executive function, assessed with the Tower test. (p<0.05) and PSI (p<0.05). Mean oxygen saturation during total sleep time was significantly associated with lower PSI (p<0.05). Additionally, participants who showed a worsening of their SDB symptoms in their second sleep study had lower cognitive scores (i.e., executive function, p=0.05 and PSI, p=0.05) (Figure 1).

**Summary/Conclusions:** SDB symptoms seem to worsen into adolescence and therefore, might have a neurodevelopmental impact if left untreated; appropriate intervention might improve cognition and quality of life.

**PB2142**

**LUNG FUNCTION IN CHILDREN AND ADOLESCENTS WITH SICKLE CELL ANEMIA: A COMPARISON BETWEEN UK AND ITALY**

C. De Pietri1,2, M. Anglani1, R. Colombati1,2, L. Sainati2, K. Vecchiato3, S. Ndomo4, P. Gogo1, B. Inusa4

1Department of Clinical and Experimental Medical Sciences, University Hospital of Udine, Udine, 2Clinic of Pediatric Hematology-Oncology, Department of Child and Maternal Health, Azienda Ospedaliera-Università di Padova, Padova, 3University of Trieste, Trieste, Italy, 4Department of Pediatrics, Evelina Children’s Hospital, London, United Kingdom

**Background:** Acute and chronic respiratory complications are common in sickle cell anemia (SCA). Subjects with SCA often have a progressive decline of lung function with age that could be influenced by the quality of healthcare and by environmental factors, such as the level of exposure to air pollution.

**Aims:** To compare lung function, evaluated cross-sectionally through spirometry, in children and adolescents attending sickle cell centers in UK and Italy.

**Methods:** Anthropometry and spirometry were recorded in patients with SCA (SS,SCD) aged 6-17 years of African ancestry followed at the Evelina Children’s Hospital, London, UK, and at the University Hospitals of Padova and Udine, northeast of Italy. Subjects from the British cohort lived in an urban area while those from Italy came from urban and non-urban areas. Exclusion criteria were the presence of SCA-related morbidity within the last two weeks and the inability to perform a spirometry meeting the European Respiratory Society acceptability and repeatability criteria (Miller, Eur Respir J 2005;26:319–338), modified for children (Kirkby, Pediatr Pulmonol 2008;43:1233–1241). Portable spirometers (Pony FX, Cosmed-IT, Easy-on PC, NDD-CH) were used. Z-scores of anthropometric and spirometric data were derived, respectively, from CDC2000 and from the Global Lung Initiative 2012 predictive equations for African Americans (Miller, Eur Respir J 2012; 40:1324–1343). Spirometry patterns were classified as normal, obstructive (zFEV1/zFVC<1.64) or restrictive (zFVC< 1.64+zFEV1/zFVC ≥ -1.64). Differences between groups were assessed by t-tests and considered statistically significant for p values <0.05.

**Results:** A total of 101 children and adolescents were included (n. 62 in UK; n. 39 in Italy; 42% girls; age-range: 6.2-17.9 years). We did not find significant differences in mean spirometry indices between the SCA cohort from London and northeast Italy (Table 1). Nevertheless while an obstructive spirometry pattern was more common in the British cohort compared to the Italian one (respectively 22.5% vs 7.7%), the picture was the opposite for the restrictive pattern (respectively 11.2% and 20.5%) (Table 1). In the whole sample age was negatively correlated with both zFEV1 (Spearman’s rho -0.20) and zFVC (Spearman’s rho -0.24).

**Summary/Conclusions:** Lung function of pediatric subjects with SCA living in London and in the northeast of Italy is overall comparable. Obstructive lung disease is more common among subjects with SCA living in London than in urban and non-urban areas in Italy. Differences in the level of exposure to ambient air pollution and in the prevalence of allergies between the rural and urban environment might have contributed to this finding and need to be further investigated.

**SICKLE CELL DISEASE: A NEW DISEASE IN MADRID**

E. J. Bardon-Concha1,*, M. García-Morín1, B. Ponce-Salas1, Y. Aguilar-de la Red1, A. Pérez-Corral2, G. Pérez-Rus2, E. Dulín3, C. Beiléndez1, E. Cela1

1Section of Pediatric Hematology and Oncology, Department of Pediatrics, 2Department of Hematology, 3Newborn Screening Laboratory (Community of Madrid), Hospital General Universitario Gregorio Marañón - Facultad de Medicina - Universidad Complutense de Madrid, Madrid, Spain

**Background:** Sickle cell disease (SCD) was scarcely diagnosed 2 decades ago in Spain, and the Community of Madrid is a paradigm of the adjustments that had to be implemented to attend an increase of cases due to immigration.

**Aims:** The aim of our study was to find out the prevalence of SCD in the referral sickle newborn screening of the Community of Madrid, in addition to the demographic characteristics of these patients. The secondary objectives were to obtain the frequency of specific treatments or prophylaxis accomplished by these patients, and the reasons for loss to follow-up.
Methods: The study is observational, unicentric, descriptive and retrospective, carried out in February 2017 in a tertiary hospital in the Community of Madrid, Spain. All patients diagnosed with SCD and who had attended at least once to the hematology clinic for this reason were included. Demographic characteristics (date of birth, gender, country of birth) and clinical characteristics (genotype, therapy and update in follow up, like alive, deceased or lost patient) were collected. Written consent was signed by patients or legal guardians in accordance with the Declaration of Helsinki. The study was approved by the hospital Ethical Committee. Statistical analyses were performed using SPSS version 18.0. Quantitative variables were reported as median or mean value and range, while categorical variables were expressed as absolute value and percentage.

Results: The total number of SCD patients included was 209. Ratio boy/girl is 1.3. Most of patients were born in Spain (85%), although 8% and 5.26% were born in Africa or America respectively. Seventy three percent of the progenitors came from Africa and 24% from America. Ninety two percent of those SCD patients born in Spain were detected in the first days of life due to universal screening detection implemented in Community of Madrid since 2003. Median age at first diagnosis was 1.42 years (0-21.4). Median age at the end of inclusion was 9.91 years (range 0.13 to 35.14). SS or S/βThal was reported in 86%. In addition, 2.39% associated alla gen deletion, and 1 (0.48%) glucose 6 phosphate dehydrogenase deficiency. No patient had congenital thrombotic diathesis. Eighteen patients (8.65%) had human leucocyte antigen (HLA) identical siblings. Hydroxyurea was added to standard treatment in 65 patients (31%) of which 47 continue to be treated to date. Penicillln prophylaxis was communicated in 165 patients (79%). Vitamin-D prophylaxis was initiated in 128 patients. The change of exchange of transfusions existed in 25 cases (12%) and 9 children (4%) underwent splenectomy. None of these patients had sepsis or meningitis. Cholecyctectomy was performed in 9 cases (4%). There were 18 progenitor stem cell transplantsations (8.61%) performed between 2.09 to 13.97 years of age (median 6.77 years). Ten patients remained on the waiting list for transplantation, and 1 attained a marrow rejections. One patient died of graft-versus-host disease. Patients lost in follow-up summed up 128: 23 for emigrating to other countries, 65 for continuing the monitor of their diseases in other centers or in adults units and 31 for unknown reasons (12.87%).

Summary/Conclusions: Early diagnosis like universal neonatal screening allows an effective health education, and antibiotic and osteopenia prophlexia with vitamin D and general and specific vaccination can be started.

PB2144

COMPLEMENT ACTIVATION IN PATIENTS WITH SICKLE CELL DISEASE IS ASSOCIATED WITH HIGHER HBS LEVELS

E. Gavrilaki1,*, M. Mainou2, I. Christodoulou2, E.-E. Koravou1, A. Paleta1, T. Touloumenidou1, A. Papalexandri1, A. Athanasiadou1, C. Apostolou2, P. Klonizakis1, A. Anagnostopoulou1, E. Vlachaki2

1Hematology Department - BMT Unit, G. Papanicolaou Hospital, 2Adults Thalassemia Unit, 2nd Department of Internal Medicine, Aristotle University of Thessaloniki, Hippokration General Hospital of Thessaloniki, Thessaloniki, Greece

Background: Older studies have suggested activation of the alternative pathway (APC) in sickle cell disease (SCD). Despite the renewed interest in SCD therapeutics, little is known about APC activation in the clinical setting of SCD, possibly due to the complexity of complement diagnostics.

Aims: We investigated firstly, whether complement activation can be detected in the sera of asymptomatic SCD patients using a simple functional assay, secondly whether it is associated with clinical parameters and thirdly whether it can be blocked in vitro by the complement inhibitor eculizumab.

Methods: Consecutive asymptomatic SCD patients were enrolled prospectively from November 2016 to 2017. Patient history, clinical and laboratory data were recorded. Complement activation was detected in patient sera using the modified Ham test, a cell proliferation assay based on the susceptibility of a unique varian in phonological fluency, suggesting that poor executive control was present. The majority of children with SCD in Italy are of immigrant families whose first language is not Italian. These children thus perform poorly in tests assessing the verbal domain with adverse impact on school performances.

Aims: To evaluate if verbal language deficits in bilingual children with SCD are mainly due to linguistic and environmental issues or to impairment of executive functions.

Methods: In this study a cohort of bilingual children with SCD and social-demographically matched healthy controls recruited from elementary schools of the same school, performed an extensive battery of tests to assess naming skills, phonological and semantic fluency, attention and Executive Functions (inhibition and planning skills) and visuo-spatial skills (Boston naming test, phonological and semantic fluency tests, Flanker task, Eithorn test, PMA spatial relations subscale). All tests were administered in Italian. A composite index considering parental education and employment was used to match socially, demographically and economically children with SCD and controls. Children were classified in 3 groups: bilingual children with SCD and Italian as mother tongue; bilingual children with SCD and Italian as second language and monolingual healthy controls. Groups were compared using ANOVA test. Subsequently, post-hoc analysis was performed to test differences between the two groups in verbal language, attention and executive functions. Hierarchical regressions explored the contribution of linguistic knowledge and executive functions (i.e. inhibition) to the verbal language deficit of children with SCD.

Results: Thirty two children with HbSS SCD aged 6 to 12 years (mean age= 9.03) and 35 controls (mean age= 9.14) were enrolled. Patients and controls were matched for gender (F 53 vs 61%), ethnicity (African 30 vs 29%), % of children born in Italy (81 vs 80%), number of years lived in Italy (8.09 vs 8.31) and Socio-Demographic Index (5.15 vs 4.59). Children’s Performance (in Z scores) at Visuo-Spatial, Boston Naming, Phonological Fluency and Semantic Fluency Tests are shown in Figure 1. The results overall showed significant differences between patients and controls in inhibition and planning (p= 0.001 and 0.001 respectively) and in verbal tasks that involved Executive Functions more (i.e. phonological fluency) (p=0.004). The poorer verbal performance of children with SCD was not associated to visible lesions in Broca’s area. In fact only 9 patients presented Silent Infarcts that were all in the white matter, in watershed areas. Regression analyses showed that in children with SCD inhibition skills explained unique variance in phonological fluency, suggesting that poor executive control

Figure 1.

Summary/Conclusions: Our results suggest that complement dysregulation is evident in asymptomatic SCD patients with increased Hbs levels, an important tool in everyday clinical practice. APC activation during a painful crisis and the role of hydroxyurea need to be further investigated in larger series validating the role of different functional assays. Effective inhibition of complement activation in vitro is promising for future studies in selected patients.

PB2145

THE ROLE OF EXECUTIVE DYSFUNCTIONS IN THE VERBAL LANGUAGE DEFICITS OF CHILDREN WITH SICKLE CELL DISEASE

B. Aref1, M. Montanaro2, E. Mottura2, R. Manara3, M. Scallitini1, G. Basso2, L. Sainati2, R. Colombatti2

1Department of Psychology, University of Padova, 2Clinic of Pediatric Hematology Oncology, Department of Child and Maternal Health, Azienda Ospedaliero-Universitaria di Padova, Padova, Italy, 3Department of Radiology, University of Salerno, Salerno, Italy

Background: Children with Sickle Cell Disease (SCD) frequently present impairment of general and specific neurocognitive functions, even in the absence of clear neurological damage at brain neuroimaging. Verbal language deficits are also common, but the etiology of poor performance in the verbal domain is still not clear. The ability to speak and communicate verbally relies on a complex interaction of cognitive and linguistic functions as well as on environmental factors, like bilingualism or second language (L2) learning. The majority of children with SCD in Italy are of immigrant families whose first language is not Italian. These children thus perform poorly in tests assessing the verbal domain with adverse impact on school performances.

Aims: To evaluate if verbal language deficits in bilingual children with SCD are mainly due to linguistic and environmental issues or to impairment of executive functions.

Methods: In this study a cohort of bilingual children with SCD and social-demographically matched healthy controls recruited from elementary schools of the same school, performed an extensive battery of tests to assess naming skills, phonological and semantic fluency, attention and Executive Functions (inhibition and planning skills) and visuo-spatial skills (Boston naming test, phonological and semantic fluency tests, Flanker task, Eithorn test, PMA spatial relations subscale). All tests were administered in Italian. A composite index considering parental education and employment was used to match socially, demographically and economically children with SCD and controls. Children were classified in 3 groups: bilingual children with SCD and Italian as mother tongue; bilingual children with SCD and Italian as second language and monolingual healthy controls. Groups were compared using ANOVA test. Subsequently, post-hoc analysis was performed to test differences between the two groups in verbal language, attention and executive functions. Hierarchical regressions explored the contribution of linguistic knowledge and executive functions (i.e. inhibition) to the verbal language deficit of children with SCD.

Results: Thirty two children with HbSS SCD aged 6 to 12 years (mean age= 9.03) and 35 controls (mean age= 9.14) were enrolled. Patients and controls were matched for gender (F 53 vs 61%), ethnicity (African 30 vs 29%), % of children born in Italy (81 vs 80%), number of years lived in Italy (8.09 vs 8.31) and Socio-Demographic Index (5.15 vs 4.59). Children’s Performance (in Z scores) at Visuo-Spatial, Boston Naming, Phonological Fluency and Semantic Fluency Tests are shown in Figure 1. The results overall showed significant differences between patients and controls in inhibition and planning (p= 0.001 and 0.001 respectively) and in verbal tasks that involved Executive Functions more (i.e. phonological fluency) (p=0.004). The poorer verbal performance of children with SCD was not associated to visible lesions in Broca’s area. In fact only 9 patients presented Silent Infarcts that were all in the white matter, in watershed areas. Regression analyses showed that in children with SCD inhibition skills explained unique variance in phonological fluency, suggesting that poor executive control

Figure 1.
was a factor of the lower performance in this task. Figure 1. Children’s Performance (in Z scores) at Visuo-Spatial, Boston Naming, Phonological Fluency and Semantic Fluency Tests. P-values: Visuo-spatial intelligence: not significant(n(s); Boston naming: ns; Phonol-Fluency: 0.004; Semantic fluency: ns.

at home to manage the onset of an acute crisis and the top 5 home strategies reported were: prescription pain medication (15%), sleep/rest (15%), apply heat using heating pad/blanket/bath/shower (13%), increase fluid intake (12%), and finally avoid stress (9%). Further it is clear, that people living with SCD are motivated to try a new therapy that could provide “significant relief” and “prevent symptoms from happening” due to their SCD.

Figure 1.

Summary/Conclusions: Selective language problems may occur in children with SCD in the absence of clear neurological damage to language areas. These problems are explained by the executive dysfunction of patients with SCD and not by environmental factors like bilingualism. Cognitive rehabilitation or extra tuition may aid in overcoming these difficulties.

PB2146

UNDERSTANDING MEDICAL HISTORY, LIFESTYLE AND NEEDS FOR FUTURE THERAPIES FOR PEOPLE LIVING WITH SICKLE CELL DISEASE - IMPLICATIONS FROM A PATIENT SURVEY

A.M. Leitgeb1,*, M. Robinson2, C. Herder1, L. Jendeberg1

1Modus Therapeutics, Stockholm, Sweden, 2Micromatter Consulting Inc, Oviedo, Florida, United States

Background: Sickle Cell Disease (SCD) is an inherited blood disorder affecting millions of people. Sevuparin/DF02 is being developed to treat people suffering from SCD and is currently in clinical phase 2 for the treatment of the acute painful crisis in hospitalized SCD patients with intravenous infusion. This is called the Resolve program. In a second program called EASE, sevuparin/DF02 will be investigated as an on-demand treatment of early symptoms of painful sickle cell crisis in an at-home setting via a subcutaneous injection. Searching in the literature and discussing with health care providers, it becomes clear that little is known about how the SCD patients sense these early symptoms of a painful crisis. In order to gain increased understanding of how people living with SCD experience daily life, coping with disease, support by health care providers and the demand for new therapies, a patient survey addressing these areas was conducted.

Aims: The aim with this survey was to gain deeper understanding of different aspects of life with SCD by providing a channel for patients to air their own views. The outcome will provide important information and, in combination with future feasibility studies, will guide the design of the first clinical study aimed at treating the early symptoms of pain crises in SCD patients.

Methods: A 29-question survey was created to gather input on a wide variety of topics related to the lives of people living with SCD. This questionnaire was developed by Modus Therapeutics AB, Sweden, in conjunction with Micromatter Consulting Inc., USA. Experts and leaders of community-based organizations participated in two focus group sessions to ensure that the text and structure were ethical and appropriate for the intended purpose. The survey was hosted at www.modustherapeutics.com. Patients answered the survey directly, or had their views entered in by a caregiver. The answers are anonymous. During the initial period, survey promotion occurred within the Sickle Cell Warriors online community and later, additional connections within the network of community-based organizations were leveraged. The survey was open for access during the period of January 10, 2017 through March 1, 2017.

Results: An interim analysis was conducted on January 31, 2017. Basic demographic data is presented in Table 1. Responders were located mainly in the US. Medical history related questions indicate that fatigue (40%), aches/pain (37%), irritability (27%) and appetite (20%) are early symptoms and increase just before the onset of a pain crises. However, 7% reported infrequent signs and 19% never experienced an indicator of pain crisis. Patients take initiative

Table 1.

Summary/Conclusions: The survey collected feedback about topics for which the patient is the best source of information. It is obvious that people with SCD are willing to self-medicate by subcutaneous injections and that there is a need for new tools and medications. With support from the answers from the survey, specific aspects will be considered while designing a first clinical study for subcutaneous sevuparin/DF02 administration to treat early symptoms of painful crisis in an at-home setting.

PB2147

LONG-TERM USE OF HYDROXYUREA IN CHILDREN AND ADOLESCENTS WITH SICKLE /BETA THALASSEmia

M. Economou1,*, A. Tsil1, E. Papadopoulo1, A. Papastergiopoulos1, S. Theodoridou2, F. Papachristou2

1Aristotle University of Thessaloniki, 2Blood Bank, Hippokration General Hospital, Thessaloniki, Greece

Background: Hydroxyurea (HU) has lately been used in the treatment of patients with severe sickle cell disease (SCD). Despite documented benefits on laboratory and clinical parameters in SCD patients, there are few reports about drug’s long-term safety and efficacy in pediatric patients with SCD – even more so in the rare patient subgroup of sickle/beta thalassemia.

Aims: A prospective, long term evaluation of HU efficacy and safety in children and adolescents with sickle/beta thalassemia (S/b thal).

Methods: Ten patients with S/b thal aged 3.5-18 years were followed for a 6 year period (Jan 2011- Dec 2016). HU was given at a daily dose that ranged from 10 to 20 mg/kg, with a mean of 14.1 mg/kg. Laboratory follow-up consisted of WBC, Hb, Ht, RBC, reticulocyte count and PLT count measured every 2 weeks until dose escalation to a stable dose, biochemistry assessed every 2 months and Hb F measured every 2-3 months. Patients were clinically evaluated prior to HU treatment and every 12 weeks during the study period. Evaluated data on clinical course included frequency of vaso-occlusive crises, hospitalizations and transfusions, as well as presence of severe clinical events. Hematologic toxicity of hydroxyurea was defined as a more than 20% decline from baseline in Hb, as an absolute neutrophil count of less than 1,000/μl and/or a PLT count of less than 80,000/μl. Moreover, presence of alopecia, rash, skin hyperpigmentation or headache was reported as drug-related toxicity.

Results: A significant reduction in vaso-occlusive crises as compared to prior to HU treatment was noted (median: 1 episode per year before HU, range: 0-2.5 vs median: 0.24 episodes per study year after HU, range: 0-1.33, p=0.011). A significant reduction in hospitalizations was also reported (median: 1 per year before HU, range: 0-3.2 vs median: 0.16 per study year after HU, 0-0.83, p=0.005). None of the patients presented with severe clinical events such as acute chest syndrome, avascular bone necrosis, stroke or splenic sequestration during the study period. With regards to hematological parameters, a significant increase in HbF (10.2±6.5% vs 16.6±7.1% p=0.02), MCV (66.1±3.9fl vs 79.3±8.4fl, p<0.001) and MCH (20.9±1.2pg vs 25.3±2.2pg, p=0.001), as well as a decrease in reticulocyte count (7.7±3.3/μl vs 5.0±1.9/μl, p=0.039), WBC count (9.56±3.674/μl vs 7.46±6.46/μl, p=0.009) and PLT count (333.778/μl±170.227 vs 272.111±160.304/μl, p=0.007) was noted. Concerning adverse events, one patient presented with mild transaminasemia, one with mild elevation of serum creatinine levels and one with pancytopenia. Due to persistent pancytopenia HU treatment was discontinued in the last mentioned patient, but was restarted a year later due to frequent vaso-occlusive events - despite the patient being put on transfusions after initial HU discontinuation. Besides the pancytopenia episode, the rest of the mentioned toxicities were short-term and dose-dependent.

Summary/Conclusions: The study indicates that HU has an overall safe profile and results in a marked improvement of clinical course in pediatric S/b thal patients.

860 | haematologica | 2017; 102(s2)
IN VITRO AND IN VIVO EVIDENCES OF SICKLING REVERSAL INDUCED BY REHYDRATION WITH HIGH K+-ISOTONIC SOLUTION
O. I. Ajayi1, O. O. Adegbe1, F. Ozdemir2
1Physiology, 2Medical Laboratory Science, University of Benin, Benin city, Nigeria

Background: Erythrocyte sickling and adhesion are favoured by cellular dehydration, which increases the rate of hemoglobin polymerization and cell sickling. Potassium ions co-transport with calcium-activated potassium channel (Gar- donos channel) mediate erythrocyte dehydration in sickle cell disease and β-thalassemia. We investigated the in-vitro and in-vivo effects of various concentration of K+ ions in physiological solutions (PSS) as well as in cocos nucifera water (CNW) which is known for its natural high potassium content and isotonicity.

Aims: This study was aimed at ascertain the efficacy of high potassium isotonic solutions in rehydrating sickling cell and possibly reversing the sickling phenomenon in vivo and in vitro situations.

Methods: 1. Erythrocytes from twenty sickle cell anemia (SCA) as well as 46 healthy subjects were studied. One part was treated with sodium metabisulphite (Na2S2O4) solution to induce maximum sickling as controls while the other was subjected to different high concentrations of K+ in PSS as well as Cocos nucifera water (40mM, 80mM and CNW - 65mMOL/L) respectively. The procedure was repeated for the normal HB AA subjects. Also, both groups of subjects were given 10ml/kg body weight of coconut water to drink as a single dose for the in-vivo experiment. Blood samples were collected longitudinally before and after the oral ingestion, at 1hr and at 24hrs for analysis of red cell indices as well as stained blood films used to ascertain the percentage sickled erythrocytes count before and after the treatment in both cases.

Results: Maximum percentage counts of sickled cells after the addition of Na2S2O4 (45%) were observed which decreased significantly (P<0.05, respectively) to about 2% with Cocos nucifera and 10% with 80mM K+PSS. The count in 40mM K+PSS was not statistically significant. In both HB AA and SS subjects, MCHC of CNW remained stable from pre-ingestion sample point (P>0.05, respectively) while MCHC increased significantly in both groups as early as 1hr and sustained till the 24th hour. MCHC was equally raised in the in-vitro samples (P<0.05, respectively). The morphology of red cells also indicated a lesser count of sickled red cells after the oral ingestion Summary/Conclusions: Cocos nucifera water and other high potassium ion solutions can activate the rehydration of sickle erythrocytes by probably de-activating the Garbos channel to increase the mean corpuscular haemoglobin concentration (MCHC) and thereby restoring the normal red cell shape. We suggest a probable pharmacological value of the cocos nucifera water as well as other formulated high potassium but isotonic fluids in SCA management.

VITAMIN D IN SPANISH CHILDREN WITH HEMOGLOBINOPATHIES.
A.M. Bobes Fernández1,2,3,*, B. Ponce1,2, Y. Aguilar1,2, C. Garrido1,2, M. García-Marín1,2, E. Celis Pascual1,3
1Hospital Gregorio Marañón, 2Facultad de medicina, Universidad Complutense de Madrid, 3Hospital Clínico San Carlos, Madrid, Spain

Background: Although vitamin D deficiency has been documented as a frequent problem in studies of children, there are limited data on the prevalence of this nutritional deficiency among children who suffer from sickle cell disease (SCD) or thalassemia. Vitamin D homeostasis is important to prevent osteopenia. Furthermore vitamin D deficiency has been associated with increased risk of common cancers, autoimmune diseases, hypertension, and infectious diseases. Vitamin D deficiency is now recognized as a pandemic. The major cause of vitamin D deficiency is the lack of sun. Although Spain has a high rate of sunny hours, we have found low levels of vitamin D in our patients with SCD or thalassemia.

Aims: The purpose of this work is to assess the status of vitamin D in children with SCD and thalassemia in our setting.

Methods: We have recruited children diagnosed with SCD and thalassemia between 1998 and 2016 and we have reviewed their vitamin D levels. We have chosen the first vitamin value we obtained and the last one till today. Vitamin D was measured by quantitative determination of 25(OH) D. Deficit of vitamin D was defined by<30 ng/ml. The study enrolled 114 children. Most of them, with SCD diagnosis (94%). The type of anaemia was Hb SS (94 patients), Hb SC (8 patients), Hb Sβ0 (3 patients) and HbSβ+ (2 patients). The remaining 6% were diagnosed with Thalassemia Major. Mostly of the children were African or Central-South American. In our centre, vitamin D prophylaxis is made since the first year of life.

Results: 60% of the children had vitamin D deficiency. We have divided children into 4 groups depending on the age. When considering vitamin D first determination; mean vitamin D levels in children below 2 years old were 39.5±13.3 ng/dl, 2-5 years old 35.7±13.5 ng/dl and five years old had a mean serum vitamin D of 35.5±14.8 ng/dl. Children aged between five and ten had 35.7±13.5 ng/dl and between ten and fifteen 35.5±14.8 ng/dl. Finally in the group older than 10, we observed mean of 7.4±14 ng/dl. When having these low levels of vitamin D, we strongly recommend to start treatment with Cholecalciferol 25000U/month. Regarding second levels of vitamin D, we have divided patients into those who presumably have the treatment for children who do not. We present the results in the following Table 1.

Vitamin D treatment

Summary/Conclusions: The study found a high prevalence of vitamin D deficiency in children older than five years old (in the first determination) with SCD or Thalassemia. Major and significant decrease of levels in those not having vitamin D therapy. It is not well known the physiopathology of this factor deficiency, although it is supposed to be multifactorial. However we confirm that living in a sunny geographical situation with a healthy diet is not enough to maintain adequate 25(OH)D levels. Although all groups had low serum vitamin D levels vitamin D increases when having correct doses. We have also checked that older children have lower levels of vitamin D than younger boys. This could be explained by the fact that pre-teenagers spend lot of time at home instead of going out. If prophylaxis is made not only the vitamin levels will increase but bone growth also.

KNOWLEDGE OF SICKLE-CELL DISEASE IN HAUTE-NORMANDIE, SOCIO-DEMOGRAPHIC CONTEXT AND HEALTH CHARACTERISTICS: INTEREST OF THE IMPLEMENTATION OF A PATIENT EDUCATION IN SICKLE CELL DISEASE
A. Van Eilanden2, A. Lahary3, J.-M. Kerleau4, H. Levesque2
1Internal Medicine, Hopital Delafontaine, Saint Denis, 2Internal Medicine, 3Hematology, CHU Rouen, Rouen, 4Internal Medicine, Centre hospitalier de Dieppe, Dieppe, France

Background: Sickle cell anemia (SCA) is a genetic disease causing a severe disease manifesting by painful crisis but which can also be marked by organ complications. Mortality is still happening at a young age. Many of these complications may be better taken care of if treated early. The best way to manage this disease is probably through Patient Education (PE). Patient Education and sickle cell anemia has been a subject of research, organized in France by association such as ROFSED, but PE in adult patients has been little studied. The main objective of this work was to evaluate SCA patients followed in Haut-Normandie, from a sociodemographic, health and socio-demographic perspective in order to establish a PE program. The secondary objective was to give them the opportunity to express their expectations of such a program.

Methods: We did an observational multicenter study. A self-identification of 39 items was sent to all patients suffering from SCA followed in Haut-Normandie. Results: Fifty patients (male / female ratio 0.92) out of 123 (40.6%) responded, mean age 33±10.5 years (SS genotypes [66%], SC[25%], S-beta-thalassemia [9%]). 56% of them were born outside of Metropolitan France, 36% came from French speaking African countries. Agerage age was 18±10.9 years. Despite the fact that their education has been disrupted by the disease for the majority (69.4%) the level of education was “satisfactory”: 68% of patients had graduated from high school or achieved a higher level, 18% had graduated from professional education, 10% had a primary / middle school level and 4% were illiterate. 68% of the patients had a job or were students. 48% of patients reported to practice physical activity at least once weekly. Tobacco was consumed on a daily basis by 14%, alcohol 2% and 4% for cannabis. Self-assessment of health status was 6.9 / 10, self-assessment of morale of 7.9 / 10 and impact of the disease on daily life was estimated at 5.4 / 10. The mean age at which specialized follow-up was started was 11±9 years. 88% of the subjects stated that they understood everything the doctor said during consultation. Missed appointments were reported by 26% which was justified by forgetfulness, lack of will or physical incapacity. Regarding sources of information regarding SCA, patients declared asking their specialist first and then looking on the internet. 68% of subjects had a first-degree relative suffering from the same disease, 71% were able to talk about the disease with their family. While the triggers of crises and the management of these crises were well-identified by patients (average scores of 13.8 and 12/20), “standards” were not met with chronic complications, prenatal diagnosis, and long term treatment (mean scores respectively of 7.4; 4.2 and 2.2 / 20). Average score on the whole questionnaire was 9/20. Most patients showed interest in PE (52.1%) vs 31.3% that claimed were not interested, 17.7% did not decide.

Summary/Conclusions: A majority of SCA adults followed in Haut-Normandie are first-generation migrants. Even if the disease has heavy impact on everyday life and school access, their education level appeared correct. PE sessions will need to focus on chronic complications, prenatal diagnosis, and the long term treatment. The majority of adults with SCA are motivated by PE, we will have to adapt to a heterogeneous population in terms of educational level, ethnic origin and knowledge of the disease.

DELAYED HAEMOLYTIC TRANSFUSION REACTIONS: A MASQUERADE OF SICKLE CELL COMPLICATIONS
H.N. Fernandez - Leyva1,2, S. Kotsiopoulou1, N. Osuji3, J. Maitland1
1Haematology, Croydon University Hospital, London, United Kingdom
Background: Patients with sickle cell disease (SCD) may require repeated red blood cells (RBCs) transfusion, putting them at risk from minor blood group alloimunization and the development of delayed haemolytic transfusion reactions. Aim: To report a prevalence of recognized DHTR syndrome in patients with SCD.
Methods: We reviewed the cases of (DHTR) in SCD patients in a 5-year period (2010-2016). A total of 10 patients had a clinical picture compatible with DHTR and underwent treatment with high dose steroids, intravenous immunoglobulins (IVIG) or erythropoietin. Any patient received Rituximab.
Results: The most common indications for transfusion were anemia due to vasococclusive sickle cell crisis or preoperative anaemia optimization. The cohort received partial exchange transfusion and phenotypically matched RBCs. Before transfusion the median of Hb level was 69 g/L (baseline range 80g/L) and the nadir at haemolysis episode was 38 g/L. Ht was 21.9%. WBC was 17.3 × 10⁹ cells/L and mean LDH 1290 IU/L. The median time to develop DHTR was seven days after the transfusion and approximately 6 days after the surgical interventions (range: 4–12 days) and all cases presented with symptoms of anaemia, jaundice, tiredness and tachycardia. The median age was 29 years with female predominance (6:4). Blood cultures were negative in 80% of patients and only positive in 2 cases, 30% of patients tested positive for viral infection on PCR. Mortality rate in our series was low (zero). Pain episodes and other complications associated with DHTR was treated as required and four cases were successfully monitored in HDU. One patient required noninvasive ventilations and inotropic support. Two patients received RBC transfusions and were discharged. None of patients received packed RBCs. Possibly as their presentation mimics an acute vaso-occlusive crisis. In all cases hemoglobin stabilized and improved, symptoms resolved and patients were discharged on small course of oral antibiotics (median admission 6 days).
Summary/Conclusions: The symptoms of DHTR can be mistaken for other SCD complications, including infection and vaso-occlusive crisis. The diagnosis of DHTR is based on clinical suspicion, when there is a rapid Hb drop after a recent RBC transfusion with clinical signs of haemolysis. To support the diagnosis, laboratory tests (serial FBCs, haemolysis screen, DAT, measurement of Hb S levels) and exclusion of other aetologies are useful. Whenever a DHTR is suspected, further RBC transfusion should be withheld unless absolutely necessary, as it may precipitate acceleration of the hemolytic reaction. Patients in whom the diagnosis of DHTR is missed may receive repeat transfusions, which may contribute to the complications associated with SCD. The use of more extensive phenotypic matching of blood and minimizing RBC transfusion help to prevent DHTR. The present data emphasize the importance of early recognition of symptoms and signs in correlation with a recent history of RBC transfusions, as DHTR can be a potentially life-threatening complication.

HBS MONITORING ON TOSOH G8 IN VARIANT HBA1C MODE IN CASE OF URGENT RCE
S. Van Aelst1, E. Nacker1, K. Desmet1,2, D. Kieffer1,2
1Department of Laboratory Medicine, University Hospitals Leuven, 2Department of Cardiovascular Sciences, 3Department of Microbiology and Immunology, KU Leuven, Leuven, Belgium
Background: Pre- and post-transfusion Hbs levels are used to document the efficacy of red blood cell exchange (RCE) in patients with sickle cell disease (SCD). In case of urgent RCE a 24/7 STAT analysis, with the ability to identify and quantify hemoglobin (Hb) S, is warranted.
Aims: We evaluated the use of Tosoh Automated Glycohemoglobin Analyzer HLC-723G8 (Tosoh Europe, Amsterdam, The Netherlands) for this purpose, using the variant Hba1c mode. Results were compared to our routine CE Minicap Flex Piercing (Sebia, Lisses, France).
Methods: Within- and between-run imprecision were assessed using a sickle cell trait and a sickle cell anemia sample, aliquoted and stored at -80°C, twice
Results: More specifically, for samples with a Hbs concentration <25%, differences in Hbs results ranged from -8.76% to -0.43%.
Summary/Conclusions: In our clinical laboratory, TOSOH G8 is used in variant Hba1c mode to quantify Hba1c. Previous studies demonstrated reliable Hbs identification using TOSOH G8 in variant Hba1c mode. Our study showed good analytical performance for Hbs quantification using TOSOH G8. Good correlation with Minicap Flex Piercing system was found, although results were statistically not interchangeable. Our results suggest that TOSOH G8 in variant Hba1c mode generates lower Hbs results in samples with a high Hbs concentration (>25%) compared to our routine analyzer. However, the goal of RCE is to achieve a post-transfusion Hbs level of 30% or less. Therefore, results obtained with TOSOH G8 are clinically acceptable to monitor post-transfusion Hbs levels. Importantly, Hbs on TOSOH G8 can only be requested in case of urgent RCE. Our routine hemoglobinopathy screening will still be performed using CZE Minicap Flex Piercing in combination with CE-HPLC Variant 1TM.

SICKLE CELL PAIN IN CHILDREN: TARGETS FOR ADMINISTRATION OF ADEQUATE INITIAL ANALGESIA
A. Rushd1, A. Ramanathan2, B. Inusa1
1KCL, 2GSTT, 3Paediatric haematologist, Guys St Thomas Hospital, London, United Kingdom

Background: Acute pain is a hallmark presentation in sickle cell disease (SCD) and frequently requires attendance to the emergency department (ED).

Aims: Here we report our findings following a complete retrospective audit cycle, documenting the timeliness of analgesia administration and post-treatment pain review as per National Institute of Clinical Excellence and College of Emergency Medicine guidelines, in children with SCD presenting to a single inner city London ED over a 14 month period.

Methods: In 2014, we evaluated 48 patient records of children presenting to the ED, with respect to mild, moderate and severe pain scores, time of analgesia administration and pain review. Completing the audit cycle, 97 records were re-audited in 2015. A total of 145 admission records were evaluated.

Results: In 2014 the ED met CEM criteria for the timeliness of analgesia administration in 100% of severe and 95% of the moderate pain category; however fell 33% short of NICE standards. Pain review was poorly performed, identifying an area for improvement. Proportions meeting the aforementioned criteria fell significantly in 2015, except review of moderate pain, which increased by 25%.

Summary/Conclusions: We conclude CEM guidelines promote timely administration of analgesia in patients with severe pain; however mild pain may be overlooked. NICE avoids this discrimination. Thus we recommend combining the mild and moderate pain categories to acknowledge the fluctuating nature of sickle pain and its tendency to rapidly escalate. In addition, we reiterate the need for regular pain reviews. This is important in ensuring analgesia is closely titrated to pain level.

PB2155
DIAGNOSTIC CHALLENGES IN A POPULATION WITH INCREASED IMMIGRATION: HEMOGLOBINOPATHIES IN THE NEW CULTURE
J. Zanabili-Al-Sibai1, A. Forseca Murelle1, T. Arias Fernández1, L.R. Morais Bras1, L.F. Ávila Idrivo1, C. Castaño Férnandez1, A. Solé Magdalena1, A. Bernardo Gutiérrez1, R. Llorente de Jesús1
1Hematology, HUCA, Oviedo, Spain

Background: The diagnosis of hemoglobinopathies (Hbpts) has changed in recent years due to immigration, with an increase in structural Hbpts. In our region, Asturias, population census is 1,061,756 habitants; 48,097 out of them are immigrants.

Aims: Review the incidence of structural Hbpts and thalassemias in our region in the last 10 years.

Methods: A retrospective analysis was performed with 1202 hemoglobin (Hb) studies at Hospital Universitario Central de Asturias between January 2006 and March 2016. The studies came from medical applications, the finding of abnormal Hb patterns in the HbA1c test or suggestive results of thalassemia on hematology test. Studies were performed by high-performance liquid chromatography (HPLC) with the Variant Hemoglobin Testing machine of Bio Rad, and Hb electrophoresis with Paragon plates until May 2013. Since then, it has been performed by capillary electrophoresis (CE) with the MINICAP System of the laboratory.

Results: We analyzed 1202 patients, 49% were males and the median age was 33 years (range 0-85). We found 562 patologic studies. - Thalassemias were detected in 390; 337 were β or δβ (86.4%); 54% came from Spain. The cases of β-thalassemia were: 5 intermedia, 3 major, 1 δβ-homozygote and 95% of the moderate pain category; however fell 33% short of NICE standards. Pain review was poorly performed, identifying an area for improvement. Proportions meeting the aforementioned criteria fell significantly in 2015, except review of moderate pain, which increased by 25%.

Summary/Conclusions: We conclude CEM guidelines promote timely administration of analgesia in patients with severe pain; however mild pain may be overlooked. NICE avoids this discrimination. Thus we recommend combining the mild and moderate pain categories to acknowledge the fluctuating nature of sickle pain and its tendency to rapidly escalate. In addition, we reiterate the need for regular pain reviews. This is important in ensuring analgesia is closely titrated to pain level.
Summary/Conclusions: L-arginine supplement should be made available in the paediatric emergency unit, clinic and pharmacy department in high risk communities to obviate the negative effects during vaso-occlusive crisis and potentially reduce the length of stay in the hospital. L-arginine, nitric oxide, total antioxidant capacity, malondialdehyde and glutathione levels should be routinely monitored in sickle cell disease patients particularly those presenting with vaso-occlusive crisis.

Saint-Justine, University of Montreal, Montreal, Canada, 11Hematology Department, Hospital Infantil Universitario Nino Jesus, Madrid, Spain, 12Institute of Hematology and Oncology Paediatrics, Hospices Civils de Lyon, Lyon, France, 13Hospital Sino Libanés, Sao Paulo, Brazil, 14Division of Stem Cell Transplantation and Immunology, Hospital for Children and Adolescents of Frankfurt, Frankfurt, Germany

Background: Body mass index (BMI) may influence outcome after allogeneic transplantation. Previous studies have demonstrated that being obese or underweight may have a detrimental effect on survival rates after chemotherapy induction in children with acute leukemia. However, the impact of BMI of transplanted patients on survival is still not clear, with conflicting results being reported on this issue.

Aims: To analyze the effect of BMI on UCBT outcomes in children with acute leukemia

Methods: We retrospectively analyzed 517 patients aged from 2 to 20 years with acute leukemia who underwent umbilical cord blood transplantation (UCBT) from 1990 to 2015. Patients were classified according to BMI as normal (5th-85th percentile), underweight (<5th percentile), overweight (85th-95th percentile) and obese (>95th percentile) by using growth charts for age and gender.

Results: Sixty-one percent (n=314) of patients were in the normal category, 12% (n=63) were underweight, 15% (n=80) overweight and 12% (n=80) obese. All patients received single-unit UCBT after a myeloablative conditioning regimen. Diagnosis was acute lymphoid leukemia in 70% (n=363) and acute myeloid leukemia in 30% (n=154). Median age at UCBT was 7.4 years (range 2-19.6). Cytomegalovirus (CMV) serology was positive in 45% patients; 60% of patients were male. Most patients (92%) were in complete remission at UCBT. Median follow-up was 52 months (range 2-201). Total body irradiation (>6 Gy) was used in 58% of cases; antithymocyte globulin (ATG) in 68% of cases. Median infused total nucleated cell (TNC) dose was 4.2x10^7/Kg (0.3-17.8); 56% of patients received a graft with 0-1 HLA mismatch donor. Four-year overall survival (OS), leukemia-free survival (LFS) and non-relapse mortality (NRM) were 22.8% (19.2-26.7%). In univariate analysis, no statistically significant difference in OS, LFS, GRFS, neutrophil engraftment, NRM and chronic GVHD between the 4 groups identified according to BMI was identified. Conversely, acute GVHD was 44.3% (33.3-58.8%) for underweight, 36% (31-41.8%) for normal, 26.2% (18.1-38%) for overweight and 23.3% (14.7-37.1%) for obese (p=0.03). Among patients underweight who experienced acute GVHD (n=27), 37.5% had grade III-IV acute GVHD with gut involvement. In multivariate analysis, infusd TNC dose>4.2x10^7/Kg was associated with higher neutrophil engraftment (HR=1.46, CI 95% 1.19-2.78, p<0.001), underweight (<5th percentile) (HR=1.8, CI 95% 1.19-2.78, p<0.001) and female gender (HR=1.5, CI 95% 1.03-2.23, p=0.03) were associated with higher NRM. ATG use (HR=1.6, CI 95% 1.05-2.31, p=0.03) was associated with higher relapse incidence. Moreover, ATG use and a positive CMV serology were associated with worse OS (HR=1.6, CI 95% 1.15-2.17, p=0.04 and HR=1.3, CI 95% 1.01-1.69, p=0.001, respectively) and LFS (HR=1.6, CI 95% 1.17-2.16, p=0.001 and HR=1.34, CI 95% 1.04-1.72, p=0.02, respectively). Infused TNC >4.2x10^7/Kg was associated with higher neutrophil engraftment (HR=1.46, CI 95% 1.19-2.78, p=0.001) and BMI <5th percentile (HR=1.8, CI 95% 1.19-2.78, p=0.001) were associated with higher incidence of acute grade II-IV GVHD.

Summary/Conclusions: In conclusion, we did not find association of obesity with transplant outcomes in this study population. However a BMI <5th percentile at UCBT was found to be associated with higher risk of acute GVHD, highlighting the importance of nutritional status before UCBT.

PB2158

PROSPECTIVE PHASE STUDY OF REDUCED TOXICITY CONDITIONING CONSISTED OF HIGH DOSE CYTARABINE, FLUDARABINE, CYCLOPHOSPHAMIDE +/- TOTAL BODY IRRADIATION FOLLOWED BY ALLOGENIC STEM CELL TRANSPLANTATION

S. Kasahara,1* H. Nakamura,2 Y. Kaneda,1 Y. Ikoma,2 E. Takada,3 Y. Shibata,1 T. Matsumoto,2 N. Nakamura,2 S. Ninomiya,2 J. Kitagawa,1 H. Goto,1 T. Hara,2 M. Sawada,2 T. Takahashi,1 K. Saito,1 M. Shimmizu,1 H. Tsurumi1
1Hematology, Gifu Municipal Hospital, 2Hematology, Gifu University Graduate School of Medicine, 3Hematology, Gifu Red Cross Hospital, Internal Medicine, Gihoku Kosei Hospital, Gifu, Japan

Background: Allogeneic hematopoietic stem cell transplantation (allo-SCT) using reduced intensity conditioning (RIC) has been widely applied to elderly or frail patients who are not eligible for conventional conditioning regimen. However, benefit provided by reduced toxicity has been often offset by increased incidence of relapse. So far, the optimal conditioning for those patients has not been established.

Aims: Here, to investigate whether addition of high dose cytarabine (AraC) to RIC regimen consisting of fludarabine (Flu) and cyclophosphamide (Cy) +/- total body irradiation (TBI) can be available for elderly or frail recipients, phase II study has been designed.

Methods: This study was conducted from April 2011 to December 2015. The protocol was approved by each institutional review board (Trial identifier: UMIN000007281). Patients aged from 55 to 70, or patients who have some organ damage or a history of SCT aged from 20 to 54 with hematologic malignancies were enrolled after obtaining written informed consent. Bone marrow (BM), peripheral blood (PB), or cord blood (CB) was used as stem cell sources. Pretransplant conditioning regimen consisted of 30 mg/m² of Flu for 5 days (total 150 mg/m²), 4 g/m² of AraC for 2-4 days (divided by 2 daily, total 8-16 g/m²) and 50mg/kg of Cy for a day. Fourgray of TBI was used for all CB transplant recipients, whereas 2 gray of TBI was used in other stem cell sources except for donor bone marrow recipients according to each institution’s policy. Calcineurine inhibitors (cyclosporine or tacrolimus) and short term methotrexate were used as GVHD prophylaxis. Donor cell engraftment and 60 day-survival were assessed as a primary end point to evaluate feasibility of this protocol.

Results: Thirty nine patients including 7 recipients with a history of SCT were enrolled. Median age was 61 (28-89), 21 were male, and 18 were female. Nineteen were acute myeloid leukemia, 11 myelodysplastic syndrome, 6 malignant lymphoma and 3 acute lymphoblastic leukemia. Donors were 4 matched related donors, 8 matched unrelated BM, 5 1-Ag/allele-mismatched unrelated BM, and 22 haploidentical donor haematopoietic progenitors (haploTPH).

Pretransplant conditioning regimen consisted of 30 mg/m² of Flu for 5 days (total 150 mg/m²), 4 g/m² of AraC for 2-4 days (divided by 2 daily, total 8-16 g/m²) and 50mg/kg of Cy for a day. Fourgray of TBI was used for all CB transplant recipients, whereas 2 gray of TBI was used in other stem cell sources except for donor bone marrow recipients according to each institution’s policy. Calcineurine inhibitors (cyclosporine or tacrolimus) and short term methotrexate were used as GVHD prophylaxis. Donor cell engraftment and 60 day-survival were assessed as a primary end point to evaluate feasibility of this protocol.

Summary/Conclusions: RIC using Flu/high dose AraC/Cy +/- TBI was well tolerated with acceptable low toxicities and was sufficient to allow donor cell- engraftment post allo-SCT for elderly or frail patients with hematologic malignancies. Longer follow up and another prospective study enrolling more patients are required to evaluate the eventual survival benefit by reducing relapse.

PB2159

LATE COMPLICATIONS OF CONDITIONING REGIMENS (CYCLOPHOSPHAMIDE - TOTAL BODY IRRADIATION vs BEAM) FOR AUTOLOGOUS STEM CELL TRANSPLANTATION IN NON-HODGKIN LYMPHOMA

I. Garcia Cadenas1, A. Esquirol1, R. Martino1, J. Sierra1, J. Briones1
1Hematology, Hospital Regional de Málaga, Málaga, Spain

Background: Autologous stem cell transplantation (ASCT) is a frequently used procedure for the treatment of patients with relapsed non-Hodgkin lymphoma (NHL). While chemotherapy-based regimens are now commonly administered, total body irradiation (TBI) was largely used in the past. The current conditioning regimen in our center is BEAM (a combination of carmustine (BCNU), etoposide, cytarabine and melphalan) although we also have a large experience with cyclophosphamide (CFM)-total body irradiation (TBI) since this was the usual conditioning until year 2000.

Aims: To analyze the cumulative incidence of secondary neoplastic complications (grade 3-4 infectious, cardiovascular and pulmonary toxicity) after the two conditioning regimens (CFM-TBI vs BEAM) for ASCT.

Methods: We performed a retrospective analysis of patients with NHL that received an ASCT between October 1992 and December 2012. The late complications were defined as those to other previous comorbidity or to aging. Statistical analysis was performed using the IBM SPSS Statistics version 21.0. Cumulative incidences were estimated using EZR version 1.27 (Saitama Medical Center, Jichi Medical University, Omiya, Japan), a graphical user interface for R (version 3.1.1).

Results: A total of 105 autografted patients were analyzed. Patient’s characteristics are in Table 1. The median follow up since ASCT was 73 months (0 – 274 months). Thirty-one percent (n=33) of patients were conditioned with CFM-TBI. The overall 5-years survival (OS) was 88.3% (58-77% - CI 95%) and the 5 years disease free survival (DFS) was 52% (42 61% - CI 95%). There were no differences regarding OS and DFS between the two conditioning regimens. The 5-years cumulative incidence (CI) of relapse was 0.48 (0.37-0.57. CI 95%). We detected 10 secondary neoplasm (myelodysplasia n=1, skin carcinoma n=2, lung carcinoma n=3, oropharangeal carcinoma n=1, intestinal adenocarcinoma n=1, renal neoplasia n=1, bladder neoplasia n=1). The median time for the neoplastic event was 10.5 years (0-18.5 years). The CI of second neoplasias (2nd neoplasia) at 10 years was 10% (1-20%, CI 95%) and at last point of follow up (18.5 years) was 40% (13%>83%, CI 95%). There were no differences in the CI of 2nd neoplasias between BEAM and CFM-TBI. Non-neoplastic complications were present in 10% of patients (n=11). Three cases were infections grade 3-4 related to ASCT. Six cases had cardiac complications (5 acute coronary syndrome, 1 myocardiopathy) and 2 had pulmonary toxicity. The CI of non-2nd neoplastic complications at 10 year was 10% (1 – 25%, CI 95%). No differences were detected between the two conditioning regimens regarding non-neoplastic complications. (see Figure 1).

Figure 1.

Summary/Conclusions: Autologous stem cell transplantation offers long disease free survival for half of the patients with a high risk non-Hodgkin lymphoma. In our series, patients conditioned with BEAM or CFM-TBI had a comparable incidence of neoplastic and non-neoplastic events.

THE MANAGEMENT OF RELAPSED HODGKIN’S LYMPHOMA AFTER HAPLOIDENTICAL STEM CELL TRANSPLANTATION: DONOR LYMPHOYCE INFUSION AND BRENTUXIMAB

I. Sánchez Bazán1,*, A.L. Contento Gonzalo1, M.J. Pascual Cascón1, A.R. Martín Cerezo1, M.Á. Cuesta Casas1, A.I. Heiniger Mazo1
1Hematology, Hospital Regional de Málaga, Málaga, Spain

Background: Hodgkin’s lymphoma, is an heterogeneous malignancy wich is possible to cure. For those patients who relapse, chemotherapy followed by an autologous stem cell transplantation (ASCT) is the option. Allogeneic transplantation (alo-SCT) is used for patients in relapse after auto-SCT or those with refractory advanced disease. Since 2012, with the experience of the Baltimore group, our Center has chosen the haploidentical family donor as a source for aloSCT in Hodgkin’s disease. Despite the promising results, the rate of relapse is between 25% and 35%, and there is not standardized treatment for this situation.

Aims: To analyze the outcome of post-transplant relapse treatment of haploident donor haematopoietic progenitors (haploTPH).

Table. 1. Patient’s characteristics.

Summary/Conclusions: Haploidentical stem cell transplantation: donor lymphocyte infusion and brentuximab.
Methods: We studied 189 patients with the diagnosis of Hodgkin lymphoma in our center between August 2004 and July of 2013. All of them were submitted to haploSCT with a median follow-up of 495 days (455-1054).

Results: The median age was 32 years (21-60). 44% (8 patients) relapsed, 60% of them (5 patients) were nodular sclerosis histological subtype and 40% (3) follicular predominance. 2 patients (25%) were diagnosed in stage IV and 75% of the patients who were lymph node negative at presentation and had a median follow-up of 36 months (range 18-60). The MCEC approach was used in 12 patients and reached complete response in 11 patients (92%). The rest (1) received three cycles of MCEC regimen and changed to RT, GPD+Donnor lymphocyte infusions (DLI) and had reached complete response after 5 DLI. The rest (4) received between 3 and 7 doses with adequate tolerance. According to the re-evaluation (PET-TC) after 3rd Brentuximab, 4 were in partial remission and one reached complete response. We associated Donor lymphocyte infusion in 6 patients. The incidences of grade 3-4 nausea (36%; p=0.78) and 78%; p<0.01), vomiting (4% vs 28%; p<0.01), diarrhea (36% vs 56%; p=0.02), and liver dysfunction (4% vs 36%; p<0.01) were significantly decreased in the LEED group. The 5-year OS rates of the patients who had received the conditioning regimens before ASCT, with a 5-year OS rate of more than 70% in patients with chemo-sensitive ML. However, the LEED regimen is considered more preferable in comparison with the MEC group based on the low frequency of severe regimen-related toxicities. A large-scale prospective study is warranted to confirm these findings.

PB2161

CONDITIONING REGIMENS BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION FOR PATIENTS WITH MALIGNANT LYMPHOMA – LEED vs MCEC –

H. Shimizu1,*, C. Naitoh2, Y. Osaki1, Y. Miyazawa3, K. Toyama2, H. Koiso1, A. Yokohama1, M. Morio3, H. Ogura4, N. Tsukamoto1, H. Handa1

1Hematology Department, Fondazione Policlinico agostino Gemelli, Rome, Italy

Background: High-dose chemotherapy before ASCT has been established as an effective treatment option for high-risk patients with chemo-sensitive ML. Although the therapeutic efficacy of this strategy highly depends on the conditioning regimens before ASCT, the appropriate regimen has been controversial. Thus, we performed a multi-center retrospective study of ASCT recipients with ML, to compare the safety and efficacy of the conditioning regimens LEED and MCEC, which are widely used in Japan.

Aims: The primary objective was to determine the preferable conditioning regimen before ASCT: LEED or MCEC.

Methods: This study analyzed 127 adult patients who underwent ASCT following LEED or MCEC as the conditioning regimen against chemo-sensitive ML at four institutions in Japan between 1997 and 2015. Any type of pathological diagnosis was included. The LEED regimen consisted of 140 mg/m² cyclophosphamide (days −4 to −3), 300 mg/m² carboplatin (days −7 to −4), 500 mg/m² etoposide (days −6 to −3), 500 mg/m² etoposide (days −6 to −4), and 50 mg/kg cyclophosphamide (days −4 to −3). The disease status at transplant was as follows: complete remission (CR) in 14 cases (45.2%), azacitidine in 11 cases (35.5%), both of them in one case (3.2%), whereas 5 patients (16.1%) were untreated. The disease was myeloblastic (MAC) in 20 patients (64.5%) or reduced intensity (RIC) in 11 patients (35.5%); the donor was a family member (REL) in 17 patients (54.8%) or unrelated (MUD) in 14 patients (45.2%). The hematopoietic cell transplantation comorbidity index (HCT-CI) was as follows: 14 patients (45.2%) had a score of 3 and 17 patients (54.8%) had a score of 4 or more. Overall survival was calculated with Kaplan-Meier method. Transplant-related mortality (TRM) and relapse-related mortality (RRD) rates were estimated by competing Censorship (BRC/AML) (1), IFD FLT3 (2), inv16 (1), NPM1 (2), NPM1+/IFD FLT3 (1).

Results: Twenty-three patients were in remission on day +10, by bone marrow cytology, 3 patients were classified as resistant disease and five patients were not evaluable. 39% of the patients (48.4%) had a history of solid tumor in 15 cases (48.4%), haematological malignancies in 15 cases (48.4%) and both of them in one case (3.2%). All but one received a median of 2 (range, 1 to 6) lines of therapy. After a median of 36 months (range 12-190) from the first neoplasia, patients developed t-AML (n=19) (61.3%), t-Ph+ ALL (n=1) (3.2%), or t-MDS (n=11) (35.5%).

Molecular abnormalities were detected in 7 (46.7%) out of 15 evaluable patients: BCR/ABL (1), ITD FLT3 (2), inv16 (1), NPM1 (2), NPM1+/ITD FLT3 (1). Karyotype aberrations were found in 18 (64.3%) out of 28 evaluable patients: 16.7% was favourable risk (n=3), 27.8% was intermediate risk (n=5) and 55.5% was adverse risk (n=10). The disease status at transplant was as follows: complete remission (n=13) (42%), refractory disease (N=10) (32%), relapsed (n=3) (10%), and resistant disease (n=4) (13%). Patients received conventional chemotherapy in 14 cases (45.2%), azacitidine in 11 cases (35.5%), both of them in one case (3.2%), whereas 5 patients (16.1%) were untreated. The conditioning was myeloablative (MAC) in 20 patients (64.5%) or reduced intensity (RIC) in 11 patients (35.5%); the donor was a family member (REL) in 17 patients (54.8%) or unrelated (MUD) in 14 patients (45.2%). The hematopoietic cell transplantation comorbidity index (HCT-CI) was as follows: 14 patients (45.2%) had a score of 3 and 17 patients (54.8%) had a score of 4 or more. Overall survival was calculated with Kaplan-Meier method. Transplant-related mortality (TRM) and relapse-related mortality (RRD) rates were estimated by competing Censorship (BRC/AML) (1), IFD FLT3 (2), inv16 (1), NPM1 (2), NPM1+/ITD FLT3 (1). Karyotype aberrations were found in 18 (64.3%) out of 28 evaluable patients: 16.7% was favourable risk (n=3), 27.8% was intermediate risk (n=5) and 55.5% was adverse risk (n=10). The disease status at transplant was as follows: complete remission (n=13) (42%), refractory disease (N=10) (32%), relapsed (n=3) (10%), and resistant disease (n=4) (13%). Patients received conventional chemotherapy in 14 cases (45.2%), azacitidine in 11 cases (35.5%), both of them in one case (3.2%), whereas 5 patients (16.1%) were untreated. The conditioning was myeloablative (MAC) in 20 patients (64.5%) or reduced intensity (RIC) in 11 patients (35.5%); the donor was a family member (REL) in 17 patients (54.8%) or unrelated (MUD) in 14 patients (45.2%). The hematopoietic cell transplantation comorbidity index (HCT-CI) was as follows: 14 patients (45.2%) had a score of 3 and 17 patients (54.8%) had a score of 4 or more. Overall survival was calculated with Kaplan-Meier method. Transplant-related mortality (TRM) and relapse-related mortality (RRD) rates were estimated by competing Censorship (BRC/AML) (1), IFD FLT3 (2), inv16 (1), NPM1 (2), NPM1+/ITD FLT3 (1). Karyotype aberrations were found in 18 (64.3%) out of 28 evaluable patients: 16.7% was favourable risk (n=3), 27.8% was intermediate risk (n=5) and 55.5% was adverse risk (n=10). The disease status at transplant was as follows: complete remission (n=13) (42%), refractory disease (N=10) (32%), relapsed (n=3) (10%), and resistant disease (n=4) (13%). IMPROVEMENT IN BIVENTRICULAR CARDIAC MECHANICS NOTED IN PATIENTS UNDERGOING MYEOABLATIVE AUTOLOGOUS-HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR AL AMYLOIDOSIS

S. Heitner1, C. Purcell2, E. Scott3
1Knight Cardiovascular Institute, 2Department of Medicine, 3Knight Cancer Institute, Oregon Health and Science University, Portland, United States

Background: Primary amyloidosis (AL) is characterized by extracellular deposition of insoluble protein fibrils often with multisystem organ involvement. The Mayo staging model for determining prognosis in patients with cardiac amyloidosis takes into account troponin, NT-proBNP, and serum free-light chain difference in order to stage patients prior to undergoing autologous hematopoietic stem cell transplant (Auto-HCT). Since amyloidosis often involves the kidneys, serum biomarkers that require renal clearance are less reliable in the setting of significant renal dysfunction. 2D-echo and strain imaging offer non-invasive modalities for identifying early cardiac changes independent of renal function. These changes may also precede symptom improvement as assessed by NYHA classification.

Aims: Our hypothesis is that strain imaging is a feasible biomarker for cardiac response after Auto-HCT in AL amyloidosis.

Methods: Seven patients with biopsy-proven AL amyloidosis who were treated with a Melphalan based myeloablative regimen and Auto-HCT were evaluated retrospectively. Each patient underwent 2D-echo up to 36-days prior to treatment followed by repeat 2D-echo within 14-months. Strain imaging was performed using Echoclesight®. Chart review was conducted to determine associated NYHA functional classification and Mayo staging. Statistical analysis was performed using SPSS.

Results: Of the 7 patients studied, 3 were Mayo stage I, 2 stage II, 1 stage III, and 1 stage IV. The median follow-up from transplant was 47.4 months. There was one death at 20.4 months. The mean NYHA classification at baseline was 2.3 and after transplant was 1.9. Longitudinal, radial and circumferential left ventricular strain (LV) were evaluated, but only the global longitudinal strain (GLS) showed significant changes. In patients with stable NYHA classification after transplant, there was also a significant improvement in Right Ventricular Free Wall Strain (RVFWS) within individual stages. In patients with stable NYHA classification after transplant was 1.9. Longitudinal, radial and circumferential left ventricular strain (LV) were evaluated, but only the global longitudinal strain (GLS) showed significant changes. In patients with stable NYHA classification after transplant, there was also a significant improvement in Right Ventricular Free Wall Strain (RVFWS) within individual stages.

Summary/Conclusions: Statistical analysis was performed using EchoInsight®. Each patient underwent 2D-echo up to 36-days prior to treatment followed by repeat 2D-echo within 14-months. Strain imaging was performed using Echoclesight®. Chart review was conducted to determine associated NYHA functional classification and Mayo staging. Statistical analysis was performed using SPSS.

AN ABSOLUTE NUMBER OF CD34+ CELLS IN BLOOD AS A PREDICTOR OF A SUCCESSFUL HARVEST OF HEMATOPOIETIC STEM CELLS IN DIFFERENT MOBILIZATION REGIMENS

I. Galtseva1, Y. Davydova1, T. Gaponova1, N. Kapranov1, L. Kuzmina1, V. Trotskaya1, E. Zvonkov1, E. Parovichnikova1, L. Mendeleeva1, V. Savchenko1
1Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Autologous stem cells transplantation (ASCT) has become necessary part in therapy of hematological diseases. Transfusion of at least 2×10^6 CD34+ HSCs per kg of patient’s weight allows achieving an adequate hematopoiesis after high-dose chemotherapy. The most optimal is to collect ≥2×10^6 CD34+ cells/kg with single harvest apheresis. Different mobilization regimens differ in count of leukocytes in blood before the first apheresis and the number of CD34+ cells/kg in the apheresis product were determined for each patient. There were three different regimens: 1) DHAP+G-CSF, 2) Cph+G-CSF, 3) G-CSF. The apheresis number of CD34+ HSCs were evaluated with ISHAGE-protocol by BD FACScount II flow cytometer. Results are presented as mean±SEM. ROC-analysis was performed for WBC and the absolute number of CD34+ HSCs in the blood as the predictor for HSCs successful harvesting (≥2×10^6 CD34+ blood before apheresis). Results: WBC mean was higher in pts with G-CSF mobilization scheme compared to Cph+G-CSF and DHAP+G-CSF (28.3±3.5 vs 10.4±2.9 and 9.2±1.8×10^9/l, respectively, p<0.001), but the absolute number of CD34+ HSCs in the blood was 26.3±9.3 vs 55.5±6.6 and 93.1±22.3×10^3/μl, p=0.03) and the number of CD34+ HSCs in the leukapheresis product (1.9±0.7 vs 5.2±0.6 and 6.9±1.3×10^6/kg, p=0.01) were lower. Differences between Cph+G-CSF and DHAP+G-CSF in all parameters were not found. There was not any relationship between WBC and the absolute number of CD34+ HSCs/kg in the blood before apheresis with sensitivity of 96% and specificity of 81%.

Summary/Conclusions: Various mobilization regimens differ in count of leukocytes and CD34+ HSCs in peripheral blood: WBC was significant higher in G-CSF than in Cph+G-CSF and DHAP+G-CSF, but the absolute number of CD34+ cells was highest in chemotherapy-based mobilization and DHAP+G-CSF than in G-CSF alone. The absolute number of leukocytes in blood before apheresis wasn’t a predictor factor of harvest success in variability of mobilization regimens. If at least 20 CD34+cells/μl in blood before apheresis it is possible to collect ≥2×10^6 CD34+ HSC/kg for single leukapheresis with high sensitivity and specificity independent of mobilization regimen.
Background: Extracorporeal photopheresis (ECP) has been incorporated in the management of graft-versus-host disease (GVHD) post allogeneic hematopoietic cell transplantation (allo-HCT) in many centres. The introduction of ECP as an early second-line treatment in steroid-dependent or refractory patients with acute GVHD (aGVHD) remains under study. The rationale of its early use is based on the low incidence of complete responses to corticosteroids and the profound immunosuppression caused by traditional secondary treatments.

Aims: Based on our long-lasting experience in chronic GVHD, we aimed to prospectively assess the role of ECP in this high-risk population.

Methods: We enrolled consecutive patients with steroid-dependent or refractory grade (gr) II–IV aGVHD post alloHCT from January 2013 to August 2016. All patients with unrelated or haploidentical donors received thymoglobulin (ATG) 5mg/kg as prophylaxis. Post-transplant GVHD prophylaxis included cyclosporine – methotrexate in myeloblastic and cyclosporine – mycophenolate mofetil in reduced toxicity or intensity regimens. ECP was commenced after assessment of response to 5 days of steroid treatment according to our protocol: 2 sessions/week for 2 months, 1 session/2 weeks for 3 months, evaluation of response and 1 session/month for 6 months.

Results: We studied 20 patients, aged 35 (18-65), post alloHCT with myeloblastic (14), reduced toxicity (4) and intensity (4) conditioning, from sibling (10), unrelated (3) and haploidentical (1) donors. Disease risk index was high (10), intermediate (9) and low (1). Acute GVHD was observed at day +7 (8-50) in 15 patients, late-onset at +130 (110-160) in 4 patients and induced at +38 post donor lymphocyte infusion in a relapsed AML patient. Skin, intestine and liver involvement was evident in 6 patients, skin and intestine in 10 and skin only in 4 patients. Nine patients (2 with GrII, 7 with GrIII) received steroid-dependent (14), reduced toxicity (4) and intensity (4) conditioning, from sibling (10), unrelated (3) and haploidentical (1) donors. Disease risk index was high (10), intermediate (9) and low (1). Acute GVHD was observed at day +7 (8-50) in 15 patients, late-onset at +130 (110-160) in 4 patients and induced at +38 post donor lymphocyte infusion in a relapsed AML patient. Skin, intestine and liver involvement was evident in 6 patients, skin and intestine in 10 and skin only in 4 patients. Nine patients (2 with GrII, 7 with GrIII) received steroid-dependent (14), reduced toxicity (4) and intensity (4) conditioning, from sibling (10), unrelated (3) and haploidentical (1) donors. Disease risk index was high (10), intermediate (9) and low (1). Acute GVHD was observed at day +7 (8-50) in 15 patients, late-onset at +130 (110-160) in 4 patients and induced at +38 post donor lymphocyte infusion in a relapsed AML patient. Skin, intestine and liver involvement was evident in 6 patients, skin and intestine in 10 and skin only in 4 patients.

Summary/Conclusions: The newly developed image-based microscopic cell counter (ADAM II TM) appears to be suitable for quantification of CD34+ cell and its viability of fresh or cryopreserved PBSCs or CBs.

PB2167

RAPID RECONSTITUTION OF NK1 CELLS IS ASSOCIATED WITH THE LOWER INCIDENCE OF GRAFT-VERSUS-HOST DISEASE AFTER ALLOGENIC TRANSPLANTATION

X. Zhao1,*, L. Xu1, X. Yu1, Y. Chang1, X. Huang1

1Peking University Institute of Hematology, Peking University People’s Hospital, Beijing, China

Background: The balance between immunostimulation and immunoregulation in T cell immunity is achieved by a Th1/Th2/Th3/Tr1 and CD4+CD25+ regulatory T (Treg) cell paradigm.

Aims: We investigated the production of type1 (IFN-gamma, NK1), type2 (IL-13, NK2), type3 (TGF-beta, NK3) and regulatory cytokines (IL10, Nkr) from human peripheral blood to discuss the cytokine paradigm of NK cells in human allogeneic hematopoietic stem cells transplantation (allo-HSCT).

Methods: Forty patients undergoing haploidentical (n=27) and HLA-identical sibling (n=13) allo-HSCT between August 2009 and December 2009 were enrolled in this analysis after being originally selected using a protocol exploring the association of reconstructed donor derived NK1/NK2/NK3/NKr cells to GVHD and CMV reactivation.

Results: Expansion of NK2 and NK3 were found post allo-HSCT compared to healthy donor. The levels of Nkr reconstituted to donor’s level since day 15 post allo-HSCT, and the levels of NK1 in recipients post transplantation were consistently lower compared to donors’ levels until day 60 post allo-HSCT. Multivariable analysis showed that the higher levels of NK1 by day 15 were associated with lower overall acute GVHD (HR 0.157, 0.039-0.642, P=0.010) as well as II-IV acute GVHD (HR 0.260, 95%CI, 0.064-1.053, P=0.059). Meanwhile, the higher levels of NK1 by day 15 correlated with lower CMV reactivation (HR 0.010, 0.005-0.348, P=0.003).

Summary/Conclusions: These results indicate that rapid reconstitution of NK cells; especially NK1 cells would be helpful to prevent the development of graft-versus-host disease as well as CMV reactivation after allogeneic transplantation.

BORTEZOMIB FOR STEROID-REFRACTORY RITUXIMAB AUTOIMMUNITY AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

M. Zine1,*, T. Khalid1, S. Kafka1, D. Bonney1, S. Hughes1, S.H. Lum1, R. Wynn1

1Bone Marrow Transplant Unit, Royal Manchester Children’s Hospital, Manchester, United Kingdom

Background: Therapy of post-transplant autoimmune manifestations remains a challenge. Many cases are steroid and rituximab refractory and continuing intensified immune suppression increase the risk of infection in the post-HSCT patient. In our institution, we have used bortezomib as our third agent after failure of steroids or rituximab, or in cases of steroid-dependence since Bortezomib appears to be effective in cases with refractory autoimmunity.

Aims: In our series, we assessed the therapeutic response to proteasome inhibitor in 4 cases of post-transplant refractory autoimmunity

Methods: Three of the 4 patients received Bortezomib for autoimmune cytopenia (autoimmune haemolytic anaemia AIHA (n=2), AIHA with acquired red Cell Aplasia (n=1)). At least 2 therapy lines had failed to resolve the cytopenia. One to two courses of Bortezomib were administered at a dose of 1.3 mg/m2 at day 1, 4, 8, 11 each course. In two cases this treatment was combined with immunosuppressive agents: Mycophenolate mofetil (MMF) alone in one case and associated with sirolimus in the other case.

Results: Resolution of autoimmune cytopenia was observed in the three cases after a median of 33 days from the first day of administration. The fourth case received 1 course of Bortezomib for persistent anti-enzyme antibodies after allogeneic transplant for Wolman disease. Therapeutic response was obtained after 25 days reflected by a complete regression of circulating anti-enzyme antibodies. In all cases, no Bortezomib related toxicity was noticed. The response was maintained in all cases.

Table 1 summarizes the clinical data and the results of the four cases.

POST-THAW CELL COUNT PREDICTS ENGRAFTMENT RATE IN CORD BLOOD TRANSPLANTATION

K. Isobe,1, 2 K. Koh1, R. Kawakami1, T. Itabashi1, M. Yanagi1, K. Sasaki1, K. Watanabe1, M. Morii1, Y. Arakawa2, R. Hanada1
1Hematology/Oncology, Saitama Children’s Medical Center, Saitama, Japan

Background: The infused cell count in cord blood transplantation (CBT) is an important element for engraftment; however, the number in the prior reports has been based on the pre-thaw cell count. Therefore, the association between post-thaw cell count and engraftment rate, especially in pediatric patients, is unclear.

Aims: The aim of this study is to reveal the association between post-thaw cell count and engraftment rate in pediatric patients in the setting of CBT at our institution.

Methods: We retrospectively reviewed the medical records of 78 patients who underwent CBT between June 1998 and April 2016. We excluded the cases of CBT that required rescuing after engraftment failure.

Results: Underlying disease was acute leukemia (AL) in 63 (ALL: 38; AML, 25) patients, chronic myeloid leukemia in one, malignant lymphoma (ML) in two, myelodysplastic syndrome (MDS) in three, aplastic anemia in one, and others (such as primary immunodeficiency syndrome) in eight. In terms of conditioning regimens, myeloablative conditioning was administered to 62 patients and reduced intensity conditioning was administered to 16 patients. The median age at CBT was 3 (range, 0–19) years, and the median follow-up period was 898 (range, 47–6236) days. The engraftment rate was 84.6%, primary engraftment failure was observed in 11 patients (AL:seven; ML; one; MDS; one, neublobiatoma; one; and others; one) and secondary graft failure was observed in one patient (sever congenital neutropenia). The post-thaw cell rate was 56%, and 23 patients had died (cause of death: progressing disease in 19 patients). We analyzed the data on 34 patients of whom both of pre- and post-thaw CD34+ cell counts in the cord blood samples were available. The median post-thaw CD34+ cell count was 1.60 × 10^6/kg in the patients who achieved engraftment and 1.01 × 10^6/kg in the patients who did not achieve engraftment. No statistically significant difference was observed between these two groups (p=0.30). When we defined the cut-off value of the pre-thaw CD34+ cell count as 1.2 × 10^6/kg in the patients who were infused with CD34+ cells more than the cut-off value, the sensitivity and specificity of graft failure was 79.3% and 60%, respectively. When we defined the cut-off value of the post-thaw CD34+ cell count as 0.7 × 10^6/kg in the patients who were infused with CD34+ cells more than the cut-off value, the sensitivity and specificity of graft failure was 96.6% and 40%, respectively.

Summary/Conclusions: We concluded that the risk of graft failure is more precisely predicted by the post-thaw than pre-thaw CD34+ cell count and that if the post-thaw CD34+ cell count is more than 0.7 × 10^6/kg, the risk of graft failure is very low.

COLONY FORMING CAPACITY OF HEMATOPOIETIC STEM CELLS MOBILIZED INTO PERIPHERAL BLOOD WITH VINORELBINE AND GRANULOCYTE COLONY STIMULATING FACTOR N.A. Zhavoronkova, V. Balashova,1, K. Kostroma,2, I. Zapreva2, V. Rugal1, S. Bessmeltsev2, A. Chechetkin2, S. Gritsiaev2
1Laboratory of Leukemia Study, 2Hematological Clinic, Russian Institute of Hematology and Blood Transfusion, St. Petersburg, Russian Federation

Background: One of the alternative method to mobilize stem cells from bone marrow to peripheral blood is using of vinorelbine with granulocyte colony stimulating factor (G-CSF). The aim of the study was to determine the colonyforming capacity of hematopoietic stem cells mobilized into peripheral blood with vinorelbine and G-CSF.

Aims: The aim of the study was to determine the colonyforming capacity of hematopoietic stem cells mobilized into peripheral blood with vinorelbine and G-CSF.

Methods: Data of 34 patients of whom both of pre- and post-thaw CD34+ cell counts in the cord blood samples were available. The median post-thaw CD34+ cell count was 1.60 × 10^6/kg in the patients who achieved engraftment and 1.01 × 10^6/kg in the patients who did not achieve engraftment. No statistically significant difference was observed between these two groups (p=0.30). When we defined the cut-off value of the pre-thaw CD34+ cell count as 1.2 × 10^6/kg in the patients who were infused with CD34+ cells more than the cut-off value, the sensitivity and specificity of graft failure was 79.3% and 60%, respectively. When we defined the cut-off value of the post-thaw CD34+ cell count as 0.7 × 10^6/kg in the patients who were infused with CD34+ cells more than the cut-off value, the sensitivity and specificity of graft failure was 96.6% and 40%, respectively.

Summary/Conclusions: We concluded that the risk of graft failure is more precisely predicted by the post-thaw than pre-thaw CD34+ cell count and that if the post-thaw CD34+ cell count is more than 0.7 × 10^6/kg, the risk of graft failure is very low.

URIC ACID LEVEL MIGHT BE A PROGNOSTIC INDICATOR FOR SURVIVAL IN PATIENTS WHO UNDERWENT ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION. SINGLE CENTER EXPERIENCE

N. Mandao Sanil,1, 2 S. Svign1, 2 L. Kaynar1, 2 B. Eser1, 2 M. Getin1, 2 A. Urai1
1Hematology and Bone Marrow Transplant Center, Erzincis University School of Medicine, KAYSERI, Turkey

Background: Uric acid (UA) is an abundant aqueous antioxidant that accounts for almost two thirds of all free-radical-scavenging activity in human serum. It is released from injured cells during conditioning for allogeneic hematopoietic stem cell transplantation (AH SCT).

Aims: The aim of this study was to evaluate the prognostic impact of pre transplantation uric acid levels on survival and mortality in allogeneic HSCT patients.

Methods: We retrospectively analyze 273 patients with hematologic diseases undergoing HSCT. The patients were categorized as patients with acute leukemia, myelodysplastic syndrome, lymphoma patients and other hematologic disease diagnoses. A serum uric acid concentration 3.4 mg/dl was considered hypouricemia. Pretransplantation uric acid, creatine, total protein and albumin were analyzed. Univariate, multivariate Cox regression models and survival analysis were performed to uric acid, creatine, total protein and albumin associated with disease-free survival (DFS) over all survival (OS), early and late relapse mortality (+30 day ) and late non relaps mortality (+100 day).

Results: Pretransplantation low uric acid levels were detected in 57 (52.0) patients. Low UA levels were significantly associated with DFS (HR: 0.52; p= 0.027). None of the creatine, total protein and albumin were significantly associated with DFS (HR:0.98; p= 0.98, HR: 0.87=0.60, HR: 1.15; p= 0.66 ). There was no significant association between UA, creatine, total protein and albumin levels and overall survival (HR: 0.84; p= 0.48, HR: 2.10; p= 0.057, HR: 0.88; p= 0.52, HR: 0.78; p=0.26), early relapse mortality (HR: 1.38; p=0.54, (HR: 2.16; p= 0.29, HR: 0.61; p= 0.25, HR: 0.53: p= 0.13 ) and late non-relapse mortality (HR:0.57; p=0.35, HR: 0.21; p=0.29, HR: 1.04; p= 0.94, HR: 1.07; p= 0.92).

Summary/Conclusions: Uric acid is a natural antioxidant compound. UA reacts with oxygen-derived free radicals and becomes oxidized. Since humans are unable to catabolize UA to the more soluble compound allantoin due to lack of urate oxidase or uricase, the serum UA concentration is higher in humans than almost all other mammals. However, this high UA level in humans has been regarded as being beneficial in the presence of elevated oxidative stress. Our study supports that the uric acid is an antioxidant compound. Further in vivo and in vitro free son studies are needed for free son transplantation. This is the first report demonstrating a positive association between UA levels and survival analyses in allogeneic HSCT patients. Our findings are potentially clinically relevant. Confirmation in independent cohorts and further investigations into underlying mechanisms, such as reduced antioxidative or increased oxidative effects was warranted. The result of increased works on this subject, uric acid may be considered a possible prognostic marker in allogeneic hematopoietic stem cell transplantation.

RISK FACTORS FOR HERPES SIMPLEX VIRUS-1/2 VIREMIA AND CLINICAL OUTCOMES FOLLOWING UNMANIPULATED HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION

F.-F. Tang1, 2 L.-P. Xu1, 2 X.-H. Zhang1, 2 H. Chen1, 3 Y.-H. Chen1, 2 X.-D. Mo1, 2 Y.-Q. Sun1, 2 K.-Y. Liu1, 2 X.-J. Huang1, 2
1Peking University People’s Hospital, Peking University Institute of Hematology, Beijing, Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China

Background: Herpes simplex virus(HSV)-1/2 can still be reactivated after allogeneic hematopoietic stem cell transplantation (allo-HSCT) even when the prophylactic acyclovir is used. However, the risk factors for HSV-1/2 viremia and the clinical outcomes following unmanipulated haploidentical HSCT remain unknown.

Aims: The aim of this study was to explore the risk factors for HSV-1/2 viremia in patients who underwent following haploidentical HSCT.

Methods: Nineteen patients with HSV-1/2 viremia and fifty-seven patients without HSV-1/2 viremia which were selected using the case-pair method after haploidentical HSCT were enrolled. We analysed the risk factors for HSV-1/2 viremia and compared clinical outcomes between the two patient groups.

Results: The risk factors for HSV-1/2 viremia included HLA disparity ≥2 loci (p=0.049) and cytomegalovirus (CMV) reactivation (p=0.028). The incidences of platelet engraftment, oral mucositis and severe haemorrhagic cystitis (HC) in patients with and without HSV-1/2 viremia were 77% and 94% (%p=0.003), respectively.
Background: Reduced intensity allogeneic stem cell transplantation (RIST) is now commonly applied for elderly patients with acute leukemia (AL) or myelodysplastic syndromes (MDS). However, the factors affecting graft-versus-host disease-free, relapse-free survival (GRFS) and overall survival (OS) remain obscure.

Aims: To identify such factors and to clarify the clinical significance of RIST with various graft sources, we retrospectively analyzed patients with AL or MDS who received RIST in our hospital.

Methods: The study included patients with acute myeloid leukemia (n=73), acute lymphoid leukemia (n=31) or MDS (n=25), who received fludarabine (Flu)/melphalan (Mel)-based RIST between 2004 and 2015 as the first transplant. The median age was 58 years (range: 18-83 years), with 73 males and 56 females. Conditioning regimens consisted of Flu (125mg/m2) combined with Mel (80mg/m2), n=21 or 140mg/m2, n=105. Total body irradiation (TBI) (3.0 Gy) was used in 86 patients who received transplantation from unrelated donors or HLA mismatched related patients.

Results: There were a total of 129 patients, including 3 in low risk (L), 74 in intermediate risk (I), 36 in high risk (H) and 16 in very high risk (V), classified by the refined disease risk index (rDRI). The median age was 58 years (range: 18-83 years), with 73 males and 56 females. Conditioning regimens consisted of Flu (125mg/m2) combined with Mel (80mg/m2), n=21 or 140mg/m2, n=105. Total body irradiation (TBI) (3.0 Gy) was used in 86 patients who received transplantation from unrelated donors or HLA mismatched related patients.

Bone marrow (BM) or peripheral blood stem cell (PB) from related donors was used in 40 patients, BM or PB from unrelated donors in 33 and cord blood (CB) from unrelated donors in 56. Primary graft failure occurred in 7 patients, and death before engraftment was observed in two. After a median follow-up of 46 months (range: 15-144 months) for the survivors, the 5-year GRFS, disease free survival (DFS) and OS were 57%, 61% and 70%, respectively. On univariate analysis for all patients, pre-transplant factors associated with the 5-year GRFS included stem cell source (BM/PB vs CB: 44% vs 68%, p=0.005), donors (related vs unrelated: 38% vs 62%, p=0.012), disease (AL vs MDS: 60% vs 28%, p<0.001) and rDRI (L/I vs H/V: 65% vs 38%, p=0.003). On multivariate analysis, BM/PB (HR 2.0, 95% CI 1.0-4.0, p=0.039), MDS (HR 2.6, 95% CI 1.5-4.6, p=0.001) and H/V (HR 2.1, 95% CI 1.2-3.5, p=0.006) were associated with a worse GRFS. The 5-year OS, cumulative incidence of relapse (CIR) and non-relapse mortality (NRM) were 55%, 36% and 18%, respectively. On univariate analysis, significant prognostic factors were hematopoietic cell transplantation-specific comorbidity index (HCT-CI) (score 0 vs >1: 78% vs 48%, p=0.007), disease (AL vs MDS: 59% vs 40%, p=0.004) and rDRI (L/I vs H/V: 64% vs 43%, p=0.003) for the 5-year OS, donors (related vs unrelated: 53% vs 27%, p=0.005) and rDRI (L/I vs H/V: 27% vs 48%, p=0.005) for CIR, and age (<60 vs ≥ 60: 10% vs 28%, p=0.021), donors (related vs unrelated: 8% vs 23%, p=0.034) and disease (AL vs MDS: 13% vs 36%, p=0.003) for NRM. On multivariate analysis, HCT-CI (HR 2.6, 95% CI 1.3-4.5, p=0.005) were adversely associated with OS, so were H/V rDRI (HR 2.5, 95%CI 1.4-4.7, p=0.003) and MDS (HR 3.7, 95%CI 1.6-8.8, p=0.002) for CIR and NRM, respectively.

Summary/Conclusions: Our data suggest that Flu/Mel-based RIST is a promising strategy for patients with hematologic malignancy, irrespective of (? ) donor or stem cell sources. However, GRFS and OS of MDS were significantly worse than those of AL, and MDS is strongly associated with high NRM even with RIST. This indicates that we should pay more attention to NRM in MDS.

Sources/Related Work

1Hematology, Kanagawa Cancer Center, 2Hematology and Clinical Immunology, Yokohama City University, Yokohama, Japan

Background: Hemorrhagic cystitis (HC) is a serious complication occurring after allogeneic hematopoietic stem cell transplantation (HSCT) more frequent on haploidentical (haplo) HSCT; with an incidence of 10% to 70% (Silva et al Haematologica 2010:95(7):1183–1190) associated mainly with the effect of cytotoxic agents such as Cyclophosphamide (Cy). The conditioning regimen, BKPyV infection and graft versus host disease have an implication in the incidence. Other authors related the reactivation of CMV and a previous transplantation as risk factors to HC development (Ruggen et al Transplant Infectious Disease 2015:17:822–830).

Aims: With this study we aim to describe the HC incidence and risk factors in all haplo-HSCT performed in the Canary Islands.

Methods: We analyzed all consecutive haplo-HSCT from family donors performed at our Hospital between 2013 and 2016. The conditioning regimen used for the transplant was the Hopkins haplo protocol with high dose Cy (50 mg/kg on days 3 and 4) posttransplantation (PTCy). We used as HC prophylaxis intense hydration on the Cy administration day and the following 24 hours (using bladder wash only in 1 patient with cardiac dysfunction) and perfused MESNA at 100% of Cy dose beginning 15 minutes before the Cy administration on 16 pts and at 20% of the last dose at 6, 8 and 10 hours on all pts. We used SPSS V.23 to determine the cumulative incidence (CI) of HC.

Results: We performed 20 haplo-HSCT, of which 10 were males (1 was transplanted 3 times) and 8 were women. The mean age was 40 (range 16-64). The pts presented the following the diagnosis: AML (10), ALL (1), EH (5), NHL (3), AM (1). 45% of pts received the haplo-HSCT in remission, 50% with 1/2 PCR should be performed on clinical suspicion.

Figure 1: Summary/Conclusions: Based on our study results, we recommend that HSV-1/2 PCR should be performed on clinical suspicion.

OUTCOME OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS UNDERGOING NON-MYELOABLATIVE ALLOGENIC STEM CELL TRANSPLANTATION AFTER TREATMENT WITH THE BRUTON TYROSINE KINASE INHIBITOR IBRUTINIB
D. Dubnyak1,*, N. Risinskaya2, M. Drokov1, N. Kostritsa3, L. Kuzmina1, F. Ramdorh1, G.-N. Franke1, M. Jentzsch1, W. Pönisch1, C. Michael1, S. Heyn1, S.-Y. Wang1, G. Behre1, S. Leiblein1, S. Schwind1, D. Niederwieser1, V. Vucinic1
1Dept. Hematology & Clinical Oncology, University of Leipzig, Leipzig, Germany

Background: Although the Bruton tyrosine kinase (BTK) inhibitor ibrutinib significantly improves the prognosis of CLL patients (pts), allogeneic hematological stem cell transplantation (HCT) remains the only curative option for the underlying disease. Data on pre-transplant treatment of CLL with ibrutinib are very limited.

Aims: Here we present our experience of HCT in pts previously treated with ibrutinib.

Methods: 11 CLL pts (median age at HCT 57 years [p], range 52-66 y) treated between 2014 and 2016 in our unit with non-myoeloblastic (nma) HCT after ibrutinib were included. Ibrutinib treatment lasted median 4.03 months (range 1 - 28). Conditioning regimen was Fludarabin 30 mg/m2 on day -4 to -2 followed by 2 Gy total body irradiation. Disease status at HCT was Binet B (n=3) or Binet C (n=8). Two pts had Richter’s transformation (RT) diagnosed before nma-HCT. Ten pts were in partial remission (PR) at nma-HCT (PR1 n=4; PR2 n=3; PR3 n=2, PR3 n=1) while one was in first relapse. Donors were human leukocyte antigen (HLA) matched related (n=3, MRD) or HLA-matched unrelated (n=8, MUD). Pts received median 3 lines of therapy (range 1-6) including ibrutinib before transplantation. Classical cytogenetic analysis and fluorescence in situ hybridization (FISH) was carried out for every pt. Five pts had a deletion (del)(17p13) and one a del(11q22.3).

Results: The average overall survival (OS) for all pts was 471 days (range 36-812) (Figure 1). The average OS of patients with del(17p13) was 379 days (range 66-628) compared to 456 days (range 36-812) for those without del(17p13, p=0.98). OS was not significantly influenced by the stem cell source (MUD vs MRD, p=0.63) or remission status PR1 vs >PR1 (353 vs 472 days, p=0.79). Non-matched CMV-Status (negative recipient and positive donor or positive recipient and negative donor) had an OS comparable to that of matched CMV-Status (p=0.73). Pts above the median age had a lower OS although this didn’t reach significance (p=0.39). EFS was median 125 days (range 26-628). Pts with or without a TP53 alteration had a similar EFS (p=0.91). Pts undergoing MRD-HCT had better EFS than those undergoing MUD transplantation (p=0.053). CMV-Status or age>median had no prognostic influence on the EFS (p=0.83 and p=0.39 respectively). Non-relapse mortality (NRM) was 32% at 10 months (Figure 1), which was consistent with a previous publication from our group (30% at 4y). The acute GVHD Grade 3-4 was present in 3 pts (27.2%).

Figure 1.

Summary/Conclusions: The outcome in this small group is comparable to studies of CLL pts undergoing nma-HCT without receiving ibrutinib upfront. Previous data from our unit (Hebenstreit et al., Leuk Lymphoma 2014) showed OS 51% and NRM 30% at 4y. ibrutinib appears to be a feasible option in a limited setting, although further testing with larger numbers of patients and a longer follow up is required.

PB2176
SHORT-TERM CHIMERISM IN T-HELPER CELL SUBSETS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION
D. Dubnyak1,*, N. Risinskaya2, M. Drokov1, N. Kostritsa3, L. Kuzmina1, D. Niederwieser1, V. Vucinic1
1Dept. Hematology & Clinical Oncology, University of Leipzig, Leipzig, Germany

Background: Despite the fact that almost all studies in transplant biology dedicate T-cells the chimerism in T-helper (Th) cells and its subsets such as T-regulatory (Treg) cells after allogeneic hematopoietic stem cell transplantation (allo-HSCT) has never been evaluated.

Aims: To evaluate Th, Treg and bone marrow cell short-term chimerism in allo-HSCT patients.

Methods: Between May 2015 and November 2016 there was 109 transplants in our center. The research included 24 patients with hematological malignancies (AML =14,ALL =7,MDS =2,CMML -1). The median age of patients was 33.5 (range 19 to 60) years old, female=18, male=8. Myeloablating conditioning regimen was used for 11 patients. The other 13 patients underwent reduced intensity conditioning regimen. Peripheral blood stem cells (PBSCs) as graft source was used in 9 patients, BM in 15 patients. 9 patients were transplanted from HLA-identical related donor ,15 - from unrelated matched. Chimerism was evaluated at +30, +60, and 90-day in blood and bone marrow. Peripheral blood mononuclear cells (PBMCs) were isolated using standard protocol. Cells were sequentially incubated with CD4-biotin and anti-biotin microbeads (Milenyi Biotec, Germany). Next pure fraction of Treg cells (CD4+CD25high) was obtained by positive selection with the use of anti-CD25 microbeads. DNA was isolated by AmpliSens DNA-sorb B nucleic acid extraction kit. Chimerism was assessed by the STR-PCR analysis (polymerase chain reaction with a panel of primers for loci of short tandem repeats).

Results: For detailed result see Figure 1. 18 patients didn’t have any signs of relapse, graft failure or acute graft-versus host disease at all observation time. In this group on day 30% of cells with donors genotype was - 97,17±0,75; on day 60 - 95,74±2,15; on day 90 - 93,57±3,12. Four patients were diagnosed with relapse at +4 and + 6 months after allo-HSCT. Two patients were diagnosed with acute GVHD.

Figure 1.

Summary/Conclusions: Impact of chimerism in different T-helper subsets still need further investigation. We will continue our research and further results will be reported later.

ADIPOSE TISSUE CHANGES IN LYMPHOMA PATIENTS IN THE PERI-TRANSPLANTATION PHASE
J. Jabbour1,2, B. Manana3, F. Rahreddine4, C. Saadeh5, C. Maya3, A. Bazarakab3, D. Blaise6, E. Cheikh3
1Clinical Nutrition, American University of Beirut Medical Center, Beirut, Lebanon, 2Ecole Doctorale Sciences de la vie et de la sante, Aix Marseille Université, Marseille, France, 3Division of Hematology/Oncology, 4Bone Marrow Transplantation Program, 5Department of Radiology, American University of Beirut Medical Center, Beirut, Lebanon, 6Programme de Transplantation et Thérapie Cellulaire, Centre de Recherche en Cancérologie de Marseille, Institut Paoli Calmettes, Marseille, France

Background: Abdominal Visceral Adipose Tissues (VAT) have been shown to have inflammatory activity and have been used to predict cancer outcomes. The ratio of VAT/Total Adipose Tissues (VAT) is a negative predictor of progression free survival in Lymphoma patients on chemotherapy.

Aim: To assess the changes in fat tissues among stem cell lymphoma recipients in the peri-transplantation phase.

Methods: Institutional Review Board approved this retrospective study for adult patients (age≥16 years) having B and T lymphoma who underwent Stem Cell Transplantation (SCT). Each patient was imaged by PET/CT scan pre-SCT and in the first 3 months post transplantation. A cross sectional image was analyzed at the level of the L3 to calculate TAT, VAT and Waist Circumference (WC). Data was analyzed by gender since body composition parameters differed significantly between the two categories in the literature.

Results: The study sample consisted of 91 patients [mean age: 37.7±13.5 years; n=52 (57%) males, n=39 (43%) females], with a median overall survival in months: 32 in males and 35 in females. Death was observed in 6 (11.5%) males and 1(2.4%) female. Patient characteristics were similar across gender categories except for weights (kg) and Body Mass Index (kg/m²): 86.1 and 26.8 vs 65.2 and 25.0, in males and females respectively (p>0.05). Changes from pre-SCT to 3 months post SCT revealed that TAT and VAT decreased with mean differences of 33.56 cm² (p<0.01) and 7.02 cm² (p=0.017) in males and 16.44 cm² (p=0.01) and 4.14 cm² (p=0.056) in females, respectively. Waist circumference decreased significantly with mean
differences of 3.9±4.9 cm and 2.8±4.4 cm in males and females, respectively (p=0.01). VAT/TAT witnessed a slight increase in males and reduction in females (p>0.05). In multivariate analysis, no significant associations were shown with mortality and progression rates (Figure 1).

PB2178

NON RELAPSE MORTALITY (NRM) ANALYSIS IN 93 UNRELATED DONOR TRANSPLANTATION - SINGLE CENTRE EXPERIENCE - HLA HAPLOTYPE ROLE?
P. Mensah-Glanowska1,2*, B. Piątkowska-Jakubas1,2, A. Radziszewska2, A.B. Skotnicki1,2
1Department of Haematology, Krakow University Hospital, 2Department of Haematology, Collegium Jagiellonian University, Krakow, Poland

Background: Unrelated donor stem cell transplantation has a curative potential against haematological malignancies. However there are concerns about associated risk of non-relapse mortality. We performed a retrospective single centre study of causes of non-relapse mortality over four year period - 2012-2016.

Aims: Purpose of the study was to analyse non-relapse mortality (NRM) in patients subjected to unrelated donor transplantation in four-year-period: 2012 to 2016 - 93 transplant procedures in 86 patients.

Methods: Study cohort was analysed - relapse rate and non-relapse mortality were assessed. Causes of both - early and late NRM were studied.

Results: There were 23 relapses in the group of assessed patient cohort (24.7%). 7 patients undergone the second transplant - five patients - because of AML relapse, one - because of graft failure. Out of re-transplanted 7 patients - 3 patients are alive - 2 patients with graft failure and one with post-transplant AML relapse in 2nd CR. Out of 93 procedures of unrelated donor transplantation there were 16 cases of death - assumed as non relapse mortality NRM (17%). There were 9 early deaths (before day +100) - 6 cases in patients with relapsed/refractory acute leukaemia without remission after conventional chemotherapy. These patients were subjected to sequential conditioning with cytreduction phase. Active disease and highly active conventional chemotherapy. These patients were subjected to sequential conditioning with cytreduction phase. Active disease and highly active antileukaemic treatment can be reason for higher treatment related toxicity and elevated risk of death. Later two patients developed infectious bacterial complications with septic shock. In one patient - antiviral treatment refractory CMV encephalitis with massive macrophage activation syndrome was diagnosed. Analysis of NRM after day100 revealed 7 affected patients. All these patients did not receive previous treatment. Of the 20 patients from our series, 12 died post transplant with an OM of 60%. The cumulative incidence (CI) of OM was 15% at 1 month (m), 35% at 3 m, 45% at 6 m, 55% at 1 year, and 40% at 2 and 3 years (Figure 1a). When we analyzed the OM depending on the different physical status scores we found no statistically significant differ-

Figure 1.

Summary/Conclusions: This study provides data on the evolution of adipose tissues parameters in the peri-transplantation phase. TAT, VAT and WC decrease 3 months post transplantation. Future studies should evaluate the associations of these parameters with major outcomes on larger sample sizes.

A SIMPLIFIED METHOD OF CRYOPRESERVATION OF PERIPHERAL BLOOD STEM CELLS WITH OVER 10% GRANULOCYTE CONCENTRATION FOR LESS THAN 36 MONTHS
T. Akagi1, K. Otsu1, T. Fujii2, K. Kamata3, K. Yasumaga3, S. Fukuda2, K. Kubo2
1Transfusion and Cell Therapy, 2Hematology, Aomori prefectural central hospital, Aomori, 3Gastroenterology and Hematology, Hiroaki University Hospital, Hiroaki, Japan

Background: The long-term stability of cryopreserved peripheral blood stem cells (PBSCs) is an important concern for patients experiencing disease relapse. However, the quality of long-term cryopreserved PBSCs stored at -80°C by using simplified method has not been elucidated in detail. Cryopreserved PBSCs undergo cell damage and decrease in viability, and those containing granulocytes might influence cell loss.

Aims: The aim of this study was to evaluate the effect of cryopreservation for less than 36 months and the number of granulocytes in the cryopreserved PBSC products on CD34+ cells.

Methods: We examined the effects of cryopreservation on the viability of CD34+ cells that were stored for less than six months and those stored for 7–24 months, and 25–36 months, and the change of CD34+ cell viability with higher granulocyte content. We also evaluated the correlations between the number of granulocytes in the cryopreserved PBSC products and the time to engraftment of lymphocyte or platelet. Informed consent was obtained prior to the procedure from all the patients following institutional guidelines.

Results: A total of 65 PBSC samples were collected. We compared three groups based on the cryopreservation period: (1) less than 6 months, (2) 7–24 months, and (3) 25–36 months. The median (range) viability of CD34+ cells after thawing was 81.8% (59.2–94.4), 80.5% (56.6–92.8), and 76.1% (54.5–89.6) in the three groups, respectively. No significant difference in the viability of the cells in either frozen period was observed (p=0.14, respectively). We compared the effect of granulocyte concentration (over 10% concentration against less than 10% concentration) on CD34+ cells viability. The median (range) viability of CD34+ cells containing >10% granulocytes was 76.6% (54.5–93.0%), and that for cells containing <10% granulocyte was 82.1% (59.1–94.4%), respectively. There was significant difference in the viability of CD34+ cells between the two groups (p=0.02, respectively). Second, we analyzed 81 autologous PBSC transplants after stored at -80°C by using simplified method. We compared two groups based on the granulocyte concentration (10% concentration against <10% concentration). No significant difference in the days to leukocyte >1.0x10^9/L and to platelet >20x10^9/L in either granulocyte concentration was observed. However, the median (range) time to platelet >50x10^9/L, containing >10% granulocytes was 27.2 (12–87), and that for cells containing <10% granulocytes was 20.3 (10–51), respectively. There was significant difference in the day to platelet >50x10^9/L between the two groups (p=0.04, respectively).

Summary/Conclusions: Long-term cryopreservation represents a means of holding a potential therapeutic modality in reserve for use at a future date. In this study, PBSCs can safely be stored for at least 36 months by using simplified method at -80°C. The loss of the viability of CD34+ cells was greater when the granulocyte content was over 10% than in cells with less than 10% of granulocytes. The effect of reduced CD34+ cells viability seems important for engraftment. Difference in the day to platelet >50x10^9/L between the two groups based on the granulocyte concentration (>10% concentration against <10% concentration) was observed. Thus, a lesser granulocyte content could give a more reliable graft with better quality. Further research is necessary to observe the effect of long-term cryopreservation period and granulocyte content on the viability of stored CD34+ cells.

LYMPHOCYTE RECONSTITUTION AFTER ALOGENIC TRANSPLANTATION, DOES EARLY RECOVERY HAVE ANY INFLUENCE IN SURVIVAL RATES?
V. Verdugo1,2,3, M.A. Correa Alonso1, V. Rubio Sanchez1
1Hematology, Hospital Jerez de la Frontera, El Puerto de Santa Maria, Spain

Background: Immune reconstitution after AT+PH has significant influence on the procedure final success. Studies have established that early lymphocyte recovery can influence survival rates, associated to a reduction in mortality unre- lated to relapse (NMR) and, in some studies, also to a reduction in relapse rate.

Aims: Analyze our patients survival rates in terms of lymphocyte reconstitution in absolute value on day+30 and +60 post-HSCT. Check if there is any relationship between the number of transfused CD34+ progenitors and LT3+ and see if that possible link affects the speed of recovery after transplant - lymphocyte count.

Methods: Analysis of the lymphocyte recovery in a retrospective study of 63 of 71 patients transplanted (ALO, and Haplo Unrelated Donor) by AML and ALL between 2008- 2015. Table 1 shows the characteristics of the pre-transplanted patients and analyze the influence of the parameters of the infused product (CD34x10^6 and LTx10^8/kg r), type of transplant, GVHD presentation, treatment and reactivation of CMV on the recovery of absolute lymphocyte numbers in +30 and +60 days post transplanting using as cut off <0.3x10^9/ml. We have analyzed the ratio of the number of lymphocytes on day +60 with survival after transplantation. It has made a statistical - analysis of OS and DFS in relation to the number of lymphocytes on day +30 and day +60 with Kaplan Meier compared the results with long-rank test and subsequent analysis of the variables collected with Cox Regression.

Results: After analyzing the product infused we observed a relationship between LT and lymphocyte recovery on day+30 (p=0.016, HR=7.06) and day +60 (p=0.059, HR=2.28) but not with the CD34+/Kg r. Table 2 shows the patient characteristics in lymphocyte absolute count in the day +60. We analyzed the overall survival (OS) and disease - free survival (DFS) and a decrease in OS with statistical difference was evident in patients with <300 (<0.0029) on day +60 and day+30 (p=0.05), a decline also in DFS, with no statistically significant difference (p=0.1). Multivariate analysis to determine which factors could influence the lymphoid recovery on day +60 and SG, we observed that the type of unrelated donor, myeloablative conditioning and ATG administration can influence a delay in a recovery. No differences were observed in the rest of the variables.

**SUCCESSFULL AUTOLOGOUS STEM CELL TRANSPLANTATION AFTER VELCADE-BASED REFRACTORY MULTIPLE MYELOMA PATIENTS**

V. Martinez-Robles1, B. Ballina1, S. Cerda3, N. de las Heras3, J.A. Rodríguez-García1, F. Escalante1

1Hematología, Complejo Asistencial Universitario de León, LEON, Spain

**Background:** The optimal induction treatment for Newly Diagnosed Multiple Myeloma Patients needs combinations with Bortezomib-Based (Bor-) based schemes. Primary Refractory patients include patients with progressive disease or rapid (<60 d) relapse after these optimal induction approach have a very bad prognosis. Lenalidomide-Dexamethasone (LenDex) were usually the next step in the treatment of these patients, until the recent introduction of triplets combination LenDex-based. Autologous Stem Cell Transplantation (ASCT) has proven efficacy in NDMM older patients that have got at least a partial response (PR) after the induction therapy. There are few data about toxicity and response of ASCT in primary refractory patient that can obtain a response with LenDex rescue treatment.

**Aims:** Analysis of tolerance, response and overall survival of ASCT-candidates that are primary refractory to Bor-Based induction treatment.

**Methods:** Retrospective analysis of our database. From 2010 to Nov-2016, 103 ASCT-Candidates (for 1st or 2nd ASCT procedures) were included. Median Age for diagnosis was 62 (46-71). Median Age for ASCT procedure was 63 (46-72). 12 of these 53 patients (22.6%) were considered primary refractory and included candidates to get Bor-Based treatment. 60% were woman. Characteristics of Disease: IgG kappa (4), IgG-lambda (3), IgA kappa (3), IgA lambda (1), Light Chain lambda (1). ISS I/II/III: 5/2/5. Induction treatment: VelDex (4), VTD (6), VCD (2). Median of cycles administered: 6 (2-8). Best Response to induction treatment: >PR (6), Minimal Response (1), progressive disease (1). The day 100 NRM was 0%. At last follow up 20 patients (83%) are alive in CR, with negative minimal residual disease and FDC.

**Results:** Morbidity or mortality (M&M) (0%) of ASCT procedure in refractory patients is similar to non-refractory patients. After a median follow up of 46 months from diagnosis for all ASCT-candidates group, the refractory patients got an overall survival of 46.2 months (3-72 m). Any of them have relapsed yet. 2 of them are in biological relapse without need of treatment.

**Summary/Conclusions:** Patients refractoriness to induction may receive ASCT after a rescue treatment LenDex based, as is effective in this group compared with other Len-based regimens. New combinations (triptet) with new drugs with LenDex-based treatment may improve the responses rates and overall survival before and after of ASCT procedure in these group.

**PB2183**

**SAFETY AND EFFICACY OF TBF CONDITIONING IN PATIENTS UNDERGOING ALLOGENEIC STEM CELL TRANSPLANTATION: A RETROSPECTIVE SINGLE CENTER EXPERIENCE.**

R. Massoud1, N. Moukalled1, B. Haffar1, A. Zahreddine1, A. Bazarbach1, J. El-Cheikh1

1Internal Medicine, American University of Beirut Medical Center, Beirut, Lebanon

**Background:** The optimal intensity of myeloablation with a reduced-toxicity conditioning (RTC) regimen to decrease relapse rate after allogeneic stem cell transplant (allo-SCT) without increasing non-relapse mortality (NRM), has not been well established.

**Aims:** In this retrospective study at the American University of Beirut medical center (AUBMC) we aimed to evaluate the outcomes of patients who underwent allo-SCT with thiotepa, busulfan and fludarabine (TBF) as RTC.

**Methods:** We included twenty four consecutive patients with hematological malignancies who received TBF as conditioning for allo-SCT from January to December 2016. All patients and transplant characteristics are listed in Table1. All patients received the myeloablative conditioning regimen consisting of thiotepa (5mg/kg/day) infused on day -7 and -6, fludarabine (30 mg/m2/day) was infused on day -5 to -2, and busulfan (130mg/m2/day) was infused on day -5 to day-3. All patients received 2.5mg/kg/day intravenous rabbit antithymocyte globulin (ATG) on days -2 and -1. GVHD prophylaxis for patients transplanted from haploidentical donor consisted of post-transplant cyclophosphamide 50mg/kg/day on day +3 and day +5, cyclosporine started at 3 mg/kg/day on day +6 and readjusted according to level, and mycophenolate mofetil 500mgx4/day started on day +6 to +28. Patients transplanted from maternal haplo-donor received cyclosporine as of day +1.

**Results:** Twenty three patients (96%) engrafted, with 14 days (range 10-18) as median time for neutrophil and platelet engraftment respectively. One patient who underwent haploidentical donor transplant with persistent disease for AML (karyotype 45,XY,-7) failed to engraft and died due to disease progression on day+22. After a median follow up of 10 months (range, 1-22) post-allo-SCT, the cumulative incidence of non-relapse mortality (NRM) was 26%. One patient developed chronic limited GVHD (cGVHD). All the complication post-allo-SCT are listed in table 1. Five patients (24%) relapsed post allo-SCT at a median of 163 days (range, 55-384), of whom 5/7 (71%) died due to disease progression and two were successfully salvaged and are in complete remission (CR) with full donor chimerism (FDC) at last follow up. Two patients developed JC virus progressive multifocal leukoencephalopathy, one of them made a full recovery and the other died in CR. The day 100 NRM was 0%. At last follow up 20 patients (83%) are alive in CR, with negative minimal residual disease and FDC.

**Summary/Conclusions:** Our results show that This TBF conditioning regimen appears to be safe, allows high rate of engraftment and low NRM rate among high-risk patients and can lead to a long-term disease control.

**PB2184**

**COMPLETE REMISSION STATUS BEFORE AUTOLOGOUS STEM CELL TRANSPLANTATION AS PROGNOSTIC FACTOR IN PATIENTS WITH NON-HODGKIN LYMPHOMA**

A. Pinto1, A. Roque2, M. Gomes1, E. Cortesão, E. Espadana1, A.B. Samarto1, C. Geraldes1, M.L. Ribeiro1

1Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra, 2Faculty of Medicine and CIMAGO, University of Coimbra, Coimbra, Portugal

**Background:** High dose chemotherapy (HDC) followed by autologous stem cell transplantation (ASCT) is commonly used for treatment of relapsed or refractory non-Hodgkin’s lymphoma (NHL), as well as for first-remission consolidation in patients with mantle cell lymphoma. Disease status before ASCT is variable and is unclear whether complete response before ASCT or after ASCT correlates with better survival.

**Aims:** To evaluate the prognostic effect of disease status before ASCT - complete remission (CR) vs partial remission (PR) - in a cohort of patients with NHL.

**Methods:** Retrospective analysis of patients with NHL treated with HDC and ASCT between 2007 and 2016 in a single institution. All patients received peripheral blood stem cell support after conditioning with BEAM regimen (carmustine 300 mg/m2, etoposide 800 mg/m2, Ara-c 1600 mg/m2 and melphalan 140 mg/m2). Response was assessed according to The Lugano Classification. The Kaplan-Meier method was used to estimate progression free survival (PFS) and overall survival (OS) and comparison between risk groups was performed by using the log-rank test. Univariate analysis was performed and significant predictors at the level of 0.05 were used to adjust a multivariate Cox regression model.

**Results:** We included 83 NHL patients, mainly males (72.3%) with a median age at diagnosis of 51 years (18-65). The most prevalent histological subtypes were diffuse large B cell lymphoma (53.0%), mantle cell lymphoma (36.1%) and follicular lymphoma (10.7%). The median number of therapeutic lines was 2 (1-5). Patients with diffuse large B cell lymphoma and follicular lymphoma were mainly treated with R-CHOP/R-CVP (82.5%) at first-line. For those who did not achieve a CR or relapsed after first-line treatment, (R)-ESHAP/DHAP/ICE (78.8%) was performed as second-line followed by ASCT as salvage therapy in order to achieve and consolidate CR. The majority of patients with mantle cell lymphoma received R-CHOP/R-DHAP (55.0%) followed by consolidation with ASCT in first remission. With a median follow-up time from ASCT of 39.66 months (0.3-117.6), OS at 2 and 5 years was 84.8%...
and 74.5% and PFS was 76.8% and 58.2%, respectively. Before ASCT, 60 patients (72.3%) were in CR and 23 (27.7%) were in PR. After ASCT, 4 patients were not assessed for response due to early death by toxicity. Of the remaining, 70 (88.6%) achieved a CR, 4 (5.1%) a PR and 5 (6.3%) failed to respond. Patients in CR before ASCT presented significantly longer PFS compared with those in PR (107.9 vs 44.0 months, p<0.01). Besides that, patients that obtained CR after ASCT also had longer OS and PFS compared with those in PR (107.9 vs 8.0 and 107.9 vs 7.3 months, p<0.001). However, these patients had significantly lower PFS compared to patients that continued in CR after ASCT (45.3 vs 107.9 months, p=0.041). Univariate analysis indicated that remission status prior to ASCT (CR vs PR) is a significant predictor of PFS after ASCT (HR 0.39; 95% CI 0.19-0.82, p=0.013). Multivariate Cox regression model showed that this factor retains prognostic value after adjustment for age, histological subtype, Ann Arbor stage and number of previous lines of treatment.

Summary/Conclusions: Our results highlight the relevance of the obtained CR after ASCT in the OS. Furthermore, we conclude that patients with NHL who are in CR before ASCT have a better PFS than those in PR before ASCT. Additionally, continued CR after ASCT may also be an important prognostic factor. Our results suggest that the use of more effective induction regimens in order to improve initial response may be advantageous in terms of clinical benefits post-ASCT.

AUTOLOGOUS STEM CELL TRANSPLANTATION FOR MANTLE CELL LYMPHOMA: SINGLE CENTER EXPERIENCE
S.K. Toprak1,∗, E. Atilla1, P. Ataca Atilla1, S. Cirviz Bozdag1, M. Kurt Yuksel1, P. Topcuoglu1, T. Deminer1, O. Arslan1, M. Ozcan1, M. Arab1, O. Ilhan1, H. Akan1, M. Beksac1, N. Konuk1, A. Uysal3, G. Gurman1
1Ankara University School of Medicine Department of Hematology, Ankara, Turkey, 2Florence Nightingale Hospital, Istanbul, 3Koru Hospital, Ankara, Turkey

Background: Mantle cell lymphoma accounts for relatively small proportion (3%-10%) of non-Hodgkin lymphoma. High-dose chemotherapy (HDT) and autologous-stem cell transplantation (ASCT) has played a critical role in the treatment of mantle cell lymphoma. Regardless of that, mantle cell lymphoma remains largely a relapsing/diagnosing disease.

Aims: Our aim is to present our mantle cell lymphoma patients who underwent ASCT.

Methods: We retrospectively evaluated our 21 mantle cell NHL patients. The results were followed after ASCT for relapse

Results: Patients were followed by a median time of 56.9 months (range, 6-170 months). The median age at diagnosis was 45 (range, 18-69), female to male ratio:5/16. The stages and MIPI scores at diagnosis were as follows: 5% stage II, 19% stage III, 76% stage IV; Low MIPI 29%, intermediate MIPI 48% and high MIPI 23%. First line treatments were R-CHOP for 6 cycles in 4 patients (25%) and R-CHOP for 3 cycles followed by R-DHAP in 15 patients (71%). The median time to ASCT was 20 months (range, 7-46 months). All patients were in at least partial remission at the time of ASCT. The transplant conditioning regimen was CBV in 5 patients (24%) and R+/-ICE in 5 patients (24%), R+/-BEAM in 11 patients (52%). Six patients (29%) achieved complete remission. Four patients (19%) died within three months of ASCT due to infection. Eleven patients (52%) was relapsed with a median time of 39 months (range, 3-123 months). Ten patients received BORID (bortezomib, rituximab, dexamethasone) and 1 patient received lenalidomide as salvage therapy and six of them achieved complete remission. Three patients underwent allogeneic hematopoietic stem cell transplantation as well as two patients who received best supportive treatment with chemotherapy followed in remission. The 3 year overall survival was 71%.

Summary/Conclusions: ASCT is a part of initial treatment strategy in fit patients with mantle cell lymphoma however 19 patients in our series had transplant related toxicity. Today, novel agents may present a less intensive approach for achieving response.

PB2187
ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PEDIATRIC MYELODYSPLASTIC SYNDROMES: A SINGLE CENTER EXPERIENCE FROM TURKEY
D. Atay1,∗, F. Erbey1, A. Akcay1, G. Ozturk1
1Pediatric Hematology Oncology Bone Marrow Transplantation Unit, Acibadem University Medicine Faculty, Istanbul, Turkey

Background: Myelodysplastic syndrome (MDS) in childhood is a rare disorder and hematopoietic stem cell transplantation (HSCT) is the only known curative treatment option. However, there exist few reports regarding the outcome of transplantation for children with various types of MDS.

Aims: We analyzed the outcome of pediatric patients who underwent HSCT at our center.

Methods: We reviewed retrospectively 14 pediatric MDS patients who received HSCT at a single center. Median age at time of HSCT of the patients was 4.3 years and disease duration from diagnosis to transplantation ranged from 3 to 36 months with a median of 10 months. Five patients had primary and one had secondary MDS. Four patients had juvenile myelomonocytic leukemia (JMML) and 4 patients had myelodysplastic related acute myeloid leukemia (MDR-AML). Diagnostic cytogenetics included monosomy 7 (n=2), trisomy 8 (n=3), KRAS (n=1) or normal/other (n=8). Patients received a median of 6.8x106 CD34+ cells/kg. Eight patients received a bone marrow, 5 had peripheral blood graft and one an unrelated cord blood (UCB) transplant; five patients were transplanted from a matched sibling donor (MUD), 5 from a matched unrelated donor (MUD) and 4 from haploidentical donor. Conditioning regimen consisted of busulfan/cyclophosphamide in MDS/MUD patients. The patients transplanted from MUD and UCB also received antithymocyte globulin (ATG) for 3–5 days pretreatment. Haploidentical transplantation was performed with RIC regimen and TCRα/CD3 depletion.

Results: Graft failure occurred in three patients with JMML (n=1), secondary MDS (n=1) and MDR-AML (n=1). All MUD patients transplanted at a median 83.5 days post-transplant and two of them died. One patient with MDR-AML underwent second transplantation from another MUD one year after first transplant and died from GVHD. Ten patients are alive with a median follow-up of 19.5 months (range 3-61). All patients with primary MDS are alive and bone marrow graft failure patients died from transplant-related toxicity (n=2) and relapse (n=2). For the entire group, estimated five-year relapse-free survival (RFS), event-free survival (EFS) and overall survival (OS) were 78.6%, 64.3% and 70.7%, respectively.

Summary/Conclusions: These data demonstrate that especially children with primary MDS may achieve encouraging OS and RFS following HSCT. Relapse remains the main cause of treatment failure in children with JMML given HSCT. All children with MDS should be referred for allogeneic HSCT soon after diagnosis.

RELATIONSHIP BETWEEN URIC ACID LEVELS AND CARDINAL FINDINGS IN A LARGE COHORT OF β-TALASSEMA MAJOR: GENDER-RELATED DIFFERENCES

A. Meloni1, C. Vassalle1, L. Pistoto1, T. Grippi2, M. G. Bisconte3, G. Palazzii, M. P. Smacchia4, N. Dello Iacono6, R. Ndreu1, A. Olivi1, V. Positano1, A. Pepe1
1Fondazione G. Monasterio CNR-Regione Toscana, Pisa, 2Azienda Ospedaliera Regionale San Carlo di Polenza, Potenza, 3Azienda Ospedaliera Cosenza - Presidio Ospedaliero “Annunziata”, Cosenza, 4Modena, Policlínico di Modena, 5Políclinico Umberto 1, Roma, 6Ospedale Casa Sollievo della Sofferenza IRCCS, San Giovanni Rotondo, Italy

Background: Iron overload, secondary to recurrent transfusions and ineffective erythropoiesis, induces oxidative stress in thalassemia (TM). Uric acid (UA), a major blood antioxidant, may act either as an antioxidant or pro-oxidant.

Aims: Our aim was to evaluate the role of UA in TM and its association with cardiac iron, dysfunction, fibrosis, and complications, and cardiovascular risk factors in a large cohort of TM patients of both sexes.

Methods: 397 TM patients (200 men, mean age 32±8 years) enrolled in the Myocardial Iron Overload in Thalassemia (MIOT) Network were considered. Multivariable analysis was performed after we have quantified the UA using the T2* technique. Attral dimensions and biventricular function were quantified by cine images. Late gadolinium enhancement (LGE) images were acquired to detect myocardial fibrosis. RESULTS: As expected, UA resulted significantly higher in male respect to female TM patients (4.7±4.1 vs 2.3±1.3 mg/dL, P=0.0001). UA levels directly correlated with BMI (R=0.25, P=0.0003), and triglycerides (TG) (R=0.20, P=0.005) in female patients. Moreover, female which presented myocardial fibrosis showed higher levels of UA (4.7±4.1 vs 3.9±0.9 mg/dL, P=0.03). The multiple regression model identified BMI (R-value 3.7, P=0.0003), TG (2.1, P=0.04) and cardiac fibrosis (2.5, P=0.01) as independent correlates of UA level in women. In men, UA levels were positively correlated with BMI (R=0.17, P=0.02), TG (R=0.38, P<0.001), and inversely with HDL (R=0.20, P=0.006) and glycemia (R=−0.15, P=0.04). Interestingly, UA was also directly correlated with global heart T2* values (R=0.3, P<0.001). After multivariate analysis adjustment, global heart T2* value (R=0.3, P<0.001) and BMI (1.9, P=0.05) remained as independent determinants of UA in male TM patients. SUMMARY/CONCLUSIONS: UA levels correlates with factors related to metabolic dysfunction in TM patients of both sex, while a more strong correlation between UA and cardiac fibrosis was observed only in females, and a direct relationship between UA and T2* global heart only in males. The differences in male and female TM patients imply some gender-specific mechanisms, providing biochemical basis for the epidemiological differences between sexes.

PB2189

CHARACTERIZATION OF HEMORHEOLOGICAL ALTERATIONS IN THALASSEMAIA BY A CHEMOMETRIC APPROACH

P. Capralì1, C. Bozzi1, S. Materazzii, R. Risolutili
1Haematology, Oncology and Molecular Medicine, Istituto Superiore di Sanità, 2Department of Chemistry, “Sapienza” - University of Rome, Rome, Italy

Background: Several studies reported a high incidence of thrombembolic events in β-thalassemia, more frequent in thalassemia intermedia than in regularly transfused thalassemia major. In these patients a chronic hypercoagulable state is evident and the red blood cells exhibit impaired flow properties that facilitate micro-circulatory disorders.

Aims: Since many abnormalities described in thalassemia may determine rheological alterations, we have investigated the viscoelastic profiles of red blood cells from patients with β-thalassemia. The hemorheological profiles of blood samples obtained from healthy subjects and thalassemic patients were studied by chemometric tools in order to develop a model of prediction of circulatory disorders according to the viscoelastic behaviour.

Methods: Blood samples from 45 β-thalassemia patients and 48 healthy individuals, after informed consent, were analyzed. Hemorheological profiles were investigated at 37 °C at native and normalized hematocrit. The evaluation of RBCs viscoelastic properties was performed by determining storage modulus G’, loss modulus G’’ and complex modulus G* in oscillation mode as a function of angular frequency ω in the range 0.1–10 Hz. Multivariate statistical analysis was performed on the resulting G’, G’’ and G* curves and Principal Components Analysis was used as display method.

Results: The hemorheological profiles of patients affected by β-thalassemia and healthy subjects showed significant differences and the chemometric analysis allowed a clear identification of the group and provided an easy classification of the profiles. Increased G’, G’’ and G* modulus were observed in thalassemia patients demonstrating a reduction in deformability and impaired flow properties.

Summary/Conclusions: In this study a characterization of haemorheological alterations in thalassemia patients has been performed by a chemometric approach. The achieved results permit to consider the viscoelastic properties as promising predictive new indices of microvascular damage in β-thalassemia and to explain the increased incidence of vascular complications in these disorders.

PB2190

HEPATITIS E IN TRANSFUSION-DEPENDENT THALASSEMIA PATIENTS, IN GREECE. A SINGLE CENTER EXPERIENCE

P. Klonizakis1, G. Gioula1, A. Melidou1, M. Exindari1, G. Karavalakis2, C. Apostolou1, E. Gigi1, E. Vetslos1, A. Kotsiati1, E. Vlachaki1
1Aristotle University of Thessaloniki, 2Papanikolou General Hospital, Thessaloniki, Greece

Background: Hepatitis E (HE) is nowadays considered an emerging disease that may be a threat in both developing and industrialized countries all over the world. The causal agent is a RNA virus, transmitted mainly through the fecal-oral route. Nevertheless, there are additional patterns of transmission, including the transfusion of infected blood products. The risk of developing chronic HE infection following transfusion of infected blood–derived products is higher among immune-compromised individuals. Transfusion-dependent Thalassemia patients consist a distinct category of immune-compromised patients, but the data regarding transfusion-transmitted HE infection are limited for this group of patients. Accordingly, there is, as yet, no consensus on whether blood products should be systematically screened for markers of the HE virus.

Aims: The aim of this study was to assess the status of Hepatitis E infection among transfusion-dependent Thalassemia patients, followed up in a single Thalassemia Unit, in Northern Greece.

Methods: Over a one-month period, we retrospectively evaluated 96 consecutive patients, from a registry of 150 adult TDT patients followed at a single Thalassemia Unit, in Northern Greece. The mean age of the study population was 44±10 years (26% <18 years, 42% were male and 58% female). According to the patients’ blood transfusion history, the participants had been transfused with 47.376 blood units during the last 14 years, whereas during the last year the same patient population had been transfused with 3.384 blood units. The detection of HEV RNA was performed by Real-Time RT-PCR method (hepatitisEannTools kit, Applied Biosystems ABI), according to the instructions. The detection of HEV was based on the identification of the “a” region of ORF2. The detection of IgG anti-HEV antibodies and their titration were performed in 92/96 samples using a commercially available enzyme-linked immunosorbent assay kit (CUSABIO BIOTECH kit), according to the manufacturer’s instructions.

Results: HE RNA was not detected in any of the 96 samples, whereas the IgG anti-HEV antibodies were also negative in all measured samples. The negative HEV RNA, in all the participants of this study, indicates the absence of an active HE infection, whereas the negative IgG anti-HEV antibody titre implicated that there was no history of previous HE infection. According to the literature, IgG antibodies may be detectable following an HE infection for a time period that varies from one year to 14 years.

Summary/Conclusions: This is the first assessment of the HE virus seroprevalence in the population of TDT patients in Greece, over the last two decades. Our results suggest that TDT patients are not at a high risk for HE infection. Further studies are necessary to evaluate the clinical importance of the transfusion-transmitted HE infection in TDT patients and clarify whether screening of blood donors is necessary for countries with a lower or higher prevalence of HE.

PB2191

Abstract withdrawn.

PB2192

A PRELIMINARY STUDY OF THE CARDIAC EFFECT OF PPAR GAMMA IN BETA THALASSEMIA MAJOR WITH IRON OVERLOAD

P.M. Eldefrawy1, P.N.A. Hamed1, D.D. Ehnliey2, D.O. Gallal1, M.A. Khalifa1
1Hematology, 2Clinical Pathology, Alexandria Faculty of Medicine, Alexandria, Egypt

Background: Peroxisome proliferator-activated receptor (PPAR)-regulated genes belong to the same family of nuclear receptors as steroid and thyroid hormone receptors. PPAR-gamma is a master transcriptional regulator involved in the expression of probably hundreds of genes. One of PPAR gamma gene polymorphisms is Pro12Ala which is present in at least 80% of Caucasians and 40-60% of African Americans. Pro12Ala polymorphism may reduce the risk of cardiovascular complications. Consistently, A1a1 allele carriers were found to have lower carotid intima-media thickness and reduced risk of myocardial infarction in type 2 diabetes patients. Pharmacological agonists of PPAR-gamma lead to a molecular
Conclusion: This study suggests that Pro12Ala polymorphism may have a cardio-protective effect in Egyptian thalassemic patients since we find the highest value of ejection fraction among the two positive cases. Further studies on a larger population of patients are still needed to confirm this finding.

PB2193
THALASSEMIA MAJOR AND INTERMEDIA IN PATIENTS OLDER THAN THIRTY-FIVE YEARS - FROM A FATAL TO A CHRONIC DISEASE
O. Pasvolsky1,*, L. Sharqian Aloni1, P. Raanani1
1Beilinson Hospital, Petach Tikva, Israel

Background: During the past four decades beta thalassemia major (TM) and beta-thalassemia intermedia (TI) have transformed from a uniformly fatal disease at a young age, into a chronic disease, with a constantly increasing life expectancy. This is attributed, amongst others, to the use of improved chelation therapy. Since prolongation of life expectancy has occurred only in recent years, there is little data regarding the older population with TM and TI.

Aims: We aimed to characterize disease and patients' characteristics in patients above 35 years of age in an adult thalassemia center in Israel.

Methods: We conducted a retrospective analysis of 14 adult patients over the age of 35 years with TM (N=10) and TI (N=4) treated in a single center, specializing in the care of adult thalassemia patients. We used descriptive statistics to describe characteristics of disease and patients and the Mann-Whitney test to compare between patients with TI and patients with TM.

Results: Between 2006 and 2016, 14 adult patients older than 35 years with TM (n=10) and TI (n=4) were followed and treated in our center. Median patients' age was 37 (range, 35-51) years, with 66% males and 50% of Arab ethnicity. Most of the patients had at least high school education (85%), and 78% were employed. Thirteen patients (all TM patients and 3 out of the 4 TI patients) were treated regularly with blood transfusions. All patients received chelation treatment. Median hemoglobin (Hb) levels and mean corpuscular volume (MCV) levels were lower in patients with TI compared to TM (8.1 vs 10 g/dl, p<0.002 and 72.4 vs 84 fl, p<0.004, respectively). Median LDH levels and indirect bilirubin levels were higher in patients with TI compared to TM (603 vs 330 u/L, p=0.004 and 2.02 vs 1.1 mg/dl, p<0.06, respectively) indicating increased hemolysis. All patients underwent splenectomy and had secondary thrombocytosis. All but two patients were treated with at least two different chelation modalities, either as single agent, including subcutaneous (SC) or intravenous (IV) deferoxamine (DFO), deferrine (DFP), or deferasirox (DFX), or as various combination therapy options. The median number of chelation treatment lines was 3. All patients treated with chelation suffered from at least one adverse event, necessitating discontinuation and usually substitution of treatment. The median number of adverse events was 1.5 per patient. Nine patients (64.2%) had goiter, 71% had hypothyroidism, 50% had hypogonadism. All females had amenorrhea and were treated with hormone replacement therapy, and none of them tried to conceive. Six of the seven male TM patients were treated with monthly testosterone injections, and three of them fathered children. All TM patients had osteoporosis, and three TI patients (75%) had metabolic bone disease. Figure 1 shows the relative rates of symptomatic cardiac iron overload and endocrine dysfunction in the cohort. Three patients (21.4%) had significant liver overload according to liver T2* MRI, necessitating chelation treatment intensification. None of the patients in our cohort underwent allogeneic hematopoietic stem cell transplantation and none developed secondary malignancy during follow-up.

Summary/Conclusions: Advances in the treatment of thalassemia patients have enabled the majority of these patients prolonged survival into adulthood. However, this has brought a new set of challenges for both patients and healthcare. This study delineates the challenges faced while treating adult patients with TI and TM in the new era.

PB2194
EVALUATION OF LIVER IRON CONCENTRATIONS IN CHILDREN WITH BETA THALASSEMIA INFECTED WITH HEPATITIS C VIRUS BEFORE AND AFTER SPIRULINA THERAPY BY MAGNETIC RESONANCE IMAGING
M. El-Shanshory1,*, M. Awad1, R. El-Shafey2, A. Alsharkawy3
1Pediatrics, 2Radiology, Faculty of Medicine, Tanta University, 3Pediatrics, Ministry of Health, Tanta, Egypt

Background: Magnetic resonance imaging (MRI) assessment of liver iron concentration (LIC) is necessary for quantitative staging of iron overload in children with β-Thalassemia. There is no enough evidence about the effect of spirulina therapy on LIC.

Aims: To assess LIC by MRI in multi-transfused β-thalassemic children infected with HCV before and after Spirulina Therapy.

Methods: Thirty multi-transfused β-thalassemic children infected with HCV were subjected to clinical evaluation, appropriate laboratory investigations and assessment of LIC by MRI. They were classified according to LIC into mild
PB2196
EVALUATION OF THREE AUTOMATIC DEVICES FOR HEMOGLOBINOPATHY DIAGNOSTICS IN MULTI-ETHNIC POPULATIONS
C. Hartveld1, Y. Daniel2, G. Bakker-Verweij1, I. Ivaldi1
1Clinical Genetics, Leiden University Medical Centre, Leiden, Netherlands, 2Special Haematology, Guy’s Hospital, London, United Kingdom, 3Laboratorio di Genetica Umana, Ospedale Galliera, Genoa, Italy
Background: We have tested three different dedicated haemoglobin separation devices for their capacity of performing the diagnostics of hemoglobinopathies. These involve the Variant II TM HPLC (BioRad), the Capillaries2 capillary electrophoresis (Sebia) and the most recently introduced HPLC, Premier Hb9210TM High Resolution HPLC of Trinity Biotech (Menarini).
Aims: As the latter device is new to the market a multivariate precision study was performed testing the reproducibility of the system across three test sites (Leiden, Genoa and London) using the same set of samples for several following days. The results between these three sites were compared and evaluated. Moreover we have tested the capacity to detect the most common structural haemoglobin variants, such as HbS, Hbc, HbD, HbE and less common Haemoglobin variants important to be diagnosed in multi-ethnic populations found in the U.K., The Netherlands and Northern Italy as well as elevated HbA2, as indicator for beta-thalassaemia carriers.
Methods: Hb variant separation using he Variant II TM HPLC (BioRad), the Capillaries2 capillary electrophoresis (Sebia) and the most recently introduced HPLC, Premier Hb9210TM High Resolution HPLC of Trinity Biotech (Menarini). Molecular analysis to verify the hemoglobin variants found.
Results: We present the data of the comparison studies using the replicates of the three different sites for the Premier Hb9210TM and of 100 normal samples and 217 patient samples for a variety of beta-thalassemia trait and haemoglobin (Hb) variants, including the molecular data of the beta-thalassaemia mutations and Hb variants.
Summary/Conclusions: All three apparatus identified the common Hb variants and beta-thalassaemia trait in carriers, homo-, hetero- and compound heterozygotes with the expected sensitivity and specificity. The Premier Hb9210TM High Resolution HPLC of Trinity Biotech shows comparable performance on quantitation on the three different sites using the same samples and is suitable for the analysis of samples suspected of having hemoglobinopathy and the diagnosis of beta-thalassaemia trait or Hb variants.

PB2197
RED BLOOD CELL EXTENDED PARAMETERS IN HAEMOGLOBINOPATHIES
M. Stamou1, E. Petridou1, A. Kotanidou1, A. Agorassi1
1Laboratory Haematology, General Hospital of Xanthi, Xanthi, Greece
Background: We aimed to establish the reference range of parameters%HYPO-H &%MicroR, to investigate their values in haemoglobinopathies and their correlation, if any, with Hb A2 levels in heterozygous β-thalassaemia.
Methods: Reference ranges were obtained from 175 healthy adult subjects (27 men, median age of 34 years & 148 women, median age of 30 years); control group (group A). 89 haemoglobinopathie heterozygotes (32 men, median age of 29 years & 57 women, median age of 30 years) were included in the study and classified into three groups; group B: β-thalassaemia heterozygotes, N=46, group C: α-thalassaemia heterozygotes, N=21 and group D: Hb C Arab heterozygotes, N=22. We retrospectively recorded the results of full blood count analysis on Sysmex® XE-5000 analyzer including%HYPO-H &%MicroR, of Hb pattern analysis (TOSOH®, G7) and ferritin levels (Roche®, Cobas e411). All subjects included in the study presented ferritin levels within the normal range for age and gender. Statistical analysis: one-way ANOVA (Tukey post hoc), Mann-Whitney, Pearson’s correlation tests were applied. Reference ranges were calculated as the mean±2SD of the distribution. P value <0.05 was considered to be statistically significant. Data refer as median (percentiles).
Results: The reference ranges of our Laboratory for the parameters%HYPO-H &%MicroR are 0.0 – 0.6% & 0.2 – 2.9%, respectively, and they are independent of gender and age (P>0.715, P=0.168 & P=0.073, P=0.843). There was no statistically significant difference between the HbA2 values calculated by one-way ANOVA for both parameters (all P >0.001). Heterozygous β-thalassaemia presents statistically significantly higher%HYPO-H &%MicroR values [11.6 (4.2-27.6)] as compared to groups A [0.3 (0.2-3.0)], C [1.9 (0.6-6.4)], D [0.6 (0.4-0.8)] (all P <0.0001), while there was no statistically significant difference of%HYPO-H &%MicroR values for the distribution of Hb C Arab and groups A and C (P=0.965 & P=0.134, respectively) based on Tukey post hoc test. Heterozygous β-thalassaemia presents statistically significantly higher%MicroR values [41.5 (22.9-58.7)] as compared to groups A [1.5 (1.1-2.0)], C [10.8 (7.9-20.5)] and D

PB2195
COMBINATION OF DEFERASIROX AND DEFEROXAMINE - A SUCCESSFUL CHELATION THERAPY IN B-THALASSEMA MAJOR PATIENTS
F. Petropoulou1, V. Vertiadi1, G. Leveta1
1Thalassaemia Unit, General Hospital of Athens “G.Gennimatas”, Athens, Greece
Background: Frequent transfusions required for β-thalassemia major patients cause iron overload. Without the appropriate chelation therapy, iron toxicity can cause significant heart, liver and endocrine morbidity.
Aims: In this case series we estimated the safety and efficacy of iron chelation with the combination chelation of DFX and DFO in transfusion dependent thalassemia patients (TDT) attending the Thalassemia Unit in a tertiary hospital in Athens, Greece.
Methods: 10 TDT patients were treated with a combination chelation therapy of DFX (30 ±10mg/kg/d) and DFO (44±12mg/kg/d for 2-6 days/wk in 12h or 24h infusion rates). Reasons for starting this combination treatment included: 1) treatment with one chelating agent did not succeed in decreasing heart and liver iron, 2) agranulocytosis or severe neutropenia due to deferiprone (DFP) treatment and 3) adverse events recorded with increased doses of one of the chelating agents. The efficacy of the treatment was estimated through MRI accompanied with significant improvements in SF after spirulina therapy as compared to their pretreatment values in patients of the moderate to severe group.
Results:

PERFORMANCE OF THE ALPHA-GLOBIN STRIPASSAY® AND MLPA® FOR THE DIAGNOSIS OF ALPHA-THALASSEMIA

J. Oosterbos1, H. Claerhout2, C. L. Harteveld3, E. Liehr4, D. Kieffer2,5
1Department of Pharmaceutical and Pharmacological Sciences, KU Leuven, 2Department of Laboratory Medicine, University Hospitals Leuven, Leuven, 3Department of Clinical Genetics, Leiden University Medical Center, Leiden, 4Center for Genomic Analysis, Leuven, 5Department of Microbiology and Immunology, KU Leuven, Leuven, Belgium

Background: Diagnosing α-thalassaemia requires second line diagnostics involving DNA analysis. Multiplex ligation probe amplification® (MLPA®) is a molecular technique introduced as a diagnostic tool for α-thalassaemia. This semi-quantitative technique determines the relative copy number of up to 60 DNA sequences and is able to detect deletions and duplications in a DNA sample. A novel commercial tool, the α-Globin StripAssay®, aims to detect the most common α-thalassaemia deletions and point mutations. The test involves three steps: DNA isolation, PCR reaction and a hybridization step to test strip containing allele-specific oligonucleotide probes immobilised as an array of parallel lines.

Aims: Our objective was to evaluate the α-Globin StripAssay® as a useful alternative for MLPA® in second line α-thalassaemia diagnostics.

Methods: Eight samples, including 7 known deletions (__SEA, __THAI, __MED, homozygous and heterozygous - α3.7, heterozygous - α4.2, (α)20.5) and 1 mutation (Hb Constant Spring) were analysed using multiplex Gap-PCR (deletions) and Sanger sequencing (point mutation) at the Leiden University Medical Center. These samples were anonymised and analysed in duplicate by MLPA® and α-Globin StripAssay® at Leuven University Medical Center. A comparison of diagnostic performance, interpretation, turnaround time (TAT) and costs (reagent and labour) was conducted.

Results: There are no significant differences between the MLPA® and the α-Globin StripAssay® results and each identification corresponded to the result of the reference lab in Leiden. MLPA® however provided additional information about underlying polymorphisms. Interpretation of the α-Globin StripAssay® was easier and faster compared to MLPA®. The α-Globin StripAssay® proved to have a shorter TAT, but on the other hand, the costs for MLPA® were significantly less.

Summary/Conclusions: Despite its straightforward interpretation, shorter TAT and high ability of detecting both (known) deletions and point mutations, the significantly higher costs of the α-Globin StripAssay® may hinder it’s routine use. Specialised laboratories are usually acquainted with the MLPA technique and in these settings the ability to detect both known and unknown deletions is a plus for research purposes.

CARDIAC AND HEPATIC IRON ASSESSMENT OF YOUNG ADULTS WITH TRANSFUSION DEPENDENT THALASSEMIA: TIME TO THINK BEYOND FERRITIN

K. Mishra1,*, S. Kashyap1, A. Khadwal1, A. Jandial1,2, D. Lad1, G. Prakash1, R. Das3, N. Varma1, P. Malhotra1, S. Varma1
1Internal Medicine, 2Pgimer, Chandigarh, Chandigarh, India, 3haematology, Pgimer, Chandigarh, Chandigarh, India

Background: With the improvement in availability of blood transfusion practices and progress in chelation therapy, there is an increasing population of thalassemic patients surviving into adulthood in developing countries. However, there is scarcity of clinical, biochemical and radiological data showing cardiac and hepatic iron assessment in these chronically transfused individuals.

Aims: 1. Cardiac and hepatic iron assessment in young adults with TDT. 2. Compare the ferritin level with T2* MRI finding.

Methods: In this prospective observational study we analysed demographic details, clinical features and cardiac and liver iron assessment of young adults with (TDT) at recently established adult thalassemia clinic at PGIMER, Chandigarh. For cardiac and liver iron assessment serum ferritin, ECG, 2D Echo, MUGA scan, Liver function test, Fibroscan (if indicated) and T2* MRI of Liver and heart was done. All patients who were diagnosed in childhood and referred to adult haematology unit at age ≥18 years and had received more than 20 blood transfusions were included in the study.

Results: A total of 53 patients (n=53) were analysed. The mean age was 23 yrs. Majority of patients (56%) were male. The average age at diagnosis and at first transfusion was 7 months & 11months respectively. The average years of PRBC transfusion was 23 yrs. The average number of transfusion in last two years prior to registration was 24 PRBC units. The mean age at start of chelation was 10.0 yrs. Mean duration of chelation was 14 yrs. Majority (88%) had growth failure with mean height of 159.6 cm & mean weight of 51.5 kg respectively. Splenomegaly was present in 47% and hepatomegaly in 25% patients. Twenty-eight percent have undergone splenectomy at an average age of 12.6 yrs. The mean of highest ferritin levels was 6131 ng/mL and the mean ferritin at the time of registration was 2919 ng/mL. LFT were deranged in 25% of patients. Evidence of cardiac dysfunction (ECG/MUGA) was present in 22% of patients. Iron overload in liver and heart as measured with T2* MRI was present in 56% & 26% respectively (Figure 1).

THALASSEMA IN MADRID: A PICTURE OF THE CURRENT SITUATION

E.J. Bardón-Cancho1,*, M. García-Morín1, Y. Aguilar-de la Red1, B. Ponce-Salas1, G. Perez-Rus2, C. Pascual3, E. Dulin1, B. Beléndez1, E. Cela1, N. Varma1, P. Malhotra1
1Section of Pediatric Hematology and Oncology, Department of Pediatrics, 2Department of Hematology, 3Newborn Screening Laboratory (Community of Madrid), Hospital General Universitario Gregorio Marañón - Facultad de Medicina- Universidad Complutense de Madrid, Madrid, Spain

Background: Diagnosis of thalassemia (Thal) in a Mediterranean country like Spain, could be thought as endemic, but few data are available so far. Moreover, attention to hemoglobinopathies is focused on sickle cell disease.

Aims: The aim of our study was to find out the prevalence of Thal and clinical significant hemoglobinopathies other than sickle cell diseases in a referral center for newborn sickle screening, in addition to the demographic characteristics of these patients. The secondary objectives were to obtain the frequency of specific treatments or prophylaxis accomplished by these patients, and the reasons for loss to follow-up.

Methods: The study is observational, unicentric, descriptive and retrospective, carried out in December 2016 in a tertiary hospital in the Community of Madrid, Spain. All patients diagnosed with Thal and other not sickle-hemoglobinopathies who had attended at least once to the hematology clinic were included. Demographic characteristics (date of birth, gender, country of birth) and clinical ones (genotype or Thal type, therapy and update in follow up, like alive, deceased or lost patient) were collected. Written informed consent was signed by patients or legal guardians in accordance with the Declaration of Helsinki. The study was approved by the hospital Ethical Committee. Statistical analyses were performed using SPSS version 18.0. Quantitative variables were reported as median or mean value and range, while categorical variables were expressed as absolute value and percentage.

Results: The total number of patients included was 31 (9 Thalassemia Major (TM), 1 Thalassemia Intermedia (TI), 21 other not sickle-hemoglobinopathies). The center follows 209 sickle patients, which leads to a ratio sickle/not sickle of 6.74 (Table 1). Ratio boy/girl is 1.21 for all group. Most of patients were born in Spain (90.32%), although 6.45% were born in Asia and 1 patient was born in Romania. Considering the parents, 32% were born in Europe, 25% from Asia, and 12% from America. 92% of those patients born in Spain were detected in their first days of life due to universal screening detection implemented in Madrid since 2003. Median age at first diagnosis was 0.70 years (0-16.35). Median age at the end of inclusion was 9.39 years (range 1.90 to 35.44). 35% of them had molecular genotyping for diagnostic confirmation.

Two out of 10 patients with Thal had HLA identical siblings. Chelation treatment was added to standard treatment to all the patients with Thal: 7 received deferasirox, 3 were treated with deferoxamine and 2 with deferrisone; 2 of the patients required double quelation. Two out of 10 patients with Thal underwent...
spleenectomy. None of these patients had sepsis or meningitis. Three Thal patients underwent progenitor stem cell transplantations and their remain on complete chimerism in the present moment. Patients lost to follow-up summed up 14; 3 emigrated to other countries, 2 continue the monitor of their diseases in other centers or in adults units and 7 for unknown reasons. There was one death (3.22%) for a cause unrelated to his illness.

Table 1.

Summary/Conclusions: Early diagnosis derived from universal neonatal screening for sickle cell disease allows an effective health education and prompt therapy to other hemoglobinopathies, and a correct and thorough follow-up of these patients.

PB2201

PREVALENCE AND CAUSES OF CLOTTING TIMES PROLONGATION IN PATIENTS WITH TRANSFUSION DEPENDENT BETA THALASSEmia

I. Tartaglione1,*, M. Caiazza1, A. Bonadies1, D. Roberti1, M. Casale1, S. Scianugieta1, F. Rossi1, S. Perrotta1
1Dipartimento della Donna, del Bambino e della Chirurgia generale e specialistica, Università della Campania "Luigi Vanvitelli", Naples, Italy

Background: Thalassaemia is traditionally known to be a thrombophilic, rather than hemorrhagic, disorder. In spite of this, prolongation of clotting times are often reported. Understanding if there is a real risk of bleeding, and what this risk can be associated to, is crucial, especially in relation to the frequent referral to surgery (e.g. for splenectomy, cholecystectomy). Hepatopathy due to iron overload or HCV infection has been addressed as a main cause of this finding, even though disorders in the clotting profile are often reported also in patients with no alterations of hepatic function. The impairment of factors XI and XII often reported has been hypothesized to be secondary to intravascular haemolysis or multiple transfusions (Caccioli et al, Acta Haematol 1978, Mcfadyen et al, Ann Hematol 2014), but no data are available to confirm this supposition.

Aims: To determine the prevalence of clotting disorders in a group of Transfusion dependent Thalassemia (TDT) patients and to assess the correlation with hepatopathy, degree of the hemolysis, transfusion frequency, erythroblastosis, iron chelation.

Methods: TDT patients followed at our center for whom clotting tests were available were included. From chart review data were collected regarding clotting times, demographics, disease history, comorbidities and concomitant medications, iron chelation therapies, iron overload (serum ferritin, LIC, cardiac T2*), liver function tests, hemolysis parameters, hemocromocitometric values. Patients on anticoagulation therapy were excluded.

Results: 22 TDT patients (female 55.35%) were enrolled in our study, mean age 26.02±13.38 years, 17 of them were pediatric. In 20/56 patients (35.71%) prolongation of clotting time was found: this included both prolonged INR (23.21%) and prolonged aPTT ratio (25%); 7 patients (12.5%) had both prolonged INR and aPTT. Subgroup with clotting disorder (group A) was compared to subgroup with clotting times within normal ranges (group B) using T-Test. No differences were found in terms of sex, age, genotyping, transfusion interval, hemolysis degree, comorbidities, HCV infection included, iron overload, liver function, erythroblastosis and platelets levels, nor in history of thrombotic complications. No patients had history of hemorrhagic disease. Pretransfusion Hb was lower in patients with prolonged clotting times (p=0.045); none of the patients in Group A was splenectomized (p=0.042).

Summary/Conclusions: In our population clotting disorders were not correlated with hepatic disease, nor hemolysis or transfusions. The mild correlation with lower Hb values and with the lacking splenectomy could be consistent with the known effect of low Ht on lab procedures for clotting tests. In relation to this observation in patients with altered coagulation tests the repetition of clotting test after blood transfusion could be advisable to overcome the low Hb effect.

PB2202

COMPOUND HETEROZYGOsITY FOR HAEMOGLOBIN ADANA AND a-THALASSAEMIA IN GREECE. CLINICAL PHENOTYPE AND GENETIC COUNSELING

S. Theodondou1,*, A. Te1i2, E. Yfantis3, T.-A. Vyzantiadis4, M. Economou2
1Thalassemia Unit, Hippokration General Hospital, 2First Department of Pedi- atrics, Aristotle University, Thessaloniki, 3Thalassemia Centre, Laikon General Hospital, Athens, 4First Microbiology Department, Aristotle University, Thessa-loniki, Greece

Background: Haemoglobin (Hb) Adana (HBA2qC.179>A) in interaction with deletional and nondeletional α-thalassaemia mutations leads to HbH or, less commonly to thalassaemia intermedia with clinical manifestations varying from asymptomatic forms to severe anemia. First line screening tests are unable to detect the highly unstable variant. Aims: We report two cases of Hb Adana co-inheritance with the a-thalassaemia 3.7 kb deletion - the only α- and Hb Adana double heterozygosity cases diagnosed in subjects of Greek origin.

Methods: The first case concerns a 3 year old girl, born from parents referred for genetic counseling at the 11th week of a second gestation. The mother showed an Hb of 10.7g/dl, MCV 80.7 fl, MCH 26.4 pg, Hb A2 2.8% and Hb F 1%, with positive inclusion bodies, and her ethnic (Greek) and regional background was of high risk for thalassaemia. The partner came from the same region, and he showed an Hb of 13.8g/dl, RBC 5.88 X 1012/L, MCV 73.1, MCH 23.5 pg, Hb A2 2.4% and Hb F 2.3%, while her ferritin levels were 228ng/ml and inclusion bodies were found. On clinical examination she was found to be of normal weight and height for her age, but presented with paleness, icteric sclera and mild splenomegaly. Genetic analysis revealed that the mother carried the α-thalassaemia 3.7 kb deletion defect. The father carried the rare non deletional α-thal Adana. As suspected from the haematolog-ical data, their offspring was a compound heterozygote for Hb Adana variant in trans to a 3.7 kb α+ thal deletion. The second case concerns an 17-year-old boy, diagnosed with Hb Adana co-inheritance with the a-thalassaemia 3.7 kb deletion at the age of 8 years. At diagnosis, findings were compatible with a very mild phenotype and growth was not impaired. The boy retained a mild hypochromic microcytic anemia (Hb~10g/dl, MCV 71 fl, MCH 23 pg, RDW 18.6%, reticulo- cytosis 5%), until age four and a half, at the age of 11 transfusion initiation was decided due to marked splenomegally and limited weight and height gain. For the following years he was transfused approximately once a month, neces- sitating chelation therapy. Weight, height and pubertal development were nor- mal by the age of 15, but splenomegaly persisted. Splenectomy was decided and transfusions were stopped shortly afterwards. During the following months the boy retained an Hb of 9.5 g/dl, however, he complained of constant fatigue and impaired physical activity and asked to get back on a transfusion program.

Results: In both cases diagnosis was incidental highlighting the mild pheno- type. However, the co inheritance of Hb Adana with the 3.7 kb α+ thal deletion is rare, with only the presenting cases in Greece, and in a few other families in Turkey, Southeast Asia, Philippines and Albania. The clinical phenotype of the combination seems to be a mild disease with a non-transfusion-dependent thalassaemia intermedia phenotype. Nonetheless, clinical severity prediction is always a difficult issue and phenotypes may change overtime as demon- strated by the second case described above.

Summary/Conclusions: Long follow-up of such rare cases is necessary in order to gain as much information as possible, so as to offer the best manage- ment to the patients and the most accurate genetic counseling.

**ANTITHROMBOTHETIC EFFECTS OF PEPTIDE PGPL IN EXPERIMENTAL THROMBUS FORMATION**

M. Grigorjeva1, L. Lyapina1, T. Oberganti1

1Biology, Lomonosov Moscow State University, Moscow, Russian Federation

**Background:** It was established that proline- and glycine-containing peptides have fibrinolytic, anticoagulant activity, inhibit platelet aggregation and thrombin activity in vitro and in vivo. Besides, it is known that short peptides of this family also have antithrombotic effects.

**Aims:** To study the influence of Pro-Gly-Pro-Leu (PGPL) and amino-acid leucine on fibrinolytic and anticoagulant blood activity, platelet aggregation and to estimate their possibility to reduce the formation of experimental blood clots.

**Methods:** Experiments were carried out on white rats (200–250 g) according to the ethical principles of the Helsinki Declaration. Peptide PGPL (1 mg/kg), leucine (0.33 mg/kg - equivalent to its content in PGPL) and saline (control rats) were intranasal entered to rats within 3 days. 1 hour after the last drugs administration we induced the formation of thrombus in n jugularis (Wessler model). The degree of thrombus formation was estimated on thrombus weight. Fibrinolytic activity and activity of tissue-plasminogen activator (t-PA) of blood plasma were measured by fibrin plate method. Anticoagulant activity (APTT-test) and ADP-induced platelet aggregation were detected by standard methods.

**Results:** Our experiments demonstrated that preliminary intranasal administration of PGPL (before formation of thrombus) leads to increase of APTT, fibrinolytic and t-PA activity on 18%, 62%, 35% accordingly from control rats. Besides, we observed the decrease of platelet aggregation. Also we indicated the reduction of thrombus weight in PGPL-treated rats on 68.5% comparatively with control rats. The thrombus weigh after leucine treatment decreased on 30% compared with control rats. But administration of leucine did not change haemostasis system parameters.

**Summary/Conclusions:** Thus administration of PGPL enhanced of anticoagulant, fibrinolytic and antplatelet activity in rats blood plasma. PGPL pretreatment lead to prevention of experimental venous thrombus formation. Therefore, PGPL may be used as a perspective anticoagulant and fibrinolytic agent with direct antithrombotic effect.

**TREATMENT AND OUTCOME OF THROMBOTIC MICROANGIOPATHY IN MALAYSIA**

Y.Y. Yap1, K.B. Law1, P.A.B. Zulkarnain1, S. Carlo1, R. Ramli1, J. Sathar1, K.M. Chang1

1Department of Haematology in Ampang Hospital, Ministry of Health, Selangor, Malaysia

**Background:** Thrombotic Thrombocytopenic Purpura (TTP) is a potentially lethal disease that is still no promising cure in this era. The ADAMTS-13 deficiency or defect in the disease has enabled clinician to recognize another entity which is Thrombotic Microangiopathy (TMA). This entity includes TTP, typical Haemolytic Uraemic Syndrome (HUS), Cancer associated TMA, Atypical entity which is Thrombotic Microangiopathy (TMA). This entity includes TTP, lethal disease that there is still no promising cure in this era. The ADAMTS-13 activity testing. There were 24% Primary Acquired TTP, 5% typical HUS, 3.4% atypical HUS, 3.4% Pregnancy TMA, 3.4% SLE related TMA, 20.3% Transplant TMA, 1.7% Cancer associated TMA and 37% TMA of other causes. The average plasma exchange was 8.4 cycles, and was higher in patients with ADAMTS-13 activity of ≤10% (11.4 cycles) as compared to those with ADAMTS-13 activity >10% (7.7 cycles). No infectious diseases were transmitted as a result of plasma exchange or plasma infusion. Treatments used in the patients included immunosuppressant therapy like cyclosporine (55.5%), monochlonal antibody like rituximab (36.2%), bortezomib (11.6%), cyclophosphamide (10.1%), cyclosporine (10.1%), and vin-cristine (26%). The survival outcome seemed to be worse among the transplant TMA in comparison to other groups (log-rank, p=0.0001). Transplantation was also associated with higher odd of death among TMA cases (OR: 14.8571, 95% CL: 1.7385, 126.9707). Those with confirmed TTP was inevitably doing better than the others in terms of overall survival (log-rank, p=0.0299). The odds of death was 4.36 times higher in patients with ADAMTS-13 activity >10% (OR: 4.36, 95% CL: 1.0961, 17.3714), indicating secondary TTP may have inferior treatment and disease outcomes than primary TTP like congenital or acquired TTP. Besides, the complications of the disease were also evaluated which revealed 26.9% of renal failure and 52.2% of neurological deficit. Furthermore, 8.7% were complicated by Venous Thromboembolism, either provoked or spontaneous. The odds of relapse is 2.9 times higher given the ADAMTS-13 activity ≤10% to ADAMTS-13 activity >10%.

**Summary/Conclusions:** This study illustrated that the standard treatment like plasma exchange and immunosuppressant therapy are only effective in genuine TTP whereas those masquerading TTP (TMA) would be more challenging to be tackled in terms of improving the outcome. The task to investigate other types of TMA prospectively will be highly desirable in the future.

**PB2205**

**ANTIPHOSPHOLIPID ANTIBODY PROFILE AND ORGAN INVOLVEMENT IN CRITICALLY ILL PATIENTS WITH AUTOIMMUNE DISEASES**

P. Zambrano1,2, J. Aporton1, A. Sanchez2, M.T. Ospina3, Y. Forero3, J. Carriozzo3, E. Aviles4, A. Cartagena1, C. Zapata3, C. Gamboa1

1Universidad de La Sabana, 2Hospital Universitario de la Samaritana, 3Fundación Santa Fe De Bogotá, Bogota, 4Universidad de La Sabana, Bogotá, Colombia

**Background:** Antiphospholipid antibodies (APA) are a group of proteins directed against the phospholipids of cell membranes, such as cardiolipins or phospholipid binding proteins. APA presence provokes microvascular, arterial or venous thrombotic events indicating somehow the relationship between the immune system, the hemostatic system, and the inflammatory response. It has been suggested that their presence in a critically ill patient is related to thrombotic manifestations, organ dysfunction, and death.

**Aims:** The aim of this study was to evaluate the prevalence of antiphospholipid antibodies in critically ill patients with autoimmune diseases and the rate of organ involvement.

**Methods:** Retrospective and descriptive study of patients admitted to the intensive care unit of Hospital Universidad de la Samaritana between 2008 and 2016, in Bogotá, Colombia.

**Results:** A total of 79 patients were found to have systemic lupus erythematosus (SLE), antiphospholipid syndrome and vasculitis. 17 patients (22%) were positive for antiphospholipid antibodies. Of these, 76% were women and mean age was 38 years (18-63 years). APA profiles showed positivity with the following distribution: one positive antibody, n=9 patients (53%) (lupus anticoagulant antibody being the most common), two positive antibodies in n=4 patients (23%) and three positive antibodies in n=4 patients. Anemia (100%), monocytosis (64%), thrombocytopenia (40%) and prolonged INR (17%) were found in 88% of patients on admission to the ICU. In descending order, other organ involvement was found to be: pulmonary and renal dysfunction (70%), shock (53%), central nervous system involvement (41%), cardiovascular (23%), and gastrointestinal (22%). 82% of this cohort had positive anti-nuclear antibodies (ANA) and 23% anti-cytoplasmic antibodies (ANCA). 100% of patients had elevated C-reactive protein (CRP), and APACHE II score average was 11 points (Table 1).

**Summary/Conclusions:** Hematologic, renal and pulmonary involvement are the most commonly compromised in patients with antiphospholipid antibodies positive. Organ involvement was less common in patients with autoimmune diseases in the ICU. Based on these results, a prospective study is proposed in order to evaluate the presence of APA and their impact on mortality and multi-organ dysfunction in these patients.

**PB2206**

**PREVALENCE OF ANTIPHOSPHOLIPID ANTIBODY AND HBA1C IN T2DM WITH DIABETIC VASCULAR COMPLICATIONS**

T. U. Nwagha1, O. Agwu1

1Haematology & Immunology, University Of Nigeria Teaching Hospital, Enugu, Nigeria
Background: Antiphospholipid antibodies (APLS) have been implicated in vascular, venous or both thrombosis. Diabetes Mellitus (DM), as a disease entity has been associated with hyper-coagulable and pro-thrombotic states, with studies showing an increased procoagulant state and thrombotic events especially in poorly controlled Type 2 Diabetes Mellitus (T2DM). Aims: The aim of the study is to assess the APLS and HbA1c levels and evaluate the correlation between APLS levels and HbA1c in T2DM patients with diabetic vascular complications.

Methods: This was a cross-sectional study of subjects with T2DM attending the diabetic clinic of University of Nigeria Teaching Hospital. A total of two hundred and one (210) subjects were recruited for this study. There were grouped into: non-vascular; T2DM, uncomplicated T2DM and health control. Each had 70 subjects matched for sex and age. Lupus anticoagulant (LA) was assayed using DRVVT (technocline GmbH Austria) IgGβ2GPI-ACA was assayed using ELISA test kit (Genway Bio-tech San Diego USA), HbA1C was assayed using D10TM haemoglobin analyzer. Ethical clearance was obtained from the ethical committee UNTH.

Results: The prevalence of LA was 7.1%, 4.3% and 4.3% for complicated T2DM, uncomplicated and healthy control subjects respectively, while the prevalence of IgG-B2GPI ACA was 4.3% in all groups. The mean HbA1C was 8.2(±1.5), 8.0 (±1.7), 5.6 (±0.3) for complicated , uncomplicated T2DM and control subjects respectively. ANOVA showed a significant difference in mean position on the risk of acute coronary syndrome (ACS).

Summary/Conclusions: The study did not find any causal or other association between T2DM and the occurrence of APLS positivity, however, APLS may be simply an aggregating factor for vascular complications especially in poor controlled T2DM.

PB2207
VWF THR789ALA GENETIC VARIANTS CORRELATE WITH DISEASE SYNDROME IN EGYPTIAN PATIENTS WITH ACUTE CORONARY SYNDROME
N. Oaman1,2, M. Younes1, R. Yaseen1, A. Fathy1
1Clinical Pathology, Menoufia University, Shebin Elkom, Egypt
22nd Congress of the European Hematology Association

Background: von Willbrand factor antigen level (vWF:Ag) was shown to contribute to the risk of cardiovascular disease. vWF Thr789Ala single nucleotide polymorphism is thought to affect factor level and function. Aims: This study aimed to investigate the prevalence of this genetic variant at that position on the risk of acute coronary syndrome (ACS).

Methods: The study included 112 patients of ACS; 31 with unstable angina (UA) and 81 with myocardial infarction (MI) as well as 118 healthy controls. vWF:Ag level was measured by ELISA. The gene analysis was carried out by polymorphic chain reaction using restriction fragment length polymorphism (RFLP-PCR) principles.

Results: vWF:Ag levels were significantly higher in MI (111.6±24.77 IU/dl) and UA (110.2±23.44 IU/ml) patients compared to healthy controls (71.13±13.72 IU/dl), p<0.001 for both groups. The majority of patients with UA (80.6%) were Ala789 homozygous, 33.1% were heterozygous and 19.5% were Thr789Ala heterozygous and 12.9% were Thr789 homozygous. Regarding the MI group, Ala789 genotype was present in 34.6%, Thr789Ala genotype was the predominant genotype and was seen in 48.1% of patients and Thr789 homozygous was present in 17.3% of patients. The genotype frequency in the control group was as follow; 47.1% were Ala789 homozygous, 33.1% were heterozygous and 19.5% were Thr789Ala heterozygous.

Summary/Conclusions: Activated partial thromboplastin time (aPTT) and prothrombin time (PT) were prolonged in the cases, however, APLS may be an aggregating factor for vascular complications especially in poor controlled T2DM.

PB2209
IMPOR TANCE OF MONITORING PATIENTS WITH DIRECT ORAL ANTICOAGULANTS
L.F. Avila Idr01, A. Bernardo Gutierrez1, A. Caro Gómez1, D. Martinez Carballeira1, I. Soto Ortega1
1Hematology, Hospital Universitario Central de Asturias, Oviedo, Spain

Background: A major advantage of these agents is the lack of a requirement for laboratory tests to monitor the drug effect, however it’s recommended monitoring the drug for Rivaroxaban Apixaban and Edoxaban use anti-Xa chromogenic studies and for Dabigatran Hemoclot thrombin inhibitor and Ecarin clotting time (DTI) test.

Aims: To determine the effectiveness of laboratory tests to monitor patients treated with direct oral anticoagulants.

Methods: We conducted a retrospective study with 227 patients who received direct oral anticoagulants (DOACs) between January 2015 and December 2016. One hundred eighteen patients (52%) receive Rivaroxaban, fifty patients (22%) receive Dabigatran and fifty nine patients receive Apixaban (26%). We monitored the variables that’s increases the bleeding risk such as: drug interactions, prothrombin time (PT) and activated partial thromboplastin time (aPTT), therapeutic range of the drug, and measurement of serum creatinine.

Results: We found 10% of toxicity with Dabigatran, 7% with Rivaroxaban and a 3% with Apixaban. Thirty-five patients (15%) developed bleeding of which 11% (4%) was major and 3% had minor bleeding. For each DOACs we found that 6% of patients with Dabigatran, 2.5% with Rivaroxaban and 1.5% with Apixaban developed thrombotic episodes. Twenty percent of patient didn’t have therapeutic range of the drug. For each DOACs is shown in Table 1. When we analyzed the patients who had hemorrhage we found that all patients on Dabigatran prolonged aPTT because of xanthine, but for other DOACs is shown in Table 1. A retrospective case-match analysis was performed comparing 35 patients who developed bleeding with an equal number of patients who did, case and control groups were matched according to age, weight and measurement of serum creatinine we didn’t find significant differences.

Summary/Conclusions: Of patients on dabigatran and who suffered bleeding, we found a significant prolongation of aTTP and PT, demonstrating the importance of laboratory tests prior to the administration of these agents and in emergency situations, for these reason should be include PT
and aPTT, therapeutic level of the drug and creatinine measurement, within the emergency and control laboratory tests in patients that receive DOACs.

PB2210
HEREDITARY RISK FACTORS OF VENOUS THROMBOEMBOLISM IN YOUNG WOMEN TAKING ESTROGEN DRUGS
A. Chechulova1, S. Kapustin2, S. Karpič3, V. Shmeleva2, V. Soldatenkov2, L. Papayam2, V. Soroka1, P. Chechulov3
1Vascular surgery, Dzanhalidze Research Institute of Emergency Medicine, St. Petersburg, 2Russian Research Institute of Hematology and Transfusiology, 3Dzanhalidze Research Institute of Emergency Medicine, St. Petersburg, St. Petersburg, Russian Federation

Background: Estrogens are recognized as the most common risk factor of venous thromboembolism (VTE) in young women. The cumulative risk of VTE in patients taking estrogens is significantly increased in carriers of inherited thrombophilia. However, the known hereditary risk factors – mutations FV Leiden and FII G20210A could be detected in only 20-30% of patients with VTE.

Methods: We examined 133 young women with acute VTE (mean age 37.4 years; 16-45), who were genotyped by PCR-RFLP method for DNA polymorphism in 9 genes: Fv:Thr312Ala, Fi-B -455 G/A, FII 20210 G/A, FV I691 G/A, FXI 48 CT, FII-Val34Leu, PAI-1 675 4G/4G, EPCR Ser219Gly, TPA 311bp Del.

Results: We compared the distribution of studied genotypes in three groups of patients with VTE: taking estrogens (n=30, group 1), with idiopathic VTE (n=42, group 2) or having other risk factors (n=61, group 3).

Summary/Conclusions: The frequencies of prothrombotic genotypes in groups 1, 2 and 3, respectively, were: FV 1691 G/A – 20.0%, 21.4% and 13.1%; FII 20210G/A – 10.0%, 9.8% and 7.1%; Fi-B -455 G/A – 10.0%, 2.4% and 1.6%; Fv:Thr312Ala – 13.3%, 14.3% and 13.1%; TPA 311bp Ins/Del – 16.7%, 28.6% and 31.1%; PAI-1 675 4G/4G – 36.7%, 42.9% and 27.9%; EPCR 219Ser/Gly – 16.7%, 19.0% and 23.0%; EPCR 219Gly/Gly – 3.3%, 7.1% and 0.0%; FVII 46TT – 13.3%, 14.3% and 13.1%; FXIII-A 34 Leu/Leu – 3.3%, 21.4% and 9.8%. Significant differences between the groups have been detected only for the FXIII-A 34Leu/Leu variant, and 9.8%; FXIII-A 34 Leu/Leu – 3.3%, 21.4% and 9.8%. Significant differences were identified (high medium and low).

PB2211
KNOWLEDGE AND ATTITUDE OF MEDICAL DOCTORS ON ANTICOAGULATION THERAPY IN TERTIARY HOSPITALS IN NIGERIA
T.U. Nwagha1,2, R. Anakwe2, O. Ukpai3, E. Owubuya4, N. Obeka5, I. Okoye6, B. Azubuike6
1Haematology & Immunology, 2Internal medicine, University Of Nigeria Teaching Hospital, Enugu, 3Internal medicine, Abia state Teaching Hospital, Umuahia, 4Internal medicine, Nnamdi Azikiwe Teaching Hospital Nnewi, Awka, 5Internal medicine, Federal Medical center , Abakiliki, 6Internal medicine, Amaku Specialist hospital, Awka, Nigeria

Background: Thromboembolic and hypercoagulable diseases are common life-threatening but treatable problems in hospital practice. The most effective and economical approach to decreasing the burden of VTE is to prevent the development of DVT and PE in patients especially in acutely ill hospitalized medical patients. Health care providers in Nigeria may have significant gaps in their anticoagulation knowledge that could affect their decision to prescribe anticoagulation therapy as there are no national guidelines on the use of anticoagulation in Nigeria.

Aims: The purpose of this present study was to examine the knowledge and attitude of medical doctors on anticoagulation in tertiary hospitals in Nigeria.

Methods: The present study is a multicentre survey of the use of anticoagulants among clinicians in South East Nigeria. A pretested questionnaire was administered to clinicians in six tertiary hospitals in the south-east of Nigeria.

Results: There were 528 respondents. 378 of them were males (71.6%) and 150 were females (28.4%). 31.1% of the respondents, were junior residents and the consultants represented only 20.6% of the respondents. Most of the respondents, 189 (35.8%) had less than 5 years clinical experience while the least number of respondents (67%) had between 16-20 years clinical experience. We observed that most respondents irrespective of their job grades didn’t know about Fondaparinux and the DOAC (except those in the specialist - registrar job grades) as the overall p=(0.000),<0.05 and was significant. We also observed that respondents were divided on malignancy as an indication of anticoagulation. The overall P=0.002, <0.05 and was significant. The p value for other indications for anticoagulation >0.05 and was not significant. The majority knew of prothrombin test and p value was 0.03, less than alpha value of 0.05 and was significant. On the contrary, Majority does not know about anti-Xa assay, p-value=0.02, <0.05, was also significant. Their affirmative response on the mode of action as one of the differences showed a p=0.000, <0.05, was significant. On the contrary, the non-affirmative response to drug and food interaction, p=0.03, was also significant. Based on results of the statement analysis, the variables were ranked according to the value of their mean. All except one variable had p-values of <0.05. The statement “Do you think anticoagulation therapy/prophylaxis is clinically important” had the highest mean of 4.60 and had a high degree of agreement. The statement “Should hospital inpatient with >3 days admission routinely receive anticoagulation?” had the lowest mean of 2.27 with a p-value of 0.015 had a low degree of agreement.

Summary/Conclusions: There is a need to upscale knowledge attitude and practice of the use anticoagulation agents especially the NOACs through well-articulated CME educational activities. A limitation of this study is the relatively small number of study participants and some subspecialties that were not reflected in this survey.

PB2214
INTERLEUKIN -10 GENE POLYMORPHISMS AND THE RISK OF UNPROVOKED DVT IN EGYPTIAN PATIENTS
H. Ellithy1,*, G. Shaheen2, S. Elmoamly1
1Internal medicine- clinical Hematology Unit, 2Clinical pathology, Kasr Al-Ainy school of medicine- Cairo university, Cairo, Egypt

Background: Thrombosis is often multifactorial, caused by both genetic and acquired risk factors. The inflammatory process is linked to pathogenesis of venous thrombosis. Venous thrombosis is considered to be mediated by an imbalance in procoagulant pathways as compared with anti-coagulant pathways. One of the important anti-inflammatory cytokine is interleukin-10 (IL-10) with important immunoregulatory functions. Primarily, IL-10 counterbalances the potentially harmful effects of tumor necrosis factor α (TNFα) and other pro-inflammatory mediators such as IL-1, β, IL-8 and from monocytes/ macrophages. Three important single nucleotide polymorphisms (SNP) were included: IL-10-1082 A/G, and -819C/T, and 592 C/A. Studying the association between genetic polymorphisms of anti-inflammatory cytokines such as IL-10, and venous thrombosis may suggest using of polymorphisms as a predictive genetic marker of future VTE.

Aims: The objective of this study was to evaluate a possible association between IL-10 -1082A/G, and -592C/A polymorphisms with DVT.

Methods: The study was conducted on 115 patients with symptomatic DVT proved by venous duplex ultrasound; divided into two cohorts: group A included...
60 patients with unprovoked DVT, and group B included 55 patients with pro-
provoked DVT. Gene mutations for IL-10 -1082AG, and -592CA were performed
using PCR-restriction fragment length polymorphism assay. We studied the
association between IL-10 gene polymorphisms and occurrence of either pro-
provoked or non-provoked DVT. We also investigated the link between these poly-
morphisms and the recurrence of DVT and family history of DVT.

Results: In group B (with provoked DVT); as AG genotype was detected in 14 patients (63.6%) versus 8 patients (36.4%) in group A and B respectively (P value=0.037); AG
genes were detected in 50 patients (66.7%) infected to 17 patients (36.2%) in
in group A and B respectively (P value=0.007). However, there is no correlation
was found between IL101082 mutant genotypes distribution and VTE recur-
pence (P value= 0.738 and 1 respectively) or positive family history of VTE (P
value= 0.101 and 0.714 respectively), compared to wild genotype. IL10592AC
gener was detected in 40 patients (66.7%) infected to 17 patients (36.2%) in
in group A and B respectively (P value=0.007). However, there is no correlation
was found between IL10592AC mutant genotypes distribution and VTE recurrence
(P value= 0.43 and 0.687 for GG and AG genotypes respectively) compared to wild genotypes distribution, also there is no correlation was found between IL10592AC mutant genotypes distribution and VTE recurrence (P value= 1 and 0.284 for GG and AG genotypes respec-
tively) compared to wild genotype distribution (AA).

Summary/Conclusions: IL101082AG gene polymorphism is associated with
risk of unprovoked DVT, however it is not associated with either risk of recur-
rence or positive family history.

PB2216
HAEMATOLOGICAL CORRELATES OF ISCHEMIC STROKE AND TRANSIENT ISCHEMIC ATTACK : LESSONS LEARNED
H. Gunasekara1; I. Pathirage2, Health, Teaching Hospital- Kegalle, Kegalle, Health, Provincial Department of Health Services, North Western Province, Sri Lanka

Background: Haematological abnormalities are known to cause Ischemic Stroke or Transient Ischemic Attack (TIA). The identification of haematological correlates plays an important role in management and secondary prevention.Aims: The objective of this study was to describe haematological correlates of stroke and their association between stroke profile. The haematological correlates screened were Lupus Anticoagulant, Dysfibroglobinemia, Paroxysmal nocturnal haemoglobinuria (PNH), Sickle cell disease, Systemic Lupus Erythe-
matosis (SLE) and Myeloproliferative Neoplasms (MPN).
Methods: A cross sectional descriptive study was conducted in a sample of
152 stroke patients referred to haematology department of National Hospital of Sri Lanka for thrombophilia screening. Following tests were performed to
assess each hematological correlates (Table 1).

Table 1.

Haematological correlate Tests performed
Lupus anticoagulant Anti-coagulant assay
Sickle cell disease Full blood count (FBC), blood picture and sickling test and high Fibrinogen level
Dysfibroglobinemia Plasma fibrinogen and Agarose electrophoresis
Paroxysmal nocturnal haemoglobinuria (PNH) Epoxy-globin, mirror, and light and Electron microscopy
Systemic Lupus Erythematous (SLE) Anti-nuclear factor, Anti-DNA, Anti-dsDNA, Anti-ssDNA
Myeloproliferative Neoplasms (MPN) Myeloperoxidase activity analysis, erythropoietic and bone marrow examination

Results: Among study sample, 134 patients had strokes and only 18 had TIA. The recurrence of stroke/TIA was observed in 13.2% of patients. The majority of patients (94.7%) have had radiological evidence of thrombotic event. One fourth of patients had past thrombotic events while 12.5% had family history of thrombosis. Out of haematological correlates screened Lupus anticoagulant was the most common haematological correlate (n=16) and dysfibro-

Background: Currently, the number of diabetes, hypercholesterolemia, meta-
bolic syndrome (MS) patients has increased sharply in the world. MS is meta-
bolic disorders with increase of cholesterol and glucose levels, dyslipemia,
endothelial dysfunction. This is accompanied by an increase in blood clotting,
including platelet aggregation strengthening and reducing the activity of the
plasminogen activator. Thus, the MS may predispose to venous thrombosis. It
is known that, regulatory oligopeptides involved in the conservation normal
functional activity of coagulation, anticoagulation, insular systems of the organ-
ism, fat metabolism. It is also known that some amino acids, particularly argi-
nine, improve rheological properties of blood and reduce platelet aggregation.

Methods: Experiments were carried out on Wistar rats weighing 300-350 g in
studies in accordance with the ethical principles of the Helsinki Declaration. Two groups of animals were used: healthy rats and rats with experimental MS. Peptides were intranasal injected in doses of 1 mg / kg once daily for 5 days. 0.85% NaCl solution was injected to control rats in the same time frame. MS in rats
was caused by a hyper-cholesterol fat-rich diet (FD) for 6 weeks. Blood samples
were taken from the jugular vein 1 hour after the last drug administration. Activ-
it of t-PA (fibrin plate method) and ADP-induced platelet aggregation (standard
method) were measured in blood plasma.

Results: The intranasal administration of peptides Gly-Arg-Pro, and Pro-Arg-
Gly to healthy animals resulted a reduction of platelet aggregation by 23%
and 52% respectively as compared with control. Both peptides induced enhancement t-PA activity of 2 or 3.5 times respectively. In rats with experimental MS these effects
were preserved, besides, platelet aggregation was decreased by 27% (Pro-
Arg-Gly) and 38% (Gly-Arg-Pro) compared with the control.
Summary/Conclusions: We concluded that intranasal administration of tripeptides Pro-Arg-Gly and Gly-Arg-Pro to organism of healthy rats and in rats with experimental MS show antiplaletante and fibrinolytic effects of the blood. Thus, arginine-containing peptides could potentially be used as antithrombotic drugs that protect the organism from the blood coagulation and thrombus formation.

PB2218
THE PRINCIPAL COMPONENT ANALYSIS USING CALIBRATED AUTOMATED THROMBOGRAM PARAMETERS AS A POTENTIAL QUALITY CONTROL FOR MEASURING PROCOAGULANT ACTIVITIES OF IMMUNOGLOBULINS
H. Oh1,*, C. Ahn1, S. Han1, H. Song1, K. Han1, G. Min1, J. Kim1, S. Park1, K. Jung1
1Blood Products Division, National Institute of Food and Drug Safety Evaluation, Cheongju-si, Korea, Republic Of

Background: The calibrated automated thrombogram (CAT) is a method to monitor the generation of thrombin. It can be described by four variables: lag time, peak thrombin, time to peak, and velocity index. Currently, due to thromboembolic event related risks of immunoglobulins, the CAT is widely used to quantify the thrombogenic potential associated with immunoglobulin manufacturing processes and products. However, there is currently no officially approved method for such assessments and even this results are highly variable in inter-laboratories comparison. In this study, to obtain a summary score, we applied the principal component analysis (PCA) for these four outcomes measured from CAT method. The PCA is a statistical procedure concerned with elucidating the covariance structure of a set of variables. In particular it allows us to identify the principal directions in which the data varies.

Aims: In this study, our interest is to apply PCA method in order to find appropriate dose related with CAT variables and to reduce variation of procoagulant values in Immunoglobulin products.

Methods: The CAT are measured in a 96 well plate fluorometer equipped with a 390/460 filter set and a dispenser. Usually experiments are carried out in triplicate. During the measurement, a dedicated software program, Thrombinoscope compares the readings from the trigger wells and the calibrater wells, calculates thrombin concentration and displays the thrombin concentration in time. Outcomes from CAT were analyzed in the principal component analysis (PCA) which is a statistical procedure that allows us to summarize high dimensional data with a smaller number of representative variables that collectively explain most of the variability. Statistical analyses were performed with R 2.5.

Results: Four variables measured from CAT have different sistribution and too large variations. For example, the mean(sd) of each variable (lag time, peak thrombin, time to peak, and velocity index) are 24.86(8.01), 80.16(94.52), 31.28(9.78), 19.08(28.86), respectively. Therefore, to remedy such high variability among variables and to find a score, PCA method is applied. Then the dose values calculated based on the PCA scores have mean 0.393 and a much smaller variation (sd=0.583) (Table 1).

Table 1.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Mean(SD)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lag time</td>
<td>24.86(8.01)</td>

Summary/Conclusions: The PCA value showed a good agreement with four CAT outcomes and less variation. The PCA method could be used to monitor the process of immunoglobulin manufacturing.

PB2219
PRIMARY THROMBOPHILIA IN MEXICO XII: MISCARRIAGES ARE MORE FREQUENT IN PERSONS WITH THE STICKY PLATELET SYNDROME
G.J. Ruiz Argüelles1,2, G.J. Ruiz-Delgado1, Y. Cantero-Fortiz2, M.A. Mendez-Huerter2, M. Leon-Gonzalez4, A.A. Leon-Pena4, A.K. Nuñez Cortes4, J.C. Olivares-Gazca4, J.A. Arizaga Berber4
1Hematology, Centro de Hematologia y Medicina Interna, 2Laboratorios Clinicos de Puebla, 3Laboratorios Clínicos de Puebla, 4Centro de Hematologia y Medicina Interna, Puebla, Mexico

Background: The sticky platelet syndrome (SPS) is an inherited condition which leads into arterial and venous thrombosis. There is scant information about the association between the SPS and obstetric complications.

Aims: To assess the relationship of the SPS and fetal loss in a single institution.

Methods: The obstetric history of all the consecutive female patients prospectively studied along a 324 month period, in a single institution with a history of thrombosis and a clinical marker of primary thrombophilia was reviewed.

Results: Between 1989 and 2016, 268 consecutive patients with a clinical marker of primary thrombophilia and a history of arterial or venous thrombosis were studied; of these, 108 were female patients. Within this subset of thrombophilic female persons, 77 (71%) had been pregnant at some moment. Twenty eight of these 77 patients (37%) had had a spontaneous abortion and 24 out of these (86%) were found to have the SPS. On the other hand, in a subset of 73 female patients with the SPS who had been pregnant, 32% had miscarriages. These figures are significantly higher than the prevalence of abortions in historical and general population of pregnant women in Mexico (chi square=7.47; p=0.0063). Accordingly, the relative risk of having a miscarriage be 2.66 times higher in female patients with the SPS than in the general population (p=0.0014) (Figure 1).

Figure 1.

Summary/Conclusions: In México, female patients with the SPS experience significantly more spontaneous abortions than the general population. Since the treatment of the SPS is simple and effective and could in turn prevent adverse obstetric outcomes, its investigation in women studied because obstetric complications may be useful and deserves further research.
A PRELIMINARY STUDY ON THE EFFECTS OF AMPHIBIAN CRUDE SKIN SECRETIONS ON SOME PARAMETERS OF HEMOSTATIC SYSTEM

I. Nikolaeva1,*, O. Marushchak1, O. Oskyrko1, T. Halenova1, O. Savchuk1
1Biochemistry, Educational and Scientific Centre "Institute of Biology and Medicine", Taras Shevchenko Kyiv National University, Ukraine, Kyiv, Ukraine

Background: A lot of bio-chemical compounds from secretion of the amphibian skin glands with various biological activities have been isolated and characterized. Several recent studies indicate that amphibian skin secretions can be a source of molecules affecting the platelet activity. We are interested to look for other bioactive components of the amphibian skin which exhibit ability to influence on diverse parameters of hemostatic system.

Aims: We performed a preliminary study of the some effects of amphibian crude skin secretions on hemostasis.

Methods: Adult specimens (both sexes) of Bombina bombina, Bombina variegata, Bufo bufo, and Bubotes viridis were collected from outdoors in Kyiv region of Ukraine. The crude skin secretions were collected by washing with ultrapure water and centrifuged to remove debris. The supernatants were lyophilized and kept at −20 °C till use. In the experiments we used fresh prepared water solution of lyophilized skin secretions. Protein concentration was determined by Bradford method with BSA as a standard. Rabbit platelet-rich plasma (PRP, 2x10⁵ cells/μL) and platelet-poor plasma were obtained following standard protocols. Platelet fraction (PF) was purified by gel-filtration on Sephadex G 50 column. Platelet aggregation was measured by aggregometer AT-02 (Medtech, Russia). Coagulation parameters (prothrombin time (PT), thrombin time (TT), as well as activated partial thromboplastin time (APTT)) were measured by coagulometer (Rayto, RT-2201C) using corresponding commercial kits (Renam, Russia).

Results: The lyophilized B. bufo skin secretions in dose-dependent manner induced platelet aggregation in both PRP and purified PF; its final concentration of 50 mg of total protein/mL caused the same effect as 5x10⁶ M ADP. These results indicated that skin components act directly on platelets, maybe through their surface receptors. The lyophilized skin secretions of B. variegata and B. bufo also activated platelet aggregation but their effects were lower than B. bufo skin secretions. The skin secretions from all studied amphibian did not influence on PT and TT except B. viridis which prolonged TT by 40%. The values of APTT were significantly enhanced in 3.4 and 2.3 times under the influence of crude skin secretions (final concentration of 0.2 mg total protein/mL, plasma) of B. bombina and B. variegata, respectively.

Summary/Conclusions: The obtained results indicate the prospects of the amphibian skin secretions for influence on diverse parameters of hemostatic system.

PB2224

LEARNING ABOUT VALIDATIONS OF THE DVT SCREENING TEST IN PATIENTS WITH SUSPECTED UPPER LIMB THROMBOSIS: A PERSPECTIVE FROM THE CLINICAL PRACTICE

H.N. Fernandez - Leyva1,*
1Haematology, Croydon University Hospital, London, United Kingdom

Background: Deep vein thrombosis (DVT) of the upper limbs represents 1-4% of DVT, most of them related to central venous catheter and/or malignancy. The management and treatment of DVT of the upper limbs represents a challenge because of the potential for both fetal and maternal complications. The most common complication is venous thromboembolism.

Aims: The aim of this study was to assess the usefulness of the DVT screening test as a tool for evaluation, diagnosis and treatment of DVT in pregnant patients during pregnancy.

Methods: We performed a retrospective study of 207 patients who were diagnosed with DVT of the upper limbs in our center during pregnancy. The success of the treatment is based on the completion of their pregnancy. The main outcome was the completion of pregnancy.

Results: Out of 172 patients in the low molecular weight heparin group managed to give birth which accounts for a 90% success rate with a reported case of fetal overgrowth and 2 cases of abruptio placenta. The remaining 17 women which represent the 10% of the treated patients were unsuccessful in completing their pregnancy with 14 women presenting pregnancy loss on the first trimester and 2 having late fetal death, only one case of preclampsia was recorded. Out of the 35 women who did not receive treatment with low molecular weight heparin and only with Aspirin, 21 managed to complete their pregnancies representing the 60% of which 2 cases presented with abruptio placenta and 4 cases with fetal growth restriction. Two cases were recorded during the first trimester while more 3 had late fetal death and 4 cases of preclampsia.

Summary/Conclusions: Women treated for thrombophilia had a lower percentage of fetal death than their no treatment group counterparts. There is an urgent need for appropriate guidelines for these patients in our medical center.
Aims: To ascertain D-dimer diagnostic accuracy for upper extremity DVT. Methods: A retrospective audit was undertaken to determine the aetiology and clinical presentation on patients which UDVVT at presentations. Patients with a formal malignancy confirmed before the diagnosis was excluded. A D dimer (DD) with a cut off cut off levels validated for lower limb DVT was performed. Results: A total of 18 patients was identify in the period of 2012 to 2016. All the cases investigations included Doppler US or CT/MRI and in 30% of the patients the thrombosis was confirmed via contrast venography as a reference standard test. The gender predominant was male in this group the symptomatology were related to physical efforts in a 60% (Pajet-Shröetter Syndrome) whereas in female serie the predominant was thromboisic defects (factor V Leiden). The average age was 33 years (ranging from 21 to 68 years) and 2 elderly patients a new diagnosis of cancer was confirmed (thyroid and lung) (odds ratio: 3.2; 95% CI, 1.13-9.38). The 85% of the patients had an unprovoked event; four patients have a diagnosis of catheter related thrombosis and four cases a thrombosis precipitated by anticoagulative. Two patients had a diagnosis of SLE. We have four cases of positive DD screening (both were marginally elevated, P <0.01). The risk of re-thrombosis was non significative but in the subsanalysis of relapsing thrombotic event populations the risk of relapse increased proportionally in relation of thromboisic defect and high BMI. A trend towards a higher rate of recurrent thrombosis (was observed among patients with BMI>25 (42.6%) compared to those with a BMI <25 (33%). This difference reached statistical significance in women with BMI>25, who had recurrent event in 51.7% of the cases vs those with BMI <25 (29.7%) (p <0.05 CI 0.03, 0.41). Summary/Conclusions: In the unprovoke serie the relation of DD was positive in less than 30% of the cases and non statistically significative (p <0.01). In the case of subclavian vein occlusion this is result in limited clot burden (which explain the correspondence with negative DD value). The risk of re-thrombosis is associated with thrombotic defect and high BMI esclusively. The DD adjust- ed-odds ratio for thrombus (in the population expressed in per cent relation to DD cut off adapted of the specific population). A prospective studies of DD in suspected UDVT need to be adressed.

PB2225 THE INFLUENCE OF HEPARINOID FROM THE PEONY ROOTS ON THE THROMBUS DISSOLVING M. Lyapina1,*, T. Obergan1

Background: Many plants have an effect on the blood clotting system. It is known that there are heparin-like substances in some types of peony roots (Paeonia lactiflora, Paeonia suffruticosa). It proved that there is an anticoagulant activity in extracts from such roots. Aims: The intention is to show the inhibitory effect of the extract of Paeonia lactiflora roots (EA) on processes fibrin and thrombus formation. Methods: We used the standard coagulocgetic methods for determining anticoagulant activity by APTT test, antiplatelet, total fibrinolytic activity (TFA), fibrin-depolymerizing activity (FDPA). Experiments were carried out in accordance with ethical principles and documents recommended by the Declaration of Helsinki of the humane treatment of animals. We used an animal model with provoked thrombosis precipitated by intravenous administration of subthreshold doses of tissue thromboplastin at a dose of 0.6-0.7 ml per 200 g body weight in rats. After 30 min after injection of thromboplastin, we injected intraperitoneal- ly 0.1 mL of 1% of extract of EP and after 30 minutes we determined parameters of hemostasis in the blood plasma. Results: It was shown that after administration of the indicated doses thromboplastin occurs hypercoagulability in blood plasma of animals (APTT decreased by 33% SFA - 15%, FDPA -12%; increased platelet aggregation by 18% compared to control animals not receiving thromboplastin). Normalization of blood clotting is installed in the experimental rats after application EP (recov- ery of platelet aggregation to 98%, APTT- to 100%, up to 95% SFA- FDPA and up to 67% compared with control). The high degree of FDPA indicates the ability of EP to obstruct the process of the formation of fibrins and thrombus. Heparin components in EP interact with fibrin monomers which do not partici- pate in their conversion to fibrin polymer. As a result, stable fibrin polymer or thrombus is not formed. Summary/Conclusions: Consequently, the extract of Paeonia lactiflora roots containing heparinoid contributes to the restoration of coagulation properties in blood of animals in prothrombotic condition and prevents thrombosis. In the initial stages of fibrin formation, it causes the thrombus dissolution.

PB2226 LOW MOLECULAR WEIGHT HEPARIN AND HIGH MOLECULAR WEIGHT HEPARIN: COMBINATION WITH ADRENORECEPTOR ANTAGONISTS AND PREVENTION OF THROMBUS FORMATION M. Golubeva1,*, M. Grigorjeva1

Background: Rethrombosis and thromboembolia are the most common side effects of thrombolytic therapy. One of the possible causes of thrombosis is the entering of thromboplastin in the blood stream. Marker of thromboplastin is an intrinsic membrane glycoprotein 5'-nucleotidase (5'NT) that is present as an enzyme in a wide variety of cells. Recently it was shown that compensatory reaction of haemostasis system by using different fibrinolytic drugs was connected with the stimulation of the sympathetic nervous system. Besides, it is known that α-adrenoreceptor blockers have fibrinolytic and antiplatelet effects. The prevention of thrombosis complication is very important field of pathophysiology and medical practices. Therefore, we studied effects of different α-adrenoreceptor antagonists and the influence of these substances combinations with various anticoagulant and fibrinolytic 5'NT activity in blood coagulation during many years. Aims: The study of the influence of low molecular weight heparin (LMWH, 4.4 kD) and high molecular weight heparin (HMWH) and their combinations with different α-adrenoreceptor antagonists (AA) on experimental thrombosis pre- vention. Methods: Experiments were carry out on 50 white laboratory rats weighing 200-230 g according to the ethical principles of the Helsinki Declaration. Anti- coagulant and antithrombotic effects of LMWH or HMWH were studied in two rat models of thrombosis – thrombosis in v. jugularis (Wessler) and thrombosis in arterio-venous shunt (direct registration of blood pressure). The α- AA dig- hydroyatrotoxin (DET – 1mg/kg), α1–AA prazosin (PZ – 2mg/kg), LMWH or HMWH (40 USP/kg) were injected in v.jugularis. Saline was administered in control rats groups. The thrombus were formed 15 or 180 min after substances injected. The degree of thrombus formation (TF) was detected in ball (Wessler model) and by time of TF (arterio-venous shunt model). In blood plasma the activity of 5'NT was detected. The results were processed statistically. Results: The increase of anticoagulant and antithrombotic effects of LMWH or HMWH by pretreatment of DET or PZ were shown in both animal models of venous thrombosis. The degree of TF by Wessler model may be estimated as 3.7 (saline), 1.2 (LMWH), 1.8 (HMWH), 0.9-1.1 (DET+ LMWH or PZ+LMWH and 1.1-1.3 (DET+ HMWH ) Besides or the degree of TF was accompanied with significant hypercoagulation of blood: 5'T activity was increased in 2 time comparatively with normal level. LMWH or HMWH combi- nations with DET or PZ administration led to normalization of 5'T level in blood plasma. In arterio-venous shunt model it has been shown that the time of TF was 2 min (saline), that was accompanying with the decrease of blood pressure (on 40-50 mmHg). In this case the time of TF was prolonged in 4 time (LMWH) or 2 time (HMWH) comparatively with saline group 15 min after injec- tion; in 4-5 time (DET+ LMWH or PZ+LMWH) or 3-3.5 time (DET+HMWH or PZ+HMWH ) comparatively with saline group 180 min after injection. Summary/Conclusions: Thus we confirmed that LMWH (as one, as in com- bination with α-adrenoreceptor antagonists) has definite advantages over HMWH. Besides our results show that α-adrenoreceptor antagonists signifi- cantly improve antithrombotic effect of anticoagulant agents (LMWH and HMWH). Therefore the combination of LMWH with selective and nonselective α-adrenoreceptor antagonists may be effective used for prevention of venous thrombosis development and thromboembolia.

PB2227 THE POLICY AND PRACTICE OF ANTICOAGULATION THERAPY AMONG CLINICIANS IN SOUTHEAST NIGERIA. T.U. OvPGA1, L.U. NNOMA1, R. AKAKILI1, B. ABUKU1, I. OKOYE6, B. AZUBUKE6

Background: In the absence of anticoagulation therapy, the risk of Venous thromboembolism; deep-vein thrombosis (DVT) and pulmonary embolism (PE) is medically ill patients comparable to that in moderate-risk surgical patients. Previous studies have revealed grossly inadequate knowledge and a dismal practice of anticoagulation among healthcare workers in some resource poor countries. Prophylactic anticoagulation is under-prescribed in Nigeria, South Africa, as well as in many other countries in Africa. Aims: The aims of the study was to evaluate the practice of anticoagulant ther- apy. It will also document the frequency of drug-induced complications resulting from the use of anticoagulants and presence of an anticoagulation policy in the hospitals surveyed. Methods: This is a multicentre cohort survey of the practice of anticoagulant therapy on blood coagulation during many years. The questionnaire was administered to clinicians in five tertiary hospitals in the southeast of Nigeria. The questionnaire was designed to assess their practices anticoag- ulation therapy. The questionnaire was administered consecutively on clinicians in the participating centers. The following institutions participated in the survey: University of Nigeria Teaching Hospital, Enugu, Federal Medical Centre, Aba Hawkins, Federal Medical Centre Umahia, Abia State Teaching Hospital, Aba and Amaku Specialist hospital, Aba, Nigeria. Background: This is a multicentre cohort survey of the practice of anticoagulant therapy on blood coagulation during many years. The questionnaire was administered to clinicians in five tertiary hospitals in the southeast of Nigeria. The questionnaire was designed to assess their practices anticoagulation therapy. The questionnaire was administered consecutively on clinicians in the participating centers. The following institutions participated in the survey: University of Nigeria Teaching Hospital, Enugu, Federal Medical Centre, Aba, Federal Medical Centre Umahia, Abia State Teaching Hospital, Aba and Amaku Specialist hospital, Aba, Nigeria.
Results: A total of 528 clinicians were involved in the survey. There were more males (71.6%) than females, 150 (28.4%) the clinicians who practiced for less than 5 years are in the majority 189 (35.8%) and those with 15-20 years of practice 46(8.7%) are in the minority. Only 52 of the respondents (9.8%) claimed their institutions had an anticoagulation policy while 274 (51.9%) of them said there was no such policy and 168 (31.2%) do not know of any policy. Unfractionated heparin was the most frequently used (96.8%) and fondaparinux was the most infrequently used (42%). Most of the prescriptions were done by younger clinicians who are the highest in number. The consultants prescribed heparin and warfarin most, with the newer anticoagulants taking the rear position. Only 193 (36.6%) of the respondents routinely prescribed anticoagulation therapy when indicated. 412(78%) of respondents believe the risk of anticoagulation outweighs the benefits while 439 (83.1%) identified cost is an important variable in prescribing anticoagulation agent. Anti-coagulation prophylaxis was the most frequently used for patients immobilized or bedridden (94.1%); malignancy and atrial fibrillation were the most infrequent reasons for using anticoagulants (50.8%). A total of 63 respondents (11.9%) were not satisfied and 219 (41.5%) atrial fibrillation were the most infrequent reasons for using anticoagulation agents frequently used for patients immobilized or bedridden (94.1%); malignancy and were not very satisfied with the laboratory monitoring tool available in their institutions. Bleeding is the most common complication of anticoagulation while the least encountered complications are skin and jaw necrosis among the respondents 492(93.2%), 1(0.2%) respectively.

Summary/Conclusions: This survey has shown the lack of anticoagulation policies among the centers that participated. Our survey has also shown deficiencies in the areas of practice of anticoagulation among the clinicians in the Southeast of Nigeria. These gaps can be remedied by continuous medical education and by the establishment of anticoagulation policies.

UMBILICAL CORD BLOOD PLASMA INFUSION PROMOTES BLOOD CELL RECOVERY IN INPATIENTS WITH ACUTE LEUKEMIA UNDERGOING CHEMOTHERAPY

Y. Lu1*, X. Zhang1, X. Li1, Y. Zou1, Z. Lin1
1the third Affiliated Hospital of Sun Yat-Sen University, 2 The Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: Umbilical cord blood plasma (UCBP) is separated from umbilical cord blood. UCBP contains a variety of hematopoietic growth factors which can stimulate hematopoiesis.

Aims: The aim of this work is to explore the influence of UCBP infusion on blood cell recovery in patients with acute leukemia undergoing chemotherapy.

Methods: Patients with the diagnosis of acute leukemia were included in this study and they were randomly distributed to experimental group and control group. Patients in experimental group received infusion of 100ml UCBP with the same ABO and Rh blood type every day after chemotherapy for five days and patients in control group received placebo for the same time. Blood routine were tested every day until WBC >4.0×10^9/L and PLT >20×10^9/L.

Results: 25 patients were included in the study of which 23 were brought into statistical. 13 patients were in experimental group and 10 in control group. There were no difference in age, gender and dose intensity of chemotherapy between the two groups (P>0.05). The average recovery time of the blood neutrophil granulocyte >0.5×10^9/L in experimental group and control group were respectively (6.52±3.26) days versus (12.92±4.75) days (P<0.05) and that of PLT >20×10^9/L was respectively (9.24±3.98) days versus (13.15±5.76) days (P<0.05). No UCBP transfusion-related side effects were found.

Summary/Conclusions: UCBP administration is safe as treatment for cytopenia and could promote blood cell recovery in patients with acute leukemia undergoing chemotherapy.

PB2229

TOWARD BETTER BLOOD TRANSFUSION PRACTICE: A SUCCESSFUL RED BLOOD CELL UTILIZATION TOOLS IN A TERTIARY CARE HOSPITAL

A. Aly1, G. Mawad1, E. Alzaabi1, A. Aly1*
1Mafraq Hospital, Abu Dhabi, United Arab Emirates

Background: The need for blood in hospitals continues to exceed the volume collected by the transfusion services. The gross over-ordering of blood, in excess of actual and anticipated needs leads to substantial costs and a burden to the transfusion services. In addition, over-ordering leads to non-availability of cross-matched units for other patients who might be in urgent need of transfusion.

Aims: We are aiming to reduce the Cross-match-to-transfusion ratio (C:T ratio) & improve blood utilization in Mafraq Hospital.

Methods: In 2011 the ordering practice at Mafraq Hospital, a designated Trauma Centre, had been evaluated. Data collected retrospectively over a one year period and a C:T ratio adopted by the American Association of Blood Bank was calculated for all various subspecialties including Surgery, Internal Medicine, Pediatrics and Obstetrics and Gynecology. All procedures related to hospital transfusion practice have been retrieved and re-evaluated to address gaps. Policy of maximum surgical blood ordering (MSBO) was implemented based upon both results of audits and by discussion and agreement between medical teams. Focused training and education has been followed to increase the awareness of the health care workers. Plus monitoring of C:T ratio on monthly basis, blood bank team had arranged meetings with the departments that were over-ordering cross-matches to explain that group & save test is a safe, effective and financially beneficial strategy. Communicating with the physicians had been the most challenging aspect of implementing the policy changes. Regular audits had been conducted to measure the compliance and effectiveness of the blood management practice.

Results: Compared to the international guidelines, C:T ratios in 2010 was outside the acceptable target and ranged between 2.5 to 3.2 highlighting the over-ordered cross-matched blood in certain sub-specialties. This practice of ordering was probably because of the fear that blood will not be available, if needed. Following implementation of control and continuous monitoring measures while establishing proper procedures such as transfusion guidelines, administration of blood and blood products and Maximum Surgical Ordering Practice, Mafraq blood bank, supported by the Transfusion and Tissue & Quality & Patient Safety Committees, achieved a great success in reducing C:T ratio <2 all through 2016 Figure 1. The reduction of C:T ratio had improved blood inventory control and reduced the workload of the blood bank staff. Because fewer units of cross-matched PRBC are being ordered, the blood bank has been able to decrease the number of units of blood in inventory, decreasing the number of expired units Areducing money loss Figure 1. The savings in technologist time is particularly significant since the blood bank is most of the time at a minimal staffing level.
Background: Prothrombin complex concentrates (PCC) are highly purified mixtures of plasma coagulation factors that contains vitamin K dependent and anticoagulation factors, they are approved for urgent reversal of vitamin K antagonists (VKA). Massive bleeding-associated coagulopathy guidelines include PCC in their management, although as an off-label indication.

Aims: The aim of the present work is to evaluate safety and efficacy of PCC in a case series of VKA reversal and refractory coagulopathy associated with major bleeding.

Methods: Retrospective review of cases treated with a four-factor PCC between January 2010 to January 2016 in two tertiary University Hospitals. As safety endpoints we evaluated infusion reactions and incidence of thromboembolic events by self-reported registry. The efficacy endpoints were studied in two separate cohorts: 1) INR correction for VKA reversal and 2) coagulopathy correction and early mortality (24 hours) in major bleeding coagulopathy.

Results: 328 patients were included (47.25% male), median age 78 years (range 19-102). PCC was used in the following cases: 1) 66.67% in VKA reversal indication; 2) 30.54% in refractory coagulopathy in major bleeding (30 patients due to massive bleeding protocol activation, 43 patients in hepatopathy); a mean dose of PCC 1681.63 IU was used. Safety endpoint: Two infusion reactions were reported potentially related to PCC use, they were not specified neither as anaphylaxis nor as pulmonary edema, and 8 thrombotic episodes were observed (2.4%).

Summary/Conclusions: The four-factor prothrombin complex was safe and effective as adjuvant treatment in refractory coagulopathy due to major bleeding as well as for the emergent reversal of VKA.

NON-HEMOLYTIC FEBRILE POST-PLATELET-TRANSFUSION REACTIONS IN HEMATOLOGICAL PATIENTS

A. Rakhmani1,*, E. Mikhaylova2, I. Dubinkin3, V. Troitskaya2, O. Kalmikova3, M. Danilevskaya3, T. Gaponova1

1Clinical Research Department of chemotherapy and bone marrow depression, 2Clinical Research Department of processing and cryopreservation of blood cells, 3Scientific clinical laboratory quality control and safety of transfusions.

Background: Platelet concentrate (PC) transfusions are the main method of thrombocytopenia correction in hematological patients, but multiple transfusions could trigger alloimmunity and refractoriness to transfusions.

Aims: Comparison of post-transfusion reactions in hematological patients with individual matching and without individual matching receiving PC transfusion support.

Methods: In 2015-2016, we observed 948 hospitalized patients, who received 12.344 PC transfusions. Individual matching of PCs was performed by cross-matching on the Galileo-Neo (Immucor) analyzer. Statistical processing was performed using the chi-squared test with Yates' correction.

Results: 107 of 948 patients developed refractoriness to PC transfusions (12% of total patients). Out of them, 21 patients received 389 PC transfusions without individual matching, 86 patients with individual matching. 86 patients with individual transfusions had 1705 PC transfusions. During transfusions without individual matching to non-refractory patients, 0.003% of non-hemolytic febrile reactions (NHFR) have been record-

Summary/Conclusions: Although we are satisfied that the results represent a reasonably accurate working model of the current situation, the trail of a unit is less reliable after blood has left the HTL. 1. Patients' notes to provide traceability are not totally reliable. It is apparent that the ward staff plays a key role part in the chain and this highlights the need for them to receive training to emphasize the importance of their contribution to hospital compliance. 2. The indicators are that the essential requirements on traceability are not fully met by the current laboratory computer system. A configuration is needed to produce a report which lists components which have been assigned for use but do not have an entry for return to stock or final fate. Ongoing problems will be referred to the Committee. 3. For the longer term ultimately only effective IT system in both wards and HTL can ensure total traceability and we recommend the inclusion of electronic tracking system in the National Blood Donor Registry Programme (EMAP).
ed, after matching to refractory patients the frequency was 0.002%. Before matching to refractory patients, the frequency of NHFR was (0.03%) (Table 1).

Summary/Conclusions: The frequency of NHFR in groups with refractoriness with individual matching is significantly lower (10 fold) compared to groups with refractoriness before the matching (P<0.01).

PB2233
RARE DONORS AND MALARIA
A. Berzuini1, B. Foglieni2, M. Spreafico1, D. Prati1
1Department of Haematology and Transfusion Medicine, Ospedale A. Manzoni, Lecco, Italy

Background: Migratory flows of sub-saharan (SSA) persons throughout the world are expected to continuously increase. A significant proportion of SSA citizens are affected by Sickle Cell Disease (SCD), condition requiring repeated blood transfusions. Many centuries of malaria pressure have induced in SSA natives a homogeneous selection of peculiar haematologic characteristics, such as the absence of high frequency red cell antigens (defining a rare blood) that cannot be found in donors of European descent so that many SCD transfused patients experience the fearful occurrence of red cell alloimmunization. For these reasons haematologists are expecting to access to Rare Blood Banks in order to assure a full match between donor and recipient’s blood, that may be obtained from donors sharing the same ethnicity. Unfortunately SSA donor recruitment is counteracted by the widespread diffusion of infections contracted before migration: one of these is malaria. In SSA malaria may occlude subclinically and is characterized by a slow antibody clearance. This peculiar condition, the so-called semi-immunity, has been induced by a strong genetic pressure, and is a kind of co-evolutionary process characterized by the co-existence and persistence of small entity of Plasmodium genome with relative antibodies. Molecular techniques are unreliable to detect a small number of Plasmodia, which may otherwise be sufficient to induce a transfusion transmitted malaria (TTM). The serologic assessment, despite the low specificity, remains the most sensitive and reliable method to detect the semi-immune status in blood donors (1).

Aims: The aim of this study was to assess the prevalence of malaria immunity in a cohort of healthy SSA citizens.

Methods: Since 2010 in our Department of Haematology and Transfusion Medicine we recruited 184 SSA citizens, in good health, who agreed to underwent clinical and laboratory investigations to become a blood donor. All of them were born in SSA Africa and lived there for at least the first 5 years of life. 70% of subjects didn’t recognize any previous malaria fever. The last travel/stay in Africa (SSA) had been less than 2 years ago (3 yrs), and 45% of returning people had received prophylaxis. Malaria serology was determined by a commercial enzyme immunoassay kit (Malaria EIA Ab, BioRad). In all cases the treatment was temporarily discontinued. In three cases, treatment was stopped because low ferritin level (under 500 microg/ml). RBCT were administered before (mean 2.43 units/month) and after starting Derasirox dose: 20-30 mg/kg. There was a significant reduction in serum ferritin from baseline for all the patients. Ferritin median at start, 3631 microg/ml decreases at 1537 microg/ml after 6 months of treatment and at 894 microg/ml after 12 months of treatment. There were 8 patients that had descendent levels of ferritin, but during infectious episodes the ferritine increases for a short period of time. Digestive adverse events appeared in three cases (two cases of diarrhea and one case of digestive hemorrhagic episode). In all these cases the treatment was temporarily discontinued. In three cases, treatment was stopped because low ferritin level (under 500 microg/ml). RBCT were administered before (mean 2.43 units/month) and after starting Derasirox dose: 20-30 mg/kg.

Summary/Conclusions: Analyzing our group of 40 patients, Deferasirox proves to be effective and safe. Adverse effects that determined a temporary stop of the treatment were mild/medium short time digestive reactions. The number of blood cell transfusion significantly decreased after starting Deferasirox treatment.

LIBERAL VS RESTRICTIVE COMPARATIVE TRANSFUSIONAL STUDY IN ONCOLOGICAL POPULATION
M.I. Touzón Andión1, M. Gestal1, A. Varela1, M. Castro1, C. Moine1, R. García de Villasuso1
1Transfusion , Centro Oncológico de Galicia, La Coruña, Spain

Background: Allogeneic transfusion therapy is perhaps one of the most widely used treatments without good evidence support, despite many years of application in clinical practice. This, coupled with blood shortages, the impossibility of a universal zero risk, the lack of evidence that transfusion may increase consumption or decrease tissue oxygen debt and the existence of an association with an increase in morbidity and mortality have favoured that we join efforts towards its optimal use.

Aims: Optimal use in our adult oncolgical population and evidence that restrictive transfusion (TR, Hb 7-9 g/s dl) is not greater or lower to the liberal transfusion (TL, Hb 8-10 g/s dl), keeping hemoglobin in safe levels for the patient.

Methods: A research was performed from October 1st, 2015 through December 31st, 2016. We analyzed the proportion of patients receiving packed red cells (CH) and the number of units transfused as well as post-transfusion control in order to describe the outcome of the CH versus TL strategies in the cancer population under the study.

Results: See Table 1.

Summary/Conclusions: The results obtained in our series of 311 cancer
patients indicate that the restrictive strategy has been equally effective and probably superior to the liberal one maintaining Hb at a safe level in each patient, as well as quality of life and comfort in a subgroup with advanced and terminal cancer.

**HIGH RISK OF HBV INFECTION IN VACCINATED POLYTRANSFUSED CHILDREN**

M. El-Sayed1,*, Z. Said2, E. A. E. Abou Elmagd2, E. Salama3, F. Ebeid1,1
1Pediatric Department, Ain Shams University, Faculty of Medicine, 2Microbiology Department, Faculty of Medicine (for girls), Al-Azhar University, 3Community Medicine Department, National Research Center, Cairo, Egypt

**Background:** Children receiving chemotherapy for neoplastic diseases are still susceptible to Hepatitis B virus (HBV) infection despite the national HBV vaccination program coverage for all infants since 1992.

**Methods:** The study included 89 children with hematological disorders and malignancies, who were categorized into group (A): 37 receiving chemotherapy (M:F: 20:17; mean age: 7.7±4.0) and group (B): 52 polytransfused children (M:F: 31:21; mean age:7.6±3.2). A matched healthy control group (n=162) was also included. All patients and controls had received their primary vaccination against HBV in infancy. Quantitative anti-HBs were tested for patients and controls. Patients’ sera were tested for HBsAg, anti-HBc, and HBV-DNA (nested PCR for surface, core & x-regions).

**Results:** Levels of anti-HBs between 10-100 IU/L and ≥100 IU/L were found among 13.5% and 21.6% [group (A)]; 44.2% and 11.5% [group (B)] and 32.1% and 10.5% of controls respectively. There was a significant difference in HBsAb between patients receiving chemotherapy [group (A)] and both groups B patients (p<0.008) and controls (p=0.032). However, no difference was found between polytransfused children [group (B)] and controls. HBsAg was positive in 21 (67.7%) children under chemotherapy [group (A)] compared to 10 (32.2%) polytransfused children [group (B) (p<0.0005). Overall, 49 patients (55%) were HBV-DNA positive; 44 c-region positive, 7 s-region positive. 2 positive for both c and s-regions and one positive a c and x-regions. Of those, only 21 patients (42.8%) were also positive for HBsAg; while 28 (47.2%) had occult HBV infection (HBsAg-negative). There was no significant difference between patients receiving chemotherapy [group (A)] and polytransfused children [group (B)] (p>0.157), regarding the rate of HBV DNA. Anti-HBs ≥10 IU/L existed in 38.7% (12/31) of HBsAg positive patients and 49% (24/49) of HBV-DNA positive patients.

**Summary/Conclusions:** Children with neoplastic diseases vaccinated during infancy were at a high risk for HBV infection. The effect of immunosuppression on the HBV protective level favored overt HBV infection in children receiving chemotherapy. The co-existence of anti-HBs with HBsAg and/or HBV-DNA demonstrated a possible residual transfusion-transmission risk with mutant HBV strains.

PB2237

**THE ISOHEMAGGLUTININ TITERS OF BLOOD BANK DONORS: THE ISOHEMAGGLUTININ TITERS OF BLOOD BANK DONORS**

Z. Karakas1,*, D. Soydemir1, M. Yanasik1, A. Ackay2, G. Ozturk3
1Pediatric Hematology-Oncology, Istanbul University Istanbul Medicine Faculty, 2Pediatric Hematology-Oncology, Acibadem University, 3Pediatric Hematology-Oncology, Acibadem University, Istanbul, Turkey

**Background:** Isohemagglutinins that develop against ABO blood group antigens are very important in transfusion and transplantation medicine. Today, 30-40% of allogeneic stem cell transplantsations are ABO incompatible transplantation, 20-25% of which are major, 20-25% are minor and remaining bi-directionally incompatible transfusion. Our study; based on the knowledge that isoagglutinins play an important role in blood transfusion policies in patients undergoing ABO incompatible hematopoietic stem cell transplantation (HSCT) has been shaped by the assumption that each healthy blood bank donor may be a potential transfusion donors for ABO incompatible HSCT transplant recipients.

<th><strong>Summary/Conclusions:</strong></th>
</tr>
</thead>
</table>
| In this study, we investigated the isohemagglutinin titer values of the individuals with A, B and O blood groups; the distribution of the isohemagglutinin titers according to the decades and gender. Also we examined the possibility of determining the isohemagglutinin cut off value in Turkish society.

**Methods:** One thousand five voluntary blood donors (48 female, 957 male), randomly chosen from the donors, providing the criteria to be a standard blood donor in Blood Center Department, Istanbul Faculty of Medicine were studied. This study was approved by the Ethics Committee of Istanbul Medical Faculty. In the donor population group; blood group A (%40) was the most common and blood group AB was the rarest blood group. According to the Rh D phenotypes; 65% of the population was Rh D positive and 15% of the population was Rh D negative. The frequency of our blood group was determined similar with other European countries. The most common age range of one thousand five voluntary blood donors, including the same rate individuals with blood group A, B and O, was the age range between 26 and 35 years. Forward and reverse blood group determination were performed to these donors and also we identified the Anti-B Ig M and Ig G isohemagglutinin titer values for blood group A; Anti-A Ig G and Ig G titer values for blood group B; eventually both Anti-A Ig M / Ig G and Anti-B Ig M / Ig G isohemagglutinin titer values for blood group O by using column agglutination methods. Statistical analysis was performed with NCCSS (Number Cruncher Statistical System) 2007 (Kaysville, Utah, USA).

**Results:** While the titer value of Anti-A Ig M isohemagglutinin was 1:128 for female individuals with blood group B; the titer values of both Anti-B Ig G (M:1:128 and 1:256), Anti-B Ig G (1:1024) and Anti-A Ig M (1:256) isohemagglutinins were statistically significance in female individuals rather than male ones. The levels of isohemagglutinin in the blood groups A, B and O are shown in Table 1.A,B. There was no statistical difference in anti-B Ig G and IgM titters in blood group A, anti-A IgG and IgM titters in blood group B and anti-A IgG and IgM titters in blood group O between males and females (p>0.05). However Anti-B IgG and IgM antibody titters were higher in females than males in donors with blood group O respectively p=0.017 (p<0.05) and p= 0.001 (p<0.01) (Figure 1.A,B).

**Figure 1.**

**Summary/Conclusions:** Female individuals of blood bank donors participated in our study have higher isohemagglutinin titer values rather then male individuals. Recurrent blood group incompatibility in pregnancy, invasive diagnostic and therapeutic approaches for risk analysis in fetal examination during pregnancy, perinatal complications causing fetomaternal hemorrhage after pregnancy or during birth and lastly autoimun diseases cause the enchancement of isohemagglutinin titer values in female individuals. Regarding the gender differences; nutrition, vaccination and recurrent blood transfusion history of blood bank donors also effect and change the isohemagglutinin titers of individuals. Population specific isohemagglutinin titer values play a key role in blood donation policy of patients undergoing hematopoietic stem cell transplantation. Consequently; we predict that Turkish community-specific isohemagglutinin cut off titer values can be identified and we will hope our knowledge on this issue in the future with the increase of research is going to increase further.

PB2238

**THE NEW METHOD OF PURIFICATION FACTOR COAGULATION VIII**

N. Shurko1,*, T. Danysh1, V. Novak2
1laboratory biochemistry of blood, 2Hematology, State Institution «Institute of Blood Pathology and Transfusion Medicine NAMS of Ukraine», Lviv, Ukraine

**Background:** The human plasma of blood can be transfused directly to patients or pooled and fractionated into plasma protein products. Plasma contains about 60-80 g/L of protein, of which about 95% are used for many therapeutic prod-
The main proteins that use for treatment many diseases are albumine (45 g/L), immunoglobulin (8-11 g/L), factors coagulations. The Factor VIII (FVIII) is one of the blood coagulation factor and it deficient causing development of bleeding disorders known as Haemophilia A. The purification of FVIII is generally required for the treatment Haemophilia A or von Willebrand’s disease and heavy loss of blood, requires relatively high purity for medical use.

Active Scarlet Damask 4GT as ligands in combination methods of antiviral treatment.

Results: The process plasma fractionation is largest industry segment in manufacture of therapeutic concentrate of plasma proteins. We developed technological scheme that involves fractionation plasma of blood in combinations of classical methods of protein precipitation and two chromatographic steps: ion exchange and affinity chromatography.

Of all plasma fractionation methods, chromatography is the best candidate for purification of factor coagulation, especially FVIII. The methods adsorption/preparation permits the fractionation of large volumes of plasma, but the quality of the product obtained by chromatography is superior. We offer: fresh frozen plasma – adsorption of proteins on the barium citrate – adsorption of proteins on Al(OH)3 – adsorption of proteins to PEG-4000 – viral inactivation (solvent-detergent method) – ion exchange chromatography on DEAE-Sepharose – viral inactivation (ammonium thiocyanate) – dye-ligand affinity chromatography (Diasoob-Active Scarlet Damask 4GT). We got the drug of FVIII with specific activity 69.65±2.4 IU/mg protein.

Summary/Conclusions: we developed technological scheme of plasma fractionation and reached a high degree of purification of coagulation FVIII.

PB2239
PRIMARY TROMBOTIC MICROANGIOPATHIES. REVISION IN A CENTER OF THE LAST 8 YEARS
T. Castaño1,*, S. Sanchez1, T. Arquero1, M. Yuste1, E. Askari1, P. Llamas1
1Fundación Jiménez Díaz, MADRID, Spain

Background: Thrombotic microangiopathies are a group of rare diseases characterized by non-immune microangiopathic hemolytic anemia, thrombocytopenia and involvement of organs of varying intensity, mainly renal and CNS damage. TTP and HUS are the most important forms of TMA and without adequate treatment administered early are associated with high morbidity and mortality.

Aims: To review our experience in the management of the primary TMA and to raise a series of questions that perhaps could improve the approach of these pathologies

Methods: We made a retrospective, descriptive analysis of ten cases diagnosed of primary thrombotic microangiopathy (TTP n=5; typical HUS n=3; atypical HUS n=2) over the last eight years, 70% of which were women with an average age between 40-60 years. Only three cases had previous records of autoimmune diseases (MTCRD, RA and HIV), all of which would eventually develop TTP. We requested ADAMTS13 levels on all cases, they were low (<5-10%) only in those patients diagnosed with TTP, and on the other hand confirming the positivity for Shiga toxin in those patients who eventually developed typical HUS.

Results: Regardless of the diagnosis, 10-12 plasma exchanges were performed to improve the biological parameters of hemolysis, requiring the placement of a central catheter, most commonly at the right jugular vein (70%) due to the lower risk of thrombotic and infectious complications. Although renal involvement is frequent in HUS, only two of the patients required dialysis without recovery of baseline renal function. It is to be noted the part played by the approval in 2011 of eculizumab and how patients eight years ago suffered a torpid course, requiring a greater number of plasmapheresis and the side effects this carries. However, we still do not know its repercussions out of indication. In our study, it was used in a patient with diagnosis HUS associated with an infection with good evolution, although perhaps this result is due only to the natural evolution of the disease. Another controversial point is the use of antibiotics and possible harm to the diagnosis made.

Summary/Conclusions: The results of the study are helpful to identify and understand the complication of adverse donor reactions though the incidence of reactions of blood donation among blood donor in the tertiary care hospital in Nepal.

Background: Voluntary blood donation is widely considered to be safe with very minimum chance of adverse reaction, which may occur during or after the end of phlebotomy procedure

Aims: To identify and understand the complication of adverse donor reactions though the incidence of reactions of blood donation among blood donor in the tertiary care hospital in Nepal

Methods: This is a prospective study done among voluntary blood donors at Grande International Hospital, Kathmandu, Nepal from February 2013 to March 2015. The outcomes of reported and communicated adverse donor reaction were collected after the blood donation from voluntary blood donors in different locations including outdoor and in-house blood donation drive

Results: In the present study 6,955 whole blood donors were included, during the period of 2 years. 105 (1.50%) adverse donor reactions were reported. Majority 89(84.76%) of adverse donor reactions were mild in nature such as; sweating; 27(25.72%), Light headedness; 19(18.09%), nausea and vomiting; 15(14.28), allergy and bruises;11(10.47%), sore arm; 9(8.58%) and hematoma; 6(7.62%) while 16 (15.24%) were severe adverse reactions similarly, anaphylaxis;11(10.49%), loss of consciousness; 3(2.85%) and convulsive syncope;2(1.90%). Markers of the adverse donor reaction were age, sex, pulse, weight, blood pressure and donation status. Age and first time status were related with significantly higher risk of adverse reaction with 18-23 years old at higher risk compared to 24-55 years old. First time donors were at higher risk compared to repeated volunteer donors

Summary/Conclusions: The results of the study are helpful to identify and understand the complication of adverse donor reactions though the incidence of reactions in the blood donor is lower than in other studies. Donor age and donation status were strong possibilities of complications.

Background: Whereas p53 is mostly non-mutated in AML, various oncogenic pathways, frequently through enhancing the activity of its major antagonist Mdm2, suppress its activity. We have previously showed that genetic ablation of CKi6a robustly activates p53 (doi:10.1038/nature09673). However, with no selective CKi6a inhibitors for in vivo use, the therapeutic value of CKi6a inhibition in hematologic malignancies cannot be validated.

Aims: To develop small molecule CKi6a inhibitors and assess their effect in mouse models of human leukemia.

Methods: CKi6a inhibitors were identified via cell-based screening based on p53 activation. We focused on a small class of pyrazole-pyrimidine scaffolds, which through extensive medicinal chemistry yielded derivatives with high affinity binding, validated by crystallography studies, potent CKi6a inhibitory activity and a good pharmacokinetic profile. Anti-leukemic activity was assessed by oral treatment in mouse models of AML. MLL-AF9 and Bcr-Abl Blast Crisis Results: We first demonstrated the inhibitors’ anti-leukemic effect by single oral dose treatment, robustly inducing p53 activation and blast cell cytoreduction (Figure 1).

These inhibitors distinguished leukemic from normal hematopoietic stem cells: they did not affect normal hematopoietic CFUs, but eliminated leukemic CFUs at an IC50 ~9nM. We tested the long-term oral therapeutic effects of the inhibitors in MLL-AF9 leukemia mice. Whereas all vehicle-treated mice succumbed to the disease within a month, 40-50% of inhibitor-treated mice survived with no signs of disease up to 5 months’ observation, nor had the surviving mice any sequela of long-term treatment; all had normal blood counts and normal organ morphology and histology. Long-term leukemia control with possible cure, attesting to eradication of LSCs and preservation of normal HPSCs was demonstrated by transplanting leukemia-treated BM into lethally irradiated mice: all transplanted mice recovered and none showed any evidence of residual disease within 6 months. To elucidate the mechanisms by which the inhibitors distinguished leukemia from normal hematopoietic cells, we profiled the kinome affinity of the inhibitors and further studied their signaling effects in vitro and in vivo. We found that CKi6a inhibitors having potent anti-leukemia activity are distinguished from less active analogues by their capacity to co-target CDK9 and P-TEFb. We found that CKIα inhibitors having potent anti-leukemia activity are distinguished from less active analogues by their capacity to co-target CDK9 and P-TEFb (CDK9-CyclinT1 complex). This property, validated by co-crystallography studies, enables the inhibitors to suppress the RNA Pol II elongation factor P-TEFb (CDK9-CyclinT1 complex). We developed a new class of small molecule inhibitors that co-target CKi6a and P-TEFb. These inhibitors induce very rapid, robust induction of p53 in synergy with shutdown of leukemic super-enhancers, resulting in a lasting, powerful and specific anti-leukemic therapeutic effects in vivo, with cure potential.

Figure 1.

Single-donor inhibitor effects treated for 4hrs (EM Western blot and blood smear) and 16hrs (tissue record).

In leukemic mice, showing strong cytoreduction in the spleen and bone marrow and pro-apoptotic signals of cancer therapeutic activity (CKi6a and CKIα, outtrended by RNA Pol II phospho-CTD inhibition and activation of DNA damage response [γH2AX] and p53).

Background: Mantle cell lymphomas (MCL) are characterized by the primary translocation t(11;14)(q13;q32) involving CCND1 and IG genes in virtually all cases. Recently, a small subset of cyclin D1-negative (cyclin D1 −) MCL has been recognized. About half of these cases have CCND2 gene rearrangements and overexpression of this gene. However, the earlier oncogenic events in cyclin D1−/cyclin D2−MCL still remain elusive.

Aims: To identify potential mechanisms driving the pathogenesis of cyclin D1−/cyclin D2−MCL.

Methods: We investigated 66 cyclin D1−/SOX11+ MCL cases by a combination of fluorescence in situ hybridization (FISH), gene expression profiling by Affymetrix U133+2.0 and qPCR (n=51), and copy number arrays (n=47) (Agilent CGH 1M, Affymetrix Oncoscan and 500K). Six cases were investigated by genomic sequencing by 4x sequencing - 5 mate-pair whole-genomes, 4 whole exomes, and 1 whole-genome sequencing. The male/female ratio was 2.5:1 and median age at diagnosis 66 years.

Results: Most cyclin D1− MCL (49/51, 96%) showed overexpression of other G1 cyclins: CCND2 in 33/35 (94%), CCND2 in 12/51 (24%), and moderate overexpression of both CCNE1 and CCNE2 in 23/51 (45%). CCND2 rearrangements were detected by FISH in 25/33 cases (76%) with CCND2 overexpression, but the remaining CCND2+ cases and those with CCND3 overexpression did not show CCND2, CCND3 and IG rearrangements using currently used break-apart probes. Interestingly, by mate-pair whole-genome and whole-exome sequencing analyses we discovered cryptic insertions of IG light chain regions including the enhancer regulatory elements (2 IGK and 1 IGL) near CCND3 gene in the three cases with cyclin D3 overexpression. These rearrangements were confirmed by Sanger sequencing and FISH with specifically designed probes to recognize the cryptic IgH regions. The normal clone of one case carried 6 additional cases with cryptic IGK-CCND3, as well as 3 cases with IGK-CCND2 juxtaposition in tumors with high levels of CCND3 and CCND2, respectively. Taken together, 74% and 18% cases corresponded to cyclin D2+ and cyclin D3+ MCL, respectively, whereas 6% showed overexpression of CCNE1 and CCNE2 without D3+ rearrangements. The whole-genome data of 7 cases with CCNE1 and CCNE2 overexpression identified 29 somatic protein-coding mutations, 42 complex structural variants and 24 copy number alterations (including CDKN2A and RB1 homozygous deletions) but no rearrangements involving any of the IG genes or G1 cyclins. The global genomic profile of 47 cyclin D1−/D2− MCL cases was highly complex compared to 13 alternative cases with conventional SOX11+ MCL, with significantly more gains at 7p and 18q in the cyclin D1− MCL. Moreover, 32% cases had chromothripsis at least in one chromosome.

Summary/Conclusions: We have identified a novel IG light chain locus-associated rearrangement, consisting of cryptic insertion of IG enhancer near CCND3 gene, which is highly specific to cyclin D1−/D2− MCL cases. In addition, the large proportion of IGK enhancer region into CCND2 gene. Both aberrations were undetectable by cytogenetics and FISH break-apart approaches. Overall, 65/66 (98%) MCL had G1 cyclin overexpression. The detection of these rearrangements with cys-
HIF-1β plays a critical role in drug resistance related to microenvironmental factors (particularly hypoxia) and 1q21 gain, therefore serving as a potential therapeutic target for development of agents or therapy to overcome intrinsic and acquired drug resistance in MM.

**Summary/Conclusions:** Together, these findings argue that HIF-1β represents a potential target for risk stratification and prognostic prediction of MM patients, especially those with high-risk cytogenetics such as 1q. They also suggest that HIF-1β might play a critical role in drug resistance related to microenvironmental factors (particularly hypoxia) and 1q21 gain, therefore serving as a potential therapeutic target for development of agents or therapy to overcome intrinsic and acquired drug resistance in MM.

**Methods:** To understand the function and clinical significance of hypoxia-induced factor-β (HIF-1β), a gene located in the 1q21 region, in 1q MM and hypoxic microenvironment.

**Results:** In a cohort of 180 NDMM patients, median OS (mOS) was 29 and 43 months for cases with (w) or without (w/o) 1q (P=0.038), among which 24.3, 43.3, and 43.8 months for 1q copy number ≥3, <3, and [2]=P(0.030, respectively; whereas Btz-based therapy displayed a marked increase in response rate ≥VGPR, it failed to improve mOS of 1q patients significantly (28.5 and 33.9 months for patients w or w/o Btz treatment, P=0.983); in contrast, Btz treatment dramatically prolonged mOS in patients w/o vs w 1q (53.7 and 28.5 months, P=0.016). To explore the molecular basis for the adverse effect of 1q on prognosis, expression of the 1q21 genes related to drug resistance was examined. Notably, robust expression of HIF-1β at protein level was found in 1q+ MM cells, while no difference observed in CKS1B, a biomarker widely used with inferior outcome. However, the molecular mechanism underlying the adverse prognostic roles of 1q remains largely unclear. Recently, 1q has been linked to hypoxia and resulting drug-resistant gene expression. We took advantage of a fully allogenic aGvHD mouse model in which wild type (WT) or CD69−/− BALBc mice were lethally irradiated and reconstituted with C57BL/6 HSCs and naïve T cells. Results were confirmed by in vivo killing assays as well as by use of CD69 neutralizing antibodies. Mouse strains deficient in T cells, B cells and NK cells were used to establish the NK cells as the only cell type capable of killing CD69−/− cancer cells in vitro. Furthermore, analysis of additional 40 1q+ MM cells, while no difference observed in CKS1B, a biomarker widely used with inferior outcome. However, the molecular mechanism underlying the adverse prognostic roles of 1q remains largely unclear. Recently, 1q has been linked to hypoxia and resulting drug-resistant gene expression. Background: CTL019 is an investigational chimeric antigen receptor (CAR) T-cell therapy with a high rate of durable complete responses (CRs) and a manageable safety profile in a previously reported single-center trial in adult patients (pts) with R/R DLBCL.

Aims: Results of a planned interim analysis of a single-arm, open-label, multicenter, global phase 2 trial of CTL019 in pts ≥18 y with R/R DLBCL (JULIET; NCT02445248) are reported.

Methods: Industry-manufactured CAR T cells were provided to pts at 27 centers on 4 continents using a global supply chain. Pts had received ≥2 lines of chemotherapy and had disease progression after or were ineligible for autologous stem cell transplant (autoSCT). Autologous CAR T cells were transduced using a lentiviral vector encoding an anti-CD19 CAR, expanded, cryopreserved, shipped, and infused at study sites. The primary endpoint (centrally reviewed by an independent review committee) was best overall response rate (ORR: CR + partial response [PR]).

Results: 141 pts were enrolled. Following restaging, bridging therapy, and lymphodepleting chemotherapy (fludarabine 25 mg/m2/cycle; cyclophosphamide 250 mg/m2/day × 3 days or bendamustine 90 mg/m2/day × 2 days), 85 pts received a single dose of CTL019 transduced cells (median, 3.1 × 10^8 [range, 0.1-1 × 10^9]) cells. Median time from infusio to data cutoff (20 December 2016) was 7 mo. 30 pts received ≥2 doses. Among 51 pts with ≥3 mo follow-up or earlier discontinuation, best ORR was 53% (95% CI, 44% to 61%). 38% of pts had PR, 17% had CR, and 52% had stable disease. Median follow-up was 11 mo. 3 pts died from disease progression within 30 days of infusion.

Summary/Conclusions: The safety and efficacy of single-dose ex vivo CAR T-cell therapy with CTL019 in pts with R/R DLBCL were consistent with the single-center trial. ORR was 53% (38% CR and 17% PR) among 51 evaluable pts. 30% of pts had ≥2 doses. Median duration of response was not reached, and within 30 days of infusion, 3 pts died from disease progression.

Background: Hemopoietic stem cells (HSCs) are multipotent stem cells capable of sustaining all mature blood cells throughout life. During development, HSCs arise directly from specialized endothelial cells called hemogenic endothelial (HE) cells within the developing aorta-gonad-mesonephros (AGM) region, in a process termed endothelial-to-hematopoietic transition (EHT). However, despite extensive studies in various animal models, the genetic program driving human HSC emergence remains largely unknown. We have previously reported the generation of hemogenic precursor cells from mouse fibroblasts with the expression of transcription factors (TFs) Notch1, ETV6, and ETV7. These TFs induce a dynamic, multi-stage hemogenic process that progresses through an endothelial-like intermediate, recapitulating developmental hematopoiesis in vitro.

Aims: Here, to better understand the molecular events underlying human HE cell specification we expressed hemogenic TFs in human fibroblasts and mapped the TF binding sites at initial stages of reprogramming.

Methods: To determine the transcription factors binding sites we used Chro- matin Immunoprecipitation coupled with sequencing (ChIP-seq).

Results: We demonstrate that human fibroblasts can be reprogrammed into HE cells by ectopic expression of GATA2A. GATA2A expressing cells express CD34 and CD45 and display dynamic endothelial to hematopoietic transcription programs. In addition, reprogrammed fibroblasts repopulate immunodeficient NSG mice and generate hematopoietic progeny of multiple lineages, including T-cells and myeloid cells. Mechanistically, GATA2A display dominant and independent targeting activity during the early phases of reprogramming while GFI1B interacts and co-occupy a cohort of target sites engaging sites preferentially with AP-1 motifs, including the RUNX1 locus. This cooperative binding is reflected by the engagement of open enhancers and promotors marked by H3K4me3, H3K4me1 and H3K27ac in the fibroblast genome sequence silencing the fibroblast genes while activating the hemogenic program.

Summary/Conclusions: Together, these findings uncover a collaborative TF interaction that specifies a human hemogenic program and EHT. These findings shed light on the processes controlling human HSC specification and provide means to generate human reprogrammed HSCs at high efficiency for transplantation.

Background: T-cell acute lymphoblastic leukemia (T-ALL) is a disease of T-cell progenitors, which mainly affects children and young adults. Numerous genomic alterations such as NOTCH1/FBXW7 mutations, TLY1/2 overexpression or SIL- TAL deletion are known to induce survival, proliferation and differentiation block in T-ALL cells. Interactions between leukemic cells and their microenvironment also contribute to T-ALL pathogenesis. Cell-cell contacts - Delta-Like/Jagged-Notch1, integrin LFA1/ICAM1 - and secreted factors - such as interleukin 7 and cIL-15 - are key players in T-ALL development. In course of the disease, T-ALL cells settle in various environments such as thymus, blood, bone marrow (BM), pleura or lymph nodes, which differ in terms of cell content, extracellular matrix and secreted factors. To which extent these distinct niches imprint niche-specific features on T-ALL cells is not well understood.

Aims: Compare the growth of leukemic cells from human and mouse T-ALL in various BM sites. Uncover novel mechanisms of chemoresistance, in relation with the BM microenvironment.

Methods: We used grafts of human and mouse T-ALL in immune-deficient and normal mice, respectively. We explored the behavior of leukemic cells ex-vivo and in vivo. In order to better identify the different microenvironmental body (femurs, Thorax and Tail vertebrae), we tested their respective chemoresis- tance to conventional drugs (dexamethasone, vincristine, cytarabine).

Results: We observed that mouse and human T-ALL develop slowly in tail vert- ebrae BM compared to thorax vertebrae and femur BM. T-ALL recovered from tail BM display lower cell surface marker expression and decreased metabolism and cell cycle progression, demonstrating a dormancy phenotype. Functionally tail-derived T-ALL exhibit a deficient short-term ex vivo growth and a delayed in vivo propagation. These features are non-cell autonomous as T-ALL from tail and thorax share identical genomic abnormalities and functional disparities disappear in vivo and in prolonged in vitro assays. Importantly tail-derived T-ALL display a more intrinsic resistance to drug therapy. Tail T-ALL is associated with quiescence and decreased response to cell cycle dependent chemotherapy indicating that adipocty-rich aged BM or pathologies enhancing BM adipocyte content may help leukemia escaping drug treatment.
