Background: Human chronic graft-versus-host disease (GVHD) shares clinical characteristics with a murine sclerodermatous GVHD (Scl-GVHD) model that is characterized by skin thickening and lung fibrosis.

Aims: This study investigated the therapeutic effect of mesenchymal stem cells (MSCs) on the development of Scl-GVHD according to each target organ.

Methods: A B10.D2 → BALB/c transplant model of Scl-GVHD was used to address the therapeutic effect of mesenchymal stem cells (MSCs) on the development of GVHD. M210B4 cells were administered after allo-HSCT at a dose standardized to mouse/mouse on days 3, 5, 7.

Results: The clinical and pathological severity of cutaneous Scl-GVHD was significantly attenuated in MSC-treated recipients relative to Scl-GVHD controls. After MSC treatment, skin collagen production was significantly reduced with consistent downregulation of TGF-β expression. Effects of MSCs on molecular markers implicated in persistent TGF-β signaling and fibrosis, such as phospthase and tensin homolog (PTEN), phosphorylated Smad-2/3 and matrix metalloproteinase-1 (MMP-1), were observed in skin tissue. MSCs neither migrate to the skin nor affect the skin fat pad and mesenchyme. MSCs to suppress fibroblast proliferation.

Summary/Conclusions: Our findings indicate that MSCs attenuate the cutaneous manifestation of T cell-mediated immune cell migration and downregulating chemokines and chemokine receptors.
Although C57BL/6N (N) and C57BL/6J (J) mice are derived from the same parental C57BL/6 strain, there are key genotypic and phenotypic differences between these sub-strains. However, more than 58% of studies published involving C57BL/6 mice do not indicate the specific sub-strain employed. J mice have a five-exon deletion in the Nicotinamide nucleotide transhydrogenase (Nnt) gene that results in a non-functional protein. NNT is involved in the resolution of oxidative stress in the mitochondria. Hematopoietic stem cells (HSCs) can reconstitute the entire hematopoietic system after transplantation into hosts whose hematopoietic compartment has been ablated. This is clinically exploited as HSCs transplantation (HSCT) to treat hematologic diseases and represents the only curative therapy for many disorders. During HSCT, HSC are subject to dramatic increases in both intra and extracellular reactive oxygen species (ROS), which compromises their self-renewal, differentiation, and survival. The absence of a functional Nnt gene in J-HSC may curtail their ability to resolve elevated ROS post-transplant.

**Aims:** As elevated oxidative stress compromises hematopoietic stem and progenitor cells (HSPC) function, here we thoroughly interrogated the frequency and function of HSPCs in J and N bone marrow (BM).

**Methods:** N and J peripheral blood (PB) and BM (n=9) was interrogated by flow cytometry for the absolute frequencies of all major hematopoietic lineages and HSPC compartments, respectively. 5000 J or N CD45.2 HSPCs (Lin-Sca-1+ c-Kit+ cells) were transplanted along with 5000 competitor CD45.1 HSPCs into lethally irradiated mice to test for competitive in vivo hematopoietic repopulating activity and ROS levels post-transplant. The lineage potential and repopulating activity of multi-potent progenitors (MPP2: Lin-Sca-1+c-Kit+Flt3+CD48+CD150-, MPP3: Lin-Sca-1+c-Kit+Flt3+CD48+CD150-, MPF4: Lin-Sca-1+c-Kit+Flt3+CD48+CD150-) was also tested by transplanting 2000 MPPs from J or N mice into sub-lethally irradiated mice and examining the PB of recipients every 3-4 days for 34 days post-transplant. Sensitivity of HSPCs to oxidative stress was tested by examining ROS levels and the in vitro colony forming unit (CFU) potential of HSPCs isolated from N and J mice treated with pI:pC.

**Results:** The frequency of the major PB lineages and bone marrow HSPC compartments was identical in J and N mice. However, J-HSPCs displayed compromised short-term (4-12 weeks post-transplant) hematopoietic repopulating activity relative to N-HSPCs that was driven by a delay in lymphoid reconstitution. No differences were found in donor contribution to bone marrow HSPC compartments at 20 weeks post-transplant. However, donor-derived MPPs and CLPs displayed a two-fold increase in ROS levels in recipients of J-HSPCs versus N-HSPCs at 20 weeks post-transplant. MPPs are responsible for repopulation of the hematopoietic system during this early window post-transplant. Different MPP subpopulations can be defined (MPP2, MPP3 and MPP4) according to their self-renewal potential and specific lineage potential. MPP3s and MPP4s are the first MPP subpopulations to reconstitute the lymphoid lineages after transplant. J-MPP3s and J-MPP4s displayed less ROS levels in vivo hematopoietic repopulation activity than N-MPP3s and N-MPP4s. It is known that pI:pC treatment increases ROS levels in HSPCs. We found about two-fold higher ROS levels in HSPCs isolated from pI:pC treated mice than N mice with the exception of J-MPP3s and N-MPP4s. As elevated oxidative stress compromises hematopoietic stem and progenitor cells evaluated the capacity (TIBC), saturation index (SI), serum ferritin (FT) and serum transferrin receptor (TFR).

**Results:** We identified 12 SNPs showing association with the 5 erythrocyte phenotypes previously related to VTE (Table 1). Interestingly, the rs56306145 that showed association with TFR is an intronic variant located in the gene tissue factor pathway inhibitor 2 (TFPI2), which encodes a protein that inhibits a variety of serine proteases of blood coagulation, such as activated factor VII (FVIIa/TF), FXa, plasmin and plasma kallikrein. These data reinforce our previous report of genetic correlation of TFR with VTE. The most significant SNP associations were reported.

**Table 1. Top SNP-associations with erythrocyte phenotypes related to VTE from GWAS in GAIT2.**

G: genetic correlation with VTE; Chr: Chromosome.

**Summary/Conclusions:** Several genetic variants involved in the variance of erythrocyte phenotype levels were identified by GWAS. Of note, TFR was associated with a SNP in TFPI2 that might influence the variance of both TFR levels and VTE risk. These data could be useful to investigate genes related to red blood cell parameters and VTE.

**ESSENTIAL THROMBOCYTHEMIA (ET) AND POLYCYTHEMIA VERA (PV) PATIENTS SHOW AN INCREASED THROMBUS FORMATION IN A DYNAMIC MODEL OF PLATELET ADHESION**

A. Vignoli, 1 F. Marchesi, 1 M. Marchetti, 1 S. Gamba, 1 C. Giacherini, 1 C. Verzeroli, 1 L. Russo, 1 S. Tessarolo, 1 G. Finazzi, 2 P.E. van der Meijden, 3 F. Swierenga, 3 H. ten Cate, 3 J.W. Heemskerk, A. Rambaldi, 3 A. Falanga 1
Results: Of all patients with major GI bleeding, 14 were taking apixaban (0.8% of all pt on apixaban), 3 (0.4% of all pt on rivaroxaban) rivaroxaban and 1 (0.3% of all pt on dabigatran) on dabigatran. The numbers were too small to identify any statistical difference between the 3 different DOAC drugs.

Summary/Conclusions: The risk of major GI bleeding in our cohort of over 2500 patients over 3 years was noted to be significantly lower than trial data. Since this is a retrospective review from patient hospital database there is a risk of reporting bias and under-reporting of bleeding events. A prospective phase IV study to identify bleeding risk in patients on DOAC is required. Majority of patients with major GI bleeding had other risk factors such as concurrent use of anti-platelets, peptic ulcer disease, alcohol abuse, oesophageal varices, diverticular disease, and bowel malignancy which would increase their bleeding risk on any anticoagulation. Further sub group analysis of this cohort and efforts to improve reporting of anticoagulation associated bleeding is underway.
postoperative day for recognition of DVT/PE was significant greater than 3.5 (7.6 vs 3.5, \( P = 0.048 \)). Patients developing DVT/PE did not differ by obesity or age when compared with non-DVT/PE population.

**Summary/Conclusions:** There have been only a few studies to assess the incidence of DVT/PE in patients undergoing lower limb surgical revascularization. In our study population, 4.4% of patients had evidence of DVT/PE. This presents a low risk of venous thromboembolism. The 2012 American College of Chest Physicians (ACCP) guidelines for prevention of venous thromboembolism in nonorthopedic surgical patients (Chest 2012; 141(2):Suppl:e227s-e277s), requires the use of a pneumatic compression devices (PCDs), over no prophylaxis, to prevent DVT/PE in low risk patients. Since, patients with lower limb surgeries are not a good candidate for PCDs, pharmacological thromboprophylaxis with low dose heparin may be warranted. Given that bleeding is a potential complication in these patients, it might be prudent to start thromboprophylaxis 3.5-4 days after the surgery. Further studies are needed to address the bleeding risks of postoperative thromboprophylaxis after surgical revascularization procedures.

**Summary/Conclusions:** In the GAIT2 study, genetic and environmental factors were related to B12, SF, RCF and HCY. Moreover, a relationship was observed between B12 and VTE. In the GWAS analysis some signals were previously reported (FUT2 and B12 or MTHFR with SF and HCY). New signals were found that need to be clarified, especially their possible relationship with susceptibility to thrombosis.

**CELLULAR ORIGIN OF CIRCULATING MICROPARTICLES (MP) ACCORDING TO SOMATIC MUTATIONS IN PATIENTS WITH MYELOPROLIFERATIVE NEOPLASMS (MPN)**

C. J. Tartarì1,*, M. Marchettil, R. Lacroix2, L. Russo1, S. Gamba1, A. Vignolil, G. Finazzil, A. Rambalid, A. Falangal

1Department of Immunohematology and Transfusion Medicine, Hospital Papa Giovanni XXIII, Bergamo, Italy, 2Department of Hematology and Vascular Biology, Hospital La Conception, Marseille, France, 3Department of Hematology, Hospital Papa Giovanni XXIII, Bergamo, Italy.

**Background:** Essential thrombocythemia (ET) and polycythemia vera (PV) are MPN characterized by a high rate of thrombotic complications. We previously demonstrated increased plasma levels of procoagulant MP in ET (Marchetti et al. A.J.H. 2013).

**Aims:** Aim of this study was to extend the analysis of MP to PV patients and to characterize the cellular origin of plasma MP in both ET and PV patients. The influence of somatic mutations [i.e. JAK2V617F, calreticulin (CaiR), thrombopoietin receptor (MPL)], and concomitant cytoreductive or antiplatelet therapies was also evaluated.

**Methods:** Thirty-seven ET (19 JAK2V617F, 9 CalR and 2 MPL mutation carriers), 35 PV patients (all JAK2V617F carriers) and 36 healthy control subjects were included into the study. Flow cytometry was performed to characterize MP phenotype in platelet free plasma samples. To define MP cellular origin, anti-CD31 (endothelial cell marker), anti-CD41 (platelet marker), anti-CD11b (leukocyte marker), and anti-CD235 (erythrocyte marker) monoclonal antibodies were used. Annexin V (AnnV) staining was used to evaluate the expression of procoagulant phosphatidylserine on MP.

**Results:** ET and PV patients displayed significantly higher MP levels compared to controls (p<0.05). The majority of circulating MP (90%) were AnnV positive, indicating the expression of phosphatidylserine on their surface. In healthy con-
trols, 71% of MP was positive for platelet (P-MP), 24% for erythrocyte (E-MP), 4% for endothelial cell (EC-MP) and 1% for leukocyte (L-MP) specific markers. In ET and PV patients, the percentage of P-MP was significantly higher (80%; p<0.05), while E-MP level was significantly lower (15%; p<0.05) than controls. L-MP and EC-MP values were comparable between patients and controls. The absolute counts of P-MP and L-MP were higher in both ET and PV versus controls. Overall, no significant correlations were found between the levels of MP derived from platelet, leukocytes or erythrocytes and the corresponding cell counts. The analysis according to patient mutations, revealed significantly higher levels (p<0.05) of both P-MP and E-MP concentration in patients carrying JAK2V617F mutation as compared to JAK2V617F negative patients. In addition, ET patients positive for CaR mutation displayed lower levels (p<0.05) of P-MP compared to JAK2V617F carriers. No influence of concomitant therapies on MP levels or composition was observed.

Summary/Conclusions: Our data confirm the presence of high levels of circulating MP in MPN, which support the role in the known hypercoagulable state of these patients. The MP cellular origin has a different distribution profile according to the presence of different mutations. Importantly, the lack of correlation found between the total and subtype-specific MP counts with the corresponding cell of origin counts suggests an active stimulation of MP formation.

IBRUTINIB IN PREVIOUSLY TREATED CHRONIC LYMPHOCYTIC LEUKEMIA: UPDATED EFFICACY AND SAFETY OF THE RESONATE STUDY WITH UP TO FOUR YEARS OF FOLLOW-UP
1Hospital of the Santa Creu i Sant Pau, Barcelona, Spain, 2The Ohio State University Comprehensive Cancer Center, Columbus, United States, 3The Leeds Teaching Hospitals, St. James’s Institute of Oncology, Leeds, United Kingdom, 4University of California Irvine, Irvine, 5Hofstra Macallum Cancer Centre and St. Vincent’s Hospital, Melbourne, 6Royal North Shore Hospital, Sydney, Australia, 7Division of Hematology and Hemostaseology, Medical University of Vienna, Wien, Austria, 8University of Rochester Medical Center, Rochester, 9Weill Cornell Medical College, New York, 10University of California San Diego, Moores Cancer Center, La Jolla, United States, 11Beaumont Hospital, Dublin, Ireland, 12Niguarda Cancer Centre, Milan, Italy, 13Swedish Cancer Institute Hematologic Malignancies Program, Seattle, 14University of Texas MD Anderson Cancer Center, Houston, 15Pharmacies LLC, An AbbVie Company, Sunnyvale, 16CLL Center, Dana-Farber Cancer Institute, Boston, United States

Background: Ibrutinib (IBR) is an oral BTK inhibitor with high response rates in CLL. Venetoclax (VEN) is a potent, highly selective, orally bioavailable small-molecule BCL2 inhibitor. Both IBR and VEN are approved by the FDA and EMA as single agents for chronic lymphocytic leukaemia (CLL). IBR leads to a rapid nodal response with re-distribution of CLL into the peripheral blood whereas VEN leads to depletion of CLL cells to levels in some patients where they cannot be detected. Two of the key cellular processes that are abnormal in CLL are proliferation and apoptosis. The combination of IBR with VEN is therefore logical as biologically the two drugs would be expected to be synergistic. The eradication of minimal residual disease (MRD) from blood and bone marrow is associated with improved outcome in any treatment of CLL where it has been reported. Aims: The CLARITY trial (ISCRTN: 13751862) is a feasibility study to investi- gate the combination and efficacy of IBR combined with VEN in patients with relapsed/refractory CLL. Here we report for the first time the safety of the combination as well as early signs of potent synergy.

Methods: After 8 weeks of IBR monotherapy (420mg/day), VEN was added at a dose of 10mg/day with weekly escalations to 20mg, 50mg, 100mg, 200mg to a final dose of 400mg/day. After the initial 3 patients when there was no sign of tumour lysis syndrome (TLS) the starting dose of VEN was amended to 20mg/day. The primary end-point of the trial is MRD eradication (defined as less than 1 CLL cell in 10,000) in the bone marrow after 12 months of IBR+VEN. Key secondary endpoints are MRD eradication from the bone marrow after 6 and 24 months of combined IBR and VEN as well as the safety of the combi- nation. Important safety events that were considered critical were the incidence of laboratory and clinical TLS. All patients were given prophylactic treatment with uric acid reducing agents beginning at least 72 hours prior to their initial dose of VEN. Over the first three months of combined therapy the level of CLL in the peripheral blood was monitored weekly during VEN escalation and then monthly thereafter. 50 participants will be treated in total.

Results: A total of 35 patients have been recruited between May 2016 and January 2017. To date 21 patients have completed the dose escalation period of VEN with IBR combination with IBR. To date there has been only a single case of labo- ratory TLS in a patient whose phosphate (1.21 to 1.48mmol/l) and creatinine (75 to 146 umol/l) both increased when VEN was increased from 100mg to 200mg. Dosing of VEN was interrupted for 7 days (due to the logistics of clinic closure periods over the Christmas break) and IBR for 24 hours. The biochemical changes were resolved with IBR resuming on the second day and the biochemical TLS was resolved on 400mg/day of VEN with no further TLS. As yet there have been a total of 5 SAES and 22 AE’s of special interest with notably lung infection (n=3) and neu- tropenia (n=11) occurring on more than one occasion. All SAES’s resolved with appropriate management and all AE’s were managed with dose reductions. No SUSAR’s have been reported and no AE’s have been fatal. The level of CLL in the peripheral blood increased during the 8 weeks of IBR monotherapy at 420mg/day from a median of 50 x 10^9/l to a median of 101 x 10^9/l. The rate of fall is rapid in all patients with a median of 0.017 x 10^9/l (range: 0 to 3.1) and then fell from the first 8 weeks of combined IBR with VEN (4 weeks dose escalation fol- lowed by 4 weeks at 400mg/day) from a median of 55 x 10^9/l to a median of 0.017 x 10^9/l (range: 0 to 3.1). The rate of fall is rapid in all patients with a median of 3 log reduction in CLL level after 8 weeks of combined therapy.

Summary/Conclusions: The combination of IBR with VEN is well tolerated in relapsed, refractory CLL with to date only a single case of laboratory TLS. The rapid decline in the level of CLL over the initial 8 weeks of combined therapy phase of VEN with IBR is promising and suggests a potent synergy between the drugs. The initial bone marrow responses are expected after 6 months of combination therapy.

VENETOCXAL IN RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA WITH 17P DELETION: OUTCOME AND MINIMAL RESIDUAL DISEASE FROM THE FULL POPULATION OF THE PIVOTAL M13-982 TRIAL
1University of Ulm, Ulm, Germany, 2AbbVie Inc, North Chicago, IL, United
CHEMO-FREE TRIPLET COMBINATION OF TGR-1202, UBLITUXIMAB, and IDRUBITIN IS WELL TOLERATED AND HIGHLY ACTIVE IN PATIENTS WITH ADVANCED CLL AND NHL

Methods: Eligible pts had CLL or rel/ref NHL w/o prior to limited therapies, including those ref to PI3Kδ /BTK inhibitors. UTX dosed on D 1, 8, 15 of C 1, D 1 of C 2-6, and C 9 & 12. TGR-1202 dose escalated (400/600/800mg QD), idrubitin dosed at 420mg (CLL) or 560mg (NHL), both on C1D1.

Results: 38 pts treated 20 CLL/SLL and 18 NHL including 6 follicular (FL), 6 DLBCL, 4 mantle cell (MCL) and 2 marginal zone (MZL). Med age 65 yrs (range 32-85); 29 M/9 F; med prior tx=3 (range 0-6). 2 pts ref to prior PI3Kδ /BTK prev treated with idrubitin (1 ref/1 rel). MTD was not reached. Most common (>20%) all causality AE’s were fatigue (42%), diarrhea (39%), dizziness (34%), nausea (32%), neutropenia, pyrexia, rash, infusion reaction, insomnia (each at 29%), thrombocytopenia, cough (each at 26%), anemia (24%) and sinusitis (21%). ORR of 34% (all causality) were minimal, the only event >10% was neutropenia (16%). ORR amongst 36 evaluable pts is shown in the following Table 1.

Table 1.

Background: Venetoclax monotherapy in patients (pts) with relapsed/refractory CLL harboring deletion 17p (del17p) resulted in an ORR of 79% with a CR rate of 7% as determined by an independent review committee at the initial analysis of the pivotal M13-982 trial (n=107). Subsequently, 51 additional pts were enrolled in a safety expansion cohort. Aim: To present results from the full trial, including minimal residual disease (MRD) status by both flow cytometry and next generation sequencing (NGS).

Methods: Pts received venetoclax 400 mg daily after initial standard ramp-up until PD or discontinuation due to other reasons. CT scan was mandatory at week 36, after which disease assessment was by clinical evaluation. MRD assessment was performed beginning with the first clinical assessment of CR or PR with nodes <2 cm and then every 12 weeks until MRD negativity (defined at 10−4 sensitivity). MRD was assessed by NGS and multicolor flow cytometry and the best response was reported. Data cutoff date was 10 June 2016.

Results: Pts (N=158) had a median age of 67 (range, 29–85) years; a median of 4 (range, 0–10) 32% were fludarabine refractory; 11% had previously received a B-cell receptor signaling inhibitor (BCR); 48% had nodes ≥5 cm; and 78% had unmutated IGHV. The median duration of venetoclax therapy was 16.7 (range 0–34.4) months. Primary reasons for discontinuation (50.6% of pts) were PD (31.0%), adverse events (AEs) (12.6%), withdrawal of consent (5.2%), and other (11%). For all 158 pts, the investigator-assessed ORR was 77% and CR rate was 18%. The 24-month estimates for progression-free survival (PFS) and overall survival (OS) were 52% and 72%, respectively. The safety expansion included 5 pts with previously untreated del17p CLL. These pts had an ORR of 80%, CR rate of 40%. All 5 were alive and progression-free at 1 year after their first clinical assessment and 1 pt was positive by flow cytometry (0.008% blood; 9 pts were also negative in the marrow although not necessarily at the same time).

Summary/Conclusions: Venetoclax monotherapy resulted in a high response rate that was durable in this high-risk population, including among pts who had previously received a B-cell inhibitor. MRD negativity by either flow cytometry or NGS correlated with outstanding outcomes.
mg and 35 mg) dosing was evaluated. Pharmacokinetics (PK), pharmacodynamics (PD), and safety were monitored, as well as an assessment of efficacy. Clinical response was assessed by standard criteria. Potency and specificity for SYK and JAK pathway inhibition were measured in whole blood assays by monitoring signaling responses following ligation of the BCR and receptors for IL-4. Serum markers of inflammation, minimal residual disease (MRD) and apoptosis in CLL patients were also measured.

**Results:** A phase 2 study was initiated in May 2016 to enroll up to 40 patients in each of three cohorts; 1) relapsed/refractory CLL/SLL, 2) relapsed/refractory indolent NHL, and 3) relapsed DLBCL, MCL and transformed FL. As of March 1, 2017, 37 patients have been enrolled, 17 with CLL/SLL, 15 with indolent NHL (10 FL, 4 MZL, 1 WM), and 5 with aggressive NHL (3 DLBCL, 1 MCL, 1 FL). Median patient age is 70 years (range, 51-93). The median number of prior therapies is 3 (range 1–7). 11 patients had prior BTK or PI3K inhibitor therapy. The safety profile has been similar to what was seen in the Phase 1 study. However, 3 patients at 35 mg BID achieved higher than expected drug concentrations and had SAEs (2 grade 5 infections, 1 grade 3 pancreatitis). The starting dose was reduced to 30 mg BID and a PK monitoring and dose reduction strategy has been implemented. To date, this has resulted in a better safety profile without PK outliers. The most common AEs of any grade have been diarrhea (27%), fatigue (27%) and nausea (24%). Grade 3 AEs occurring in more than 1 patient are infection (5 patients), abdominal pain (3 patients) and hypertension (3 patients). As seen in phase 1, significant inhibition of SYK and JAK signaling pathways in peripheral blood is observed. Evidence for tumor cell mobilization to peripheral blood in CLL/SLL is consistently observed following one week of therapy. PRs have been seen in all 3 cohorts including 10 of 13 (77%) CLL/SLL and 3 of 6 (50%) FL patients evaluated. Of these 13 PRs, 12 are still on drug therapy. PRs have been seen in all 3 cohorts including 10 of 13 (77%) CLL/SLL to peripheral blood in CLL/SLL is consistently observed following one week of therapy. Evidence for tumor cell mobilization to peripheral blood is observed. Of 609 pts with a baseline PET scan, 595 had detectable lesions, and 535 also had an evaluable PET at EOI. Baseline demographics and disease characteristics were similar in PET and non-PET populations. Pts with NA (n=52) or NE (n=8) scans were considered non-responders; these pts and those with PD prior to S1 were excluded from landmark PFS analyses. At EOI, 390/535 (65.5%) pts achieved a PET-CR according to IRC, comprising 212/297 (71.4%) G-chemo pts and 178/298 (59.7%) R-chemo pts. However, for these 390 pts, 50 (8.4%) pts achieved a PET-CR in 161/365 (44.1%) CT-CR and 54 (14%) pts achieved a PET-PR in only 117/362 (32.3%) of pts with CT-PR. Concordance between CT and PET assessment was 52.6% for IRC and 54.1% for INV. Concordance between IRC and INV evaluation was 71.9% for CT and 68.6% for PET. After a median follow-up of 34.5 mo (range 0–54.5), IRC-PET status was highly predictive of PFS (PET-CR vs PET non-CR: HR 0.39; 95% CI 0.25–0.60; p=0.0001) and OS (HR 0.41; 95% CI 0.19–0.86; p=0.018). 2.5-yr PFS from EOI was 87.6% (95% CI 83.5–90.8) for PET-CR pts compared with 70.9% (95% CI 61.3–78.6) for PET non-CR pts; corresponding OS was 96.6% (95% CI 94.1–98.1) vs 90.9% (95% CI 84.7–94.6) (Figure 1).

**Summary/Conclusions:** Cerdulatinib demonstrates clinical activity in heavily pretreated patients with CLL/B-cell NHL and is generally well tolerated. Consistent activity is seen in patients with CLL and FL. Accrual is proceeding; updated PK/PD, safety and efficacy will be presented.

**COMPARISON OF CONTRAST-ENHANCED CT-BASED RESPONSE WITH PET RESPONSE AFTER FIRST-LINE THERAPY FOR FOLLICULAR LYMPHOMA IN THE PHASE III GALLIUM STUDY**

1Haematology Department, Concord Repatriation General Hospital, University of Sydney, Sydney, Australia, 2KCL and Guys' & St Thomas PET Imaging Centre, Division of Imaging and Biomedical Engineering, Kings College London, London, United Kingdom, 34th Department of Internal Medicine – Hematology, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic, 4Faculty of Medicine, Charles University, Prague, Czech Republic, 5Service de Médecine Nucléaire, Hôpital Henri Mondor and Université Paris Est Créteil, Créteil, France, 6Institute of Oncology, University of Alberta Cross Cancer Institute, Edmonton, Canada, 7Clinical Medical Centre and Tom Baker Cancer Centre, Calgary, Canada, 8Department of Nuclear Medicine, First Faculty of Medicine, Charles University, Prague, Czech Republic, 9Department of Medicine, National Institute of Oncology, Budapest, Hungary, 10Pharma Development Clinical Oncology, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 11Ludwig-Maximilians-University Munich, Munich, Germany, 12Department of Haematology, Kings College Hospital, London, 13Cancer Research UK Centre, University of Southampton, Southampton, United Kingdom

**Background:** Published data show 18F-FDG PET-CT (PET) is predictive after first-line immunochemotherapy in advanced-stage symptomatic FL, and PET is now the recommended modality for response assessment. However, no large-scale prospective comparison of the value of standard contrast-enhanced CT vs PET response has been performed.

**Aims:** To compare CT and PET response assessment for FL pts in the prospective Phase III GALLIUM study, which evaluated chemotherapy plus obinutuzumab (G-chemo) or rituximab (R-chemo) induction followed by maintenance antibody therapy (Marcus 2016).

**Methods:** PET scans, introduced after an early protocol amendment (July 2011), were performed at baseline and end of induction (EOI; all pts gave informed consent) and assessed by the investigator (INV) and an independent review committee (IRC) comprising two radiologists, with a third adjudicator; final response was determined by a clinician. Response was assessed by CT and PET plus bone marrow biopsy, applying the revised International Working Group (IWG) criteria (Cheson 2007, Juweid 2007). Complete remission (CR) status at EOI for each assessment, CT-CR and PET-CR, was compared with pt characteristics, PFS and OS.

**Results:** Among 1202 ITT pts with FL enrolled in GALLIUM, IRC-assessed CT showed a CR in 330 pts (27.5%), PR in 747 (62.1%), SD in 20 (1.7%), PD in 35 (2.9%), unavailable (NA) in 48 (4.0%) and un evaluable (NE) in 22 (1.8%). Of 609 pts with a baseline PET scan, 595 had detectable lesions, and 535 also had an evaluable PET at EOI. Baseline demographics and disease characteristics were similar in PET and non-PET populations. Pts with NA (n=52) or NE (n=6) scans were considered non-responders; these pts and those with PD prior to S1 were excluded from landmark PFS analyses. At EOI, 390/535 (65.5%) pts achieved a PET-CR according to IRC, comprising 212/297 (71.4%) G-chemo pts and 178/298 (59.7%) R-chemo pts. However, for these 390 pts, 50 (8.4%) pts achieved a PET-CR in 161/365 (44.1%) CT-CR and 54 (14%) pts achieved a PET-PR in only 117/362 (32.3%) of pts with CT-PR. Concordance between CT and PET assessment was 52.6% for IRC and 54.1% for INV. Concordance between IRC and INV evaluation was 71.9% for CT and 68.6% for PET. After a median follow-up of 34.5 mo (range 0–54.5), IRC-PET status was highly predictive of PFS (PET-CR vs PET non-CR: HR 0.39; 95% CI 0.25–0.60; p=0.0001) and OS (HR 0.41; 95% CI 0.19–0.86; p=0.018). 2.5-yr PFS from EOI was 87.6% (95% CI 83.5–90.8) for PET-CR pts compared with 70.9% (95% CI 61.3–78.6) for PET non-CR pts; corresponding OS was 96.6% (95% CI 94.1–98.1) vs 90.9% (95% CI 84.7–94.6) (Figure 1).

**Summary/Conclusions:** This large prospective analysis confirms EOI PET as an early predictor of PFS and OS in FL, with good concordance between INV and PET.
and IRC PET evaluation. Comparison of PFS based on CT-response and re-analysis of PET scans applying the now recommended 5-point scale for PET response assessment will be presented. Pooled analyses of these and data from other studies with longer follow-up may determine PET response as a reliable early surrogate for PFS and OS, providing a platform for study of response-adapted therapy.

**S775**

**IMMUNOCHEMOTHERAPY WITH OBINUTUZUMAB OR RITUXIMAB IN PREVIOUSLY UNTREATED FOLLICULAR LYMPHOMA IN THE RANDOMIZED PHASE III GALLIUM STUDY: ANALYSIS BY CHEMOTHERAPY REGIMEN**

1Department of Medicine III, Ludwig-Maximilians-University Munich, Munich, Germany, 2Department of Hematology, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, 3Department of Medicine, Hospital Universitario la Paz, Madrid, Spain, 4Haematology Department, Fiona Stanley Hospital, Murdoch, Australia, 5Department of Clinical Haematology, Oxford Cancer and Haematology Centre, Churchill Hospital, Oxford, United Kingdom, 6Medical Faculty (Haematology), Universitätsklinikum Essen, Essen, Germany, 7Oncology Center, HELIOS-Klinikum Erfurt, Erfurt, Germany, 8Department of Haematology, Prince of Wales Hospital, Sydney, Australia, 9First Faculty of Medicine, Charles University General Hospital and Institute of Pathological Physiology, Charles University, Prague, Czech Republic, 10Pharma Development Clinical Oncology, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 11The University of Manchester and The Christie NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, 12Department of Hematology, National Cancer Center Hospital, Tokyo, Japan, 13Pharma Development Safety and Risk Management, 14Pharma Development Biometrics Biostatistics, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 15Department of Haematology, Kings College Hospital, London, United Kingdom

**Background:** The Phase III GALLIUM study (NCT01332968) showed that obinutuzumab (GA101; G) significantly prolonged PFS in previously untreated FL pts relative to rituximab (R) when combined with chemotherapy (chemo; CHOP, CVP or bendamustine [B]). Grade 3–5 and serious AEs were more common with G-chemo.

**Aims:** To explore outcomes by immunochemotherapy regimen.

**Methods:** Pts were aged ≥18 yrs with documented, previously untreated FL (grades 1–3a), advanced disease (stage III/IV or stage II with tumor diameter ≥7cm), ECOG PS 0–2, and requiring treatment according to GELF criteria. Chemo regimen was allocated by center. Pts were randomized 1:1 (stratified by chemo, FLIPI-1 group and geographic region) to R 375mg/m² on day (D) 1 of each cycle (C) or G 1000mg on D1, 8 and 15 of C1 and D1 of C2–8, for 6 or 8 cycles depending on chemo. Pts with CR or PR at EOI (per Cheson 2007) continued to receive R or G every 2 months for 2 yrs or until progression. The cut-off date for this analysis was September 10 2016. All pts gave informed consent.

**Results:** 1202 FL pts were randomized. Baseline characteristics were generally similar across chemo groups, although B and CVP pts had relatively more comorbidities, e.g. GI and vascular disorders, than CHOP pts. After 41.1 months’ median follow-up, investigator (INV)-assessed PFS remained superior for G-chemo relative to R-chemo (HR, 0.68; 95% CI 0.54–0.87; p=0.0016) with consistent HRs across chemo groups (Figure 1). HRs for secondary time-to-event endpoints were supportive of the primary analysis. Difference in frequency of grade 3–5 AEs between arms was highest with CHOP and CVP (Table 1). Rates of second neoplasms and grade 3–5 infections were similar in G and R arms for CHOP and CVP but not for B. In all chemo groups, SAEs were more frequent with G than R, and AEs causing treatment discontinuation and fatal AEs were similar. Reductions in T-cell counts were more pronounced and prolonged in the B group than CHOP or CVP groups.

**Summary/Conclusions:** In treatment-naive FL pts, PFS was superior with G-chemo relative to R-chemo with consistent effects across chemo regimens. Some differences were seen in safety profiles between chemo regimens, but comparisons may be confounded by the lack of randomization.

**S776**

**EFFICACY AND SAFETY OF COPANLISIB IN PATIENTS WITH RELAPSED/REFRACTORY FOLLICULAR LYMPHOMA: A SUBSET ANALYSIS OF THE CHRONOS-1 STUDY**

1Department of Hematology, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, 2Department of Hematology, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, 3Department of Medicine, Hospital Universitario la Paz, Madrid, Spain, 4Manchester Academic Health Science Centre, Manchester, United Kingdom, 5Department of Hematology, National Cancer Center Hospital, Tokyo, Japan, 6Pharma Development Clinical Oncology, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 7Department of Hematology, National Cancer Center Hospital, Tokyo, Japan, 8Pharma Development Safety and Risk Management, 9Pharma Development Biometrics Biostatistics, F. Hoffmann-La Roche Ltd, Basel, Switzerland, 10Department of Hematology, Kings College Hospital, London, United Kingdom

**Background:** The Phase III CHRONOS-1 study (NCT01530860) showed that copanlisib (G108-F) significantly prolonged PFS in previously untreated FL pts relative to Gleevec® (G) and was associated with lower serious AEs compared with chemotherapy (CHOP, CVP or bendamustine [B]). Grade 3–5 AEs were more common in G arm compared with B, CHOP or CVP.

**Aims:** To assess outcomes by prior regimens.

**Methods:** Pts with relapsed/refractory FL were randomized 1:1 to G vs B, CHOP or CVP vs G. Pts with PR or CR at EOI (per Cheson 2007) continued to receive G or CHOP vs CVP or B every 2 months for 2 yrs or until progression. The cut-off date for this analysis was October 1 2016. All pts gave informed consent.

**Results:** 241 FL pts were randomized. Baseline characteristics were similar across groups. After 15.3 months’ median follow-up, investigator (INV)-assessed PFS was superior for G (HR, 0.62; 95% CI 0.45–0.85; p=0.003); consistent HRs were observed across groups (Figure 1). HRs for secondary endpoints were supportive. Difference in frequency of grade 3–5 AEs between arms was highest with CHOP and CVP (Table 1). Rates of second neoplasms and grade 3–5 infections were similar in G and CHOP vs CVP or B.

**Summary/Conclusions:** In relapsed/refractory FL pts, PFS was superior with G relative to chemotherapy with consistent effects across regimens. Some differences were seen in safety profiles between regimens, but comparisons may be confounded by the lack of randomization.
Background: Follicular lymphoma (FL) is the most common indolent non-Hodgkin lymphoma (NHL) subtype, yet treatment options in the relapsed/refractory setting are limited. Copanlisib is a potent and selective pan-class I PI3K inhibitor with predominant activity against the δ- and α-isoforms.

Aims: We report results from the FL subset of a large phase II study in NHL patients (NCT01660451, part B).

Methods: Patients with histologically confirmed indolent indolent FL (grade 1-3a) relapsed/refractory to ≥2 prior lines of treatment were treated with copanlisib (40 mg IV infusion) administered on days 1, 8 and 15 of a 28-day cycle until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) as assessed by independent radiology review according to the response criteria for lymphoma (Cheson et al., JCO 20:579, 2007). Secondary endpoints included progression-free survival (PFS) and duration of response (DOR), safety and tolerability.

Results: A total of 141 patients with iNHL were treated in the phase II study, including 104 patients with FL. The FL subset was characterized as: 52% male, 83% white, median age 62 years, 62% ECOG 0, 63% refractory to last therapy, median time from most recent progression 8 wks (range 1-73) and median prior lines of therapy 3 (range 2-8). At the time of primary analysis the ORR was 58%, comprising 15 patients (14.4%) with complete response and 46 (44.2%) with partial response. Stable disease was observed in 35 (33.7%) patients and progression of disease as best response in 2 patients. The median duration of response was 370 days (range 0-687), with 43 responders censored at data cut-off. Median duration of treatment was 22 wks (range 1-103); 33 (32%) patients remained on treatment. Per investigator assessment, 87 of 96 evaluable patients (91%) had some degree of tumor shrinkage as best response, and 58/96 (60%) had >50% tumor shrinkage (Figure 1). For all patients in the phase II study, the most common treatment-emergent AEs occurring in >25% of patients included (all grade/grade 3): diarrhea (24%/6%), reduced neutrophil count (30%/24%), fatigue (30%/2%), and fever (25%/4%). Hyperglycemia (50%/41%) and hypertension (30%/24%) were transient. The incidence of pneumonitis (8%/14%), hepatic enzycympathy (AST 28%/14%; ALT 23%/14%), opportunistic infection (1.4%) and colitis (0.7%) were low. Six deaths were observed, 3 of which were attributed to copanlisib: one lung infection, one respiratory failure, and one thromboembolic event.

Figure 1.

Summary/Conclusions: Copanlisib was highly active as a single agent in heavily pretreated relapsed/refractory FL patients and resulted in responses in the majority of patients with a median duration of response exceeding one year. Toxicities were manageable, with a low incidence of severe AEs associated with other PI3K inhibitors, especially hepatic enzycympathy, opportunistic infections, and colitis.

S777

DYNAMO: A PHASE 2 STUDY DEMONSTRATING THE CLINICAL ACTIVITY OF DUVELISIB IN PATIENTS WITH DOUBLE-REFRACTORY FOLLICULAR LYMPHOMA

1Institute of Hematology Seràgnoli, University of Bologna, Bologna, Italy, 2Siteman Cancer Center, Washington University, St. Louis, USA, 3Department of Hematology, Hermann Hospital, Houston, TX, 4Department of Hematology, Cleveland Clinic, Cleveland, Ohio, USA, 5Florida Cancer Specialists Tallahassee, Tallahassee, USA, 6Jewish General Hospital, Montreal, Canada, 7Ospedale Di Circolo e Fondazione Macchi U.O. Ematologia, Varese, Italy, 8Florida Cancer Specialist - Fort Myers, Fort Myers, USA, 9University of Toronto, Toronto, Canada, 10University of Liverpool, Liverpool, United Kingdom, 11Semmelweis Egyetem, I. sz. Belgyogyaszati Klinika, Budapest, Hungary, 12CHU Estaing - Service d’hématologie, Clermont-Ferrand, France, 13Centre intégré de santé et de services sociaux de lOutaouais, Quebec, Canada, 14Tennessee Oncology, Nashville, United States

Background: Duvelisib is an oral, dual inhibitor of PI3K-δ,γ in development for the treatment of hematologic malignancies. DYNAMO is a Phase 2 study to evaluate the safety and efficacy of duvelisib monotherapy in a double refractory iNHL population, which included a majority of patients (pts) with follicular lymphoma (FL).

Aims: The primary objective was to evaluate the antitumor activity of duvelisib monotherapy in pts whose disease is refractory to rituximab and to either chemotherapy or Rit, with an additional objective to further characterize the safety profile of duvelisib.

Methods: DYNAMO is an open-label, single-arm, safety, and efficacy study in patients (pts) with FL, small lymphocytic lymphoma (SLL), or marginal zone lymphoma (MZL), whose disease is double-refractory to rituximab (monotherapy or in combination) and to chemotherapy or radioimmunotherapy. Pts who had received ≥25 mg/m² of duvelisib 21 days prior to the study were excluded. The study enrolled 111 pts with relapsed/refractory FL, in whom duvelisib monotherapy was administered at doses of 150 mg twice daily, with or without PJP prophylaxis. Pts were excluded if they had a history of brain metastasis, any prior treatment with a PI3K inhibitor, or any history of lymphomatous polyposis.

Results: A total of 134 pts with FL were evaluable for efficacy and safety in the primary analysis. Among the 111 FL pts with a response per IRC, the median DoR was 9.2 months. The median PFS for all FL pts was 8.3 months, while the median OS was 25.8 months. Among the 34 FL pts with a response per IRC, the median DoR was 9.2 months. The median TTR was 1.9 mo. (range: 1.6 - 11.7). 80% of FL pts experienced disease progression or unacceptable toxicity. The primary endpoint is overall response rate (ORR) as assessed by an independent review committee (IRC) per revised IWG criteria. Secondary endpoints include duration of response (DoR), progression-free survival (PFS), overall survival (OS), time to response (TTR), adverse events (AEs) and other safety parameters.

Summary/Conclusions: In DYNAMO, duvelisib showed clinical activity in a double-refractory FL population (41% ORR, median DoR 9.2 mo., 80% with disease progression or unacceptable toxicity. Duvelisib monotherapy in pts whose disease is refractory to rituximab and to either chemotherapy or Rit, with an additional objective to further characterize the safety profile of duvelisib.
Background: Between March 2000 and May 2005 a multicenter randomized trial comparing frontline use of CHOP-R vs R-HDS with autograft has been performed on 134 Follicular Lymphoma (FL) patients, selected for age less than 60 yrs. and poor prognostic features according to age-adjusted IPI (2-3) and IIL-score (3 or greater). Results at 4-yr follow-up were previously published (Ladetto M et al, Blood 2008), showing superior disease control with R-HDS without any survival advantage.

Aims: We have recently performed a long term update and the results at a median follow-up of 13 yrs are here presented.

Methods: The long-term outcome has been updated for 119 out of the original 134 randomized patients (56 CHOP-R and 63 R-HDS arms). Main features of the updated patients included: median age 51 yrs. (22-60), M/F ratio 68/51, aalPI 2-3 90%, high LDH 43%, bulky disease 60%, B-symptoms 46%, BM involvement 86%; no significant differences were observed in clinical presentation between the two arms, as previously reported. Treatment schedule consisted of: i. CHOP-R arm: 6 courses of cyclophosphamide/doxorubicin/vincristine/prednisone followed by 4-weekly rituximab courses; ii. experimental R-HDS arm: rituximab with high-dose sequential chemotherapy followed by autografting. The analysis was intention to treat with event-free survival as the primary endpoint. Minimal residual disease (MRD) was evaluated post treatment in 56 patients with a bcl-2/IgH MBR or mcr translocation confirmed at diagnosis by nested PCR. The trial was registered at www.clinicaltrials.gov, no. NCT00435955. The long-term outcome has been updated in January 2017 by 27 out of 30 participating Centers, on 119 patients (88% of the whole series).

Results: Complete remission (CR) was achieved by 86 (72%) patients, including 32 (57%) with CHOP-R and 54 (85%) with R-HDS (p <.001); Molecular Remission (MR) was achieved in 37 out of 56 (66%) evaluable patients. At a median follow-up of 13 yrs., 74 patients (63%) are alive. Overall, 22 patients died for lymphoma progression (13 CHOP-R, 9 R-HDS), 12 died for secondary malignancy (3 in the CHOP-R, 9 in the R-HDS arms), 11 patients died for other causes, including four early toxic deaths. The overall survival (OS) for the whole series is 63% at 13 yrs, as shown in Figure 1A. No significant differences in the long-term OS were observed between the two arms, with 13-yr survival of 65% and 61% for CHOP-R and R-HDS, respectively (p=0.51). At 13 years, the event free survival is 35%, whereas the disease-free survival (DFS) is of 53%, as shown in Figure 1B. Response to induction therapy had a major impact on the OS, with 13 yr survival of 75% for patients achieving CR vs 33% for those with less than CR (p <.001). Similarly, Molecular Remission (MR) achievement was associated with prolonged OS, with 13 yr survival of 81% for patients in MR on BM cells, and of 47% for those with positive MRD (p<.02) (Figure 1C).

Summary/Conclusions: i. poor risk FL may have a prolonged survival, with 63% of patients alive at 13 yrs.; ii. no survival differences between CHOP-R and R-HDS can be detected even at 13 yrs of follow-up; iii. achieving CR is still crucial for the long-term survival; iv. the MRD analysis has a prognostic impact not only on progression-free but also on OS; v. lymphoma progression remains the major cause of death, while secondary neoplasms represent the second cause of treatment failure; vi. a subgroup of advanced-stage FL may experience a prolonged DFS lasting at least 13 yrs: this raises the issue of the potential curability of FL.
Changing the strategy of therapy in multiple myeloma

S779

PHASE II TRIAL OF COMBINATION OF ELOTUZUMAB, LENALIDOMIDE, AND DEXAMETHASONE IN HIGH-RISK SMOLDERING MULTIPLE MYELOMA

I. Oboh1, A. Cadil1, P. Henrick1, A. Savell2, J. Cappuccio1, P. Henrick1, A. Savell2, J. Cappuccio1, B. Rivotto1, N. Munshi1, C.-J. Liu1, M. Bustoros1, A. Badros3, J. Matous4, J. Rosenblatt5, A. Yee6, R. Maegawa7, S. Usmani8, J. Vredenburg9, I. Ghobrial1, A. Caola1, P. Henrick1, A. Savell2, J. Cappuccio1, B. Rivotto1, A. Badros3, J. Matous4, J. Rosenblatt5, A. Yee6, R. Maegawa7, S. Usmani8, J. Vredenburg9, I. Ghobrial1, A. Caola1, P. Henrick1, A. Savell2, J. Cappuccio1, B. Rivotto1

Aims: The overarching objective of this trial is to determine progression free survival to symptomatic myeloma (MM). Furthermore, the study examined whether genomic studies can help in determining patients who would benefit the most from early therapeutic intervention.

Methods: Patients enrolled on study met eligibility for high-risk SMM based on the newly defined criteria proposed by Rajkumar et al, Blood 2014. Patients with NDMM (SCRT-eligible) received twice-weekly oral ixazomib (3.0 or 3.7 mg on days 1, 4, 8, and 11) plus lenalidomide (20 mg [10 mg in cycles 9–16] on days 1, 2, 4, 5, 8, 9, 11, and 12) for up to sixteen 21-day cycles, followed by maintenance therapy with single-agent twice-weekly ixazomib. Patients not proceeding to SCT did not receive further ixazomib therapy. Response/progression was assessed per IMWG criteria after cycles 1, 2, 3, 4, and then every 2 cycles during induction and maintenance.

Results: Of the 64 enrolled patients, 40 continued on study treatment without withdrawal for SCT long-term follow-up of these 40 patients is reported here. The median age of patients was 66 years (range 34–82), and 45%/38%/18% of patients had ISS disease stage I/II/III. At a median follow-up of 47.0 months, the overall response rate (ORR; partial response [PR] in the absence of progression) was 94%, the complete response rate (CR+VGPR) rate was 68%, and the CR rate was 32%. Median time to first response was approximately 1 cycle (0.72 months). Median time to a best response of CR was 4.2 months. Patients received a median (range) of 14 (1–75) treatment cycles. Median progression-free survival (PFS) for patients not proceeding to SCT was 24.9 months. Median overall survival (OS) was not estimable; the 2-year Kaplan-Meier estimate for OS was 92%. A total of 78% of patients had grade ≥3 treatment-related adverse events (AEs); the most common treatment-related grade ≥3 AEs and serious AEs are shown in the Table 1. After completing induction therapy with IRd, 18 patients went on to receive maintenance with single-agent ixazomib on a twice-weekly dosing schedule. Patients who went on to maintenance received a median (range) of 31.5 (17–75) treatment cycles. Among the patients who received maintenance therapy, the ORR (PR%) was 54%, the CR+VGPR rate was 67%, and the CR rate was 44%. Two (11%) patients improved their responses during maintenance. Common treatment-related grade ≥3 AEs occurring in ≥25% of patients are shown in the Table 2.

Aims: This phase II study of elotuzumab, lenalidomide, and dexamethasone (IRD) is feasible and active in patients with NDMM, with weekly and twice-weekly ixazomib dosing having been investigated (Kumar et al, Lancet Oncol 2013).

Results: Of the 64 enrolled patients, 40 continued on study treatment without withdrawal for SCT long-term follow-up of these 40 patients is reported here. The median age of patients was 66 years (range 34–82), and 45%/38%/18% of patients had ISS disease stage I/II/III. At a median follow-up of 47.0 months, the overall response rate (ORR; partial response [PR] in the absence of progression) was 94%, the complete response rate (CR+VGPR) rate was 68%, and the CR rate was 32%. Median time to first response was approximately 1 cycle (0.72 months). Median time to a best response of CR was 4.2 months. Patients received a median (range) of 14 (1–75) treatment cycles. Median progression-free survival (PFS) for patients not proceeding to SCT was 24.9 months. Median overall survival (OS) was not estimable; the 2-year Kaplan-Meier estimate for OS was 92%. A total of 78% of patients had grade ≥3 treatment-related adverse events (AEs); the most common treatment-related grade ≥3 AEs and serious AEs are shown in the Table 1. After completing induction therapy with IRd, 18 patients went on to receive maintenance with single-agent ixazomib on a twice-weekly dosing schedule. Patients who went on to maintenance received a median (range) of 31.5 (17–75) treatment cycles. Among the patients who received maintenance therapy, the ORR (PR%) was 54%, the CR+VGPR rate was 67%, and the CR rate was 44%. Two (11%) patients improved their responses during maintenance. Common treatment-related grade ≥3 AEs occurring in ≥25% of patients are shown in the Table 2.

Aims: This phase II study of elotuzumab, lenalidomide, and dexamethasone (IRD) is feasible and active in patients with NDMM, with weekly and twice-weekly ixazomib dosing having been investigated (Kumar et al, Lancet Oncol 2013).

Results: Of the 64 enrolled patients, 40 continued on study treatment without withdrawal for SCT long-term follow-up of these 40 patients is reported here. The median age of patients was 66 years (range 34–82), and 45%/38%/18% of patients had ISS disease stage I/II/III. At a median follow-up of 47.0 months, the overall response rate (ORR; partial response [PR] in the absence of progression) was 94%, the complete response rate (CR+VGPR) rate was 68%, and the CR rate was 32%. Median time to first response was approximately 1 cycle (0.72 months). Median time to a best response of CR was 4.2 months. Patients received a median (range) of 14 (1–75) treatment cycles. Median progression-free survival (PFS) for patients not proceeding to SCT was 24.9 months. Median overall survival (OS) was not estimable; the 2-year Kaplan-Meier estimate for OS was 92%. A total of 78% of patients had grade ≥3 treatment-related adverse events (AEs); the most common treatment-related grade ≥3 AEs and serious AEs are shown in the Table 1. After completing induction therapy with IRd, 18 patients went on to receive maintenance with single-agent ixazomib on a twice-weekly dosing schedule. Patients who went on to maintenance received a median (range) of 31.5 (17–75) treatment cycles. Among the patients who received maintenance therapy, the ORR (PR%) was 54%, the CR+VGPR rate was 67%, and the CR rate was 44%. Two (11%) patients improved their responses during maintenance. Common treatment-related grade ≥3 AEs occurring in ≥25% of patients are shown in the Table 2.

Summary/Conclusions: In patients with NDMM, twice-weekly ixazomib plus Rd resulted in excellent response rates in patients who did not receive a SCT and who received maintenance therapy. The responses were deep and durable, with long PFS and a high 2-year OS estimate. The majority of AEs had an onset during induction, and the incidence of AEs during maintenance was infrequent.

S782

COMPARISON OF DENOSUMBOT WITH ZOLEDRONIC ACID FOR THE TREATMENT OF BONE DISEASE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA; AN INTERNATIONAL, RANDOMIZED, DOUBLE-BLIND TRIAL

1Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, 2Indiana University Simon Cancer Center, Indianapolis, United States, 3Medical University of Innsbruck, Innsbruck, Austria, 4National Hospital Organization Higashi Nagoya National Hospital, Nagoya, Japan, 5Hospital Universitario de Salamanca, Salamanca, Spain, 6Cedars-Sinai Medical Center, Los Angeles, 7Amgen Inc., Thousand Oaks, 8Massachusetts General Hospital Cancer Center, Boston, United States

Background: Multiple myeloma is characterized by osteolytic bone disease, with up to 80% of pts presenting with detectable lesions. Myeloma bone disease is mediated by osteoclast activating factors such as RANKL, increasing the risk of skeletal-related events (SREs) and impacting morbidity and mortality. DMB, a human monoclonal antibody that targets and binds to RANKL, can be administered subcutaneously (SC) to pts regardless of renal function.

Aims: This study evaluates the efficacy and safety of DMB compared withZA in newly diagnosed myeloma pts.

Methods: In 2184 adult pts were randomized 1:1 to DMB 120mg SC Q4W or ZA 4mg IV (adjusted) Q4W along with anti-myeloma therapy. Key stratification factors included type of first-line therapy (novel or non-previous) and previous SRE. Pts with renal insufficiency were excluded if baseline creatinine clearance (CrCl)<30mL/min. The primary endpoint was non-inferiority of DMB to ZA with respect to time to first on-study SRE. Secondary endpoints included superiority of DMB for time to first on-study SRE and first-and-subsequent on-study SRE, and overall survival (OS). Progression-free survival (PFS) was an exploratory endpoint. Safety was also assessed.

Results: A total of 1718 pts were randomized, 859 to each arm. Baseline demographic and disease characteristics were balanced, with 68% of DMB and 67.2% of ZA pts reporting prior SRE history; CrCl<30mL/min was reported in 26.7% of pts. During the primary blinded treatment period (median follow-up 17.4 months [m]), 43.8% DMB pts and 44.6% ZA pts had a first on-study SRE. The median time to first on-study SRE was similar between DMB (22.83 m) and ZA (23.98 m) pts. DMB was non-inferior to ZA in delaying time to first on-study SRE (HR[95%CI]=0.98[0.85,1.14]). Superiority was not demonstrated for time to first on-study SRE (P=0.82) and time to first-and-subsequent on-study SRE (P=0.84). In this high-risk study population the effect of antiresorptive therapy may only be evident later in the treatment course. A post-hoc, landmark analysis at 15 m for time to first SRE demonstrated a HR[95%CI]=0.66[0.44,0.98], P=0.039 (Figure 1) between DMB and ZA. OS was similar between DMB and ZA (HR[95%CI]=0.90[0.70,1.16]; P=0.41), with fewer deaths with DMB (129[14.1%]) than ZA (129[15.0%]). PFS yielded a HR[95%CI]=0.82[0.68,0.99], descriptive P=0.036, with median times of 46.09m (95%CI:34.3,NE) for DMB and 35.38m (95%CI:30.19,NE) for ZA. The most common AE (≥25%) for DMB and ZA were diarrhea and nausea. The rates of SAEs (DMB,ZA [%];46.0,47.3), hypocalcemia (16.9,12.4; serious:0.9,0.2), and positive adjudication ONJ (4.1,2.8) were comparable to known safety profiles. Fewer DMB pts (%) compared with ZA pts had AEs potentially related to renal function (10.0,17.1;P<0.001), most notably in pts with baseline CrCl≤60mL/min (12.9,11.5).

Figure 1. Summary/Conclusions: DMB demonstrated non-inferiority to ZA in delaying time to first on-study SRE in myeloma pts, meeting the primary endpoint of the study. A landmark analysis at 15 m suggests a significant benefit for DMB with respect to time to first SRE. The rates of renal AEs were significantly lower in DMB pts while the overall rates of AEs, including hypocalcemia and ONJ, were consistent with the known DMB safety profile. The results of the landmark analysis and possible prolongation of PFS with DMB therapy is promising.
Background: Pembrolizumab (pembro) is a humanized, highly selective, high-affinity IgG4/Aκ antibody that blocks the interaction between programmed death 1 (PD-1) and its ligands PD-L1 and PD-L2, activating antitumor immunity. Pembrolizumab plus lenalidomide (len) and low-dose dexamethasone (dex) may provide synergistic antitumor activity in relapsed/refractory multiple myeloma (RRMM). Biomarkers indicative of response, pharmacodynamic activity, and/or mechanism of action to combination therapies are also needed.

Aims: To determine the maximum tolerated dose (MTD) and safety and tolerability of pembro plus len and low-dose dex in patients with RRMM. Additionally PD-L1 and PD-L2 expression in bone marrow (BM), immune profiles in circulating lymphocytes, and gene expression in blood were evaluated.

Methods: This open-label, phase 1 KEYNOTE-023 (NCT02038502) study of pembro plus len and low-dose dex enrolled patients with RRMM previously treated with ≥2 prior therapies, including both a proteasome inhibitor and an immunomodulatory drug. Patients received pembro 200 mg IV every 2 weeks (Q2W), len 25 mg orally on days 1-21, and dex 40 mg day 1 (C1D1); and cycle 2, day 1 (C2D1) blood samples.

Results: MTD was determined as pembro 200 mg IV Q2W plus len 25 mg and dex 40 mg. Median (range) age was 61 years (46-77); median (range) number of prior lines of therapy was 4 (1-10); 38 (75%) patients were len-refractory, and 27 (53%) were double refractory. Most common grade ≥3 treatment-related AEs (TRAEs) were neutropenia (33%), thrombocytopenia (18%), and anemia (12%). 2 patients (4%) died because of TRAEs (hepatic failure, ischemic stroke). Immune-related AEs occurred in 5 (10%) patients. No pneumonitis was reported. ORR in the efficacy population was 39/40 (98%) in the efficacy population and 37/38 (97%) in the safety population. The disease control rate for len- and double-refractory patients, respectively. The disease control rate (sCR+CR+ VGPR+PR+SD) was 39/40 (98%) in the efficacy population and 29/28 (97%) in the len-refractory population. 35/40 (88%) patients had a reduction in M protein or free light chains. In 16/32 patients with FC-evaluable BM aspirate with >100 CD38+CD138+ cells, all were PD-L1+, while PD-L2 expression was variable. At C2D1, proportion of circulating HLA-DR+, central (CD45RO+CCR7−), and effector memory (CD45RO+CCR7+) CD8+T cells was variable. At C2D1, proportion of circulating HLA-DR+, central (CD45RO+CCR7−), and effector memory (CD45RO+CCR7+) CD8+T cells signif-

Summary/Conclusions: The combination of pembro, len, and low-dose dex induced immune activation in the periphery and a phenotypic shift in effector CD8+ T cells among the circulating T-cell pool in blood.

RUXOLITINIB FOR THE TREATMENT OF INADEQUATELY CONTROLLED POLYCYTHEMIA VERA WITHOUT SPLENOMEGALY: 80-WEEK FOLLOW-UP FROM THE RESPONSE-2 TRIAL

RUXOLITINIB (RUX) is a Janus kinase (JAK) inhibitor approved for the treatment of hydroxyurea (HU)-resistant/intolerant pts with PV ≥18 years of age. The RESPONSE-2 trial (NCT01743603) evaluated the efficacy and safety of RUX in HU-resistant/intolerant pts with PV ≥18 years of age randomized 1:1 to RUX 10 mg twice daily or best available treatment (BAT). Primary end point was the proportion of pts who achieved hematocrit (HCT) ≤45% at wk 80. house (HU)-resistant/intolerant pts with PV ≥18 years old and new drugs in MPN

Old and new drugs in MPN

POLYCYTHEMIA VERA WITHOUT SPLENOMEGALY: 80-WEEK FOLLOW-UP FROM THE RESPONSE-2 TRIAL

RUXOLITINIB (RUX) is a Janus kinase (JAK) inhibitor approved for the treatment of hydroxyurea (HU)-resistant/intolerant pts with PV ≥18 years of age. The RESPONSE-2 trial (NCT01743603) evaluated the efficacy and safety of RUX in HU-resistant/intolerant pts with PV ≥18 years of age randomized 1:1 to RUX 10 mg twice daily or best available treatment (BAT). Primary end point was the proportion of pts who achieved hematocrit (HCT) ≤45% at wk 80. house (HU)-resistant/intolerant pts with PV ≥18 years old
PHASE 3 RANDOMIZED TRIAL OF MOMELOTINIB VERSUS RUXOLITINIB IN JAK INHIBITOR NAIVE PATIENTS WITH MYELOFIBROSIS: RESULTS OF THE SIMPLIFY-1 STUDY

1Stanford University Medical Center, Stanford, United States, 2Saint-Louis Hospital (APHP) and Paris Diderot University, Paris, France, 3Monash University, Melbourne, Australia, 4University Hospitals Leuven, Leuven, Belgium, 5Kaposi Mar Teaching Hospital, Kapovaro, Hungary, 6Medical University of Gdańsk, Gdańsk, Poland, 7Guy’s and St. Thomas’ NHS Foundation Trust, London, United Kingdom, 8University of Miyazaki, Miyazaki, Japan, 9Emory University School of Medicine, Atlanta, 10Gilead Sciences, Inc., Foster City, United States, 11Hospital Clinic, University of Barcelona, Barcelona, Spain, 12Mayo Clinic Cancer Center, Scottsdale, United States

Background: Momelotinib (MMB), an investigational oral JAK inhibitor (JAKi), has been shown in early trials to reduce spleen volume, improve disease-associated symptoms and improve red blood cell (RBC) transfusion requirements in patients with myelofibrosis (MF).

Aims: To test the non-inferiority of MMB vs ruxolitinib (RUX) in splenic volume reduction and symptom amelioration, and superiority in transfusion requirement, in JAKi naive patients with primary myelofibrosis, and post-polycythemia vera or post-essential thrombocythemia myelofibrosis.

Methods: Eligibility included primary myelofibrosis or post-polycythemia vera/essential thrombocythemia myelofibrosis; International Prognostic Scoring System (IPSS) high risk, intermediate-2 risk, or intermediate-1 risk associated with symptomatic splenomegaly; palpable spleen ≥5cm; platelets ≥50 K/μl; no Grade ≥2 peripheral neuropathy. informed consent was obtained. Stratification was by transfusion dependency and platelets (<100K, 100K-200K, and >200K/μl). Patients were randomized 1:1 to 24 weeks of MMB 200 mg QD or BAT. Assessments included spleen volume by MRI, and patient-reported symptoms using a daily eDiary of modified MPN-SAF Total Symptom Score (TSS).

Results: Of 73 of 104 (70%) and 40 of 52 (77%) patients receiving MMB or BAT, respectively, completed the 24 week randomized treatment phase. BAT for patients included ruxolitinib, and 27% of patients were on ruxolitinib in combination with other drugs. Efficacy results are in Table 1. The most common treatment-emergent adverse events in MMB patients were diarrhea (33%), asthenia (19%), nausea (19%), and cough (17%), and in BAT patients, asthenia (21%), fatigue (19%), anemia (15%), diarrhea (15%), and abdominal pain (15%); the most common Grade ≥3 adverse events in MMB patients were anemia (13%) and thrombocytopenia (7%), and in BAT patients, anemia (13%), thrombocytopenia (6%) and abdominal pain (6%). Treatment emergent peripheral neuropathy occurred in 11 (11%) of MMB (1 Grade 3) and in no BAT patients; MMB was discontinued in 3 patients due to neuropathy.

Summary/Conclusions: In patients with JAKi naïve myelofibrosis, 24 weeks of momelotinib is non-inferior to ruxolitinib for spleen response but not for symptom response. Momelotinib treatment is associated with a reduced transfusion requirement. NCT01969838

S786

PHASE 3 RANDOMIZED TRIAL OF MOMELOTINIB VERSUS BEST AVAILABLE THERAPY IN PATIENTS WITH MYELOFIBROSIS PREVIOUSLY TREATED WITH RUXOLITINIB: RESULTS OF THE SIMPLIFY-2 STUDY

1University of Texas MD Anderson Cancer Center, Houston, United States, 2University of Florence, Florence, Italy, 3Medizinische Fakultät Carl Gustav Carus, Technische Universität, Dresden, Germany, 4Hospital Clinic, University of Barcelona, Barcelona, Spain, 5Princess Margaret Cancer Centre, University of Toronto, Toronto, Canada, 6Hadassah-Hebrew University Medical Center, Jerusalem, Israel, 7University of Insibria, Varese, Italy, 8Emory University School of Medicine, Atlanta, 9Gilead Sciences, Inc., Foster City, United States, 10Saint-Louis Hospital (APHP) and Paris Diderot University, Paris, France, 11Guy’s and St. Thomas’ NHS Foundation Trust, London, United Kingdom

Background: Momelotinib (MMB), an investigational oral JAK inhibitor, has been shown in early trials to reduce spleen volume, improve disease-associated symptoms and improve red blood cell (RBC) transfusion requirements in patients with myelofibrosis.

Aims: To test the superiority of MMB versus best available therapy (BAT) in splenic volume reduction, symptom amelioration, and transfusion requirement at 24 weeks in patients with primary myelofibrosis (PMF), post-polycythemia vera or post-essential thrombocythemia myelofibrosis (Post-PV/ET MF) who were previously treated with ruxolitinib.

Methods: Eligibility included PMF or post-PV/ET MF; Dynamic International Prognostic Scoring System (DIPSS) high risk or intermediate-2 risk, or intermediate-1 risk associated with symptomatic splenomegaly; previously treated with ruxolitinib for at least 28 days who either required transfusions or dose reduction to <20 mg BID with at least one Grade ≥3 thrombocytopenia, anemia, or bleed; palpable spleen ≥5cm; and no Grade ≥2 peripheral neuropathy. Informed consent was obtained. Stratification was by transfusion dependency and platelets (<100K, 100K-200K, and >200K/μl). Patients were randomized 2:1 to 24 weeks of open-label MMB 200 mg QD or BAT. Assessments included spleen volume by MRI, and patient-reported symptoms using a daily eDiary of modified MPN-SAF Total Symptom Score (TSS). Primary endpoint was spleen response rate at 24 weeks (SRR24; ≥35% reduction in volume from baseline). Secondary endpoints, evaluated sequentially, were rates of TSS response (TSS RR; ≥50% reduction from baseline), RBC transfusion, RBC transfusion independence (TI), and RBC transfusion independence (TD).

Results: Of 320 (70%) and 40 of 52 (77%) patients receiving MMB or BAT, respectively, completed the 24 week randomized treatment phase. BAT for patients included ruxolitinib, and 27% of patients were on ruxolitinib in combination with other drugs. Efficacy results are in Table 1. The most common treatment-emergent adverse events in MMB patients were diarrhea (33%), asthenia (19%), nausea (19%), and cough (17%), and in BAT patients, asthenia (21%), fatigue (19%), anemia (15%), diarrhea (15%), and abdominal pain (15%); the most common Grade ≥3 adverse events in MMB patients were anemia (13%) and thrombocytopenia (7%), and in BAT patients, anemia (13%), thrombocytopenia (6%) and abdominal pain (6%). Treatment emergent peripheral neuropathy occurred in 11 (11%) of MMB (1 Grade 3) and in no BAT patients; MMB was discontinued in 3 patients due to neuropathy.

MOLECULAR RESPONSE TO HYDROXYUREA AND ROPEGINTERFERON ALFA-2B IN THE PROUD-PV RANDOMIZED PHASE 3 TRIAL

J.-J. Kladjan1,2,3,4,5, B. Cassinat2,4, J. Soret-Dulphy6, E. Verger7, L. Roy6, J. Rey8, N. Masliah9, B. Grohmann-İzay10, C. Klaide11, H. Gisslinger11,2,12

1Clinical Investigations Center, Hopital Saint-Louis, 2INSERM UMRs-1131, 3Paris Diderot University, 4Hôpital Saint-Louis, Paris, 5Hôpital Henri Mondor, Créteil, 6University of Caen, Caen, 7NAP orphan Pharmaceuticals AG, 8Medical University of Vienna, Vienna, France

Background: Interferon alfa (IFNa) has been successfully used to treat myeloproliferative neoplasms (MPN) for many years and several phase 2 studies have independently shown high rates of hematological and molecular responses assessed by the quantification of mutant JAK2 allele burden (%JAK2V617F) in peripheral blood. However, direct in vivo studies investigating the impact of IFNa treatment on proliferation of bone marrow (BM) normal and malignant hematopoietic progenitors are lacking.

Aims: We report the randomized controlled phase III trial (PROUD-PV) comparing the novel, long-acting Rogepinterferon alfa-2b (AOP2014) with hydroxyurea (HU) in polycythemia vera (PV) patients (pts) to assess correlation between evolution of %JAK2V617F in peripheral blood and the impact of therapy on malignant clones by functional assays testing mutant BM hematopoietic progenitors in the French study population.

Methods: Randomized, controlled, multicenter phase 3 trial comparing efficacy, safety and tolerability of hydroxyurea and Rogepinterferon Alfa-2b in PV pts (NCT01949805). The primary endpoint was non-inferiority of AOP2014 vs HU at 12 months (mos) of therapy in terms of complete hematological response (CHG) according to ELN criteria and normal spleen size. An important secondary endpoint the effect of treatment on %JAK2V617F was assessed as rate of complete and partial molecular response (C/PMR) according to modified ELN criteria. In the group of pts enrolled in France, we could study BM progenitors clonogenic potential by cultures with or without Erythropoietin (EPO) at baseline and after 12 months of therapy. The presence of colonies without EPO, namely Endogenous Erythroid Colonies (EECs) is a hallmark of PV. After 14 days, erythroid colonies were enumerated and picked for molecular analyses.

Results: A total of 257 pts were randomized in 13 European countries including 13 pts in France. Non-inferiority of AOP2014 versus HU regarding CHG could be demonstrated in the whole study population (43.1% vs 45.6%). In the subgroup of French pts (54 males, mean age 55 years) CHG at 12 mos was 40% in pts receiving AOP2014 (n=5) and 50%, in those receiving HU (n=8). %JAK2V617F at baseline in the AOP2014 and HU arms were 39.4% and 46.6% respectively (p=0.08). HU patients were older (median age 61, 5 of 12 vs. 65, 7 of 12 years, respectively; p=0.03). AOP2014 treatment induced an important decrease of the proportion of EECs in cultures with or without EPO at baseline as well as after 12 months of therapy compared to HU (median decrease 25%). In addition, clonal architecture studies showed that the % of JAK2V617F mutant colonies before and after treatment profoundly decreased in all AOP2014-treated pts (median decrease 25%) while it was not different in the baseline at 12 months of therapy in AOP2014-treated pts. Among EUC-treated pts, only 1 experienced a decrease in the % of mutated colonies while mean ratio of mutant vs wild type JAK2 colonies didn’t significantly decrease (from 87% at baseline to 79% after 12 mos).

Summary/Conclusions: In this phase 3 trial comparing Rogepinterferon alfa-2b versus HU, we found a different impact of both drugs on hematopoietic cells. Although both treatment induced a decrease of JAK2 mutant allele burden at 12 mos in peripheral blood, BM clonogenic assays suggest that AOP2014 is able to specifically target JAK2 mutant progenitors, an effect not seen in HU treated pts. Such targeted impact of AOP2014 may account for the strikingly different kinetics in allele burden reduction and suggests that sustained long-term molecular response may only be achieved with IFNa based treatment.

Background: AdSM (ie, aggressive SM [ASM], SM with an associated hematologic neoplasm [SM-AHN], and mast cell leukemia [MCL]) comprises rare hematologic neoplasms with a poor prognosis. Kit D816V mutations occur in a majority of patients with adSM. Midostaurin is a multitargeted kinase inhibitor that blocks wild-type and D816V-mutated Kit. Two single-arm phase 2 studies (D2201+A2213) evaluated the safety and efficacy of midostaurin in a large cohort of SM. Overall, 60% and 69% of patients in D2201 and A2213, respectively, achieved the primary endpoint of partial or complete normalization of SM-related organ damage.

Aims: We compared pooled data from these studies with data from a patient registry to determine the effects of midostaurin on overall survival (OS).

Methods: Data from the midostaurin studies, in which patients received midostaurin 100 mg twice daily until progression or toxicity, were pooled. Historical control data were obtained from a contemporary patient registry based at University Medical Centre Mannheim, Germany. Although the primary analyses did not include matching for patient selection, subgroup analyses, and multivariate analyses were performed to assess the impact of baseline patient characteristics affected OS and estimated HR. Propensity scoring was used for supportive analyses to match the patients in the registry. Patients were evaluated for OS based on time from diagnosis to death; patients in the pooled analysis with known dates of diagnosis were included in the primary analysis. A sensitivity analysis to compensate for potential bias of patient selection was conducted using the start date of last treatment to death.

Results: The primary analysis of OS in patients with adSM included 89 patients from the midostaurin pooled analysis for whom the date of diagnosis was available (77% of the entire pooled cohort) and all 46 patients from the German registry who had not been treated with midostaurin. SM subtypes among patients from the pooled analysis and registry were similar; 66% of patients in the pooled cohort and 63% in the registry had an AHN (Table 1). Kit D816 mutations were present in 82% of patients in the pooled analysis and 96% in the registry. More patients in the registry (67%) vs the pooled analysis (42%) were aged >65 y. Median follow-up (time from diagnosis to data cutoff for the analyses) was similar for the 2 patient groups: registry, 54.9 (range, 1.9-150.4) mo and midostaurin, 53.6 (range, 31.6-215) mo. Patients in the midostaurin pooled analysis had a clinically relevant improvement in OS vs historical controls (HR=0.62 [95% CI, 0.39-0.98]; P=0.024; Figure 1). Median OS was 42.8% (95% CI, 31.0-53.9) mo in the pooled analysis vs 24.0% (90% CI, 13.0-39.5) mo in the registry. Multivariate Cox regression analysis after adjusting for covariates was consistent with the primary analysis: HR=0.51 (95% CI, 0.30-0.88); P=0.0147. Data using propensity score for matched pairs (n=44) were also consistent (HR=0.38 [95% CI, 0.22-0.65]; P=0.0004).

Table 1.

In this phase 3 trial comparing Rogepinterferon alfa-2b versus HU, we found a significant improvement of immune cell function in the activated state as compared to HU. Although both treatment induced a decrease of JAK2 mutant allele burden at 12 mos in peripheral blood, BM clonogenic assays suggest that AOP2014 is able to specifically target JAK2 mutant progenitors, an effect not seen in HU treated pts. Such targeted impact of AOP2014 may account for the strikingly different kinetics in allele burden reduction and suggests that sustained long-term molecular response may only be achieved with IFNa based treatment.
Midostaurin was associated with a 38% lower risk of death vs historical controls. Benefit was generally consistent across key subgroups.

**Background:** Approximately 10% of the children with Down syndrome are diagnosed with transient myeloproliferative disorder (TMD) within the first days of life. Previous studies have shown that TMD patients face an around 20% risk of early death and a 20% to 30% risk to develop myeloid leukemia during the first 4 years of life (ML-DS).

**Aims:** The aim of the AML-BFM TMD Prevention 2007 trial was to analyze the outcome of patients diagnosed with TMD and to evaluate whether the application of a low-dose cytarabin treatment can prevent the progression to ML-DS.

**Methods:** The AML-BFM TMD Prevention 2007 trial is a multi-center, non-randomized, historically controlled study. Patients with TMD were prospectively enrolled. They received a low-dose cytarabin treatment (1.5 mg/kg i.v./s.c. daily) for one week respectively if they met the following criteria: TMD-related symptoms (n=59), no significant differences were observed regarding EFS (81±5% vs 71±5%, p=0.15) than patients without these symptoms in the historic control (n=101).

**Results:** Here we report a cohort of 108 patients (male: 60, female:48) diagnosed with TMD. The median age at diagnosis was 4 days. As common in children with Down syndrome, many of the patients presented with comorbidities (cardiac defects: 68%, other malformations: 15%); 36% were delivered preterm. 45 patients received low-dose cytarabin treatment, 57 patients did not receive this treatment. Overall, patients in this trial do not show a significantly better event-free survival (EFS; 72±4% vs 63±4%, p=0.15) and overall survival (OS; 91±3% vs 85±3%, p=0.15) than the historic control group (n=146). The cumulative incidence (CI) of death was lower, (8±3% vs 15±3%) albeit not significantly (p=0.09). The CI of ML-DS was also similar (19±4% vs 22±4%, p=0.88).

**Summary/Conclusions:** The outcome treatment with low-dose chemotherapy does not seem to prevent the development of subsequent leukemia in TMD-patients. Therefore, a general preventive chemotherapeutic treatment of children diagnosed with TMD cannot be recommended. However, children with TMD-related symptoms should receive low-dose cytarabin to reduce disease-related mortality.
Background: AML is a heterogeneous disease based on genetic characteristics with impact on prognosis. So, it becomes necessary to treat patients according to risk-adapted therapies.

Aims: To analyze the results of intensive induction and post-remission treatment in 868 patients with the novel AML enrolled into the CETLAM-03 trial between 2003 and 2012 with a prolonged follow-up (results reported at 10 years).

Methods: Patients received bolus days 1 or 2 induction chemotherapy courses of IDICE-G (idarubicin, intermediate cytarabine (IDC), VP-16 and priming with G-CSF) followed by mitoxantrone and IDC as consolidation therapy. Further treatment was assigned according to the CETLAM risk groups as follows: Favorable risk (FR) defined as favorable cytogenetics according to MRC; autologous stem cell transplantation (ASCT) in case of leukocyte index (LI) leukocytosis (BM blasts<10%) ≤20 or high dose cytarabine (HDAC) (one course) if LI>20. Intermediate risk (IR), defined as patients in CR after a single induction course, ≤50x10E9/l white blood cells at diagnosis, normal karyotype and absence of FLT3 internal tandem duplication (FT3-ITDwt) and no MLL rearrangement: ASCT. Adverse risk (AR), patients not considered in FR or IR or ASCT or allo-SCT or allo-SCT (allo-SCT) depending on donor availability (HLA-identical sibling or unrelated donor if high risk of relapse).

Results: There were enrolled 868 patients. Median age was 53 years-old (16-70). According to MRC cytogenetics, available in 802 patients, 99 belonged to the favorable (12%), 581 (73%) to the intermediate and 122 (15%) to the adverse groups. 66 patients with no metaphases. FLT3-ITD was present in 128 patients with normal karyotype (36%). Four patients died before treatment and 864 patients received induction therapy. 77% of patients achieved a CR (88% with a single course), 11% were refractory and 12% died during induction. CR rates were 94% in patients with normal karyotype and no mutations, 91% in NPM1 mutation without FLT3-ITD, 77% in intermediate cytogenetic and no mutations, 74% if FLT3-ITD, 70% in adverse cytogenetics and 62% if monosomal karyotype was present (p<0.001). The multivariate analysis showed that mutational status (adverse cytogenetics, FLT3-ITD and absence of NPM1 mutation) had an adverse impact on CR achievement. The percentage of CR (OS) -evaluated in patients cured in CR and cell expansion (allo-SCT) during study period, we identified 13 cases (maintenance) and 26 controls using log rank test and cox proportional hazards regression analysis. In this, the largest such study reported to date, the demonstration that mutations in CDKN2A, IDH1 and TP53 are associated with reduced OS and survival, and that FLT3-ITD mutation is a genetic alteration found in approximately 30% of patients with AML who did not receive maintenance post SCT(control group); we identified mutations in CDKN2A (p=0.0001), IDH1 (p=0.004) and TP53 (p=0.003), NPM1 (p=0.037) and FLT3-ITD (p=0.04) as significant molecular markers for survival, and 82% of these patients were associated with reduced OS.

Summary/Conclusions: In this, the largest such study reported to date, the demonstration that mutations in CDKN2A, IDH1 and TP53 are associated with reduced OS and survival, and that FLT3-ITD mutation is a genetic alteration found in approximately 30% of patients with AML who did not receive maintenance post SCT(control group); we identified mutations in CDKN2A (p=0.0001), IDH1 (p=0.004) and TP53 (p=0.003), NPM1 (p=0.037) and FLT3-ITD (p=0.04) as significant molecular markers for survival, and 82% of these patients were associated with reduced OS.

S792

SORAFENIB MAINTENANCE IN FLT3-ITD MUTATED ACUTE MYELOID LEUKEMIA AFTER ALLOGENIC STEM CELL TRANSPLANTATION

S. Ahmed1, R. Saliba1, G. Rondon1, A. Alousi1, Q. Bashir2, S. Ciurea3, G. Al-Atrash1, K. Patel1, A. Olson1, D. Marin1, K. Revzani1, P. Kebriaei1, U. Popat1, E. Shapall1, R. Champlin1, B. Grant1, 1Bone cell transplant and cellular therapy, 2Hematopathology, University of Texas, MD Anderson Cancer Center, Houston, United States

Background: The fms-like tyrosine kinase 3 internal tandem duplication (FLT3-ITD) mutation is a genetic alteration found in approximately 30% of patients with acute myeloid leukemia (AML). Although FLT3-ITD mutated AML achieve remission rates similar to those with FLT3 wildtype status with induction chemotherapy regimens; patients with FLT3-ITD have significantly shorter remission durations and increased rates of relapse. Even though allogeneic SCT improves outcomes, patients still have higher rates of relapse compared to patients with FLT3 wildtype status.

Aims: To assess the outcomes, including progression free survival (PFS) and overall survival (OS), in patients with FLT3-ITD mutated AML who receive SFB maintenance after allogeneic SCT.

Methods: We analyzed adult patients (age<18) with a diagnosis of FLT3-ITD mutated AML leukemia (aTAC) treated between 1/2010 and 7/2015. FLT3-ITD mutated AML who did not receive maintenance post SCT(control group); we matched each case to two control patients accounting for disease status, type of SCT, donor type and donor status. For patients who received maintenance post SCT, the study was censored at the time of last contact.

Summary/Conclusions: The CIR when comparing ASCT (p=0.033) and allogeneic SCT (p=0.003) as well as identify molecular predictors of outcome in patients treated on the RAVVA trial and correlated with response. Separately serial immunophenotypic quantitation of leukemic stem/progenitor cells (LSC) was performed in 44 patients.

Background: In the RAVVA study, a randomized II trial which compared AZA monotherapy with AZA/VOR combination therapy. To analyze the results of intensive induction and post-remission treatment in 250 patients treated on the RAVVA trial and correlated with response.
characteristics were comparable between groups as presented in Figure 1. Patients were classified by the European Leukemia Net (ELN) classification and 23% in both groups were categorized as adverse risk while 77% were intermediate risk. All patients received myeloablative conditioning and diseases status at SCT was first/second complete remission (CR1/2) with or without count recovery (CnR) in 69% while it was active disease in 31%. PFS at 24 months post SCT was 82% in the maintenance and 45% in control group HR 0.3; 95% CI (0.1-1.3) p=0.1. Overall survival at 24 months was also higher in SFB cases as 100% compared with 60% in control group p=0.035. Only 2 patients relapsed post SCT on SFB maintenance, one with new TP53 mutation at relapse, and other received only <30 days of SFB. However, more than half the patients had disease progression within the control period. The most commonly administered dose was 400 mg daily (5 patients) for 28 days cycle; only 2 patients tolerated higher doses and 6 patients received SBF as 300mg daily or less. There were delays in subsequent cycles in 10 of 12 patients, and the most common reasons for delays included cytopenias, liver function test abnormalities, and fatigue.

**Figure 1.**

Summary/Conclusions: Sorafenib maintenance is safe and can produce long term durable remissions after allogeneic stem cell transplant in a high risk population with FLT3-ITD mutated AML.

S793

**A PHASE 1B STUDY OF THE COMBINATION OF VADASTUXIMAB TALIRINE AND 7+3 INDUCTION THERAPY FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA**

1Baylor University Medical Center, Dallas, TX, 2Gehr Family Center for Leukemia Research - City of Hope, Duarte, CA, 3Ohio State University Comprehensive Cancer Center, Columbus, OH, 4Colorado Blood Cancer Institute, Denver, CO, 5Cleveland Clinic, Cleveland, OH, 6Massachusetts General Hospital, Boston, MA, 7John Theurer Cancer Center, Hackensack, NJ, 8Fred Hutchinson Cancer Research Center, Seattle, WA, 9Loyola University Medical Center, Maywood, IL, 10Karmanos Cancer Institute, Detroit, MI, 11Sarah Cannon Research Institute, Nashville, TN, 12University of Washington Medical Center, Seattle, WA, 13MD Anderson Cancer Center, Houston, TX, 14Seattle Genetics, Inc., Bothell, WA, 15University of Alabama-Birmingham, Birmingham, AL, United States

**Background:** For patients <65 yrs with newly diagnosed AML, standard induction treatment is continuous infusion of cytarabine for 7 days and an anthracycline for 3 days (7+3). Although a high percentage of patients achieve a CR by morphologic criteria, some requiring a 2nd induction, many are resistant to treatment or achieve a morphologic CR with evidence of minimal residual disease (MRD). Vadastuximab talirine (SGN-CD33A; 33A) is a CD33-directed antibody conjugated to 2 molecules of a pyrrolobenzodiazepine dimer. Combining 33A with 7+3 could result in enhanced and deeper (MRD negative) remissions, resulting in reduced relapse rates and improved OS.

**Aims:** This phase 1b study (NCT02326584) evaluated the safety and antileukemic activity of escalating doses of 33A on 2 schedules: split dose (D1 only) with 7+3. Most patients had blast clearance (CR+CRi+mLFS), 73% (27/37) achieved MRD negative status. The CR rate at the 40 mcg/kg dose level was 91% (10/11); all 11 patients had blast clearance and 90% (9/10) of evaluable patients achieved MRD negative status. Across schedules (N=67), the CR rate was 76%; 79% (44/56) of evaluable patients with blast clearance achieved MRD negativity. The 30- and 60-day mortality rates were 1% and 7%, respectively. Median OS is not reached for either schedule and 52 patients (78%) were alive at the time of analysis.

**Summary/Conclusions:** 33A can be safely combined with 7+3 with acceptable count recovery in this population at the doses and schedules studied. Extramedullary AEs, including hepatotoxicity, and induction mortality rates were similar to reported rates for 7+3 alone in this AML population. A high remission rate with the 1st induction cycle was observed, the majority of which were MRD negative.
21-COLOR FLOW CYTOMETRY REVEALS IMMUNOPHENOTYPES ASSOCIATED WITH RESPONSE IN ACUTE GRAFT-VERSUS-HOST DISEASE PATIENTS TREATED WITH THE JANUS KINASE INHIBITOR INCB039110

K. Staser1,2, J. Choi1, J. Khoury2, M. Jagasia3, H. Ali4, G. Schiller5, M. Arbushites6, P. Delaite7, Y. Yan4, K. Rhein4, Y.-B. Chen7, M.-A. Perelas8, L. Gehrs1, J. Ritchey1, J. DiPersio1, M. Schroeder1
1Washington University in Saint Louis, Saint Louis, 2Emory University School of Medicine, Atlanta, 3Vanderbilt-Ingram Cancer Center, Nashville, 4City of Hope, Duarte, 5David Geffen School of Medicine at UCLA, Los Angeles, 6Incyte Corporation, Wilmington, 7Massachusetts General Hospital, Boston, 8Memorial Sloan Kettering Cancer Center, New York City, United States

Background: Although ~50% of aGVHD patients respond to steroids, no consensus second-line treatment exists. Recent preclinical models, retrospective studies, and this prospective trial have demonstrated safety and efficacy of JAK inhibitors (e.g. ruxolitinib, INCB039110) in steroid-refractory aGVHD.

Aims: Here, we present 21-marker FACS analysis of blood from patients enrolled in a prospective, randomized, parallel-cohort, open-label phase 1 trial of the potent and selective JAK1 inhibitor INCB039110 for aGVHD (NCT02614612). Preliminary results were previously presented at ASH 2016 (Schroeder et al).

Methods: Patients (n=30) were >18 years old undergoing first alloHSCT from any source with steroid-refractory or treatment-naive grades IIb-IV aGVHD, randomized 1:1 to 200 or 300 mg oral daily INCB039110 combined with corticosteroids. Peripheral blood, obtained at treatment days 7, 14, 28, 56, 100, and 180, was analyzed by 21-color FACS quantifying >30 cell types, including B, CD4+ and CD8+ T, memory T, regulatory (Treg), Th1, Th2, Th17, T follicular helper (Tfh), Th9, Th22, ThGM-CSF cells, granulocytes, monocytes, myeloid-derived suppressor cells (MDSCs), natural killer (NK) cells, and monocytes and plasmacytoid dendritic cells (DCs). Patients were stratified by treatment response (e.g. complete response (CR), partial response (PR), mixed response (MR)).

Results: During INCB039110 treatment, overall B, T, and myeloid proportions did not correlate with response. However, the CR group increased expression of NK92 and NK10 T cells (CD3-CD20-CD14-CD56+, mDCs (CD3-CD20-CD14-HLADR+CD56+), mDCs (CD3-CD20-CD14-HLADR+CD11c+), and memory CD4+ T cells (CD3+CD4+CD45RA-). Among CD4+ memory cells, the CR group showed significant or trend-toward-significant increases in Tfh (CXCR5-CX3CR1+C), Th1 (CXCR5-CXCR6-CX3CR1+CXCR10+), Th2, Th17 (CXCR5-CXCR6+CXCR4+CX3CR3-CXCR10-), Th17 (CXCR5-CXCR6-CX3CR3-CXCR10-), Th22 (CXCR5-CXCR6+CX3CR3-CXCR10-), and Th22 (CXCR5-CXCR6+CX3CR3-CXCR10-). Tregs (CD4+CD25+CD127-) trended toward a ~2-fold increase in the CR group. Within the monocyte subgroup (CD3-CD20-CD14+), the CR group skewed toward classical monocytes (HLADR+CD16+) (84.7% vs 38.0%, CR vs PR/MR, p=0.0078) and away from MDSCs (HLADR+CD11c+) (30.0% vs 58.4%, CR vs PR/MR, p=0.0139) during treatment. Interestingly, the NK-to-MDCS ratio was a sensitive and specific predictor of CR vs all other responses, a finding consistent for both CD16+ and CD16- NK cells (Figure 1 a, b). Before INCB039110 treatment, decreased naive CD8+ T cells (CD45RA+CCR7+) predicted CR versus PR/MR (12.6% vs 32.3% of CD8+ cells, CR vs PR/MR, p=0.0047) with a similar trend toward decreased naive CD4+ T cells (13% vs 24.4% of CD4+ cells, CR vs PR/MR, p=0.0749). While naïve T cells did not correlate with pretreatment aGVHD grade, grades III-IV aGVHD demonstrated increased Th2 cells (CD45RA-CCR5+CCR6-CX3CR3+CXCR10-) and activated CD8+ T cells (CD38+HLADR+) as compared to grade II aGVHD. Further correlation with serum cytokines, JAK-STAT signaling, and pharmacology will be available at time of presentation.

Figure 1.

Summary/Conclusions: Decreased pre-treatment naïve T cells may predict better outcomes in INCB039110-treated aGVHD. During treatment, increased DCs, NKs, and memory T cell subsets correlated with better response. Surprisingly, increased MDSCs associated with poorer response, suggesting MDSC expansion during persistent inflammation. The NK-to-MDCS ratio may be an important clinical marker to track treatment progress. Finally, this study establishes a novel FACs-based 21-marker immunophenotyping method with superior throughput, sample preservation, and flexibility as compared to cytometry time of flight (CyTOF) methods.

GUT COLONIZATION BY MULTI-DRUG RESISTANT BACTERIA IS AN INDEPENDENT RISK FACTOR FOR DEVELOPMENT OF INTESTINAL ACUTE GRAFT-VERSUS-HOST DISEASE

Z. Coric1,2, N. Durakovic1,2, L. Desnica1, V. Rezo Vranjes2, M. Marekovic3, R. Serventi-Severini1, J. Bilinski4, G. Basak1, G. Vrhovac1
1Hematology, University Hospital Centre Zagreb, 2School of Medicine, University of Zagreb, 3Department of Microbiology, University Hospital Centre Zagreb, Zagreb, Croatia, 4Hematology, Medical University of Warsaw, Warsaw, Poland

Background: Research has recently highlighted the importance of healthy gut microbiota in the prevention of graft-versus-host disease (GVHD). Gut decontamination and the use of broad-spectrum antibiotics have led to the loss of natural microbiota diversity and the overgrowth of opportunistic pathogens with emerging antimicrobial resistance. However, the role of multi-drug resistant by VSR is still under development. G. Vrhovac et al.

Aims: Our aim was to evaluate the impact of gut colonization with MDR bacteria on the acute GVHD and related outcome.

Methods: Retrospectively we evaluated 145 adult patients who consecutively underwent allologeneic stem cell transplantation (allo-SCT) in our institution between 2011 and 2014. All patients were weekly screened by cultivating stool specimens for gut colonization by the following MDR bacteria: vancomycin-resistant Enterococcus (VRE), methicillin-resistant Staphylococcus aureus (MRSA) and multidrug-resistant Gram-negative bacilli (MDR-GNB). Univariate and multivariable proportional hazards models using the Fine and Gray approach were considered to evaluate the variables for acute GVHD, treating death as competing event.

Results: Our study population included 88 male and 57 female patients who underwent allo-SCT at a median age of 46 years (range 18-64). Among them, most patients were treated for myeloid malignancies (70%) and had lymphoproliferative disorders and one patient had aplastic anemia. The donors were unrelated in 74 cases, related in 67 patients and haploidentical in 4 patients. Most of the patients (70%) received peripheral blood stem cells after a reduced-intensity conditioning regimen (56%). At the time of allo-SCT 37% patients were colonized with MDR bacteria, while another 19% became colonized in the early postransplantation period. Among colonized patients, 12% patients were colonized by VRE, 1% by MRSA, 43% by extended-spectrum β-lactamase (ESBL)-producing Enterobacteriaceae, 27% by carbapenem-resistant Enterobacteriaceae (CRE), 9% by MDR Acinetobacter baumannii and 50% by MDR-GNB in the pathogenesis of severe acute GVHD. To our knowledge, we are the first to show that gut colonization with MDR-GNB represents an independent risk factor for GVHD.

Summary/Conclusions: In summary, this report shows a significant role of MDR-GNB in the pathogenesis of severe acute GVHD. To our knowledge, we are the first to show that gut colonization with MDR-GNB represents an independent risk factor for GI GVHD. With growing resistance and lack of efficient antibiotics, decolonization strategies as fecal microbiota transplantation become an attractive strategy for restoration of healthy gut flora and prevention of severe acute GVHD.
Advanced total body irradiation (TBI)-based chemotherapy-based regimens (Cy/TBI or etoposide (Vep/TBI).

**LEUKEMIA WORKING PARTY OF THE EBMT**

**TOTAL BODY IRRADIATION AS CONDITIONING FOR ADULTS WITH CYCLOPHOSPHAMIDE**

The advantage of TBI-based chemotherapy-based regimens (Cy/TBI or etoposide (Vep/TBI).

**LEUKEMIA WORKING PARTY OF THE EBMT**

**TOTAL BODY IRRADIATION AS CONDITIONING FOR ADULTS WITH CYCLOPHOSPHAMIDE**

observed had no impact on OS, NRM, CI of Relapse and acute and chronic GvHD. Setting of a MA conditioning with PT-CY the real degree of HLA mismatching was 6.6%; no correlation was observed with the amount of HLA mismatch in GvHD (12.6% vs 3-4 mm:58.8%, p=0.58 and 0-2 mm:18.2% vs 3-4 mm:19.1%, p=0.93, respectively). Considering only GVH directed mismatches, no difference was highlighted between low or high HLA mismatch burden in cumulative incidence of grade II – IV aGVHD (12.6% vs 3-4 mm:58.8%, p=0.58 and 0-2 mm:18.2% vs 3-4 mm:19.1%, p=0.93, respectively). Considering only GVH directed mismatches, no difference was highlighted between low or high HLA mismatch burden in cumulative incidence of grade II – IV aGVHD (12.6% vs 3-4 mm:58.8%, p=0.58 and 0-2 mm:18.2% vs 3-4 mm:19.1%, p=0.93, respectively).

**S797 CYCLOPHOSPHAMIDE VERSUS ETOPOSIDE IN COMBINATION WITH TOTAL BODY IRRADIATION AS CONDITIONING FOR ADULTS WITH PH(-) ALL UNDERGOING ALLO-HCT: A STUDY FROM THE ACUTE LEUKAEMIA WORKING PARTY OF THE EBMT**

**Summary/Conclusions:** In this series, about one third of haploidentical donor/recipient pairs differ for less than 4/8 HLA antigens. Furthermore, in the setting of a MA conditioning with PT-CY the real degree of HLA mismatch observed had no impact on OS, NRM, CI of Relapse and acute and chronic GvHD.

**S798 ALLOGENEIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKEMIA WITH DELETION 5q OR MONOSOMY 5: A STUDY FROM THE ACUTE LEUKAEMIA WORKING PARTY OF THE EBMT**

**Background:** Acute myeloid leukemia (AML) is mainly defined by the presence of determined poor-risk cytogenetic abnormalities and is a standard indication for allogeneic stem cell transplantation (SCT). Nevertheless, high-risk AML is a very heterogeneous group including several abnormalities with different levels of prognostic impact. Deletion 5q or monosomy 5 (-5q/-) has been part of the high-risk group of AML for many years. SCT seems to improve their survival, but the long-term effects on high-risk cytogenetic features on survival have never been thoroughly studied.

**Aims:** To evaluate the role of SCT in -5q/- AML with additional cytogenetic abnormalities such as complex karyotype (CK), monosomal karyotype (MK), monosomy 7 (-7), or 17p abnormalities (abn(17p)).

**Results:** Five hundred and one pts, 21% of them with secondary AML, have been included in this study. The incidence of -5q/-, with -5q/- reported to the EBMT registry as having their first SCT between 2000 and 2015.

**Methods:** Adult patients with Ph-negative AML (n=1498) treated with alloHCT from either HLA-identical sibling (n=696) or unrelated donor (n=802), in CR1 (n=1186) or CR2 (n=312), between year 2000 – 2015, were included in the analysis. Peripheral blood was used as a source of stem cells in 62% of the patients. Conditioning was myeloablative in all cases (the median TBI dose was 12 Gy); 1346 patients were treated with Cy/TBI while 152 patients with Vep/TBI. Patients in the Vep/TBI group were younger (median 28 y. vs 30 y., p=0.04), treated in more recent period (median year of HCT: 2009 vs 2007, p=0.009) and treated more frequently in CR1 (87% vs 78%, p=0.01).

**Results:** In an univariate analysis, as compared to Cy/TBI, the use of Vep/TBI was associated with significantly reduced incidence of relapse (17% vs 30% at 5 years, p=0.007), increased rate of leukemia-free survival (LFS, 60% vs 50%, p=0.04) as well as improved “GVHD and relapse-free survival” (GRFS, 43% vs 33%, p=0.04). No significant effect could be observed in terms of the incidence of non-relapse mortality, acute or chronic GVHD. In a multivariate model the use of Vep/TBI was associated with reduced risk of relapse (HR=0.62, p=0.04) while the effect on other study end-points was no longer significant. Among other factors, recipient age (HR=1.17 per every 10 years, p<0.0001), year of alloHCT (HR=0.97 per every year, p=0.001) and disease stage (HR=2.14 for CR2, p<0.0001) had significant influence on the risk of treatment failure, either relapse or non-relapse mortality. The risk of relapse was additionally increased for siblings vs unrelated donor transplants (HR=1.47, p=0.01) and donor/recipient gender combination other than female/male (HR=1.80, p=0.04).

**Summary/Conclusions:** Conditioning regimen based on etoposide combined with TBI appears more effective than the cyclophosphamide TBI combination for adult patients with Ph-negative ALL treated with alloHCT. Further, prospective studies are needed to confirm our observation and potentially discriminate subgroup of patients who are most likely to benefit from the use of etoposide.
27%. The main cause of death was disease-related. In multivariate analysis, active disease correlated strongly with worse OS, LFS and NRM. The other factors influencing outcomes were UD with increased NRM, and age with decreased OS and LFS.

Based on the frequencies of the different additional cytogenetic abnormalities, we identified 4 groups within our cohort. Group 1 (None) included 47 pts with -5/5q- but without CK, MK or abn(17p). Group 2 (CK) included pts with -5/5q- and CK but no MK or abn(17p) (N=90). Group 3 (MK) included 169 pts with -5/5q- and MK but no abn(17p). Finally, group 4 (17p) included pts with -5/5q- and abn(17p) (N=193). The 4 groups were quite similar in terms of characteristic. The 2-year probability of LFS was 39% for group 1, 25% for group 2, 20% for group 3 and only 13% for group 4 (p<0.001). OS decreased also significantly from group 1 to group 4 (p<0.001). NRM was similar across the groups. In multivariate analysis, factors associated with worse OS and LFS were active disease, age, MK and abn(17p). The corresponding 2-year probability of GvHD and relapse-free survival was 27% for group 1, 17% for group 2, 14% for group 3 and 7% for group 4 (Figure 1).

Summary/Conclusions: SCT in -5/5q- AML provides a durable response for approximately 20% of pts. Active disease at time of transplantation was the most powerful predictor of an inferior outcome. The presence of -5/5q- without CK, MK or abn(17p) was associated with a significant better survival and the addition of MK or abn(17p) translated into worse outcomes. We confirmed the deleterious effect of the combination of -5/5q- and CK but no MK or abn(17p) on SCT outcome. Future efforts should be focused on this subgroup in order to improve their outcome.

IDENTIFICATIONS OF NOVEL RECURRENT PU.1 FUSIONS WITH HIGHLY AGGRESSIVE PHENOTYPE IN PEDIATRIC T CELL ACUTE LYMPHOBLASTIC LEUKEMIA

1Department of Pediatrics, The University of Tokyo Hospital, Tokyo, 2Department of Pediatrics, Hiroshima University, Hiroshima, 3Department of Pathology and Tumor Biology, Graduate School of Medicine, Kyoto University, Kyoto, 4Laboratory of DNA Information Analysis, Human Genome Center, Institute of Medical Science, The University of Tokyo, Tokyo, 5Division of Systems Biology, Nagoya University Graduate School of Medicine, Nagoya, 6Department of Pediatrics and Developmental Biology, Tokyo Medical and Dental University, Tokyo, 7Department of Cellular and Molecular Medicine, Graduate School of Medicine, Chiba University, Chiba, 8Department of Pediatric Hematology and Oncology Research, National Research Institute for Child Health and Development, Tokyo, 9Department of Hematology/Oncology, Saitama Children’s Medical Center, Saitama, 10Division of Pediatrics, Faculty of Medicine, University of Miyazaki, Miyazaki, 11Department of Pediatrics, The Jikei University School of Medicine, Tokyo, 12Department of Pediatrics, Sapporo Hokuyu Hospital, Sapporo, 13Department of Pediatrics, Mie University Graduate School of Medicine, Tsu, 14Department of Pediatrics, Osaka University Graduate School of Medicine, Suita, 15Department of Pediatrics, Kyoto Prefectural University of Medicine, Graduate School of Medical Science, Kyoto, 16Department of Hematology and Oncology, Miyagi Children’s Hospital, Sendai, 17Gunma Graduate Medical Center, Shibukawa, 18Department of Pediatrics, St. Luke’s International Hospital, 19Department of Pediatrics, Toho University, Tokyo, 20Clinical Research Center, National Hospital Organization Nagoya Medical Center, Nagoya, 21Department of Cellular Signaling, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan

Background: T-cell acute lymphoblastic leukemia/lymphoma (T-ALL/LBL) accounts for 10% to 15% of newly diagnosed cases of childhood acute lymphoblastic leukemia (ALL), arising from the malignant transformation of hematopoietic progenitors primed toward T cell development, as result of a multistep oncogenic process. However, since the prognostic significance of these genetic alterations in pediatric T-ALL is not clear, genetic basis which contributes aggressive phenotype or progression of pediatric T-ALL is still to be elucidated.

Aims: To discover driver genetic events, which involved in the aggressive phenotype of pediatric T-ALL and to identify its novel prognostic markers, we performed integrated genetic analysis in a large cohort of T-ALL case.

Methods: Our cohorts included samples from Tokyo Children’s Cancer Study Group (TCCSG) and Japan Association of Childhood Leukemia Study (JACLS). Whole transcriptome sequencing (WTS) was performed in 123 cases. Whole transcriptome sequencing (WTS) was performed in 123 cases.

Results: Representative recurrent fusion genes were as follows, S1L-TAL1 (n=25), MLL-ENL (n=5), PICALM-MLLT10 (n=5), and NUP214-ABL1 (n=2).

Intriguingly, novel recurrent in-frame PU.1 fusions (STMN1-PU.1 n=2; TCF7-PU.1 n=5) were detected, and RT-PCR analysis in additional 60 cases revealed other 2 TCF7-PU.1 fusions. Thus, PU.1 fusions accounted for 4% of pediatric T-ALL/LBL.

Expression data of WTS revealed cases with PU.1 fusion showed significantly higher expression of PU.1 compared to cases without PU.1 fusion, implicating that aberrant high expression of PU.1 involved in leukemogenesis.

Using consecutive two-step unsupervised consensus clustering, we obtained 5 stable clusters. Among these, 4 clusters largely recapitulated distinct T-ALL subtypes characterized in previous studies by an early T-cell precursor (ETP) signature (ETP-ALL), 2 clusters of high TAL1 expression (TAL1-RA and -RB-ALL) and mutually exclusive expression of TAL1, and TAL3 (TAL-related-ALL). However, the remaining one was newly identified and exclusively consisted of the 7 PU.1 fusion-positive cases. Compared to ETP-ALL, these PU.1 fusion cases typically showed a reduced expression of the phase I genes implicated in early T-cell development, except for PU.1, which was ectopically up-regulated by the relevant gene fusions. All cases with PU.1 fusion were grouped into PU.1 high cluster. Moreover, PU.1 high cluster had distinct genetic features with mutations of transcription factors, such as GATA3, RUNX1, and EVI6. Of note, significant patient outcome was confirmed by multivariate analysis in cases with PU.1 high cluster (p<0.048). Consistently, we defined PU.1 overexpression cases as outliers of PU.1 expression, which resulting in extremely poor prognosis (3-year OS 21%, log-rank p=6.9 x10^-7).

Summary/Conclusions: PU.1 fusions expressing cells expanded and they remained at an immature stage, implicating a potential leukemogenic activity of these fusions. Not only the cases with PU.1 fusions, but also the cases with
high PU.1 expression without fusions showed extremely poor prognosis, suggest- 
gig the prognostic value of abeant PU.1 expression in pediatric T-ALL. Although it remains unclear, why cases with PU.1 fusions/high PU.1 expression have a poor prognosis, our results indicate that these cases are genetically distinct subgroup from other pediatric T-ALL.

POST-INDUCTION MRD PREDICTS HIGH RELAPSE RISK FOLLOWING REDUCED INTENSITY CONDITIONED ALLOGENEIC STEM CELL TRANS- 
PLANTATION: A PROSPECTIVE STUDY OF ADULT ALL (UKALL14.ISRCTN 66541317)

London, United Kingdom
Background: Reduced intensity conditioned allogeneic haematopoietic stem cell transplant (RICalloHCT) enables HCT to be performed in older patients. The UK NCRI UKALL14 study of adult acute lymphoblastic leukaemia (ALL) considers patients ≥41 years “high risk” and recommends a RICalloHCT where there are high quality donors. Other “high risk” factors are high WBC at presentation, t(8;22), t(4;11), hypodiploid/near triploidy, complex karyotype and positive minimal residual disease (MRD) after completing induction therapy. The presence of MRD at this time-point predicts poor outcome after conventional chemotherapy. There is evidence that myeloablated alloHCT can overcome this risk, but the benefit of RICalloHCT is uncertain.

Aims: To determine whether RICalloHCT mitigates the high relapse risk predicted by MRD positivity after induction therapy.

Methods: Protocol treatment: patients receive a steroid pre-phase before 2 cycles of induction chemotherapy. At the end of induction, patients are assigned subsequent therapy on the basis of risk. All patients over 41 years are allocated RICalloHCT, conditioned with fludarabine, melphalan and alemtuzumab. Post HCT, escalating doses of donor lymphocyte infusions were given for T-cell mixed chimerism +/- MRD persistence or relapse. MRD assessment: BCR/ABL1 or Ig/TCR MRD was assessed and analysed per EuroMRD guidelines. MRD is negative (undetectable with an assay quantitative range of 1x10^-4 or less), positive (≥1x10^-4), positive outside quantitative range (POQR)<1x10^-4) or indeterminate (undetectable but assay quantitative range ≥5x10^-4). Patients with indeterminate MRD were excluded from this analysis.

Results: There are 736 patients randomised to date, of whom 184 received a RICalloHCT, of these, 115 had analysable MRD. The following Table 1 shows patient characteristics.

Table 1.

| MRD at Induction (median range) | 6 (0-40) | Unknown | 10 (8.7)

At 2 years post transplant, overall survival (OS) was 63.1% in the 115 patients with evaluable MRD and 62.7% in the 184 patients receiving RICalloHCT; event free survival (EFS) was 55.2% and 55.8% respectively. By contrast, in the 38 of 115 patients with positive MRD after induction, OS and EFS were 40.6% and 28.4% respectively. Twenty eight of the 115 patients relapsed, with a 2 year actuarial relapse risk of 31.5% (22.2-43.5). We assessed the association of the following factors; age, sex, immunophenotype, presenting WBC, BCR/ABL1, other cytogenetics, post-induction MRD and donor type with the risk of relapse. Among this population of high risk patients, post-induction MRD was the only independent prognostic factor for relapse (univariable HR: 3.82 (1.59-9.16), p = 0.001 (see Figure 1) and multivariable HR: 4.14 (1.61-10.65), p = 0.003). The relapse rate of the MRD+ patients was 57.2% at 2 years post HCT.

Figure 1.

Summary/Conclusions: The 2-year OS of 62.5% in UKALL14 participants over 41 years of age after RICalloHCT is greater than would be expected with chemotherapy alone. However, MRD positivity after induction is associated with significantly lower OS, EFS and a higher risk of relapse, which is not abrogated by RICalloHCT.

T-CELL RECEPTOR B REPertoire characteristics in Relapsed/ Refractory B-Cell Precursor Acute Lymphoblastic Leukemia on Blinatumomab Treatment

H. Knecht1,2, M. Kotreva1,2, T. Reigl1, A. Krejci1, D. Herrmann2, M. Schwarz2, V. Bystrý3, N. Darzentas3, M. Brüggemann2

1contributed equally. 2Department of internal medicine II, Laboratory for Hematological Diagnostics, University Hospital Schleswig-Holstein, Kiel, Germany. 3Central European Institute of Technology, Brno, Czech Republic.

Background: Blinatumomab (Blin) is a bispecific monoclonal antibody, activating autologous effector T-cells and redirecting them against CD19-positive malignant cells. This leads to polyclonal effector T-cell expansion which is the necessary component of its antitumour mechanism. Recent reports indicated promising antitumour activity of Blin in relapsed/refractory (rr) B-cell precursor acute lymphoblastic leukemia (BCP-ALL). However, approximately half of these patients do not achieve minimal residual disease (MRD) response. Thanks to recent advances in next generation sequencing (NGS) of immunoglobulin and T-cell receptor gene rearrangements the deep and comprehensive evaluation of expanded T-cell repertoire on Blin treatment is now possible.

Aims: To compare the differences in TRB repertoire diversity and composition between two groups of patients with rr ALL: 1) responders: reaching MRD negativity at the latest at day 29 of 1. Blin cycle (C1D29), and 2) persisters: with quantifiable MRD positivity (>0.01%) at C1D29, or with MRD >1% at cycle 1 day 15 (C1D15) if C1D29 sample is not available.

Methods: We used NGS to investigate TRB repertoire in bone marrow samples (114× at time of screening (scr), 74× C1D15, 59× C1D29) of 114 rrPh-negative BCP-ALL patients (median age: persisters 47; responders 42; p-value=0.81). Patients received Blinatumomab within the phase II trial (MT103-211). Sequencing libraries were prepared using 100ng of DNA via 2-step PCR and sequenced on the Illumina MiSeq (2 x 250bp) with a median coverage of 117,563 reads (range 59,512 - 447,767 reads) per sample. In the first PCR virtually all TRB rearrangements present in the investigated sample were amplified using universal V(D)- and J-regions primers. In the second step, sequencing adaptors and sample-specific barcodes were added. Annotation of V(D)- and J-regions of TRB sequences was performed using ARRestInterrogate (Bystrý, Bioinformatics, 2016). Diversity of TRB repertoire within patient groups and time points was expressed as the Shannon index, using the R-package vegan. Analysis of variance was employed to assess statistically significant differences in diversity between groups and time.

Results: Diversity of TRB repertoire (Figure 1) was significantly higher in responders compared to persisters at time of scr (p=0.02) and at C1D29 (p=5.47E-6). Patients in the persisters group had significantly higher blast counts, which is in accordance with previously published data (Topp, The Lancet Oncology, 2015). The increase of diversity between scr and C1D29 of Blinatumomab treatment was sharp and highly significant in responders (p=3.96E-6), but not statistically significant in persisters (p=0.4).
Summary/Conclusions: We showed that Blin responders have significantly higher TRB repertoire diversity at scr compared to persisters and that the repertoire expansion during Blin treatment is sharper in responders. Other repertoire characteristics did not differ significantly between groups. Further studies on larger patient cohorts are necessary in order to elucidate whether the response to treatment can be predicted by repertoire diversity at scr. Amplicon NGS is a useful tool for monitoring of T-cell repertoire. Development, standardization, and validation of TRB primer sets is in progress within Euro-Clonality-NGS Consortium.

DISCONTINUING ANTIBACTERIAL THERAPY AFTER APYREXIA AND CLINICAL STABILITY REGARDLESS OF NEUTROPHIL COUNT IN FEBRILE NEUTROPENIA IS SAFE AND REDUCES EXPOSITION TO ANTIBIOTICS (HOWLONG RANDOMIZED TRIAL)

I. Espigado1,*, M. Aguilar-Guisado2, A. Martin-Peña3, C. Gudio3, J. Falantes1, L. Vazquez1, I. Montero1, M.L. Martino1, R. Parody1, J. Gonzalez-Campos1, S. Garzon2, C. Calderon-Cabrera1, P. Barba4, N. Rodriguez-Torres1, M. Rovira1, J.A. Perez-Simon1, J.M. Cisneros-Herreros5

Background: In neutropenic patients with unexplained fever the classical approach is maintaining the empirical antibacterial therapy (EAT) until neutrophil recovery. This strategy may result in unnecessarily prolonged EAT favoring bacterial resistance, organ toxicity and damage to microbiota. Nevertheless, the available scientific evidence supporting the alternative approach of stopping EAT before neutrophile recovery is moderate.

Aims: To investigate if a clinical approach (based on apyrexia and clinical recovery) is better than and as safe as the standard criteria (recovery from neutropenia) to decide the discontinuation of EAT.

Methods: After local Ethical Committee approval, a randomized, controlled, multicenter, open-labeled phase IV clinical trial was performed (EudraCT: 2011-005152-34). Study period: May-2012 to May-2016. Inclusion criteria: a) Adult patients (≥18 years); b) Hematologic malignancy or autologous or allogeneic hematopoietic stem cell transplantation (SCT) recipients; c) High risk febrile neutropenia (FN) d) Informed consent signed. Exclusion criteria: etiological diagnosis of FN. Patients were randomized 72 hours after fever onset to: 1. Experimental group (EG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h (independently of neutrophil count) or 2. Control group (CG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h, plus c) >0.5x106/L neutrophils. Follow-up: 28 days from EAT. Primary (efficacy) end-point was number of EAT-free days. Secondary (safety) end-points were total days of fever and crude mortality.

Results: One hundred and fifty seven patients were included (EG 78 and CG 79). There were no differences in baseline characteristics or clinical presentation between groups. The most frequent underlying conditions were induction/re-induction chemotherapy for acute leukemia (n=42; 26,7%), autologous SCT (n=42, 45,8%), and allogeneic hematopoietic stem cell transplantation (SCT) recipients; c) High risk febrile neutropenia (FN) d) Informed consent signed. Exclusion criteria: etiological diagnosis of FN. Patients were randomized 72 hours after fever onset to: 1. Experimental group (EG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h (independently of neutrophil count) or 2. Control group (CG): EAT discontinuation if a) apyrexia ≥72 h, plus b) clinical recovery ≥72 h, plus c) >0.5x106/L neutrophils. Follow-up: 28 days from EAT. Primary (efficacy) end-point was number of EAT-free days. Secondary (safety) end-points were total days of fever and crude mortality.

Summary/Conclusions: In hematological patients with febrile neutropenia of unknown origin the discontinuation of empirical antibacterial therapy after 72 hours of apyrexia and clinical recovery regardless of neutrophils count is safe and reduces unnecessary exposure to antibiotics.

S805
CONJUGATED PNEUMOCOCCAL VACCINE TRIGGERS A BETTER IMMUNE RESPONSE THAN POLYSACCHARIDE PNEUMOCOCCAL VACCINE IN PATIENTS WITH CHRONIC LYMPHOUCYTIC LEUKEMIA: A RANDOMIZED STUDY DONE BY THE SWEDISH CLL GROUP

1Section of Heamatology, Institution of Medical Sciences, Uppsala, 2Department of Medical Sciences, Orebro University Hospital, Orebro, 3Falun Hospital, Falun, 4Institution of Clinical Sciences, Faculty of Medicine, Lund University Hospital, Lund, 5Hematology and Coagulation Section, Sahlgrenska University Hospital, Göteborg, 6Eskilstuna Hospital, Eskilstuna, 7Karlstad Hospital, Karlstad, 8Section of Haematology, Institution of Medical Sciences, Uppsala, 9Department of Medicine, Unit of Hematology, Karolinska Institute and University Hospital, Huddinge, Sweden

Background: Patients with CLL have an increased risk for infection and Streptococcus pneumoniae is one of the most common pathogens with high morbidity. Patients with CLL are known to respond poorly to the traditionally used polysaccharide vaccines. Conjugation of polysaccharide to protein carriers renders a thymus-dependent, memory-inducing and more immunogenic vaccine. In patients with CLL, there is no consensus on a recommendation for pneumococcal vaccination, due to a lack of comparative studies.

Aims: To determine if patients with untreated chronic lymphocytic leukemia (CLL) benefit from vaccination with a 13-valent conjugated pneumococcal vaccine (PCV13), Prevenar13®, compared with a 23-valent capsular polysaccharide vaccine, Pneumovax®, in terms of immune response.

Methods: 128 treatment naïve CLL patients from eight hematology clinics in Sweden were randomized to vaccination with PCV13 (n=63) or PPSV23 (n=65) after stratification by IgG levels and CLL clinical stage (Rai). Blood samples for evaluation of immune response were obtained at baseline, at one and at six months after vaccination. Analyses for each of the 12 pneumococcal serotypes common for PCV13 and PPSV23 were performed by opsonophagocytic assay (OPA) and enzyme-linked immunosorbent assay (ELISA).

Results: PCV13 elicited a superior immune response than PPSV23 in 10/12 serotypes one month after vaccination and in 5/12 serotypes six months after vaccination, measured as OPA geometric mean titers (GMTs). Geometric mean concentrations of serotype-specific IgG antibodies elicited by PCV13 as measured by ELISA, were higher than those elicited by PPSV23 in half of the common serotypes, both after one and six months. The proportion of patients with good response (defined as response in 8 of 12 common serotypes according to predefined response criteria) was higher in PCV13 recipients than in PPSV23 recipients after one month (40% vs 22%, p=0.034) as well as after six months (33% vs 17%, p=0.041). Never did PPSV23 trigger a better immune response for any of the serotypes, than PCV13, regardless of analysis. For two of these serotypes, OPA GMTs were lower in the six months than at the one-month follow up. Negative predictive factors for vaccination response were hypogammaglobulinemia and long disease duration. Both vaccines were well tolerated.

Summary/Conclusions: In patients with previously untreated CLL, the efficacy of a conjugated pneumococcal vaccine is better than that of the traditional polysaccharide vaccine, for many serotypes common for the two vaccines. PCV13 should be considered as a part in vaccination programs against Streptococcus pneumoniae for these patients and administered as early as possible during the course of the disease.

S806
INFECTION-RELATED MORTALITY AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: AGE, CMV AND PRE-TRANSPLANT LEVELS OF IGA/IGM PREDICT IRM IN A NEW CLINICO-BIOLOGICAL SCORING SYSTEM

A. Forcina1,*, P. Rancicola2, V. Marascol1, R. Greco1, M.T. Lupo Stanghellini1, M. Garrabba1, M. Marchia1, C. Di Serro2, M. Bernardi1, J. Peccatori1, C. Corti1, A. Bondanza1, F. Ciceri1
1RCCS San Raffaele Scientific Institute, 2Vita-Salute San Raffaele University, Milan, Italy

Background: Infection-related mortality (IRM) is a major challenge after allogeneic hematopoietic stem cell transplantation (allo-HSCT).

Aims: The aim of this study was to develop a scoring system predicting IRM based exclusively on pre-transplant data.

Methods: A total of 589 adult patients receiving allo-HSCT were studied (Jan 2007-Mar 2016). The set of patients (n=273, Jan 2012-May 2015) the ROC curve analysis defined the optimal cut-offs predicting 100-day IRM for continuous data. All clinical and biochemical variables were challenged in a multivariate analysis and a 3-tiered weighted score was elaborated and tested firstly in a retrospective validation set (n=219, Jan 2009-Dec 2011) and then in a prospective validation set (n=97, Jun 2016-Nov 2016).

Results: Median follow-up was 43 months (range 1-85). Acute leukemia was the main indication to transplant, accounting for 60% (n=356) of patients. The majority of the patients received an alternative-donor transplant (44% a HLA-haploidentical, 37% a matched unrelated donor). Forty-seven percent (n=277) of patients had advanced diseases. Multivariate analysis revealed age >60 yrs (P=0.003), CMV host/donor serostatus different from negative/negative (P<0.001) and pre-transplant levels of IGA <1.11 g/L (P=0.004) and IGM <0.305 g/L (P=0.028) as the only independent predictors of increased IRM. Noticeably, these associations were independent from disease type or status, donor type, intensity of conditioning, in vivo T or B-cell depletion or from previous colonization by multidrug-resistant bacteria. According to the proposed IRM score, patients were divided into 3 classes: low (<10.17 points), intermediate (10.17-11.11 points) or high-risk (>11.11 points). In the training set, 100-day and 2-yrs IRM were 5% (95% CI 2-10) and 9% (95% CI 4-16) for low-risk, 11% (95% CI 5-18) and 23% (95% CI 14-33) for intermediate-risk, and 16% (95% CI 16-37) and 41% (95% CI 28-53) for high-risk patients, respectively (P=0.001). In the prospective validation set, 100-day and 2-yrs IRM were 7% (95% CI 3-14) and 14% (95% CI 8-26) for low-risk, 17% (95% CI 10-26) and 23% (95% CI 15-33) for intermediate, and 28% (95% CI 15-42) and 33% (95% CI 19-44) for high-risk patients, respectively (P= 0.044), with a c-index of 0.608 (Figure 1). In the prospective validation set, only 100-day IRM was calculated due to a shorter follow-up, being of 0%, 3% (95% CI 0-13) and of 14% (95% CI 3-33) for low, intermediate and high-risk patients (P=0.003). Additionally, in both training and retrospective validation sets (n=492), the 2-yrs OS was different among the 3 groups, being 59% (95%CI 52-67), 50% (95%CI 43-59) and 37% (95%CI 29-48) for low, intermediate and high-risk groups, respectively (P=0.0001). In the prospective validation set, only 100-day OS was evaluated, being of 95% (95%CI 88-100), 91% (95%CI 82-100) and 80% (95%CI 65-100), respectively (P=0.003). Out of a total of 125 infection-related deaths, 94/129 (73%) were attributed to bacteria, 22/129 (17%) to viruses, 11/129 (8%) to fungi and 2/129 (8%) to parasites.

Figure 1.

Summary/Conclusions: This new clinic-biological score based on age, CMV serostatus and levels of IGA and IGM, may contribute to the prompt identification of patients at higher risk of fatal infections prior to allo-HSCT, thus promoting post-transplant personalized intensive active surveillance strategies and immune-intervention approaches to improve the overall outcome of transplant.

A multicentric Italian study in currently in on the way for the external validation of these results.

Background: CMV remains a common complication of HCT, yet no antiviral drug suitable for prophylaxis is available in HCT. LET is a first-in-class drug
that inhibits the CMV terminase complex. A dose-escalation phase 2 trial showed that LET prophylaxis for up to 12 weeks post-HCT was effective with a safety profile similar to placebo.

Aims: To compare LET prophylaxis to placebo for the prevention of clinically significant CMV infection (CS-CMV), defined as CMV disease or CMV viremia leading to preemptive treatment (PET) in a Phase III randomized, double-blind, placebo-controlled trial.

Methods: CMV seropositive HCT recipients 18 years or older who had undetectable plasma CMV DNA within 5 days of randomization were eligible (full eligibility at clinicaltrials.gov, NCT02137772). Subjects had to start treatment by Day+28 post-HCT. Subjects were randomized 2:1 to receive LET or placebo PO, 9% through Week 14 (Day +100) post-HCT, stratified by study site and high or low CMV disease risk. LET was dosed at 480 mg/d (or 240 mg/d if on cyclosporine due to drug-drug interaction). Subjects were assessed weekly through Week 14, biweekly through Week 24, and every other month through Week 48 after HCT. Plasma obtained at each visit was assayed for CMV DNA in a central laboratory. Subjects who developed CS-CMV discontinued study drug and received anti-CMV treatment. Local CMV assay results could be used to start PET. The primary endpoint was the stratum-adjusted proportion of subjects with CS-CMV through Week 24 post-HCT among subjects with undetectable CMV DNA at randomization; subjects who discontinued the study for any reason or with missing data at Week 24 were considered failures. All adverse events (AEs) were analyzed through 14 days after the last dose of study drug.

Results: From June 2014 to March 2016, 565 randomized subjects received study treatment; 31% were at high CMV disease risk. 50% subjects received myeloablative conditioning, 35% received ATG. Donors included 14% mismatched unrelated, 13% haploidentical and 4% cord blood. Study arms were balanced. Subjects began study drug a median of 9 days post-HCT; 37% had engrafted prior to start. Of 495 treated subjects with undetectable CMV DNA at randomization, fewer subjects developed CS-CMV or were considered failures in the LET arm (122/325, 38%) compared to placebo (103/170, 61%; p<0.0001) by Week 24 post-HCT. Figure 1 shows the time to CS-CMV analysis. The most common AEs (LET, placebo) were GVHD (39%, 39%), diarrhea (26%, 25%), and nausea (27%, 23%). More frequent vomiting (19%, 14%), edema (19%, 13%), atrial arrhythmias (10%, 5%), and ALT levels >5xULN (4%, 2%) was noted in LET-treated subjects; no increased myelotoxicity or nephrotoxicity was observed. The Week 24 all-cause mortality was 10% for LET recipients and 15% for placebo recipients.

Summary/Conclusions: Letermovir prophylaxis was effective in reducing clinically significant CMV infection, was overall well tolerated, and provides a new approach to CMV prevention after HCT.

Efficacy and Safety of Defibrotide to Treat Hepatic Veno-Occlusive Disease/Sinusoidal Obstruction Syndrome Post-Chemotherapy: A Post Hoc Analysis of Final Data of an Expanded-Access Protocol

N. Kernan1, P. Richardson1,2, S. Grupp3, J. Antin4, Y. Messinger5, W. Liang6, R. Ryan1, R. Hume1, W. Tappe4, R. Soiffer4

1Pediatric Bone Marrow Transplantation Service, Memorial Sloan Kettering Cancer Center, New York, New York; 2Jerome Lipper Multiple Myeloma Center, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA; 3Pediatric Oncology, The Children’s Hospital of Philadelphia, Philadelphia, PA; 4Stem Cell/Bone Marrow Transplantation Program, Division of Hematologic Malignancy, Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA; 5Children’s Hospitals and Clinics of Minnesota, Minneapolis, MN; 6Jazz Pharmaceuticals, Inc., Palo Alto, CA

Background: Hepatic VOD/SOS, which may be unpredictable and potentially life-threatening, is typically considered a complication of hematopoietic stem cell transplantation (HSCT), and VOD/SOS with multi-organ dysfunction (MOD) may be associated with >80% mortality. Defibrotide is approved to treat severe hepatic VOD/SOS post-HSCT in the European Union and to treat hepatic VOD/SOS with renal or pulmonary dysfunction post-HSCT in the United States. However, VOD/SOS can occur after chemotherapy without HSCT.

Aims: To perform a post hoc analysis of final data on safety and response to defibrotide in patients developing VOD/SOS after primary chemotherapy without HSCT.

Methods: In an expanded-access protocol for patients with VOD/SOS post-HSCT or chemotherapy, with or without MOD (renal and/or pulmonary dysfunction), defibrotide 25 mg/kg/d (4 divided doses of 6.25 mg/kg) was given a recommended ≥21 days after patients provided informed consent. Post-chemotherapy subgroup survival was analyzed post hoc from the day defibrotide was started (days 0–30 after start of chemotherapy) for 70 days (because follow-up data were collected for 100 days post-chemotherapy).

Results: Of 1154 VOD/SOS patients receiving defibrotide, 137 (12%) developed VOD/SOS post-chemotherapy without HSCT. Among the 82 patients (38 with MOD) treated with DF by day 30 after start of chemotherapy, median age was 7.5 years (range, 0–68 years) and 66 (81%) were pediatric patients (≥16 years of age). Among pediatric patients, 15% were age 0–23 months, 74% were 2–11 years and 11% were 12–16 years. Most common primary diseases were acute lymphocytic leukemia (50%), acute myeloid leukemia (13%), and neuroblastoma (6%). Kaplan-Meier estimated survival at Day +70 was 74% overall (95% CI, 63–82%), 86% (49–79%) in patients with MOD and 81% (66–90%) in patients without MOD. By age subgroup, Kaplan-Meier estimated survival at Day +70 was 80% (95% CI, 68–88%) in pediatric patients (Figure 1) and 50% (95% CI, 25–71%) in adults. Adverse events (AEs) were reported in 54/82 patients (66%), Hemorrhagic AEs (≥2%) were pulmonary (6%), epistaxis or mouth (4%), and hematochezia (2%). There were 22 (27%) patients with AEs assessed as being at least possibly related to defibrotide, the most common (≥2%) were pulmonary or mouth hemorrhage (4% each) and hematochezia, nausea, encephalopathy, epistaxis, or hypotension (2% each). Related AEs led to discontinuation in 6 patients and were associated with 1 death (pulmonary hemorrhage, hypotension).

Summary/Conclusions: The 74% survival rate at Day +70 in patients with VOD/SOS receiving defibrotide within 30 days of starting chemotherapy (81% in patients ≥16 years of age) is clinically encouraging. Of note is the 66% survival rate in patients with MOD. The defibrotide safety profile was consistent with that previously reported in the overall population of this expanded-access protocol. LACK OF THE FERROPTOSIS INHIBITOR GPX4 IN ERYTHROID CELLS CAUSES A BLOCK IN RETICULOCYTE MATURATION AND A HYPOXIC SIGNATURE WITH IMPAIRED HEPCIDIN REGULATION

1MPMU - Molecular Medicine Partnership Unit, 2Department of Pediatric Haematology, Oncology and Immunology, University of Heidelberg, Heidelberg, 3Institute of Experimental Cancer Research, University Hospital Ulm, Ulm, 4Institute of Clinical Molecular Biology and Tumor Genetics, Helmholtz Zentrum München, 5Institute for Stroke and Dementia Research, Klinikum der Universität München, Munich, Germany, 6Department of Biosystems Science and Engineering, Swiss Federal Institute of Technology in Zurich, Basel, Switzerland, 7Institute for Tumor Biology and Experimental Therapy, Georg-Speyer-Haus, Frankfurt, 8Research Unit Analytical Pathology, 9Institute of Molecular Immunology, 10Institute of Experimental Genetics, 11Institute of Developmental Genetics, Helmholtz Zentrum München, Munich, Germany

Background: GPX4 is a selenoprotein belonging to the family of the glutathione peroxidases, a class of enzymes involved in cellular defence against oxidative stress. This enzyme is essential for life since it is the only peroxidase able to use lipid peroxides as substrate. Mice constitutively lacking GPX4 die at embryonic day 18.5 due to a block in tissue-specific aération in neurons and T-cells cause neurodegeneration and impaired immune response. Recent studies have identified GPX4 as the main regulator of ferroptosis, an iron-dependent ROS-mediated form of nonapoptotic cell death. Erythrocytes are highly specialized cells that utilize a large amount of iron to bind and deliver oxygen to all tissues. Being constantly exposed to oxygen, erythroid cells need to continuously fight against oxidative stress by expressing a variety of antioxidant enzymes, including GPX4. Iron availability for erythropoiesis depends on systemic iron levels which are regulated via the hepcidin/ferroportin regulatory system. Hepcidin binding to the iron exporter ferroportin reduces systemic iron export regulating body iron levels. In hypoxic conditions the erythrocyte hormone ErFe suppresses hepcidin synthesis to provide iron for the elevated erythropoietic demand.

Aims: The aim of this study is to identify how the lack of GPX4 in the hematological compartment affects iron homeostasis.

Methods: Lethally irradiated C57BL6 female mice were reconstituted with bone marrow cells from Gpx4fl/fl; Rosa26-CreERT2or Gpx4wt/wt; Rosa26-CreERT2 and allowed to recover for 8 to 10 weeks. GPX4 deletion in the hematopoietic system was induced by feeding tamoxifen citrate for 3 weeks and blood and organs were drawn at 3 and 6 weeks after terminating the tamoxifen-containing diet. Erythroid cells have been analysed in FACS. Serum iron levels have been assessed using the SFBC and UIBC iron kits (Biolabo). Gene expression analysis has been performed using SYBR-green qRT-PCR. Circulating Hepcidin has been measured with a colorimetric assay. All animal experiments were approved by and conducted in compliance with institutional guidelines. In vivo studies. RESULTS: Compared to Gpx4fl/fl; CreERT2 controls, Gpx4fl/fl; CreERT2 transplanted mice lacking GPX4 in the haematological compartment show a decrease in the number of red blood cells, haemoglobin and haematocrit. Reticulocytes and reticulocyte count measurement revealed a strong increase in this population, suggesting that the erythropenia could be due to a block in the reticulocyte maturation. Reticulocytes FACs characterization revealed a shift towards a more immature population while electron microscopy analysis showed an accumulation of unphagocytosed vesicles containing remnants of mitochondria. Analysis of the spleen revealed extramedullary erythropoiesis. The anaemia and the erythropenia trigger a hypoxic signature hallmarking by an increase in circulating EPO and increased ErFe expression. However, both hepatic mRNA analysis and circulating protein measurement failed to show alteration in hepcidin production. Analysis of the liver showed an increase in non-heme iron content and in the lipid peroxidation causing an elevated mRNA and protein expression of heme oxygenase 1. Hepatic ferritin and ferroportin are also increased as a consequence of the increased iron content.

Summary/Conclusions: Our data show for the first time that the presence of GPX4 in the haematological compartment is essential for the proper hepcidin downregulation upon ErFe stimulation. This finding opens new insights in the mechanism that regulate hepcidin during hypoxia.

IDENTIFICATION OF GUANOSINE 5'-DIPHOSPHATE AS POTENTIAL IRON MOBILIZER: PREVENTING THE HEPCIDIN-FERROPORTIN INTERACTION AND MODULATION OF THE INTRACELLULAR IL-6-STAT-3 PATHWAY

S. Angmo1, N. K. Singha2

1Food science and Nanobiotechnology, 2National Food Biotechnology, Mohali, 3Mumbai, India

Background: Anemia of inflammation (AI) is one of the most common manifestations of iron deficiency in the patients with inflammatory conditions. AI is responsible for hypoferrremia, with consequent iron-restricted erythropoiesis and high level of hepcidin, which stimulate the internalization of ferroportin (FPN) transporter. Therefore, inhibiting hepcidin-mediated FPN degradation can be an important strategy to ameliorate AI.

Aims: To increase iron bioavailability we selected a Novel compound against hepcidin action through natural compound libraries that might provide a new alternative approach to increase iron absorption for prevention of hepcidin-mediated FPN internalization and to ameliorate the anemic state with different insilico, invitro and invivo studies. Methods: A systematic approach involving in silico, in vitro and in vivo studies was employed to identify hepcidin inhibiting agents. To identify a potent hepcidin-binding agent, natural compounds were screened using molecular docking and dynamics simulations and further investigated on cell lines (GFP-FPN, Caco-2, HepG2) using flow cytometry and western blotting. Normal or turpentine induced anemic mice were used in the associated studies.

Results: The virtual screening via molecular modelling showed that GDP as a potent hepcidin-binding agent as shown in the Figure 1A. In vitro studies revealed that GDP significantly increased ferroportin stabilization in GFP-FPN cell lines (Figure 1C) and Invivo results showed that co-administration of GDP and ferrous sulphate (FeSO4) significantly improved the turpentine-induced anemic state with increase in haemoglobin level (Figure 1B).

Figure 1.

Summary/Conclusions: AI as a normocytic anemia, common among patients with chronic infection and inflammatory disorders. We found that GDP molecule have higher contribution to the stability of hepcidin-GDP complex and thus blocks its interaction with FPN. The results support the novel hypothesis that GDP along with iron supplement regime can overcome the binding of hepcidin from interaction with FPN that would be an effective treatment for AI.

UNRAVELING THE MOLECULAR PATHOGENESIS OF INEFFECTIVE ERYTHROPOIESIS IN CONGENITAL DysERYTHROPOIESIS Anemia TYPE II: RAPID EVALUATION OF RAP-011 TREATMENT

G. De Rosa1, I. Andolfi1, I. Fanina1, A. Gambale1, R. Marra1, B. E. Rosato1, A. Iolascon1, R. Russo1

1Molecular Medicine and Medical Biotechnology, CEINGE - Biotecnologie Avanzate, Naples, Italy

Background: Congenital Dyserythropoietic Anemias (CDAs) are subtypes of bone marrow failure syndromes, hallmarkled by ineffective erythropoiesis. The most common form is CDA type II (CDAII), showing moderate/severe anemia, relative reticulocytopenia, jaundice, and iron overload. It is inherited as autosomal recessive disorder due to large deletion mutations in SEC23B gene. More than 300 CDAII cases and 80 causative mutations have been described so far. Despite this high allelic heterogeneity, two variants, R14W and E109K, represent more than 50% of the mutational events. To date, treatments for CDAII patients consist of supportive therapy, such as erythrocyte transfusions, or bone marrow transplantation or splenectomy in transfusion-dependent cases. Recently, members of TGF-β superfamily have been studied as potential regulators of erythropoiesis, especially the growth differentiation factor 11 (GDF11). Through the binding of specific receptors, GDF11 leads to an inhibited late-stage erythropoiesis. Indeed, two GDF11 inhibitors, ACE-011 and ACE-536 have demonstrated promising preclinical and clinical parameters. Studies with the mouse counterpart of ACE-011, RAP-011, on mouse model of β-thalassemia showed increased differentiation of erythroid cells, improvement of anemic condition and reduced iron overload in treated mice.

haematologica | 2017; 102(s2) | 333

Madrid, Spain, June 22 – 25, 2017
**Aims:** The main aim of our study is to assess the effects of RAP-011 on different cell types of CDAII treated with ESA.

**Methods:** We measured circulating GDF11 levels in CDAII patients and healthy controls (HC) by western blot (WB). To assess the effectiveness of RAP-011 (provided by Celgene Corporation) in vitro, we established two different cellular model systems: (i) K562 cells stably silenced SEC23B by shRNA carried in lentiviral vector (LV) (ii) K562 ESAs stably overexpressing SEC23B-WT and the two variants, R14W and E109K. In vitro treatment has been performed at 0, 3, and 6 days of erythroid differentiation by hemin+GDF11 in presence or absence of RAP-011 in K562 cells stably silenced for SEC23B.

**Results:** WB and subsequent densitometric analysis showed an increase of GDF11 overexpression in SEC23B silenced K562 cells, at 3 and 6 days of erythroid differentiation. The given network was not fully connected, we performed pairwise comparisons on the four subnetworks with 2 treatments each. On the one hand, reticulo-endothelial macrophages are central for the regulation of iron homeostasis. The phagocytosis and degradation of senescent red blood cells (RBC) by macrophages enable efficient recycling of iron and the maintenance of systemic iron balance. On the other hand, iron exerts multiple effects on macrophage polarization and functionality. Macrophages exhibit a remarkable functional plasticity, reflected in their capacity to integrate diverse signals from the microenvironment and acquire distinct phenotypes. Macrophage polarization has been shown to dictate the expression of iron-regulated genes and determine cell iron handling. Authors showing evidence that iron availability itself has significant effects on immune effector functions and macrophage polarization. However, it is still unclear how different iron sources and acquisition pathways affect macrophage phenotypes.

**Methods:** To investigate this aspect, we analyzed both in vivo and in vitro, and compared the phenotypic switching of macrophages induced by different iron sources, including heme and iron, as well as hemolitic or intact RBCs.

**Results:** Hemolitic RBCs, free heme and iron-dextran treatment in mice shape macrophage polarization towards an M1-like pro-inflammatory phenotype. Splenic and hepatic macrophages from treated mice show an increased expression of pro-inflammatory cytokines (IL-6, TNFα), and a reduced expression of anti-inflammatory markers (M2). Moreover, in these cells, the expression of M1 markers such as CD86 and CD80 is strongly increased, whereas the expression of M2 markers such as CD206 and CD163 is significantly suppressed. Consistent results have been obtained treating bone marrow-derived macrophages with hemolytic RBCs, free heme and Fe-NTA. Importantly, the addition of the heme scavenger hemopexin and the iron carrier transferrin or the chelator deferoxamine fully abolish the ability of free heme and iron to trigger M1 polarization. On the contrary, RBC transfusions in mice shape macrophages towards an M2-like anti-inflammatory phenotype. After three transfusions, serum iron and hepcidin levels significantly rise, and tissues as well as macrophages are heavily iron loaded. Macrophages show a drastic suppression of M1 markers and inflammatory cytokines, and induction of M2 markers. Interestingly, repeated transfusions result in extensive macrophage death and new macrophage recruitment in both liver and spleen.

**Summary/Conclusions:** Collectively, these results suggest that the source and route of iron acquisition have a key role in shaping macrophage phenotype, and demonstrate a dynamic role of iron overload in determining macrophage polarization and function. When iron is provided in the form of free heme or non-transferrin-bound iron, it exerts a clear pro-inflammatory effect on macrophages; whereas when provided via a controlled physiological acquisition pathway such as erythropoietin, it dampens macrophage immune effector functions, being its clearance activity more active.

Figure 1.

**Summary/Conclusions:** While our analyses show that ESA use increases mortality and risk for thromboembolic events, there is no evidence that iron supplementation alters these risks. However, addition of iron to ESA does further decrease the need for RBC-transfusions compared to ESA alone. Further investigation, with regards to iron type and route of administration may yield further distinct results.

This project was funded by the Federal Ministry of Education and Research, grant number: 01KG1405
Our findings have potential implications, on one side, for hemolytic diseases, where RBC hemolysis and elevated circulating heme might promote a detrimental chronic inflammatory state, and, on the other one, for infectious diseases, where free heme and iron, released upon cell damage, might boost inflammation and enhance resistance to infections. Conversely, accelerated RBC clearance, by suppressing macrophage pro-inflammatory response, is rather expected to promote infections in transfused individuals.

Gene therapy, cellular immunotherapy and vaccination 2

A PHASE 3 STUDY TO EVALUATE SAFETY AND EFFICACY OF LENTIGLOBIN GENE THERAPY FOR TRANSFUSION-DEPENDENT B-THALASSEmia IN PATIENTS WITH non-B0/B0 GENOTYPES: THE NORTHSTAR-2 (HGB-207) TRIAL

1UCSF Benioff Children’s Hospital and Research Center, Oakland, 2Lurie Children’s Hospital, Chicago, United States, 3Ramathibodi Hospital, Bangkok, Thailand, 4Children’s Hospital of Philadelphia, Philadelphia, United States, 5IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, 6University College London Hospital, London, United Kingdom, 7Medizinische Hochschule Hannover, Hannover, Germany, 8Great Ormond Street Hospital, London, United Kingdom, 9Hôpital d’enfants de La Timone, Marseille, France, 10General Hospital of Thessaloniki, Thessaloniki, Greece, 11bluebird bio, Cambridge, United States

Background: Standard treatment for transfusion-dependent β-thalassemia (TDT) includes regular red blood cell (RBC) transfusions and management of iron overload. Successful autologous hematopoietic cell transplantation (HCT) can eliminate RBC transfusions and, eventually, chelation. However, due to transplant-related risks such as graft-versus-host disease (GVHD), as well as donor constraints, HCT is rarely an option for TDT patients. By transferring a functioning copy of the β-globin (HBB) gene into hematopoietic stem cells (CD34+ cells) and re-infusing the modified cells, gene therapy may be an alternative one-time treatment available to all patients with TDT, without risks of GVHD. LentiGlobin gene therapy is an investigational treatment consisting of autologous CD34+ cells transduced with the BB305 lentiviral vector. The Northstar (HGB-204) phase 1/2 clinical study of LentiGlobin gene therapy for TDT included 18 patients who received LentiGlobin drug product (DP). As of September 2016, all patients in Northstar with non-β0/β0 genotypes and at least 12 months of follow-up stopped transfusions (median total hemoglobin [Hb] 11.2 [range 9.4–12.2] g/dL) and there was >60% reduction in transfusions in patients with a β0/β0 genotype. The safety profile was consistent with autologous HCT. In this initial study, the average number of therapeutic gene copies per CD34+ cell in the DP (i.e. DP vector copy number per diploid genome or DP VCN; median 0.7, range 0.3 to 1.5) correlated with peripheral HbAT87Q expression at 6 months (ASH, 2016). In an effort to optimize the proportion of patients able to discontinue blood transfusions to achieve “transfusion independence” in all patients and increase unsupported Hb levels after treatment, the manufacturing process for LentiGlobin DP was modified to increase the DP VCN and the proportion of genetically modified cells. Northstar-2 (HGB-207) is a recently initiated phase 3 study using this new manufacturing process in patients with TDT and a non-β0/β0 genotype.

Aims: To evaluate safety and efficacy of autologous HCT with LentiGlobin DP in patients with TDT and a non-β0/β0 genotype.

Methods: After providing informed consent, patients 12 to 50 years of age (N=15) will have CD34+ cells collected via mobilization and apheresis. After individualized DP manufacture and satisfaction of release criteria, the patient will receive myeloablative conditioning with single-agent busulfan (starting dose 3.2 mg/kg/day for 4 days, with target AUC 4500 [range 4000–5000] µM*min) followed by infusion of LentiGlobin DP. Patients will be followed for engraftment, safety and efficacy endpoints for 2 years after infusion; patients will then have the option to enroll in a 13-year follow-up study. The primary endpoint is the proportion of patients who achieve transfusion independence after DP infusion, defined as total Hb ≥9g/dL without RBC transfusions for a continuous period of ≥12 months. Secondary endpoints include time to neutrophil engraftment, adverse events, and biological parameters including VCN in peripheral blood and levels of HbAT87Q over time.

Results: As of March 1, 2017, two 20-year-old females with β0/βE genotypes have been treated with LentiGlobin DP in the Northstar-2 trial. The DP VCN was 2.9 and 2.4 copies per diploid genome, respectively. Outcomes in all evaluable patients will be presented.

Summary/Conclusions: Results from the Northstar-2 study will provide data on safety and demonstrate the extent to which an increase in LentiGlobin DP VCN yields normalization of total Hb and consistently achieves transfusion independence in patients with TDT of non-β0/β0 genotypes. Optimizing DP VCN has the potential to improve outcomes across all TDT genotypes treated by investigational LentiGlobin gene therapy.

S815

CIS IS A POTENT CHECKPOINT IN NK CELL ANTI-LEUKEMIA IMMUNITY

N. Huntington1,*
1Molecular Immunology, Walter and Eliza Hall, Parkville, Australia

Background: The detection of leukemia by natural killer (NK) cells is controlled
by the integration of signals from activating and inhibitory ligands and from cytokines such as IL-15.

Aims: We set out to identify the negative regulators of NK cell function in order to understand why immunogenic tumours and leukaemia can evade or overcome NK cell detection and killing.

Methods: We used a multidisciplinary approach including RNAseq, Mass Spectrometry, structural biology, kinase enrichment and activity assays, NK cell in vitro analysis, biochemistry and de novo/experimental tumour/leukaemia in vivo models.

Results: We identified cytokine-inducible SH2-containing protein (CIS, encoded by Cish) as a critical negative regulator of IL-15 signaling in NK cells. Cish was rapidly induced in IL-15-activated NK cells and deletion of Cish rendered NK cells hypersensitive to IL-15, as evidenced by enhanced proliferation, survival, IFN-gamma production and cytotoxicity toward tumors. This was associated with increased JAK-STAT signaling in NK cells in which Cish was deleted. Correspondingly, CISH interacted with the tyrosine kinase JAK1, inhibiting its enzymatic activity and targeting JAK for proteasomal degradation. Cish/-/- mice are resistant to leukaemia in vivo, and this was independent of MHC-I expression.

Summary/Conclusions: Our data uncover a potent intracellular checkpoint in NK cell-mediated tumor immunity and suggest possibilities for new cancer immunotherapies directed at blocking CISH function.

S816

GENERATION OF MEMORY STEM T CELLS MODIFIED WITH A NOVEL OPTIMIZED CD30-SPECIFIC CHIMERIC ANTIGEN RECEPTOR FOR THE TREATMENT OF CD30+ T-CELL MALIGNANCIES

Background: Peripheral T-cell lymphomas (PTCL) represent the most aggressive form among non-Hodgkin lymphomas with a very poor prognosis (5-year survival of 30%), demanding innovative novel treatment strategies. Adoptive immunotherapy with chimeric antigen receptor (CAR) engineered T cells has demonstrated its therapeutic potential in advanced hematological malignancies. However, its application to PTCL remains a formidable challenge mainly due to a lack of truly tumor-specific antigens that are not expressed on normal T cells. Anaplastic large T-cell lymphomas (ALCL) and several other subtypes of PTCL express CD30, which is expressed by activated normal T cells but no other healthy tissues. Indeed, brentuximab vedotin, an anti-CD30 antibody-drug conjugate, has shown some clinical efficacy in ALCL and ALC patients although duration of responses is short in the majority of cases. Here, we developed a refined second generation CD30-CAR T-cell approach to target CD30+ PTCL as a potential novel therapeutic strategy. We selected a novel targeting domain that is unaffected by soluble CD30 protein to prevent blockade of the CD30-CAR in vivo. Moreover, we optimized the therapy by using memory stem T cells (TSCM) to promote engagement and persistence of CD30-CAR T cells after transfer, and we have included an EGFRt depletion marker as a safety feature.

Aims: We evaluated the antitumor effect of memory stem T cells (TSCM) genetically-modified with a novel CD30-specific CAR that recognizes a membrane-proximal epitope in the CD30 molecule in a CD30+ T-cell lymphoma model.

Methods: A second generation CD30-41BBz-EGFRt CAR was generated using a scFv that recognizes a tumor-cell membrane-proximal epitope of CD30 protein (Nagata S et al. Clin Cancer Res, 2002). Naive T cells from healthy donors were activated with anti-CD3/CD28 beads in presence of IL-7, IL-15 and IL-21 during 10 days to obtain a TSCM enriched population (Alvarez G et al. J Transl Med, 2016): on day 2 of culture, cells were transduced with a third-generation lentiviral vector encoding the CD30-CAR. The anaplastic large T-cell lymphoma cell line Karpas 299 was used as tumor model. Cytotoxicity assay was performed at 4 hours at 10:1, 5:1, 1:1 and 1:0.5 effector/target (E/T) ratio, and the tumor cell death induced by flow cytometry analysis of the membrane antigens (IFN-y and IL-2) were analysed at 24 hours in a 5:1 E/T ratio culture using Luminescence technology.

Results: Two TSCM were the most prevalent T-cell subset at day 10 of culture, representing 84 ± 3% of total cells, and the CAR expression by CD30-CAR in expression was in these cells was 76.9 ± 1.0% in CD4+ TSCM and 77.3 ± 2.0% in CD8+ TSCM. Although CD30-CAR protein was detected in a fraction of activated T cells in culture (CD4+ T cells: 32.4 ± 2.1%; CD8+ T cells: 59 ± 4.3%), lentiviral transduction of TSCM with our CD30-CAR did not compromise their ex vivo expansion (CD4+ CD30-CAR TSCM: 96.0 ± 3.2 fold expansion; CD8+ CD30-CAR TSCM: 109.0 ± 4.2 fold expansion). CD8+ CD30-CAR TSCM conferred specific cytotcic activity and lysed CD30+ PTCL in a dose-dependent manner (tumor cell death 1:1 ratio: 92.6 ± 2.2% vs 0% with untransduced TSCM; p<0.001), while control CD30+ target cells (Raji) were not recognized. In addition, CD30-CAR TSCM secreted IFN-y and IL-2 after stimulation with Karpas 299 cells (IFN-y: 126.6 ± 18.12 pg/ml with control targets, p=0.002; IL-2: 20.47 ± 2.3 pg/ml with control targets, p=0.002).

Summary/Conclusions: Collectively, our data demonstrate the potential to generate CD30-CAR T cells with enhanced functional attributes against CD30+ PTCL. TSCM cells can be efficiently transduced and ex vivo expanded with a novel CD30-CAR and confer potent antitumor efficacy against CD30+ PTCL in vitro. Our findings suggest the potential to improve outcome of patients with CD30+ PTCL through adoptive therapy with CD30-CAR modified T cells.
ing to the first dose, failed to respond to the second one. When we evaluated potential factors for response, organ involvement, age at transplant and the cumulative dose of MSC infused were found statistically significant. Response rate was 67% among patients with involvement of gut, skin or both, but only 22% among those with involvement of the liver (alone or in combination with skin and/or gut). Patients younger than 20 years fared better, with 88% of them responding. Conversely, only 30% and 42% of those aged 20-50 years or older than 50 responded, respectively. Lastly, higher cumulative MSC dose (>3.0x10^6/Kg) was associated with a response in 76%, while none of those receiving less than 1.5x10^6/Kg responded. All 3 factors remained significant in multivariate logistic regression analysis. Patient gender, pre-MSC therapy, interval from transplant or aGvHD diagnosis to MSC treatment and grade of aGvHD did not affect response. The impact of achieving a response 1 week after MSC had a profound impact on the overall survival at 18 months accounting for 59% in responders and 17% in non-responders (log-rank test, p<.001).

Summary/Conclusions: In our cohort of patients, MSC treatment was safe and well tolerated. We conclude that the presence of a response at one week highly impacted on the survival of patients with an otherwise very poor prognosis. Importantly, younger age at the transplant, absence of liver aGvHD involvement and use of higher MSC doses were strong predictors of a response.

CARD9 CONTROLS DECTIN-1-INDUCED T-CELL CYTOTOXICITY AND TUMOR GROWTH IN MICE

T. Haas1,*, S. Heidegger1, H. Poeck1, J. Ruland2
1Klinik und Poliklinik für Innere Medizin III, 2Institut für Klinische Chemie und Pathobiochemie, Klinikum rechts der Isar, TU München, München, Germany

Background: Activation of the C-type lectin receptor Dectin-1 by beta-glucans triggers multiple signals within dendritic cells (DCs) that result in activation of innate immunity. While these mechanisms can potently prime CD8+ cytotoxic T cell (CTL) responses without additional adjuvants, the Dectin-1 effector pathways that control CTL induction remain unclear.

Aims: Aims of this study were: To define details of the intracellular signalling pathway responsible for cross-priming of a CTL response after activation of the C-type lectin receptor Dectin-1. To analyze whether identified signalling molecules were indispensable for antitumor immunity. To analyze whether NK cells played a role in antitumor immunity after Dectin-1-mediated CTL induction.

Methods: We used in vitro coculture between DCs (wildtype vs gene deficient) and CD8 T cells to define signalling components of Dectin-1 induced CTL cross-priming. We used WT and gene-deficient mice to define the signalling pathway of Dectin-1 induced CTL crosspriming in vivo and to test the role of this pathway for antitumor immunity by challenging mice with B16-Ova tumor cells intravenously, with or without depletion of CD8 T cells or NK cells, respectively.

Results: Here we demonstrate that Dectin-1-induced CTL cross-priming in mice does not require inflammasome activation but strictly depends on the adapter protein Card9 in vitro. In vivo, Dectin-1-mediated Card9 activation after vaccination drives both expansion and activation of antigen-specific CTLs, resulting in long-lasting CTL responses which are sufficient to protect mice from tumor challenge. This Dectin-1-induced antitumor immune response was independent of natural killer (NK) cell function and completely abrogated in Card9-deficient mice. Thus, our results demonstrate that Dectin-1-triggered Card9 signaling but not inflammasome activation can potently cross-prime antigen specific CTLs, suggesting that this pathway would be a candidate for immunotherapy and vaccine development (Figure 1).

Summary/Conclusions: We identify Card9 as central regulator of Dectin-1-induced cross-priming of cytotoxic T cells (CTLs) in mice. These antigen specific CTLs mediate potent antitumor immunity independent of inflammasome activity and NK cells. This pathway is a candidate for immunotherapy and vaccine development.
Preclinical Combination of a Novel IRE1 RNAse Inhibitor MKC-8866 and Tyrosine Kinase Inhibition Acts Synergistic in Acute Lymphoblastic Leukemia

M. Vieri1, A. Salimi1, J.B. Patterson2, A. Samali3, E. Cheve4, T.H. Brümmendorf1, I. Appelmann1, B. Kharabi1

1Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, University Hospital RWTH Aachen, Aachen, Germany. 2KainKind Corporation, Valencia, United States. 3Department of Biochemistry, National University of Ireland, Galway, Ireland. 4Centre de Lutte Contre le Cancer Eugène Marquis, Université Rennes 1, Rennes, France

Background: The role of the Unfolded Protein Response (UPR) in BCR-ABL+ ALL is controversial. Previous studies were performed using either IRE1 or BCL-2 ALL cell lines and did not compare their responses side by side.

Aims: To study the effect of IRE1 inhibition alone and in combination with Tyrosine Kinase Inhibitors (TKI, using Imatinib or Nilotinib) on BCL-2 ALL cell lines, SUP-B15 and TOM-1.

Methods: Cells were treated with different concentrations of IRE1 inhibitor or TKI, alone or in combination, for 72 hours. Cell survival and viability were evaluated by CellTiter-Glo assay.

Results: IRE1 inhibitor MKC-8866 (MKC) was effective in terms of cell death, and its combination with the TKI resulted in improved cell death compared to single treatments. The most promising combination was 30µM MKC and 10µM IM, which showed a synergistic effect.

Overall, our data demonstrate that simultaneous inhibition of IRE1 and BCL-2 ALL cell lines could be a promising therapeutic strategy for this disease.

E821 Critical Role for Notch Signalling in B-Cell Precursor Acute Lymphoblastic Leukemia (B-ALL) Drug Response

P. Takam Kamga1, G. Dal Ccolo1, M. Midolo1, A. Adamo1, A. Gatti1, R. Carusone1, M. Bonifacio1, M. Krampera1

1Medicine, University of Verona, Verona, Italy

Background: Notch signalling is known to be involved in B-ALL pathogenesis. However, its role in drug resistance and treatment response is still unclear.

Aims: To investigate the role of Notch signalling in B-ALL drug response.

Methods: E821 vs. B-ALL xenograft models were established using the B-ALL line RS4;11. Flow cytometry and western immunoblotting were used to study the role of Notch signalling in drug resistance.

Results: Notch-3 and Notch-4 were found to be activated in B-ALL xenografts. Treatment with Notch inhibitors selectively reduced tumour growth compared to standard chemotherapy. This suggests that Notch inhibition may be a potential therapeutic strategy for B-ALL.

Conclusions: Notch signalling plays a critical role in B-ALL pathogenesis and its inhibition could be a promising therapeutic target.

E820 High-Throughput Copy Number Profiling in Pediatric Acute Lymphoblastic Leukemia Using Multiple Ligation-Dependent Probe Amplification in Combination with Next-Generation Sequencing

1MTA-SE Lendület Molecular Oncology Research Group, 1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Budapest, Hungary. 2MRC-Holland, Amsterdam, Netherlands. 32nd Department of Pediatrics, Semmelweis University, Heidelberg, Germany

Background: Chromosomal abnormalities are common in B-ALL and are used to predict clinical outcomes. However, the wide spectrum of abnormalities makes it challenging to develop targeted therapies.

Aims: To develop a high-throughput, high-resolution and comprehensive disease-relevant CNA profiling approach applicable to all subtypes of pALL.

Methods: A novel dMLPA (digital MLPA) technique was developed which combines the advantages of MLPA and next-generation sequencing (NGS), massively improving the number of simultaneously analyzable genomic loci. The number of simultaneously analyzable genomic loci is limited to 55-60.

Results: dMLPA showed a sensitivity of 99.3% for detecting all CNAs, and was able to detect subclonal aberrations with an improved efficacy and confidence as compared to conventional NGS. It was also able to detect subclonal aberrations with an improved efficacy and confidence as compared to conventional NGS.

Conclusions: dMLPA is a robust, fast and cost-effective technique that can be used to detect subclonal aberrations in B-ALL and may provide insights into the heterogeneity of this disease.

E819 Preclinical Combination of a Novel IRE1 RNAse Inhibitor MKC-8866 and Tyrosine Kinase Inhibition Acts Synergistic in Acute Lymphoblastic Leukemia

NOD/Shi-scid/I.L-2Rnull mice (NOG). Cell viability was evaluated by Annexin-V/PI and MTT assay; proliferation was assessed through CFSE dilution.

Results: Western blot and flow cytometric analysis showed that B-ALL cell lines as well as primary blast cells displayed the same Notch expression pattern consistent in low expression levels of Notch2 and Jagged1, high expression levels of Notch1, Notch3, Notch4, Jagged2, DLL3 and DLL4. Notably, in primary blast cells derived from patients, the expression of Notch3, Notch4, Jagged2, DLL3 and DLL4 was significantly higher in the cases refractory to treatment as compared to patients achieving complete remission, thus suggesting that Notch signalling could be involved in the response to chemotherapy. In line with this hypothesis, we found that the treatment in vitro of B-ALL cell lines with Ara-C or Dasatinib regulates the expression of Notch receptors. This down regulation was also observed in human CD19+ blast cells isolated from bone marrow of recipient mice treated with Ara-C compared to cells isolated from not treated mice. In addition, Notch inhibitors significantly improved in vitro the cytotoxicity of Ara-C toward B-ALL cells. Finally, we evaluated the administration to mice of a pan Notch inhibitor, i.e. the GSI XII, significantly lowered the CD19+ leukemic burden in the bone marrow of recipient mice, potentiating anti leukemic effect of Ara-C.

Summary/Conclusions: In this study we used both in vitro and in vivo assays to highlight the prognostic value of Notch expression in B-ALL, as well as its critical role in B-ALL cell survival and response to chemotherapy. We also demonstrated that Notch inhibitors were able to improve Ara-C-mediated reduction of blast cells in bone marrow, revealing that Notch signalling is a possible therapeutic strategy to eradicate minimal residual disease in B-ALL.

REGULATION OF NOTCH AND WNT SIGNALING PATHWAYS BY NRARP IN T-CELL ACUTE LYMPHOBlastic LEUKEMIA

I. Pinto1, M. L. Oliveira1, J. T. Barata1, R. Fragoso1,2
1Barbar Lab, Instituto de Medicina Molecular, Lisboa, Portugal

Background: T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive hematological malignancy. Although the outcome of T-ALL patients has improved over recent years, the poor prognosis of patients with resistant or relapsed disease is still a major concern. Even though NOTCH is a known driver in T-ALL, its inhibition cannot be efficiently achieved with the drugs currently available, due to their weak therapeutic effects and severe toxicity. We have shown that loss of mir-18-181b1 blocks Notch-induced T-ALL development partly by de-repressing the expression of NRARP (NOTCH regulated ankyrin repeat protein) a negative regulator of NOTCH signaling. Importantly, NRARP over-expression in murine hematopoietic stem cells impairs T-cell development suggesting that de-regulation of NRARP expression can contribute to the pathogenesis of T-ALL.

Aims: To investigate the role of NRARP in human T-ALL cell growth and survival and its therapeutic potential in T-ALL.

Methods: mRNA and protein expression were determined by real time-PCR and western blot analyses. in vitro functional evaluation of NRARP in T-ALL cell lines was performed by flow cytometry analysis of proliferation and viability upon NRARP overexpression using lentiviruses.

Results: We started by characterizing NRARP expression in human T-ALL cell lines and compared it with the expression of NRARP in human thymocytes.

We found that NRARP protein levels are significantly increased in T-ALL cells. This result, although consistent with the fact that NRARP is a transcriptional target of NOTCH, suggests that NRARP is not sufficient to block NOTCH oncogenic signals. To test this hypothesis, we overexpressed NRARP in human T-ALL cell lines. Curiously, NRARP overexpression blocks the expansion of the T-ALL cell lines that display NOTCH1-activating mutations but promotes the expansion of the T-ALL cells without NOTCH1 mutations. Although in both cell types (WT and NOTCH1-mutated) NRARP overexpression blocks NOTCH signaling, in NOTCH1+W T-ALL cells we observe an increase in c-Myc expression.

Consistent with these results, NOTCH1-WT NRARP overexpressing cells are more sensitive to JQ1, a small-molecule bromodomain inhibitor that targets c-Myc. NRARP is known to positively regulate LEF1, a DNA binding transcription factor acting downstream of WNT. Thus we sought to investigate the impact of this interaction in the signaling pathway. Very interestingly, our results show that in NOTCH1-mutant cell lines NRARP overexpression results in the down-regulation of the WNT signaling pathway while in NOTCH1-WT T-ALL cells results in its up-regulation.

Summary/Conclusions: Taken together our results suggest that NRARP may play a dual role in T-ALL pathogenesis, regulating both NOTCH and WNT pathways, with opposite functional effects on leukemia cells depending on NOTCH mutational status and signaling levels. This dual role may have important biological and therapeutic implications.

ETV6/RUNX1-LIKE ACUTE LYMPHOBlastic LEUKEMIA: A NOVEL B-CELL PRECURSOR LEUKEMIA SUBTYPE IDENTIFIED BY THE CD27/CD44 IMMUNOPHENOTYPE

M. Zaliova1,2,3, M. Kotrova1,2,3, S. Bresolin4, J. Stuchly1,2, J. Stary1,2, O. Hrusak1,2,3, G. te Kronnie4, J. Trka1,2,3, J. Zuna1,2,3, M. Vaskova1,2,3,*
1Department of Paediatric Haematology and Oncology, Second Faculty of Medicine, Charles University, 2University Hospital Motol, 3CLIP - Childhood Leukaemia Investigation Prague, Prague, Czech Republic, 4Department of Women’s and Children’s Health, University of Padova, Padova, Italy

Background: We have shown previously that ETV6/RUNX1-positive acute lymphoblastic leukemia (ALL) is distinguishable from other ALL subtypes by CD27/CD44low-neg immunophenotype. During diagnostic immunophenotypic analysis of 573 childhood B-cell precursor ALL (B-ALL), we identified eight cases with this immunophenotype among “B-other ALL” (B-ALL cases negative for hyperdiploid cytogenetics, ETV6/RUNX1, TCF3/PBX1 and BCR/ABL1 fusion genes and KMT2A-rearrangements).

Aims: We aimed to characterize their genetic and biological background, to reveal to what extent they resemble ETV6/RUNX1-positive ALL and to elucidate whether hyperdiploid ETV6/RUNX1+ cases have a unique genomic landscape.

Methods: We utilized microarrays to study the gene expression profile (GEP) and biological similarity of the B-ALL subtypes. Five ETV6/RUNX1-positive and five hyperdiploid ALL cases were analyzed using microarrays in parallel to seven CD27/CD44low-neg B-other ALL cells and compared it with the expression of NRARP in human thymocytes.

Results: Consistent with these results, microarray data from all 17 B-ALL cases were combined with data from an independent Italian cohort of 291 B-ALL cases (including ETV6/RUNX1-positive, BCR/ABL1-negative, TCF3/PBX1-negative, KMT2A-rearranged, hyperdiploid and B-other ALL cases) whose specimens were analyzed using the same microarray. To study the genomic background, we performed comprehensive profiling using single nucleotide polymorphism (SNP) arrays and whole exome and whole transcriptome sequencing (WES and RNAseq).

Results: In the hierarchical clustering based on GEP all five ETV6/RUNX1-positive cases and 5 of 7 CD27/CD44low-neg B-other cases clustered within the ETV6/RUNX1-positive cluster. These B-other cases were thus classified as ETV6/RUNX1-like ALL. We identified multiple regions of acquired copy number aberrations (CNA) uniparental disomies (5 to 27 per case) and point mutations (10 to 41 per case) in all 7 cases and 3 in-frame fusions transcripts each in one patient. The most important findings are summarized in Figure 1. All 5 ETV6/RUNX1-like cases harbored a deletion of the ETV6 gene, resulting in an in-frame ETV6/BORC5 fusion in one of them. The deletion of ARP221 was found in 3 cases, and the deletions of PAX5, ATR10A, BTG1 and the gain of RUNX1 were found in 2 cases each. The ARPP21 deletions displayed a strikingly uniform character and were highly enriched in ETV6/RUNX1-like ALL. Using WES and RNAseq, no recurrently mutated gene and no in-frame fusions were found, respectively, except for the ETV6/BORC5. Integrating data from all platforms, we identified IKZF1 as another recurrently affected gene; a deletion, a nonsense mutation and an IKZF1-involving out-of-frame fusion were found in one case. The other cases with available material.

Summary/Conclusions: We showed that similarly to ETV6/RUNX1-positive ALL, ETV6/RUNX1-like ALL is also associated with CD27/CD44low-neg immunophenotype. We identified deletion of ARP221 to contribute to the specific genomic profile of ETV6/RUNX1-like ALL in addition to lesions of ETV6
and IKZF1. In conjunction with the single published study, our study establishes the ETV6 lesion as the only common genetic aberration and thus the most likely key driver of ETV6/RUNX1-like ALL.

GENETIC ALTERATIONS IN CHILDREN WITH T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA IN TAIWAN
1Mackay Children’s Hospital and Mackay Medical College, Taipei, 2Chang Gung Memorial Hospital and Chang Gung University, 3Chang Gung Memorial Hospital, Taoyuan, Taiwan, Republic of China

Background: The leukemogenesis of T-cell acute lymphoblastic leukemia (T-ALL) involves multistep processes of genetic alterations.

Aims: We aimed to determine the genetic alterations including common fusion transcripts, overexpression of T-cell transcription factor oncogenes and deletion or mutations of targeted genes in pediatric T-ALL in Taiwan as well as their impact on outcomes in those treated with TPOG-ALL-2002 protocol.

Methods: Between 1995 and 2015, bone marrow samples from 102 children (<18 years old) consecutively diagnosed with T-ALL were examined. SIL-TAL1, MLL-ENL, and CALM-AF10 transcripts were detected by RT-PCR assays. RQ-PCR with TaqMan assays were used to measure the expression of HOX11, TAL1, and LYL1 oncogenes expressed as normalized copy number (NCN) to ABL internal control gene. TAL1 overexpression was defined as NCN > the lowest level of SIL-TAL1 positive patients. Overexpression of HOX11 and TAL1 and LYL1 was defined as NCN > the upper limits of the 95th normal bone marrow controls.

Mutations of NOTCH1, FBXW7, PHF6, JAK1, JAK2, RUNX1, WT1, NRAS, and KRAS genes were analyzed by PCR-based assays followed by direct sequencing. P16 deletion was determined by RQ-PCR or multiplex ligation assay amplification (MLPA), PTEN and PHF6 deletions, MYB duplication and NUP214 deletion were detected by real-time PCR and immunoblotting, respectively. Downregulation of PRDX1 was estimated by Western blotting.

Results: The frequency of SIL-TAL1 fusion transcript was 16.2%, MLL-rearranged 5.1%, CALM-AF10 1.0%, and no NUP214-ABL1. The frequency of NOTCH1 mutations was 46.9%, FBXW7 13.0%, RUNX1 5.2%, WT1 6.3%, NRAS 6.2%, KRAS 2.1%, and no JAK1 or JAK2 mutations. P16 deletion was present in 56.2%, PTEN in 11.1%, PHF6 deletion/mutation in 13.4%, and MYB duplication in 4.8%. Overexpression of TAL1 was present in 46.5%, 22% for LYL1, and 9% for HOX11. The correlation among the genetic alterations showed that LYL1 overexpression occurred more frequently in P16 wild-type compared with P16-deleted patients (P=0.003) and absence of SIL-TAL1 transcript was significantly associated with wild-type HOX11 overexpression (P=0.018). A comparative assessment of outcomes was made according to the status of each genetic abnormality. NOTCH1 mutations conferred a favorable overall survival (OS) (P=0.025), PHF6 deletion/mutation conferred an inferior OS (P=0.030). PTEN deletion was associated with shorter relapse-free survival (RFS) (P=0.001) and OS (P=0.001). Status of other gene mutations, deletion or duplication did not influence the RFS or OS. TAL1 overexpression predicted a higher risk of relapse (37% vs 21%, P=0.006), an inferior RFS (P=0.002) and OS (P=0.025) whereas HOX11 or LYL1 overexpression had no prognostic impact. By multivariate analysis, NOTCH1, PTEN, and PHF6 mutations/statistical significance and statistical independence for an independent predictor of OS (HR 0.167, P=0.112), PHF6 deletion/mutation was an independent unfavorable predictor for OS (HR 5.096, P=0.006), and PTEN deletion was also an independent predictor for both RFS (HR 29.493, P=0.007) and OS (HR 15.830, P=0.003). TAL1 overexpression was an independent risk factor for both RFS (HR 3.989, P=0.014) and OS (HR 2.701, P=0.047).

Summary/Conclusions: The present study showed that LYL1 overexpression was negatively associated with SIL-TAL1 or P16 deletion. PHF6 deletion/mutation, PTEN deletion, and TAL1 overexpression were the independent predictors of adverse outcomes. COMPUTATIONAL METHODS TO FIND NEW THERAPEUTIC TARGETS IN ALL, SYSTEMATICAL IDENTIFICATION OF ESSENTIAL GENES
L. Ekdahl1,*, M. Pertesi1, A. Palm1, L. Järnström1, E. Johnsson1, U. Gullberg1, A.-K. Whibley2, B. Nilsson1
1Division of Hematology and Transfusion Medicine, Lund University, Lund, Sweden

Background: Deletion of chromosomal material is a hallmark of cancer genomes. While these lesions primarily target tumour suppressor genes, neighbouring genes are frequently disrupted in parallel. Loss of one copy (haploinsufficiency) of a neighbouring gene that is essential for the survival of the cancer cells may constitute potential therapeutic targets in that the cancer cells may be selectively sensitive to further suppression of the function of that gene. Identifying such vulnerabilities is one of the current challenges in cancer genomics. We show that vulnerabilities in cancer cells can be identified by analyzing by applying pattern recognition techniques to a copy-number dataset. This approach will identify genomic regions with potential essential genes. Genes in these regions can be evaluated downstream by genome editing techniques to find novel targets for treatments. Using pattern recognition techniques to find essential genes is a straightforward, easily applied and non-time-consuming method compared to genome wide experimental approaches.

Aims: Develop a computational framework to find regions with potential essential genes from copy-number data, with a primary focus on hematological malignancies and in particular ALL.

Methods: Our computational framework first selected regions of the tumour genome with heterozygous, but not homozygous, deletion. In sections spanning these regions we scanned for linear increases in homozygous deletion frequency. Genes near the start of these increases that have more than one case with homozygous deletion are discarded. Remaining genes were scored by calculating a line of best fit using the least square method towards the nearby peak in homozygous deletion. We sorted the results by settings cut-offs for the slope, amplitude and correlation coefficient of the linear regression line. Genes with the highest scores were then manually evaluated by comparing to known mean copy-number loss dependence score from other data-sets, by graphical analysis and by investigation of their known function. The framework thus analysed contains copy-numbers from tumour samples matched to normal blood samples or normal tissue from the same donor. To validate the essentiality of genes in the discovered regions we used pooled CRISPR/Cas9 editing in ALL cells with and without a deletion of the driving tumour suppressor.

Results: Our framework identified several regions with potential essential genes around well-known tumour suppressors. The strongest signals in the data set were located around the tumour suppressor CDKN2A. Downstream analysis with pooled CRISPR/Cas9 editing in ALL cells with and without a CDKN2A deletion provided evidence for the essentiality of several genes in the identified region, including one gene that was essential only in CDKN2A-deleted cells.

Summary/Conclusions: In conclusion, we explored a computational approach to identify regions with essential genes in copy-number datasets. Application of our approach to real data showed several regions with essential gene candidates around well-known tumour suppressors, indicating the framework works. Downstream genome-editing experiments in model cell-lines provided further evidence for the essentiality of some genes found in such identified regions. While we cannot yet draw conclusions on whether some of these genes are viable therapeutic targets it allows for informed guesses on limited sets of genes for further focused analysis in hematological model cell-lines.

TARGETING ANTIOXIDANT ENZYMES FOR THE TREATMENT OF B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA
K. Fridy1,*, K. Szczygiel2, A. Pastorczak2, A. Graczyk-Jarzynka1, E. Patkowska1, M. Finczuk3
1Department of Immunology, Medical University of Warsaw, Warsaw, 2Department of Pediatrics, Oncology, Hematology and Diabetology, Medical University of Lodz, Lodz, 3Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: B-cell acute lymphoblastic leukemia (B-ALL) is a genetically heterogeneous disease characterized by abnormal expansion of B cell precursors and is mainly affecting children and adolescents. The backbone of the treatment is chemotherapy providing high cure rates in pediatric ALL (> 85%) but much worse treatment response in adolescents and adults (50%). Patients who relapse develop refractory, chemotherapy resistant disease and remain a clinical challenge. Growing body of evidence suggests that disturbance of redox homeostasis is a promising anticancer approach. Due to high metabolic demands and proliferation rate cancer cells elevate their antioxidative capacity to overcome excessive ROS production and depend on these antioxidants for their survival. One of the oxidative stress protectors are peroxiredoxins (PRDXs) that next to thioredoxins (TXNs) belong to the TXN-family and are the key components of TXN antioxidant system. PRDXs are enzymes involved in scavenging peroxides. TXNs are responsible for cysteine-thiol disulfide interchange in numerous protein substrates.

Aims: To investigate the potential of targeting the TXN antioxidant enzymes as a novel pro-oxidative strategy in B-ALL treatment.

Methods: We have used three different cell lines representing distinct cytoge- netic subgroups of B-ALL: BV-173 (BCR-ABL), SEMK-2 (MLL-4AF4) and NALM-6 (t(12;21)(p13;q22);PHF6). ROS levels were measured using E827.

CRISPR v2 plasmid to produce lentiviral vectors encoding PRDX1-specific sgRNA and Cas-9 and used them to generate BV-173 cells with PRDX1 genomic deletion. Proliferation rate was evaluated by trypan blue exclusion method. Cytostatic/cytotoxic effects of TXN-family enzymes inhibitors, such as adenanthin (ADE), auranofin (AUR) and SK053 were assessed by MTT viability assay and by detection of propidium iodide-positive cells in flow cytometry.

Figure 1.

Results: We have found that B-ALL cell lines exhibit significantly higher levels of ROS compared to normal B cells isolated from human tonsils (Fig 1A). In agreement with this observation, our analysis of TXN antioxidant enzymes gene expression in B-ALL cell lines showed their upregulation (Fig 1B). Analysis of deposited data revealed that PRDX1 expression level is the highest in B-ALL among the other types of leukemia (Fig 1C). Moreover, we have observed elevated expression of PRDX1 in malignant lymphoblasts derived from pediatric patients both at RNA and protein levels. Genomic deletion of PRDX1 in BV-173 cells leads to suppression of their proliferation rate, comparing to parental cells and cells transduced with mammalian non-targeting sgRNA. These results allow us to suspect that PRDX1 may play growth-supporting role in these cells. Targeting TXN-family enzymes was also performed with the use of various small molecule inhibitors. Both B-ALL cell lines and primary cells are sensitive to PRDX and TXN inhibitors, which reduce cell viability in dose-dependent manner.

Summary/Conclusions: All the above results suggest that targeting TXN antioxidant system may exert desirable anticancer effects in the treatment of B-ALL. Inhibitors of TXN-family enzymes can be considered as putative agents to use in combination with classical drugs and improve existing therapeutic approaches. Further studies are underway.

Background: The IGF2 mRNA binding protein 1 (IGF2BP1, other aliases IMP-1 (IMP1), CRD-BP (CRDBP), ZBP-1 (ZBP1), and VICKZ1) belongs to a family of regulatory RNA-binding proteins with an oncofetal expression pattern. IGF2BP1 has also been identified to be exclusively specific for ET6V/RUNX1-positive acute lymphoblastic leukemia (ALL) but biological significance of IGF2BP1 overexpression has not been thoroughly investigated to date (Andersson, Olofsson et al. 2005; Stoskus, Gineikiene et al. 2011). We have recently contributed by reporting that ET6V/RUNX1 transcript is a target of RNA-binding protein IGF2BP1 in t(12;21)(p13;q22)-positive ALL, suggesting a role of IGF2BP1 in ET6V/RUNX1-mediated leukemogenic events (Stoskus, Vaitkevičiūnė et al. 2016).

Aims: To define the biological significance of IGF2BP1 overexpression in t(12;21)(p13;q22) ET6V/RUNX1-positive ALL.

Methods: In this study we have used stable sublines with downregulated IGF2BP1 from our previously published study (Stoskus, Vaitkevičiūnė et al. 2016). Dynamics of viable cell population was assessed by flow cytometry using 7-AAD staining (BD Biosciences) following 72 hrs culture in complete medium. An EdU flow assay (Thermo Fisher Scientific, TFS) was used to assay DNA replication in proliferating cells. Spontaneous and doxorubicin (Doxo), staurosporine (STS), and STAT3 selective inhibitor S3i-201 (all from Santa Cruz Biotechnology) induced cell death rates were determined by Annexin V (TFS) and 7-AAD staining. All samples were analyzed on Accuri C6 cytometer (Accuri Cytometers) using CFlow Plus and FCS Express software (De Novo Software). IGF2BP1, ET6V/RUNX1, and STAT3 RT-qPCR was performed previously (Stoskus, Gineikiene et al. 2011). Statistical analyses performed using GraphPad Prism software (GraphPad Software).

Results: Downregulation of IGF2BP1 by 2-fold have rendered into approximately 2-fold lower population growth rate, increasing levels of spontaneous cell death in dynamics, and modest yet statistically significant attenuation of cell cycle progression (35.13% vs 40.40%, p<0.0001). Data from treatment with 50 nM of Doxo, 250 nM of STS suggest that IGF2BP1 downregulation has no effect on pharmacological effectiveness of these drugs. In contrast, IGF2BP1-downregulated cells are more sensitive to pharmacological inhibition of STAT3 even upon treatment with suboptimal 25 µM concentration of S3i-201. Lastly, we have probed if STAT3 transcript levels could be sustained by IGF2BP1 protein as in agreement with previously reported (Stohr, Kohn et al. 2012) and our unpublished insights from anti-IGF2BP1 RNA immunoprecipitation datasets. Correlation analysis of RT-qPCR data have confirmed these assumptions as downregulation of IGF2BP1 expression have resulted in a decrease of ET6V/RUNX1 mRNA (r2=0.8253, p<0.001, slope 0.9459) and also STAT3 transcript levels (r2=0.7709, p=0.002, slope 0.6436). These data suggest that STAT3 transcript is also a potentially regulated by RNA-binding protein IGF2BP1 in t(12;21)(p13;q22)-positive ALL model cells (Fig 1).
suggest that 6-MP inhibits the phosphatidylinositol 3 kinase (PI3K)/ mammalian target of Rapamycin (mTOR) pathway and modulates the transcriptional activity of hypoxia inducible factor 1α (HIF-1α). As mTOR and HIF-1α are key mediators of metabolic reprogramming in cancer and normal T cells, we hypothesized that 6-MP can impact cellular metabolic remodeling through its action on nucleotide synthesis. Metabolic reprogramming fosters glycolysis, glutaminolysis, and expression of lipostatic genes to sustain cell growth, proliferation, and a key feature of cancer cells. This metabolic switch is regulated by metabolic checkpoints, including mTOR, AMP-activated protein kinase (AMPK) and the oncogenes Myc and HIF-1α.

Aims: Our objective is to study the impact of the antiproliferative molecule 6-mercaptopurine (6-MP) on glucose uptake and on glucose transporters (Glut1 or Glut3, SLC2A1 or SLC2A3) and the impact on clinical outcome.

Methods: In vitro experiments were performed in a Jurkat T cell line. Cells were incubated with 6-MP from 6h to 72h. We used RT-PCR, Western Blot, glucose uptake and glycolytic and glucometabolism flux to evaluate the metabolic effects of 6-MP.

Results: Our results showed that 6-MP reduces ATP content as early as after 2 hours of treatment and this decrease is maintained up to 72 hours. As AMPK is an energetic sensor activated with low ATP content, we studied AMPK activation after 6-MP treatment. We observed that 6-MP treatment activates AMPK after 6 and 48 hours of treatment. Moreover, 6-MP significantly modifies the transcriptional activity of genes implicated in glycolysis, glutaminolysis and nucleotide synthesis after 24, 48 and 72 hours of treatment. In addition, 6-MP inhibits the expression of the metabolic checkpoints mTOR, HIF-1α and Myc after 24, 48 and 72 hours of treatment. 6-MP also decreases glucose and glutamine oxidation after 48 hours of treatment by 60% and 35%, respectively, suggesting that 6-MP inhibits TCA (tricarboxylic acid cycle) and oxPKCS (oxidative phosphorylation). The production of lactate, a marker of aerobic glycolysis, is significantly decreased by 30% after 6-MP treatment for 48 hours, meaning that aerobic glycolysis is also inhibited. However, 6-MP has no effect on glucose uptake or on glucose transporters (Glut1 or Glut3, SLC2A1 or SLC2A3) and the main expression, suggesting that 6-MP metabolic effects are not linked to glucose uptake.

Summary/Conclusions: In conclusion, our findings offer new insights on the cellular effects of 6-MP treatment by promoting an early energetic stress that influence proliferation and raise apoptosis in leukemia T cells. Interestingly, the suppression of the metabolic checkpoints (mTOR, HIF-1α, Myc) and the diminution of glycolytic and glutaminolytic fluxes by 6-MP treatment provide an original approach to better understand the cellular effects of 6-MP treatment.
Results: With a median follow up of 12.43 [2.4;30.3] months, the median OS of the 31 patients at first relapse was 7.9 months, [2.4;13.8]. The OS of patients at first relapse was significantly lower in those having more than 3 CNA by MLPA (median ≤3 CNA 9.7 months [0-20.7] vs median >3 CNA 4.2 months [0.6-7.8], p=0.042). CDKN2A/B deletion was the most common CNA observed at relapse (16/31, 52%) and most of these deletions were homozygous (12/16, 75%). CDKN2A/B deletions, homozygous or more frequent at relapse (from 8 heterozygous CDKN2A/B deleted patients at diagnosis, 7 became homozygous at relapse, p=0.070). SNAP arrays detected 554 CNA (409 DEL, 125 DUP and 20 LOH) in 34 samples of 19 patients. At diagnosis (n= 16 patients) the mean number of CNA was 12.5 (9.6 DEL, 2.3 DUP and 0.4 LOH), while at 2nd relapse (n=13 patients) it was 17.8 CNA (12.6 DEL, 4.2 DUP and 1 LOH) and in second relapse (n=5 patients) was 21 CNA (14.6 DEL, 6.4 DUP and 0 LOH) (p=0.007). All matched diagnosis and first relapse samples (available for 10 patients) showed common CNA. In 6/10 cases some of CNA were retained from diagnosis while others were acquired or lost at relapse (suggesting that most of them are not due to clonal evolution). CNA were also observed in 6/10 patients at diagnosis, acquired new CNA at relapse (indicating an evolution from diagnosis clone) and 1/10 showed the same CNA signature at relapse (suggesting a primary resistance of the diagnosis clone). Gene ontology analysis showed a significant enrichment of gene deletions involving B cell differentiation, activation and proliferation, and regulation of cytokine-mediated signaling pathway at relapse (Benjamini Hochberg test, p<0.01). Table 1 summarizes the frequencies of the most retained or acquired CNA at relapse in at least 4 out of 15 patients. Besides the high genetic heterogeneity observed, some recurrent CNA could be identified such as 9p, 1q, 12q, 22q and 7p deletions and 1q, 8q, 17q, 21+ and t(8;21) duplications. Several recurrent tumor suppressor genes such as TP53, FOXO1, FOXO3 or RB1 were detected in 3 patients.

Summary/Conclusions: BCP-ALL has a high genetic heterogeneity at relapse, with most of the genetic alterations playing important roles for disease progression. This heterogeneity points out the need for search of personalized treatment modalities based on their molecular adaptations. Finally, we intend to focus our efforts on the Instituto de Salud Carlos III, Ministerio de Economía y Competitividad, Spain, Red Temática de Investigación Cooperativa en Cáncer (RTICC, FEDER) (RD12/0036/0044); Sociedad Española Hematología y Hemoterapia; 2014 SGR226 (GRE) Generalitat de Catalunya; Fundació Internacional Josep Carreras, Celgene Spain and "la Caixa" Foundation.

IGF1R/IRS PHARMACOLOGICAL INHIBITION REDUCES CELL PROLIFERATION AND MIGRATION IN ACUTE LYMPHOBластIC Leukemia CELLLS
A.P.N. Rodrigues Alves1,*, J. Machado-Neto1, R. Scopim-Ribeiro1, J.C. Fernandes1, A.A. Fenerich1, F.B. Da Silva1, P.S. Scheucher1, B.P. Simões1, E.M. Rego1, A.J. Ridley2, F. Traina1
1Internal Medicine, University of Sao Paulo at Ribeirao Preto Medical School, Ribeirão Preto, Brazil, 2Randall Division of Cell and Molecular Biophysics, King’s College London, London, United Kingdom

Background: A recurrent clinical complication of the acute lymphoblastic leukemia (ALL) is the infiltration of lymphoblast into central nervous system. The IGF1/IGF1R signaling pathway is initiated through binding of the ligand (IGF1) to its transmembrane receptor (IGFR1), and the subsequent activation of its substrates, IRS1 and IRS2, which transmit mitogenic and antiapoptotic signals, mainly through the modulation of the PI3K/AKT/mTOR and MAPK signaling pathways. These signaling pathways play an important function in cell proliferation, survival and migration of leukemia cells. We have previously noticed that NT157 (10µM OSI-906 pharmacological inhibitor) significantly decreased cell viability and induced apoptosis in T-ALL (Jurkat and MOLT-4) and in B-ALL (Namalwa and Raji) cell lines and in primary ALL cells (T-ALL [n=2] and B-ALL [n=2]), although it did not presented citotoxicity in peripheral blood mononuclear cells (PBMC) from healthy donors. In addition, NT157 was able to induce the p21 (CDKN1A) expression, which is a cell cycle arrest-related gene. We also observed that OSI-906 (GI254C1R/IR pharmacological inhibitor) significantly reduced cell viability, but did not induce apoptosis in ALL cell lines tested, and did not modulate viability and apoptosis of primary ALL cells and normal PBMC. The molecular mechanism by which leukemia cells break the blood-brain barrier, allowing the infiltration of the central nervous system and causing serious complications, remains poorly understood.

Aims: We herein aimed to investigate the impact of the pharmacological IGF1R/IR and IRS1/2 inhibition on cell proliferation and migration in ALL cells.

Methods: T-ALL Jurkat and B-ALL Namalwa were used. Cell lines were treated or not with NT157 at 0.2, 0.4, 0.8, 1.6 and 3.2µM, or with OSI-906 at 0.5, 1, 10 and 50µM, for 24 and 48 hours. After drug exposure, cell lines were evaluated for cell proliferation (Ki-67 assay), migration (Time-Lapse microscopy analysis) and cell adhesion (using human umbilical vein endothelial cells HUVEC monoclayer). Statistical analyses were performed by the ANOVA. Value p<0.05 was considered statistically significant.

Results: NT157 decreases cell viability (p<0.05) over 24 hours of treatment. OSI-906 was not able to reduce cell proliferation in these cell lines. The 24 hours treatment with 10µM OSI-906 decreased accumulated distance (µm) and velocity (µm/min), while 0.4µM NT157 reduces only the accumulated distance of Jurkat cells under migration assay into fibronectin monolayer, after being filmed by time-lapse microscopy for 3 hours; the images were captured every 1.5 minutes. Although there is a trend for reduction, cell adhesion between Jurkat and Nalmaw leukemia cells and the human endothelial cell monolayer was not significantly modulated by treatment with both inhibitors.

Summary/Conclusions: The reduction on cell proliferation found during IRS/2 pharmacological inhibition reaffirms the important role of these proteins on malignant phenotype of ALL cells. Migration analysis indicated that NT157 and OSI-906 are potential inhibitors of transendothelial migration in ALL cell lines and contribute with new perspectives on the participation of the IGF1R/IRS1 pathway in the break of the blood-brain barrier.
Aims: This study aimed to determine the regional-specific hospitalization days per patient in the INO-VATE trial.

Methods: Patients receiving study treatment (safety population) and recruited from the US and the EU were included in the analyses. The total number of days hospitalized for each patient was calculated. Hospital days prior to randomization and those after the end of study treatment were excluded. Due to different durations of treatment for InO compared to SOC (median 1 vs 3 cycles), calculations were performed for cycle 1 treatment period (randomization to end of cycle 1) and for the entire treatment period (all cycles - randomization to end of treatment).

Results: A total of 264 patients from the safety population of the phase 3 INO-VATE trial were available for the analyses. 149 were from the US, and 115 from 11 of the EU countries. The percentage of patients requiring hospitalization was lower for InO compared to SOC (Table). The median and mean hospitalization days were shorter for patients in the InO arm compared to the SOC arm across both regions. The difference between the two treatment arms appears to be greater in the US compared to the EU. Hospitalizations in the US appear to be shorter than in the EU, particularly for patients receiving InO.

Table 1. Hospitalizations in R/R ALL patients from the INO-VATE trial.

Summary/Conclusions: InO treatment in R/R ALL is associated with less hospitalization across both the US and EU compared to SOC, consistent with InO’s better efficacy, tolerability, PRO and dosing schedule. The finding that US has lower hospitalization than the EU might be explained by different patient care practices in the two regions. Given that hospitalization is the biggest cost driver in cancer care, the data suggest both EU and US could benefit from cost-savings of less hospitalization with InO treatment.

E835

HOSPITALIZATION FOR PATIENTS IN THE U.S. AND EU TREATED WITH INOTUZUMAB OZOGAMICIN VS STANDARD OF CARE FOR RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA IN A GLOBAL PHASE 3 TRIAL

Y. Su 1, 2, I. Van Costrum 2, E. Vandendries 1, V. Welch 1, F.R. Loberriz 1
1Pfizer Inc, New York, United States, 2Ingress-health Netherlands, Rotterdam, Netherlands

Background: Inotuzumab Ozogamicin (InO), an anti-CD22 antibody-calicheamicin conjugate, with its once a week one-hour infusion schedule, has demonstrated lower hospital utilization, in association with a clinically meaningful improvement in overall survival, high rate of complete remission, favorable patient-reported outcomes (PRO), and generally manageable safety profile versus standard of care (SOC, intensive chemotherapy) for relapsed/refractory acute lymphoblastic leukemia (R/R ALL) in the phase 3 INO-VATE trial.

Aims: This study aims to determine the regional-specific hospitalization days per patient in the INO-VATE trial.

Methods: Patients receiving study treatment (safety population) and recruited from the US and the EU were included in the analyses. NON-INTERRUPTIVE BUT NON-INTERRUPTIVE TREATMENT WITH FEWER ALLO-HSCT IS EFFECTIVE STRATEGY FOR ADULT PH-NEGATIVE B-CELL PRECURSOR (BCP-) ALL: OUTCOME OF THE RUSSIAN PROSPECTIVE MULTICENTER ALL-2009 STUDY

E. Parovichnikova 1, V. Trotskaya 2, A. Sokolov 2, O. Davvinova 2, S. Bondarenko 3, O. Baranova 4, Z. Akhmerzeva 2, G. Kliasova 2, L. Kuzmina 1, E. Gribanov 2, G. Baskhaeva 2, I. Piskunova 2, T. Obukhova 5, M. Rusinov 6, S. Kulikov 7, V. Savchenko 1
1BMT department, 2Haematology department, National Research Center for Hematology, Moscow, 3BMT department, Raisa Gorbacheva Memorial Research Institute for Pediatric Oncology, Hematology and Transplantation, St. Petersburg, 4Haematology department, N.N. Blokhin Russian Cancer Research Center, 5Scientific clinical laboratory of clinical bacteriology, mycology and antibiotic therapy, 6Cytogenetics laboratory, 7Department of biostatistics, National Research Center for Hematology, Moscow, Russian Federation

Background: As Ph-negative-BCP-ALL in adults remains less favorable in prognosis than T-ALL, and by expert opinion needs intensive protocols with high portion of allo-HSCT, the results of treatment based on the different approaches at escalated but non-interruptive treatment with low numbers of allo-HSCT- may be of interest and can provide new insights to the common view.

Aims: to evaluate survival data and risk groups in Ph-neg-BCP-ALL pts in the RALL-study.
Methods: The ALL-2009 (NCT01193933) was initiated in Apr 2009. The treatment plan was identical for all risk groups with allo-HSCT indicated only for patients with MRD-SR (26 months vs 35 months. Median EFS of MRD-HR patients was significantly inferior as compared to MRD-SR & 58% as MRD-HR. Twenty patients relapsed & of them, six died (2 were ETP ALL & 18 non-ETPALL: 3 MRDSR & 17 MRD-HR) within 26 months. Median EFS of MRD-HR patients was significantly inferior as compared to MRD-SR (26 months vs did not reach; & 70.67% vs 92.86%; p=0.0017) (Kaplan-Meyer curve shown in Figure 1). Interestingly, there was no difference in EFS for MRD-HR <0.01% vs >0.01%, suggesting any level of PI-MRD positive indicated inferior EFS. Furthermore, the PC-MRD response was not found to be significant over PI-MRD (P-value=0.17). ETP vs non-ETP status was also not found to be associated with EFS (P-value=0.85).

Figure 1.

Summary/Conclusions: Our data demonstrate that non-intensive but non-interruptive treatment with fewer allo-HSCTs is more effective in adult BCP-ALL producing more than 50% OS at 7 years, though the TP is high. In our study among common risk factors only age, initial WBC and t(4;11) - remained the most valuable markers of poorer prognosis, while immunophenotype, time to CR, CNS involvement, and other cytogenetic markers did not matter. So RALL protocol without intensive highly myelosuppressive consolidation courses and high portion of allogeneic HSCT, may become an alternative and reproducible approach for adult Ph-negative ALL.

E837

POST-INDUCTION MINIMAL RESIDUAL DISEASE RESPONSE DETERMINED BY MULTICOLOR FLOW CYTOMETRY IS A POWERFUL INDICATOR OF EVENT-FREE-SURVIVAL IN THE CHILDHOOD T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

P. Tembhare1,1, G. Chattopadhyay2, J. L. Sanyal3, P. Devre1, S. Ghogale1, N. Patkar1, G. Narula1, A. Arora2, N. Deshpande1, Y. Badrinath1, S. Gujral1, S. Banawali2, P. Subramaniam2

1Hematopathology Laboratory, Tata Memorial Centre, Mumbai, Navi Mumbai, India
2Medical Oncology (Paediatrics), Tata Memorial Centre, Mumbai, Mumbai, India
3Department of Pediatrics and Adolescent Medicine, University Medical Center, Utrecht, The Netherlands

Background: Minimal residual disease (MRD) is a powerful predictor of event-free survival in acute leukemia including T-cell acute lymphoblastic leukemia (T-ALL). Due to lower incidence of T-ALL, MRD studies are limited and restricted to a small cohort of patients. Moreover, flowcytometry based MRD (FC-MRD) studies in T-ALL are very few. AIEOP-BFM group showed that late (Day-78) MRD response determines overall risk of-relapse and event-free survival (EFS) using RQ-PCR. However, a larger study by COG (Brent Wood et al. ASH, 2014) showed a positive result only in the low risk patients (Day-29). FC-MRD was more sensitive as compared to EFS. This indicates that the best time for MRD evaluation for the risk stratification in T-ALL is still not clear and need more studies. We investigated the value of post-induction FC-MRD response in an assessment of EFS in childhood T-ALL. It is a first T-ALL MRD study from India.

Methods: We studied post-induction (Day-35) MRD (PI-MRD) & post-consolidation (Day-78) MRD (PC-MRD) in bone marrow samples from 100 patients of T-ALL treated under modified MCP-841 protocol between 2014 & 2016. In T-ALL with early-thymic-precursor (ETP) immunophenotype, patients received dexaxamethasone in place of prednisolone. MRD was performed using 10-color FC-MRD assay on Navios flow-cytometer (Beckman Coulter, BC) and MRD analysis was performed with Kaluza software v-1.3 (BC). Any detectable level of MRD (≥20 events) was defined as MRD-positive. Events included relapse & disease-related deaths. Statistical analysis was performed using SPSS v.16.

Results: The median age of patients was 11.5 years (range 2–16 y; MF=4–6). Based on the immunophenotypic criteria, 13 patients were diagnosed as ETPALL & remaining 87 as non-ETPALL type. PI-MRD was positive in 58/100 (58%) with the median level of 0.23% (range, 0.002% to 6%). PI-MRD was not performed in 71.4% (30/42) of Ph-MRD-negative & 1.2% (6/58) Ph-MRD-positive patients. PI-MRD was available in 64 patients (30/42 of PI-MRD-negative & 6/58 of PI-MRD-positive). PI-MRD was positive in 28% (18/64) (median, 0.2% & range, 0.009% to 4%). PI-MRD positivity was significantly high in ETPALL as compared to non-ETPALL (93% vs 53%; p=0.01). Median follow-up of all patients was 14 months (3-38 months). Patients were categorized MRD standard-risk (MRD-SR) if PI-MRD was negative and MRD high-risk (MRD-HR) if PI-MRD was positive with any level. Thus, 42% were categorized as MRD-SR & 58% as MRD-HR. Twenty patients relapsed & of them, six died (2 were ETPALL & 18 non-ETPALL: 3 MRDSR & 17 MRD-HR) within 26 months. Median EFS of MRD-HR patients was significantly inferior as compared to MRD-SR (26 months vs did not reach; & 70.67% vs 92.86%; p=0.0017) (Kaplan-Meyer curve shown in Figure 1). Interestingly, there was no difference in EFS for MRD-HR <0.01% vs >0.01%, suggesting any level of PI-MRD positive indicated inferior EFS. Furthermore, the PC-MRD response was not found to be significant over PI-MRD (P-value=0.17). ETP vs non-ETP status was also not found to be associated with EFS (P-value=0.85).

Figure 1.

Summary/Conclusions: We concluded that 10-color FC-based post-induction MRD response is a powerful indicator of EFS in childhood T-ALL. The frequency of PI-MRD positivity was significantly high in ETPALL indicating a lower tumor clearance rate. There was no difference in the EFS based on the level of PI-MRD-positivity indicating even a low level (<0.01%) PI-MRD is important in risk-stratification of childhood-TALL.

E838

SMAC MIMETICS - A NOVEL THERAPEUTIC APPROACH IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

M. Meyer1,1, J. Zinggrebe1, L. H. Meyer1, K. -M. Debatin1

1Department of Pediatrics and Adolescent Medicine, University Medical Center, Ulm, Germany

Background: Pediatric acute lymphoblastic leukemia (ALL) is one of the most common malignancies in childhood. Survival rates have increased enormously over the past decades, but the prognosis for patients with relapsed ALL or ALL following chemotherapy is poor. Thus, novel therapeutic options are urgently required. The family of inhibitor of apoptosis proteins (IAPs) has been shown to play an important role in the prevention of cell death, and to mediate gene activation important for cell survival. Many of the cellular processes regulated by IAPs are deregulated in cancer. Thus, IAPs represent a promising target in anticancer therapy. IAP antagonists, also known as Smac Mimetics (SMs), were developed to counteract IAPs function. SMs have been shown to induce cell death in a number of different cancer entities, amongst them B cell precursor (BCP)-ALL. In BCP-ALL, SM-induced cell death was
Results: 22 patients were enrolled; median age was 29 years (range 16–79), 12 (55%) patients were male, 6 (27%) patients had previously received an allogeneic stem cell transplant (SCT), the most common disease subtype was pre-B-ALL (15, 68%), and 2 (9%) patients had Ph+ B-ALL. 6 (27%) patients received ≥2 cycles of MOR208 and had a subsequent response assessment. Responses were seen in 2 patients; and included a CR and a CRi, giving an overall response rate of 9%. These 2 patients received extended MOR208 treatment. A further 3 (14%) patients did not fulfill the criteria for PR but did not progress; 16 (73%) patients withdrew before completing cycle 2, in most cases due to progressive disease (PD). The patient in CR met the criteria for allo- genetic SCT, but declined this at the time; response duration was 6 weeks, with progression of PD. The patient with the CRi had a response duration of at least 4 weeks, but discontinued due to a treatment-emergent adverse event (TEAE), sclerosing cholangitis. For 12 out of 13 patients with available data, MOR208 treatment led to a rapid reduction in blast/B-cell counts in the peripheral blood; in most cases a reduction of >90% within 1 week of treatment initiation was seen. IL-15 levels were not significantly elevated. Half maximal Caspase cleavage of Poly-(ADP-ribose)-Polymerase (PARP), Caspase 8 and 3, in the SM-sensitive B-ALL cell lines whereas no Caspase cleavage was detectable in the sensitive T-ALL cell lines following stimulation with different SMs. In addition, the bivalent SMs BV6 and Birinapant more effectively induced cleavage of PARP and Caspases than the monovalent SMs in Reh and UoCB6 cells. In addition, we found that SM-induced cell death in Reh and UoCB6 cells is partially dependent on autocrine TNF-secretion. Interestingly, we identified ALL- SCL cells to die in a TNF-dependent manner, whilst CEM cells die independently of TNF. This strongly suggests that TNF is not the only driver of SM-induced cell death in ALL cells.

Summary/Conclusions: We identified a subset of both, BCP- and T-ALL cell lines to be sensitive to SM-induced cell death with IC50 values below 1 micromol. Monovalent SMs are less effective than bivalent SMs in killing ALL cell lines. SMs induce differential modes of cell death with a variable dependency on autocrine TNF secretion in the sensitive ALL cell lines. In-depth molecular characterization of resistance mechanisms of ALL cells to SM-induced cell death is required to identify patients that will benefit from a SM-based treatment regimen.

E839

SINGLE-AGENT MOR208 IN PATIENTS WITH RELAPSED/REFRACTORY (R/R) B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA (B-ALL): A SINGLE-ARM PHASE II STUDY

R. Klosic1,*, M. Winderlich2, S. Ambarkhane3, E. Jabbour3
1Department of Internal Medicine, Division of Hematology & Oncology, The Ohio State University, Columbus, OH, United States, 2MorphoSys AG, Planegg, Germany, 3Department of Leukemia, Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, TX, United States

Background: CD19 is a type I transmembrane glycoprotein that is expressed throughout B-cell development until terminal plasma cell differentiation. CD19 is also broadly and homogeneously expressed across different B-cell malignancies, including B-ALL. MOR208 is a CD19 monovalent antibody with an enhanced Fc region, which leads to a potentiation of antigen-dependent cell-mediated cytotoxicity and antigen-dependent cell-mediated phagocytosis. Additionally, it has a high occupancy and safety of single-agent MOR208 in the treatment of patients with R/R B-ALL.

Methods: This is a single-arm phase II study of MOR208 in patients aged ≥16 years with histologically confirmed R/R B-ALL with progression after at least one prior therapy. Patients with Philadelphia-chromosome-positive (Ph+) B-ALL were eligible if they had received ≥2 dose-limiting cycles of a tyrosine kinase inhibitor. MOR208 was administered at 12mg/kg IV, weekly, over 28-28 days, with a loading dose on day 4 of cycle 1. Patients with a partial response (PR) could receive a further 2 cycles of MOR208; patients with a complete response (CR) or CR with incomplete count recovery (CRi) after 2-4 cycles could receive an extended phase of consolidation. The primary endpoint was the overall response rate. The trial was prematurely terminated due to insufficient evidence of single-agent activity leading to slow recruitment.

Background: Acute lymphoblastic leukemia (ALL) exhibits a bimodal age distribution with 60% of cases occurring in children and adolescents (<20 y) and 25% in older adults (>45 y; http://seer.cancer.gov/csr/1975_2013/) and is the most common childhood malignancy (Hematol Rep 2014;6:5554; Front Oncol 2014;4:63). ALL has an incidence of 1.2 to 1.4 per 100,000 per year in Europe (BM C Cancer 2015;15:771). As many as 20% of children relapse after initial therapy, with subsequent poor clinical outcomes (Front Oncol 2014;4:63). Promising results were observed with KTE-C19, an anti-CD19 chimeric antigen receptor (CAR) T cell therapy, in B cell malignancies, including refractory, aggressive non-Hodgkin’s lymphoma in the ZUMA-1 trial (Blood 2016;128:LBA-6). Here, we present updated data from the phase 1 portion of ZUMA-1, a phase 1/2 trial of KTE-C19 in pediatric and adolescent patients with relapsed/refractory (R/R) ALL.

Aims: The aim of the phase 1 study is to evaluate the safety of KTE-C19 in pediatric and adolescent patients with R/R ALL.

Methods: Pediatric and adolescent patients (aged 2-21 y) with high burden R/R ALL (>25% marrow blasts), adequate renal, hepatic, pulmonary and cardiac function received 2×106 CAR T cells/kg after low-dose conditioning chemotherapy consisting of cyclophosphamide (900mg/m2 onced) and fludara- bine (25mg/m2/d for 3 days) (CyFlu). The primary endpoint of phase 1 is the safety profile. The secondary endpoints include efficacy outcomes and biomarker assessments.

Results: As of 19 Jan 2017, 5 patients have enrolled and 4 have been treated with KTE-C19 at ≥2×106 CAR T cells/kg. KTE-C19 was successfully manufactur- ed in a centralized, streamlined 6-8-day process for all patients across a wide range of baseline absolute lymphocyte counts (0.21–1.0×109/L), except in 1 patient who had disease progression with white blood cells 150,000/L at apheresis and <0.2% T cells in the apheresis collection. All 4 treated patients had high disease burden with a median marrow lymphocytosis content of 57%
(range, 41–99%). All 4 patients received bridging chemotherapy during the manufacturing period before conditioning chemotherapy and KTE-C19. No patient experienced a dose-limiting toxicity. One patient had a grade 5 adverse event of disseminated mucormycosis which was not related to KTE-C19. Cytokine release syndrome was reported in all 4 patients (all ≤ grade 3); neurologic events were reported in 1 patient (grade 3). All cytokine release syndrome events resolved with tocilizumab, corticosteroids, and/or siltuximab plus other supportive care with a median duration of 8.5 days (range, 4–16 days). Minimal residual disease-negative remission was observed in all 4 patients. One patient received stem cell transplant post-remission, which is allowed per protocol at investigator discretion. Peak expansion of CAR T cells occurred 1-2 weeks post-KTE-C19 infusion. Updated data with additional patients, different dose of KTE-C19, earlier tocilizumab use, and biomarkers will be presented.

Summary/Conclusions: KTE-C19 after low-dose CyFlu has been tolerable and appears safe for further analysis in pediatric and adolescent patients with R/R ALL. No infections were observed with KTE-C19 at the 2×106 cells/kg dose in patients despite high leukemic burden. All patients receiving KTE-C19 achieved a minimal residual disease-negative remission. Based on these results, ZUMA-4 continues to enroll (NCT02625480).

COMPARISON OF 8-COLOR FLOW CYTOMETRY AND PCR-BASED METHODS IN MEASUREMENT OF MINIMAL RESIDUAL DISEASE IN ADULT ACRE LYMHPHOCYTIC LEUKEMIA

S. Hrabovsky1,2,*, F. Folber1,2, J. Horacek3,4, O. Stehlikova1, H. Jelinkova1, C. Salek1,6, M. Dubek1,2,7
1Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, 2Faculty of Medicine, Masaryk University, Brno, 34th Department of Internal Medicine – Hematology, University Hospital and Charles University, Faculty of Medicine Hradec Kralove, 4Department of Military Internal Medicine and Hygiene, University of Defence, Faculty of Military Health Sciences, Hradec Kralove, 5Institute of Hematology and Blood Transfusion, 6First Faculty of Medicine, Charles University, Prague, 7Central European Institute of Technology, Brno, Czech Republic

Background: The presence of minimal residual disease (MRD) is the most important prognostic factor in adult acute lymphoblastic leukemia (ALL). MRD monitoring is routinely performed by flow cytometry (FCM) and real-time quantitative polymerase chain reaction methods (RT-PCR).

Aims: We conducted a retrospective analysis comparing these MRD measurement methods in ALL patients treated in three Czech hematology/oncology centers within the CELL group (Czech Leukemia Study Group for Life).

Methods: Adult patients (age 18-55) with both Ph-negative and positive ALL were enrolled in the study, all treated consecutively between 2008 and 2016 according to a pediatric-inspired CELL ALL protocol. Samples for MRD evaluation were acquired from bone marrow on day 26 of induction (D26) and in the 11th week of treatment before the first consolidation (W11). We divided RT-PCR MRD positive and negative groups using three different cut-off values and analyzed them separately: 1) 1.0×10⁻³, 2) 1.0×10⁻⁴, 3) every RT-PCR positive result considered MRD positive even below 1.0×10⁻⁴. Cut-off value 1.0×10⁻³ was used for FCM MRD. Results were statistically analyzed by the Kaplan-Meier method and log-rank (Cox-Mantel) test.

Results: Total number of 103 patients was evaluated. Nine of them (8.7%) did not reach a hematological remission on D26 were excluded from the study. The median follow-up of the final cohort was 36.9 months. MRD evaluation was carried out by 8-color FCM (N=73) and RT-PCR of immunoglobulin heavy chain (IgVH, N=62) or T-cell receptor (TCR, N=3) clonal rearrangements and BCR-ABL (N=24), MLL-AF4 (N=4) and E2A-PBX1 (N=1) fusion genes.

Methods with strongest sensitivity for OS prediction on D26 were RT-PCR with 1.0×10⁻³ cut-off (4-year OS: 76.6% vs 48.8%, median OS: not reached vs 39.1 months; p=0.012) and FCM (4-year OS: 78.3% vs 30.3%, median OS: not reached vs 27.4 months; p=0.016). The most sensitive method in W11 was RT-PCR with every positive result considered MRD positive (4-year OS: 79.6% vs 53.1%, median OS: not reached vs 46.5 months; p=0.013). Flow cytometry and PCR with other cut-offs were not sufficiently sensitive. The sub-analysis of Ph-negative patients has shown the same results for RT-PCR (p<0.01).

Summary/Conclusions: Our analysis has shown both RT-PCR and FCM to be suitable methods for MRD assessment on D26 of induction in adult ALL patients requiring an intensive treatment. Furthermore it seems convenient to take any RT-PCR positivity (even below 1.0×10⁻⁴) into account in W11 and later stages of treatment. FCM can be used for MRD assessment on D26, but it is not sufficiently sensitive in later stages of treatment. We suggest using RT-PCR as a method of choice for MRD assessment in adult ALL while reserving FCM as a backup method for patients without applicable RT-PCR target or when faster MRD evaluation is needed.

QUALITY-ADJUSTED LIFE YEARS (QALY) FOR INOTUZUMAB OZOGAMICIN VS STANDARD OF CARE FOR RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA (R/R ALL)

I. van Oostrom1, Y. Su2, B. Heeg1, T. Wilke1, A. Smith3, F.R. Loberiza2, 1Ingress-health Netherlands, Rotterdam, Netherlands, 2Pfizer Inc, New York, United States, 3Ingress-health Germany, Wismar, Germany, 4Pfizer, Ltd, Walton Oaks, United Kingdom

Background: Inotuzumab Ozogamicin (InO), an anti-CD22 antibody-calicheamicin conjugate, has demonstrated superior superior clinical activity versus standard of care (SOC; intensive chemotherapy), including clinically meaningful improvement in overall survival (OS), high rates of complete remission (CR) and potentially curative hematopoietic stem cell transplantation (HSCT), and favorable patient-reported outcomes for R/R ALL in the phase 3 INO-VATE trial. Quality of life (QoL) is an important consideration for R/R ALL patients in both short- and long-term survival.

Aims: This study aimed to estimate mean overall survival adjusted for QoL (QALY) for patients treated with InO vs SOC.

Methods: A Markov model was developed with five health states - No CR, CR, post-HSCT, progression, and death. Lengths and transition probabilities between health states and mortality rates were based on the InO-VATE trial. These rates were extrapolated to duration using survival fits obtained in survival regression for health states not captured in the trial. Disutilities from adverse events experienced during and after treatments, including adverse events as a result of subsequent HSCT such as veno-occlusive disease (VOD), were taken into account in overall QoL. Outcomes were discounted at 1.5% and half-cycle corrected.

Results: The estimated mean LY and QALY in each health state for InO and SOC and their differences are shown in Table. Most gains in LY and QALY for InO over SOC were from Post-HSCT. These gains are greater in the InO arm versus SOC and their differences are shown in Table. Most gains in LY and QALY for patients treated with InO.

Summary/Conclusions: This analysis taking into account both quality and quantity of life estimates shows that InO offers an average of nearly 2 more years of QALY compared to SOC in R/R ALL, based on higher CR and HSCT rates, “tail-of-the-curve” survival gains, and better QoL. This can help inform patients, physicians and payers in decision making.

A COST-EFFECTIVE, HIGH SENSITIVITY 10-COLOR SINGLE TUBE FLOW-CYTOMETRY BASED B-CELL PRECURSOR ACUTE LYMPHOCYTIC LEUKEMIA MINIMAL RESIDUAL DISEASE (MRD) ASSAY WITH STUDY OF ARTIFACTS AND MIMICS

G. Chatterjee1,*, D. Dhaliwal1, S. Ghogale1, B. Yajamanam1, N. Deshpande1, G. Oaks, United Kingdom

Supported by MUNI/A/1106/2016 grant of Masaryk University, Czech Republic and the Czech Leukemia Study Group for Life.

haematologica | 2017; 102(s2) | 347

Madrid, Spain, June 22 – 25, 2017
FC-MRD assay with high sensitivity of at least 1 in 10^5 and applicability in >97%

We studied 230 BCPALL MRD samples. FC-immunophenotyping and described their prevalence and immunophenotypic features.

Aims: 1. To study the applicability and sensitivity of a 10-color high event single tube FC-MRD assay for BCPALL; 2. To document the rare BM cellular elements with description of rare BM cellular elements and artifacts causing interference in analysis.

Methods: We studied 230 BCPALL MRD samples. FC-immunophenotyping was performed on Navios flow-cytometer using bulk-lysis-and-stain method and data was analyzed with Kaluza-software. MRD was monitored using 10-color single tube FC-MRD assay including CD45, CD10, CD19, CD20, CD34, CD38, CD58, CD98, CD123 and CD25/CD73 with an additional 4-color nuclear dye (SYTO13) tube. Samples with cluster of ≥20 and ≥2 leukemia associated phenotypes (LAIPs) were called MRD-positive. High number of events were acquired for MRD-assay (1.5 to 6 million). To evaluate the applicability of assay, number of LAIPs were determined in diagnostic and MRD samples. In addition, the frequency and antigen expression pattern of mimics and artifacts were studied.

Results: We studied 230 BCPALL MRD samples. High number of events was acquired for MRD-assay with median-events 342700 (range, 1678800 to 6052800). We determined the limit of detection (LOD=10 events) and limit of quantitation (LOQ=30 events) by performing dilution assay. MRD was positive in 107 (46.5%) samples with median of 0.135% and range of 0.0003% to 48.3%. We categorized positive MRD results into samples with MRD <0.001% ,<0.01% ,<0.1%, <1% , <10% and >1% and they were respectively 1.74%, 10.43%, 13.48%, 5.65% and 10.00%. Furthermore, in 24 samples with MRD-positive ≥0.01% and >1.5 million acquired-events, the results were compared between time-gated initial 500000-events and initial 1000000-events and all events acquired. Sixteen samples among these were found to be negative in initial 5000000-events and eight in initial 10000000-events highlighting the importance of acquisition of >1.5 million cells.

We categorized different rare cellular events and artifacts in the following way: 1) CD34+ mature B cells; 2) CD10+ mature B cells; 3) CD73+ mesenchymal stromal/ stem cells and endothelial cells; 4) CD123+ CD19+ 7DC precursors; 5) CD86+ CD58+ B cell precursors (BCP); 6) CD19+ NK cells (Table 1). We also described their immunophenotypic features highlighting the differentiating features from MRD and B cell precursors (Figure 1).

Results: Basal evaluation was performed on 26 SR and 16 HR pts. Three SR pts with severe anemia (<7g/dl and/or BMI>25) showed altered GLS at TP0. At the succeeding evaluation, 2 patients recovered, while one obese adolescent confirmed GLS and LVEF alterations. Follow-up after induction therapy (TP120) was performed on 10 SR pts and on 11 HR pts: GLS was altered in 3/10 SR pts (30%) and in 7/11 HR pts (63.6%). Two SR pts showed alterations in both GLS and LVEF values, while one child had isolated GLS impairment. Out of the 7 HR pts, one had both GLS and LVEF impairment and 3 worsened in LVEF at TP150. The 3 remaining HR pts subsequently recovered in GLS value.

SPECKLE TRACKING ECHOCARDIOGRAPHY IN PEDIATRIC ACUTE LYMPHOBLASTIC LEUKEMIA: A PRELIMINARY STUDY

M. Belloni1,2, G. Biddeci1, G. Bordini2, E. Varotto1, M. Pillon1, G. Geranio1, G. Basso1, B. Buiolini1, A. Tedeschi1, B. Castaldi1, M.C. Putti1

1Clinic of Pediatric Hemato-Oncology - Department of Woman and Child Health, 2Pediatric Cardiology Unit - Department of Woman and Child Health, University of Padua, Padova, Italy

Background: Children with acute lymphoblastic leukemia (ALL) are at risk for late-onset anthracycline-related cardiotoxicity. Left ventricular Global Longitudinal Strain (GLS) by Speckle Tracking Echocardiography has been recently used to identify preclinical late-onset heart failure in both adult and pediatric ALL patients. Nonetheless, efficient strategies for the early diagnosis and management of cardiac toxicity during chemotherapy are still not defined.

Aims: We prospectively studied LV function in ALL patients treated at our Centre, according to AIEOP-BMF ALL 2009 protocol, measuring both GLS and M-Mode Left Ventricular Ejection Fraction (LVEF).

Methods: Out of 42 consecutively examined ALL patients (pts), 32 (76%) underwent prospective follow-up (Table 1). At basal evaluation, 19 pts had Hb<9 g/dl, 7 pts had fever, 7 pts had hyperleukocytosis, 2 had BMI>25. The influence of there factors on cardiological parameters could not be evaluated due to low numbers. Echocardiography was performed with Vivid E9 ultrasound system (GE Medical System) and MSRS probes at the following time points (TP): diagnosis (TP0), after induction phase (anthracycline cumulative dose 120mg/m2, TP120), at the end of anthracycline exposure (TP240 in standard risk-SR-pts; TP320 in high risk-HR-pts). HR pts underwent intermittent controls before each re-exposures (TP150, TP210, TP270). GLS values>19% (or GLS drop >10% from basal value) and LVEF values<65% (or LVEF drop >10% from basal value) were considered as abnormal. Statistical analysis was performed using Student’s t-test.

Figure 1.

Summary/Conclusions: We established a cost-effective 10 color single tube FC-MRD assay with high sensitivity of at least 1 in 10^5 and applicability in >97% BCPALL MRD samples. We also described the frequency and extent of different cellular events and artifacts that can interfere with high-sensitivity BCPALL FC-MRD analysis. The knowledge regarding presence and antigen expression pattern of these cellular events and artifacts are critical to avoid potential false positive results.
with b-blockers, as they could limit anthracycline toxicity by their heart rate-lowering activity and antioxidant effect. All the 8 patients subsequently improved in both GLS and LVEF values, despite the occurrence of one episode of mild hypotension in 2 patients.

Summary/Conclusions: ALL children, even if exposed to low doses of anthracycline, show early signs of LV impairment. Overt drop in LVEF, when present, mostly follow GLS alterations. Alterations seem more frequent in HR pts, possibly due to the higher burden of both leukemia itself and HR treatment. Further studies on wider series are needed to confirm the relevance of the early diagnosis of LV preclinical dysfunction in pediatric ALL patients.

Methods: Rearranged products from within the TRG and TRB locus were generated by PCR using proprietary multiplex master mixes with consensus primers targeting all TRG and TRB V and J exon families, synthesized with MiSeq specific adapter and individual barcode ID sequences. The PCR products were purified, quantified and pooled into equimolar library. The final library was sequenced on the MiSeq. The sequencing data FASTAQ output file was analyzed using the Illumina® MiSeq® software. The software generated frequency distributions for the top 200 rearranged sequences, identified the DNA sequences, generated V-J assignments and V-J usage. Cell line DNA known TRG and TRB V-J rearrangements was tested for the analytical performance. DNA from different clinical sample type (FFPE, PB, BM) was used to assess the clinical performance.

Results: This NGS assay was able to correctly detect all known TRB and TRG rearrangements from cell line DNA. The on-target reads per sample were 90% - 100%. Excellent linearity (R²>0.90), sensitivity of 2.5% for clonality, and reproducibility (<20% CV) were demonstrated with serial dilutions of contrived cell line DNA. The clinical performance of the LymphoTrack® TRG + TRB NGS assays was evaluated on different clinical samples that have also been tested using the PCR-CE TRG and TRB assays. Assessment of clonality using the LymphoTrack® MiSeq and PCR-CE assays for TRG and TRB demonstrated good concordance.

Summary/Conclusions: This combo NGS assay provides a fast, simple, and accurate method to detect clonality. In combination with the LymphoTrack software, the TRG + TRB MiSeq assay can identify clonal TRG and TRB V-(D)-J rearrangements and the specific V-(D)-J region DNA sequences required to track clones in follow-up testing. Excellent concordance of clonality with specific rearrangements was demonstrated between LymphoTrack® MiSeq and PCR-CE method.

Background: NUDT15 polymorphism has been recently identified as a determinant of thiopurine intolerance. 6-thioguanine nucleotides (6-TGN) is monitored to prevent hematopoietic toxicity in acute lymphoblastic leukemia (ALL). Aims: This study intended to evaluate the impact of NUDT15 polymorphism on thiopurine intolerance and 6-TGN level in Korean children with ALL.

Methods: Genotyping of NUDT15 was performed in 258 children with ALL who were registered in Samsung Medical Center. According to NUDT15 diplotype, patients were classified into low risk (LR, wild-type), intermediate risk (IR, heterozygous variant) or high risk (HR, homozygous or compound heterozygous variant). Total of 182 were finally included after 76 patients were excluded for TPMT variation or lack of information during maintenance therapy; LR (n=131), IR (n=46), and HR (n=5).

Results: The least 6-mercaptopurine (6-MP) dose (mg/m²/day) were administrated at 0.9, 2.6, 5.9, 9.5, 13.8, 15.1, 16.9, 19.0, 21.5, 25.0, 28.7, 31.2, 34.0, 35.9, 38.7, 41.9, 43.5, 45.3, 47.1 mg/m²/day for LR, IR, and HR, respectively. The lowest WBC and platelet counts and hemoglobin level were observed in HR. 6-TGN level (pmol/8x10⁸ RBC) divided by 6-MP dose (mg/m²) was the lowest in HR group (4.4 vs IR 13.3 vs HR 14.7, p<0.01).

Summary/Conclusions: Patients with NUDT15 variants encountered significant thiopurine intolerance even with low level of 6-TGN. This concurs with the existing hypothesis that NUDT15 protein may prevent incorporation of thiopurine active metabolites into DNA. Therefore 6-TGN monitoring is not useful to predict hematopoietic toxicity for patients with NUDT15 variant.

E847 DETECTION OF CLONALITY IN CLINICAL SPECIMENS FROM SUSPECTED B-CELL MALIGNANCIES USING COMPREHENSIVE IGH LYPHOTACK® MISEQ® AND PGAM ASSAYS

Y. Huang1, K. Huttl1, J. Panganiban1, A. Jacobsen1, N. Wong1, D. Duong1, R. Bob2, S.A. Plien3, L. Bernard2, E. Gerbino1, T. Stenzel1, J. Miller1
1Invisioescape Technologies, San Diego, United States, 2Institute for Pathobiology, Berlin, Germany, 3Haematopathology Unit at European Institute of Oncology, Milan, Italy

Background: PCR-based capillary electrophoresis (PCR-CE) methods targeting immunoglobulin heavy chain (IGH) were designed to include both platform specific adapter sequences and individual barcodes so multiple independent PCR products could be combined and sequenced together on the MiSeq or PGAM platforms. MiSeq IGH FR master mixes were individually manufactured with 24 indices to allow analysis of 22 samples with 2 controls. PGAM IGH FR master mixes were manufactured with 12 indices to allow analysis of 10 samples with 2 controls. DNA was extracted from 21 PB, 37 FFPE and 1 BM clinical samples. Single step PCR amplification of 50 ng DNA input was followed by ampiclon purification. Equimolar amounts of purified amplicons were pooled and loaded onto the sequencer. MiSeq and PGAM instruments used were the LymphoTrack® IGH (FR1, FR2, FR3) Assays for both the illumina® MiSeq® and Thermofisher Scientific® ion PGM™ platforms, which detect the vast majority of rearrangements in a single NGS run. In this pilot study, we compared the performance of both LymphoTrack® IGH MiSeq and PGAM Assays to the IGH PCR-CE assay by testing in 59 anonymized, blinded clinical samples.

Aims: To assess the clinical performance of LymphoTrack® IGH MiSeq and PGAM Assays

Methods: LymphoTrack® IGH Assay has been developed for both the MiSeq and PGAM platforms. Proprietary consensus primers targeting the V and J gene segments of IGH were designed to include both platform specific adapter sequences and individual barcodes so multiple independent PCR products could be combined and sequenced together on the MiSeq or PGAM platforms. MiSeq IGH FR master mixes were individually manufactured with 24 indices to allow analysis of 22 samples with 2 controls. PGAM IGH FR master mixes were manufactured with 12 indices to allow analysis of 10 samples with 2 controls. DNA was extracted from 21 PB, 37 FFPE and 1 BM clinical samples. Background: Minimal residual disease (MRD) monitoring in Acute Lymphoblastic Leukemia (ALL) is an accepted standard of care in both adult and pediatric patients as one of the strongest predictive factors for disease outcome and as a stratification tool for treatment intensification and allogeneic stem cell transplantation. The currently accepted standard of molecular monitoring with either immunoglobulin heavy or kappa chain (IG) or T-cell receptor (TCR) quantitative PCR (qPCR) in Philadelphia negative ALL allows for sensitive monitoring of MRD, but requires a high degree of expertise, and factors such as cost and turnaround time may limit general applicability of this technique. Flow cytometric MRD monitoring is utilized in many centers, with increased sensitivity seen with implementation of multi-parameter flow cytometry at 8-colours or more.

Aims: We sought to compare a 10-color flow cytometry assay for detecting MRD in B-ALL with standard molecular monitoring.

Methods: To facilitate rapid identification of MRD in patients with B-ALL, we developed a 10-colour single tube flow cytometry assay utilizing CD19, CD22, CD20, CD38, CD58, CD13/33, CD66c, CD10, CD45 and CD34 as markers. This assay was sensitive to as many as 1 x 10^6 cells. Once normal maturation patterns were established, patient samples were analyzed in parallel to standard of care molecular monitoring with either IG/TCR qPCR in Philadelphia negative (Ph-) disease and BCR-ABL qRT-PCR in Philadelphia positive (Ph+) disease. Statistical correlation was performed in Graphpad Prism version 7.0 for linear regression and calculation of correlation coefficient.

Results: 33 samples at different time points from 13 patients were analyzed by flow cytometry. 9 samples from 9 patients were taken at diagnosis. Whilst an informative MRD phenotype was identified by flow cytometry in all 9 patients, a molecular assay was not able to be developed in one patient due to lack of an identifiable marker. 24 samples from 13 patients were tested for MRD by flow cytometry. The median lower limit of detection was 0.0078% (range 0.0016% to 0.028%) with a median lower limit of quantification of 0.018% (range 0.002% to 0.07%). A sensitivity of <0.01% was attained in 21 of 24 samples (88%). 20 samples from 11 patients were tested concurrently for MRD by both molecular and flow cytometry methods. 11 samples were in Ph- disease and 9 were in Ph+ disease. MRD was detected by both molecular and flow cytometry in 11 samples and not detected by both methods in 8 samples. In one sample, MRD was detected only by molecular at an unquantifiable level. There was a strong correlation co-efficient between molecular and flow cytometric MRD analysis (R2=0.905, p<0.001). Correlation was strong with both IG/TCR based molecular analysis (R2=0.949, p<0.001) and BCR-ABL based molecular assays (R2=0.904, p<0.001).

Summary/Conclusions: 10-color flow cytometric minimal residual disease analysis with bulk lysis attains a high degree of sensitivity in minimal residual disease determination in precursor B-lineage Acute Lymphoblastic Leukemia. There was a strong correlation with molecular MRD monitoring for both quantification of MRD and determination of MRD negative status. Flow cytometric methods may also permit MRD monitoring in patients where a suitable molecular assay cannot be developed.
in experimental arms as well as in case of preceding hypoglycemic events in other patients of the respective trial center. Despite these analytical limitations, our data suggest that hypoglycemia during ALL treatment is a relevant and probably underestimated clinical problem. Further investigation including possible identification of predisposing metabolic conditions is required to avoid harm to patients by this preventable complication.

NUDT15 VARIANT IN KOREAN CHILDREN WITH ACUTE LYMPHOBlastic LEUKEMIA

Summary/Conclusions:

We examined the association between NUDT15 polymorphism and clinical outcome of children with acute lymphoblastic leukemia (ALL) in Korea. We conducted this study to investigate the treatment outcome of AYA ALL in Korea, and to define any patterns of care related to the treatment outcome of AYA ALL.

Background: Acute lymphoblastic leukemia (ALL) is the most prevalent pediatric cancer with cure rates approaching 90% with current therapy. Patient with ALL require long-term maintenance therapy. The combination of weekly methotrexate and daily 6-mercaptopurine (6-MP) is the backbone of ALL treatment regimen. Genetic polymorphism in thiopurine methyltransferase (TPMT) is well known to affect the 6-MP tolerance. However prevalence of non-function variant of TPMT is rare in Far East. Recently, a study has identified a variant of the NUDT15 gene associated with intolerance of 6-MP.

Aims: We examined the association between NUDT15 polymorphism and clinical outcome of Korean pediatric ALL.

Methods: NUDT15 genotyping and collection of clinical data was performed for 74 Korean pediatric ALL patients from two different hospital. For NUDT15 genotyping, DNA was extracted from whole blood/or bone marrow sample and Sanger sequencing was performed for exon 1 and 3 of NUDT15 gene. 6-MP dose intensity, defined as the ration of prescribed 6-MP dose over protocol planned dose.

Results: We found two kinds of variants, c.55_56insGAGTCG(rs869320766) in exon 1 from 8 patients and c.415C>T(rs116855232) in exon 3 from 14 patients of them, 7 patients had both variants and all variants were heterozygote. Patients could be divided to four distinct groups according to combinations of genotype (Table 1). 6-MP dose intensity in wild type was higher than three other genotypes during maintenance therapy (p=0.003) (Fig 1). The number of hospitalized days in wild type is small compared to other three genotypes (p=0.017).

Frequency of febrile neutropenia, hepatotoxicity, cumulative days of antibiotics use and overall survival did not significantly differ by NUDT15 genotype.

TREATMENT OUTCOME OF ACUTE LYMPHOBLASTIC LEUKEMIA IN KOREAN ADOLESCENTS AND YOUNG ADULTS

1Center for Pediatric Oncology, 2National Cancer Control Institute, 3Hematologic Oncology Clinic, National Cancer Center, Goyang-si, Gyeonggi-do, Korea, Republic Of

Background: The background of acute lymphoblastic leukemia (ALL) has markedly improved for last centuries, but the improvement was mainly observed in children under 10 years old. In contrast, the treatment outcomes of ALL in adolescents and young adults (AYA) still lag behind those of younger children.

Aims: We conducted this study to investigate the treatment outcome of AYA ALL in Korea, and to define any patterns of care related to the treatment outcome of AYA ALL.

Methods: Clinical data of 10-29 years old ALL patients diagnosed between 2002 and 2010 was extracted from Korean national health insurance service.

Data about patients’ diagnosis, age, gender, mainly treated department (internal medicine vs pediatrics), usage data of medications (L-asparaginase, 6-mercaptopurine, vincristine, prednisolone or dexamethasone), hematopoietic stem cell transplantation (HSCT), radiotherapy, survival, and follow-up duration were collected. Patients who were treated with steroid over 2 weeks, and L-asparaginase at least once in initial 2 months were considered to be treated as pediatric protocol, and who did not fulfill this criteria were considered to be treated as adult protocol.

Results: Total 1,223 ALL AYA patients were diagnosed between the 2002 and 2010, and excluding those who never treated, 1,208 patients underwent ALL treatment. Among them, 665 (55%) patients were treated with pediatric protocol, and the other 543 (45%) patients were treated with adult protocol. Radiotherapy was done in 278 (41.8%) and 186 (34.3%) in each group, and HSCT was done in 205 patients (30.8%) and 216 patients (39.8%) in each group, respectively.

Pediatric protocol group showed significantly better overall survival compared to adult protocol group in total age (65% vs 43%, P<0.0001), 10-13 years old (76% vs 57%, P<0.0001), and 20-24 year old patients (51% vs 31%, P=0.0116). In univariated analysis, patient age (younger), treatment protocol (pediatric), L-Asparaginase, 6-mercaptopurine, and steroid over 2weeks in initial 2 months were associated with better overall survival (P=0.0001 for each).

Summary/Conclusions: The overall survival rates in Korean AYA ALL were comparable with previous studies done at other countries. Patients treated with pediatric protocol tended to result better overall survival rate when compared to patients treated with adult protocol. Radiotherapy and early HSCT were widely used in the 2000s, and further study is needed to follow up the recent trend of treatment, and outcome as a result.

AUTOLOGOUS TRANSPLANTATION AS TIME-DEPENDENT FACTOR FOR SURVIVAL OF PATIENTS WITH T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA: STUDY DATA TO SIMULATION MODEL

S. Kulikov1, M. Rusinov1, A. Kulikkov1, E. Parvinchkovova2

1Biostatistics, 2Hematologic Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation

Background: The role of autologous hematopoietic stem cells transplantation (aHSCT) for patients with T-cell ALL is still being discussed. The resent Russian study of ALL shows the promising effect of aHSCT but there is a skepticism as the study was not randomized. The possible bias was referred to the “time selection” factor.

Aims: It’s need to prove that time selection cannot explain the magnitude of the effect of aHSCT on patient’s survival. The methods: We have developed SAS macros time-depend graphical and analytic procedures for time dependent factors: Land Mark (LM) methods, Mantel-Bay test, Cox regression model (CM) and also a base for simulation all end points and study events like remission, transplantation, relapse and death are well approximated by a mixture of exponent distributions. Non-constant (dropping) hazard rate exists in real study data. The consequence of violation of constant hazard assumption as most possible source of biases was tested on our simulation model in different situations. Real data multicenter study of ALL was used to fit simulation model parameters. Russian ALL study group held a prospective multicenter trial RALL-2009 in the treatment of Ph-negative adult ALL patients based on non-intensive but non-interruptive treatment (NCT01193933). The therapy was unified for all Ph-negative ALL pts, but in T-cell ALL/LBL autologous hematopoietic stem cell transplantation (auto-HSCT) after non-myeloablative BEAM conditioning was scheduled as late intensification (+3-4 mo of CR) followed by prolonged 2 years maintenance. From Jan 2009 till Jul 2016, 30 centers enrolled 107 T-ALL/LBL pts. Median age was 28 years (15-54 y), 34 f / 73 m; early T-cell (T/I) phenotype was verified in 56
(52.3%), mature (T-IV) - in 10 (0.4%), thymic (TII, CD1a+) ALL - in 41 pts (36.3%). T-lymphoblastic lymphoma (T-IVL <25% b/m blasts) was diagnosed in 22 pts (20.5%). Autologous HSCT was performed in 35, allogeneic in 7 pts.

Results: The survival analysis of real data shows 4-fold dropping hazard rate. The effect of aHSCT was confirmed by LM analysis, Mantel-Bay test - $P_{M/B}=0.0004$, Cox model output: 1/HR=15.9, $P=0.008$. Simulation model for remission consists of 3 fractions: early ($\alpha=10\%$, $\tau=0.05\$ m, $\delta=0\$ m), normal ($\alpha=57\%$, $\tau=0.28\$ m, $\delta=1\$ m) and late remission ($\alpha=33\%$, $\tau=1.31\$ m, $\delta=2.2\$ m), for survival consists of 2 fractions: short life ($\alpha=59\%$, $\tau=22\$ m), long life ($\alpha=41\%$, $\tau=600\$ m), (Fig.2). The first simulation experiment was performed in preposition that transplantation has no effect (HR=1). To exclude the random effect the sample size was N=4000, Mantel-Bay and Cox model show significant ($P_{M/B}=0.50$, $P_{Cox}=0.50$, HR=93) but LM plot demonstrates recognizable bias in transplanted patient group (Fig.3). The second experiment supposed that the existed effect of aHSCT (HR=0.5), N=5000. Mantel-Bay and Cox model would show significinance, but hazard rate was underestimated (PMB=.03, PCM=.03, HR=70. (0.50-0.97)). Other experiments were done for repeated simulation, which demonstrated a very good agreement of Mantel-Bay and Cox methods and their robustness.

Summary/Conclusions: The effect of autologous HSCT in T-cell ALL was confirmed by usual analysis and by simulation experiments. It was shown that potential bias caused by no constant hazard rate cannot explain the magnitude of HSCT effect demonstrated on real data. LM plot could express small bias. Mantel-Bay and Cox model are robust against violation of constant hazard assumption and give very concordant outputs. Cox model underestimates the effect of time-depending factor in case of dropping hazard. Simulations model is a good instrument for testing tests in situations of deviation from theoretical assumptions.

E854
INDUCTION WITH TYROSINE KINASE INHIBITORS, CONSOLIDATION WITH FLUDARABINE, ARA-C AND DAUNOXOME FOLLOWED BY ALLOGENIC STEM CELL TRANSPLANT IS AN EFFECTIVE AND FEASIBLE STRATEGY FOR PH+ ALL PATIENTS
N. Di Felice1,*, P. Minetto1, F. Guolo1, N. Clavio1, N. Bisso1, G. Pastori1, D. Guardo1, M. Gambella1, A. Bellodi2, E. Arboscello2, N. Colombo1, F. Ballerini1, M. Miglino1, R.M. Lemoli1, M. Gobbi1
1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genoa, 2Clinic of Internal Medicine III, Department of Internal Medicine (DIMI), University of Genoa, IRCCS AOU San Martino-IST, Genova, Italy

Background: The prognosis of Philadelphia positive (Ph+) acute lymphoblastic leukemia (ALL) patients has improved since the introduction of tyrosine kinase inhibitors (TKI). Following TKIs treatment almost all patients rapidly achieve complete hematologic remission (CR). However, only a minority of patients obtain complete molecular response and mot of all will eventually relapse without further treatment. On the other hand, the concomitant combination of TKIs to conventional chemotherapy regimens greatly increases complete molecular responses, but at the price of significant toxicities and high rates of deaths due to toxicity.

Aims: We present here the preliminary results of a sequential therapeutic strategy starting with TKI (Dasatinib) as single agent induction until CR is achieved. Fludarabine (Flu), Cytarabine (Ara-C), Lymphosar Daunorubicine (DNSX), FLAD regimen and Dasatinib were given as consolidation therapy, in order to maximize efficacy and reduce toxicity. Allogeneic stem cell transplantation (HSCT) was planned for all patients in MRD negative CR.

Methods: Dasatinib was given in association with steroids at the dosage of 140mg idie until the achievement of CR. FLAD regimen consisted of a three-days administration of Flu 30mg/sqm followed by Ara-C 2000mg/sqm and DNSX 100mg/sqm. Dasatinib was administered again from the end of chemotherapy and G-CSF was given to all patients starting from day 4 until complete hematological recovery. FLAD was administered for up to two cycles. Minimal residual disease (MRD) was evaluated in all patients after each FLAD either by multicolor flow cytometry (MFC), RQ-PCR for VDJ rearrangements, and RQ-PCR for BCR/ABL.

Results: From January 2008 to December 2016, 8 Ph+ ALL at diagnosis (medi-an age 52 years) have been enrolled in this protocol. The median follow-up was 27 months. All patients received 70 days induction with Dasatinib + Steroids and achieved CR with complete hematological recovery. In all patients but one, however, BCR/ABL was still positive both on day 33 and on day 70. Then to cure them we used MFC MRD positive on day 33 (one on day 70 also), whereas five patients achieved MFC MRD negativity on day 33. After the first FLAD course all patients achieved MFC MRD negativity, with four patients achieving also negativity for VDJ rearrangements and BCR/ABL transcript. FLAD was very well tolerated, with a median ANC and platelet recovery of 7.5 and 4 days, respectively. No patient experienced relapse so far and 5/8 patients proceeded to HSCT. Two patients are currently waiting for transplant. Overall, 6 patients are alive and in MRD negative CR at the time of analysis. One patient died at day +289 after SCT due to non-relapse mortality and one has died after the first FLAD in molecular CR because of an unrelated event.

Summary/Conclusions: This therapeutic strategy proved to be very well tolerated and extremely effective for Ph+ ALL patients. Administering FLAD in patients who had already achieved complete hematological response with Dasatinib + steroids allowed us to reduce the period of neutropenia and thrombocytopenia compared to what is reported after combined TKI and chemotherapy treatment given at diagnosis. Most patients underwent HSCT in molecular CR.

BONE MARROW MRD EVALUATION ON DAY 7 OF STERoidal TREATMENT OF MODIFIED ST JUDE TOTAL XV THERAPY IN STANDARD/LOW RISK PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA
S. Aytaç1,*, M. cetin1, I. Yaman Bajin1, I. Altan1, S. unal1, B. kuskonmaz1, D. uckan1, F. gumruk1
Pediatric Hematology, Hacettepe University, Ankara, Turkey

Background: In the recent years it was cleary showed that levels of minimal residual disease (MRD) studied by flowcytometry during treatment reflect the overall response to the chemotherapy and give a chance to individualize treatment and improved outcome.

Aims: To determine the clinical significance of MRD on day 7 of initial steroid treatment in patients with childhood ALL we analyzed data from 173 patients treated with modified St Jude Total XV therapy between 1 January 2008 and 31 December 2015.

Methods: According to our previous successfull results with high dose methilprednisolone (HDMXP) we add 7 days of HDMXP to the modified St Jude Total XV as an initial treatment and randomized patients at doses of 10mg/kg/d or 20mg/kg/d HDMXP: not exceeding at maximum 1000mg methylprednisolone. After the end of 7th day of steroid concomittant chemotherapy was given and the doses were tapered gradually to 5mg/kg/d and 10mg/kg/d in each group respectively. By the 3rd week of treatment steroid dose was tapered to 2mg/kg/d in both groups and continued with this dose till the end of 3rd week of induction phase. MRD levels were studied at the 15th, 22nd and 42nd days of treatment according to the protocol. However we also analyse steroid response rate by the peripheral smear on day 7. Moreover, patients were asked to obtain simultaneously optional bone marrow aspiration after getting informed consents to show whether there will be any concordance with the steroid response and/or whether it can give any idea of the outcome.

Results: Steroid response rate on day 7 by peripheral smear was 91% (n=158) for the whole group. However simultaneously bone marrow MRD measurement was done in 22 of the 173 patients. There were 13 female and 9 male patient with a median initial WBC count of 8400/mm$^3$ (1100-55300/mm$^3$),all were Calla+ pre B cell ALL (17 low risk ALL, 6 standart risk and 1 high risk ALL),all were in complete remission and all except one is alive at the time of the analy-sis. There were 10 patients receiving 10mg/kg/d HDMXP and 12 patients were in the group of 20mg/kg/d HDMXP. MRD levels were not statistically different on day 7 between these two groups. Furthermore all patients except 2(one in each group) were steroid responsive by means of peripheral absolute blast count <1000/mm$^3$. Bone marrow MRD on day 15th and 42nd there were no statistically significant difference in each group(P=0.05).Although some of those patients in each group have high levels of MRD on day 7, interestingly they were all steroid responsive.

Summary/Conclusions: Our preliminary results suggest to think that MRD level on day 7 in a small group of low/standart ALL patients may not predict outcome.
Acute leukemia microenvironment is essential for development of new treatment options. Further knowledge gained from multiple cytokine and adhesion molecule evaluation could help to improve treatment outcomes. Aims: The aim of this study was to evaluate baseline levels of cytokines, cytotoxic receptor molecules and adhesion molecules in newly diagnosed acute lymphoblastic leukemia (ALL) patients and to assess their correlation with baseline characteristics and prognostic factors.

Methods: A total of 30 newly diagnosed ALL patients (median age 46, range 22–75 years, 20 males) were included in this study. We evaluated serum levels of 31 analytes, specifically 21 cytokines, 4 soluble cytokine receptors, 5 soluble adhesion molecules and 1 hormone (C-peptide). All analytes were measured by biochip array technology on Evidence investigator analyzer (Randox). Serum levels of tested analytes were correlated with baseline characteristics and prognostic factors, such as age, sex, risk group according to GMALL (SR 9, HR 9, VHR 12 patients), full blood count parameters (including percentage of blasts), biochemical parameters (LDH, CRP), response to induction therapy (CR rate after induction), progression-free survival (PFS) and overall survival (OS).

Results: Comparing analytes with baseline characteristics, we found significant negative correlations between IL-7 and leukocyte count (r=-0.633; p=0.032), percentage of blasts in peripheral blood (r=-0.695; p=0.004) and LDH (r=-0.604; p=0.075). Furthermore, we found significant positive correlations between IL-7 and sGLUT4 (r=0.801; p=0.0001), sIL-2R and CD163 (r=0.573; p=0.0012). Correlations with baseline risk stratification according to GMALL did not reach statistical significance. In the study population, CR rate after induction was 86% (MFD negative in 29%), 1-year PFS 68% and 1-year OS 73% (2 patients died during induction therapy). Higher levels of EGF were associated with failure to achieve CR after induction therapy (r=0.689; p=0.073). So far, no significant correlations between baseline analyte levels and inferior PFS or OS were found. In newly diagnosed ALL patients, we found statistically significant correlations between sTNFR-1 and sTNFR-2 (r=0.805; p=0.0001), IL-1α and IL-4 (r=0.700; p=0.008), sTNFR-2 and M-CSF (r=0.657; p=0.037), sTNFR-2 and VCAM-1 (r=0.652; p=0.004). Correlations between IL-7 and other analytes did not reach statistical significance.

Summary/Conclusions: Our series of resistant pts is comparable to the PACE study population by initial characteristics and high frequency of BCR-ABL mutations. CR was achieved in most pts, suggesting the role of PON as a bridge-agent in resistant disease. This finding is similar to 61.2% of JL1 expression in adult ALL and 57.9% of expression in adult ALL reported previously. The JL1 expression was significantly associated with some immunophenotypic features, but was not significantly associated with clinical outcome. These findings demonstrates that anti-JL1 antibody might be used in childhood acute leukemia patient showing JL1 expression.

JL1 ANTIGEN EXPRESSION OF LEUKEMIC CELLS IN CHILDHOOD ACUTE LEUKEMIA E. You1, S. Kim2, C.-J. Park1, S. Jang1, Y.-U. Cho1, C.H. Yoon1, K.-N. Koh3, H.J. Im1, J.J. Seo2

1Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, 2DNonA, 3Department of Pediatrics, Asan Medical Center Children’s Hospital, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: JL1 is a novel epitope of CD43, which is known to be specifically expressed depending on the differentiation stages of hematopoietic cells. JL1 antigen is expressed on tumor cells of T, B, and myeloid lineage in >80% of acute leukemia patients, and its expression is limited in normal multipotent hematopoietic cells. The antigen is not expressed on mature peripheral blood cells or other normal tissues. Thus, the clinical phase 1 test of a therapeutic agent for leukemia targeting JL1 is being conducted, and when anti-JL1 antibody was combined with a toxic substance, its therapeutic effect was found earlier in preclinical trials. Aims: This study aims to examine JL1 expression of leukemic cells in childhood acute leukemia.

Methods: Between December 2014 and January 2016, a total of 71 patients younger than 21 years with acute myeloid leukemia (AML, n=25), and acute lymphoblastic leukemia (ALL, n=46) were enrolled in this study. Expression of JL1 antigen was measured using the JL1 monoclonal antibody (Beckton-Dickinson, San Jose, CA USA) based flow cytometry, and an expression of 20% or above was defined as positive JL1 expression. Pathological and immunophenotypic characteristics, and clinical outcomes of the patients were analyzed.

Results: Positive JL1 expression was observed in 16 (64.0%) patients with AML, and 27 (58.7%) with ALL. In AML patients, positive JL1 group showed higher expressions than negative JL1 group in CD 14 (P=0.043), CD7 (P=0.026), CD56 (P=0.016) and lower expressions in CD65 (P=0.05). With regard to ALL patients, CD 20 (P=0.002) and CD2 (P=0.005) expressions were significantly higher in JL1 positive group than JL1 negative group. Positivity of JL1 antibody did not show significant difference between B- and T-lineage ALL (P=0.671). Positivity of JL1 expression was not significantly associated with overall survival in 71 patients with newly diagnosed childhood acute leukemia (P=0.570).

Summary/Conclusions: 60.5% of childhood acute leukemia displayed positive JL1 expression. This finding is similar to 61.2% of JL1 expression in adult AML and 57.9% of expression in adult ALL reported previously. The JL1 expression was significantly associated with some immunophenotypic features, but was not significantly associated with clinical outcome. These findings demonstrate that anti-JL1 antibody might be used in childhood acute leukemia patient showing JL1 expression.

SERUM LEVELS OF CYTOKINES AND ADHESION MOLECULES AND THEIR ASSOCIATION WITH PROGNOSTIC FACTORS IN NEWLY DIAGNOSED ACUTE LYMPHOCYTIC LEUKEMIA PATIENTS M. Moreno1,2,3, K. Kusagawa1, K. Okuda1, L. Favaro1, P. Vassough1, P. Sasaki1,2,*, T. Kussa1,2, J.M. Horacek1,2,*, T. Vanek3, L. Jebavy1,2, P. Zak2

1Department of Military Internal Medicine and Hygiene, University of Defence, Faculty of Military Health Sciences (FMHS), 24th Department of Internal Medicine - Hematology, University Hospital and Charles University, Faculty of Medicine, Czech Republic

Background: Dysregulated production of cytokines and adhesion molecules has been implicated in the onset and progression of various types of leukemia. Further knowledge gained from multiple cytokine and adhesion molecule evaluation could help to improve treatment outcomes.

Aims: The aim of this study was to evaluate baseline levels of cytokines, cytotoxic receptor molecules and adhesion molecules in newly diagnosed acute lymphoblastic leukemia (ALL) patients and to assess their correlation with baseline characteristics and prognostic factors.

Methods: A total of 30 newly diagnosed ALL patients (median age 46, range 22–75 years, 20 males) were included in this study. We evaluated serum levels of 31 analytes, specifically 21 cytokines, 4 soluble cytokine receptors, 5 soluble adhesion molecules and 1 hormone (C-peptide). All analytes were measured by biochip array technology on Evidence investigator analyzer (Randox). Serum levels of tested analytes were correlated with baseline characteristics and prognostic factors.

Results: Serum levels of cytokines and adhesion molecules have been implicated in the onset and progression of various types of leukemia. Further knowledge gained from multiple cytokine and adhesion molecule evaluation could help to improve treatment outcomes.
Background: The survival of patients with Philadelphia chromosome positive acute lymphoblastic leukemia (Ph+ALL) who received allogeneic stem cell transplant (allo-HSCT) has improved over the development of tyrosine kinase inhibitors (TKIs). Currently, Imatinib (IMA) and Dasatinib (DAS) are widely used for the treatment of Ph+ALL. However, there has been no data comparing the outcomes between the patients who received allo-HSCT and the two distinctive TKIs respectively.

Aims: We conducted a retrospective analysis for comparing the two TKIs for the outcome after allo-HSCT.

Methods: Clinical data of patients were retrospectively collected from Hokkaido University Hospital and Sapporo Hokuyu Hospital. The patient’s eligibility were as follows: diagnosed as Ph+ALL, aged more than 16 years, and received allo-HSCT between 1990 and 2016 and first time for SCT.

Results: Sixty-six patients were eligible for the study. Fifty-six out of the 66 were administered TKIs (TKI group) and the remaining ten who developed Ph+ALL in the early phase were treated without TKIs (non-TKI group). Overall survival was not different between the two groups. Of the 56 patients in the TKI group, 39 received IMA (IMA-pts), and the remaining 17 received DAS (DAS-pts). Compared with DAS-pts, IMA-pts received allo-HSCT in relatively older years of age, more frequent myeloablative conditioning regimen, and cyclosporine-containing, not tacrolimus-, regimen for GVHD prophylaxis more frequently. Outcomes of OS and DSS were not significantly different between the two groups. Incidences of Neutrophil engraftment and acute GVHD incidence were not statistically different between IMA-pts and DAS-pts. Incidence of chronic GVHD was marginally increased in IMA-pts (IMA; 63%, DAS; 33%, P=0.06). At the median follow-up of 10 years (range: 14-460 days), overall survival was not different between the two groups by univariate analysis (Logrank, P=0.16). However, by multivariate analysis using Cox regression model for adjusting confounding factors, including, overall survival was superior for IMA-pts [Hazard ratio; 0.32 (0.11-0.94), P=0.04]. Incidences of transplant-related mortality and relapse were not different between the groups, even though relapse rate tended to be increased in DAS-pts (IMA; 16.1%, DAS; 47.1%, Gray P=0.2).

Summary/Conclusions: Our analysis suggests that overall survival may be superior for the Ph+ALL patients treated with allo-SCT and IMA compared with those with DAS. There are some limitations for our analysis due to retrospective fashion and relatively small number of the patients analyzed. Therefore, prospective study comparing survival of the Ph+ALL patients treated with the two distinctive TKIs before HSCT is needed.

IS OLDER AGE AN EXCLUSION CRITERION FOR ALLOGENEIC HEMATOPOIETIC STEM-CELL TRANSPLANTATION IN PATIENTS WITH PHILADELPHIA-POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA?
A. Shigematsu1,*, S. Ota1, H. Goto2, K. Minauchi3, J. Sugita2, D. Hashimoto2, M. Obara1, T. Endo1, M. Inamura1, T. Teshima2, N. Kobayashi1
1Department of Hematology, Sapporo Hokuyu Hospital, 2Department of Hematology, Hokkaido University Hospital, Sapporo, Japan

Background: Philadelphia-positive acute lymphoblastic leukemia (Ph+ALL) is diagnosed more often in older than in younger patients. This type of the acute lymphoblastic leukemia is characterized by very aggressive course of the disease. All clinical recommendations for such conditions indicate allogeneic bone marrow transplantation (BMT) after achieving complete remission. The addition of tyrosine kinase inhibitors (TKI) to chemotherapy has dramatically improved the long-term outcome in Ph+ acute lymphoblastic leukemia patients. Nevertheless whether to administer chemotherapy at all and if yes – how intensive it should be, is still the matter of debate. We have conducted two consecutive trials in Ph+ ALL aiming to evaluate the efficacy of more and less intensive chemotherapy approaches in combination with constant non-stop 600 mg Imatinib. All patients in both protocols with suitable donors underwent hematopoietic stem-cell transplantation (HSCT).

Aims: To analyze the effectiveness of RALL–2009+TKI and RALL–2012+TKI protocols in Ph+ ALL patients with or without HSCT. To analyze the efficacy of treatment with or without transplantation regarding the patient’s age.

Methods: From 2010 January to 2017 January, 35 new Ph+ ALL cases were diagnosed in 3 centers of the RALL–group. From 2010 to 2012, 12 Ph+ ALL pts were treated according to RALL–2009 protocol (ClinicalTrials.gov: NCT00793933) with concurrent administration of Imatinib. This protocol includes 8 cytostatic drugs and no intervals between treatment phases. Since 2012 till now 23 pts were included in ongoing RALL–2012 protocol, based mainly on 600 mg Imatinib with prednisolone, VNCR, L-asp, followed by 6-MP and MTX. Both protocols suggested the shift to Dasatinib (100-140mg) after non-achievement of MoCR on day 70 of treatment. MoCR was stated if bcr/abl chimeric transcript was <0.01% by PCR with 10⁻⁴ sensitivity. All patients were considered as candidates for allogeneic HSCT if HLA-identical donor was available. 13 pts (37%) underwent allo-HSCT as the first-line therapy. 1 autologous, 5 matched related and 7 matched unrelated.

Results: MoCR on day 70 was achieved in 36% and 59% in RALL–2009 (n=44) and RALL–2012 (n=13) respectively. Death on therapy (within 2 months of induction/consolidation) was registered in 2 cases on less intensive RALL–2012 protocol and 2 cases on RALL–2009. Hematological CR was achieved in 30 (85.7%) of 35 pts (except four early deaths and 2 refractory cases). There was one autologous HSCT in MoCR on the first protocol. Allo–HSCT was carried out in 5 of RALL–2009 protocol pts and in 9 of RALL–2012. The major issue was the non-relapsed mortality after unrelated allo–HSCT in 3 older pts (49, 56 and 59 years old) who were included in RALL–2012 (aGVHD and severe infections, at a median +4 months after HSCT and more than 12 months of CR duration). The 5y overall survival (OS) and relapse-free survival (RFS) for all 35 pts constituted 54.6% and 40.4% respectively. The long-term outcome on both protocols (RALL–2009 and RALL–2012) was similar: OS – 62.8% vs 49.4% (p=0.6), RFS – 55.7% vs 45% (p=0.7), respectively. In order to evaluate the impact of allogeneic HSCT we performed a comparison of transplanted and non-transplanted patients by a landmark analysis. The landmark was chosen as the median time from CR to allo–HSCT – 4,3 mo (3-16 mo). So, the 5y OS from allo–HSCT was 65.6% in transplanted patients (p=0.18), and RFS was 25% vs 62.5% (p=0.19), respectively. OS for older pts (>45 y) was 40% vs 25% in transplanted vs non-transplanted group of the pts, and RFS was 25% vs 66.6%, respectively. OS in younger (≤45 y) pts was 83.3% vs 58.9% for transplanted vs non-transplanted pts, EFS was 77.1 vs 21.4%, respectively.

Summary/Conclusions: The results very pessimistic in older (>45 years) patients who received HSCT. The contrary was observed in younger adult patients with very good results after HSCT – OS was 83.3% and EFS 77.1%. We conclude that patients aged>45y should continue chemotherapy without allogeneic HSCT or may be we could apply autologous HSCT for that group of the patients.

E861
TARGETABLE BLINATUMOMAB + TYROSINE KINASE INHIBITORS TREATMENT IN RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA PATIENTS: CLINICAL EFFECTIVENESS AND PERIPHERAL LYMPHOCYTES SUBPOPULATIONS KINETICS
A. Sokolov1,*, E. Parovichnikova1, V. Troitskaya1, N. Kapranov1, I. Lukyanova1, T. Lobanova1, K. Zarubina1, E. Usikova1, V. Savchenko1
1National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Blinatumomab is a bispecific monoclonal anti-CD3/CD19 antibody which has clinical activity in relapsed/refractory Ph-positive acute lymphoblastic leukemia (ALL) as monotherapy. Combination of Blinatumomab with...
tyrosine kinase inhibitors (TKI) is the promising approach in treating Ph-positive ALL. Some other rearrangements like IKZF1 in Ph-like ALL, FLT3 and JAK2 in Ph-negative ALL are the potential targets to some TKIs.

**Aims:** To demonstrate effectiveness and toxicity profile of Blinatumomab+TKI treatment. To evaluate peripheral blood lymphocytes subpopulations kinetics during blinatumomab treatment.

**Methods:** From October 2015 to February 2017 10 patients (pts) aged from 24 to 42 (median 31), 7 female and 3 male, with relapsed/refractory ALL were treated in our center. The diagnosis was relapsed ALL in 8 pts (7 - overt hematological, 1 - cytogenetic relapse) and persistent/increasing minimal residual disease of ALL in 2 pts. All pts had strong CD19 positivity. 8 pts was diagnosed as Ph-positive ALL (p190), 1 - Ph-like ALL (IKZF1 rearranged). 1- FLT3+ ALL. Two pts has T315I ABL mutation. In all pts blinatumomab continuous infusion + TKI therapy was started. Blinatumomab dose during 1st week of 1st cycle was 9 mcg/day, 28 mcg - subsequent three weeks. Blinatumomab dose in subsequent 4-weeks cycles was 28 mcg/day. 7 pts were treated with TKI Dasatinib, 1 - Bosutinib (Dasatinib/Nilotinib interloater), 1 - Ponatinib (T315I), 1 - Sorafenib (FLT3+). ATRA was added to Dasatinib in 1 pt with IKZF1 rearranged Ph-like ALL. 1 pt received 1 cycle of 4 weeks blinatumomab, 1 pt – 2 cycles, 6 pts - 4 cycles, 2 pts – 5 cycles. TKIs were administered continuously in all pts. T-helper, T cytotoxic, T-regulatory and NK cells were measured by flow cytometry in every week during all cycles of blinatumomab treatment.

**Results:** No one pt has neurological toxicity of any grade. All pts has significant decrease of normal Ig level and all of them received intravenous human normal immunoglobulin replacement. Palmar-planter syndrome in one pt on sorafenib completely resolved after temporarily TKI discontinuation. Disappearance in 1 pt on dasatinib/nilotinib completely resolved on bosutinib. 8 pts achieved molecular remission (MoCR), one pt – cytogenetic remission and one pt with T315I progressed to overt hematological relapse. T-helper and T-lymphocyte subpopulations were on or below of lower limit of normal range. T-cytotoxic and NK subpopulations gradually returned into normal range (Fig. 1). AlloBMT was performed in 4 pts. Three pts are awaiting alloBMT and three are continuing Blinatumomab + TKI treatment.

**Summary/Conclusions:** Lowering toxicity in non-chemotherapy treatment has its significance in such a heavily pretreated patients with relapsed ALL. The treatment has high MoCR rate and low toxicity profile. Treatment effectiveness correlated with T-helper and T-regulatory subpopulations exhaustion. T-cytotoxic and NK cells subpopulations restoring also correlated with clinical effectiveness.

**E863**

**NOVEL CRLF2 MUTATIONS AND CLINICAL SIGNIFICANCE IN ADULT ACUTE LYMPHOBLASTIC LEUKEMIA**

Z. Ge1,2, Y. Gu2,3, Q. Han2,3, X.-L. Zhou2,3, B.-A. Chen1,2, J.-Y. Li3, C. Song2,4,*

**Background:** Cytokine receptor-like factor 2 (CRLF2) plays an important role in the development of normal B lymphocytes, which can mediate early B cell proliferation and survival. CRLF2 overexpression and rearrangement have been observed in acute lymphoblastic leukemia (ALL), and they are reported to contribute to oncogenesis and unfavorable outcome in ALL. We reported that CRLF2 overexpression in the patients without CRLF2 rearrangement, indicating the reason other than CRLF2 rearrangement is responsible to the CRLF2 overexpression. There is few reported CRLF2 mutations in adult ALL.

**Aims:** We aim to investigate the mutations of CRLF2 and its clinical significance in adult ALL without CRLF2 rearrangement.

**Methods:** The 129 patients’ BM samples (95 B-ALL, 33 T-ALL and 17 B-T-ALL) were collected between April 2010 and Jan 2015 at the First Affiliated Hospital of Nanjing Medical University. The ALL diagnosis was made according to the cytogenetic, morphologic, Immunophenotypic and molecular criteria. The mutations of CRLF2 were analyzed by MiSeq (Illumina) and Sanger sequencing.

**Results:** A total of 7 mutations were identified in 129 patients without CRLF2 rearrangement. Six were single nucleotide mutations (Ser394Leu, Thr395Met, Ser414Asp, Ser421Asp, Asp422Glu and Ser422Gly) and one was a small insertion (Ser422Ile). The most frequent mutations were Ser414Asp and Ser422Gly. The Ser414Asp and Ser422Gly mutations were observed in 32 (24.6%) and 21 (16.2%) patients, respectively. The Ser422Gly mutation was the most common mutation in patients without CRLF2 rearrangement.

**Summary/Conclusions:** The rate of very late B-cell ALL recurrence was only 12.8% of all recurrences. The prognosis is worse in patients, older than 18 years, treated with adult type protocols.

**E862**

**VERY VERY LATE RELAPSES OF CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA: A SINGLE SERIES**

M. Bak1, D. Doganis1, M. Nikita1, A. Pourtsidis1, M. Servitzoglou1, D. Bouhouss1, M. Varvoutsi1, K. Kapetanion1, H. Dana1, V. Douina2, T. Anastasiou2, H. Kosmids1

**Background:** Recurrence of acute lymphoblastic leukemia (ALL) during childhood usually occurs within the first six years after initial diagnosis.

**Aims:** The aim of this study is the identification of all relevant characteristics and outcomes in a group of patients with childhood ALL, who relapsed more than six years after initial diagnosis or more than three years after bone marrow transplantation (BMT). We aimed to determine the incidence of all relevant characteristics and outcomes in a group of patients with childhood ALL, who relapsed more than six years after initial diagnosis or more than three years after bone marrow transplantation (BMT).

**Methods:** All children diagnosed with a first relapse of ALL in our Department, from January 1992 till December 2010 were included in this study.

**Results:** During this period, a total of 353 patients with childhood ALL were treated in our Department, according to BFM protocols. Recurrence occurred in 86 patients (24.4%, 56 male - 30 female - median age: 4.83 years), within 3 to 184 months from initial diagnosis. Very very late recurrence was noted in 3.1% of our relapses (8 male - 3 female) at 53, 72, 83, 84, 107, 112, 116, 120 and 184 months from initial diagnosis. In 9 patients recurrence involved the bone marrow, in 1 both bone marrow and central nervous system (CNS) and in 1 only the testicles. Two children had received allogeneic BMT from a matched related donor in first complete remission (CR1) and they had a bone marrow relapse 4 and 5 years later, respectively. The mean WBC, Hb, Blasts and PLT values at diagnosis were 29260/mm³, 5.6g/dl, 21360/mm³ and 18000/mm³, respectively. All of them were B-cell ALL except for 1 who had CD33 and CD13 co-expression. Regarding the immunophenotypical profile of the disease at recurrence, it remained almost identical to the initial. Regarding cytogenetic characteristics of the patients at diagnosis, 3 of them had high hyperdiploidy, one del(6)(q12), one BCR-ABL fusion and one 47.XY,t(19;22)(q11.2;q12) (t(12p13q14?); none hadMLL rearrangement orETV6-RUNX1. In 9 cases, the cytogenetic profile remained identical at recurrence, while in 1, trisomia 13 was not detected and another had heterozygous absence of IKZF1, PAIX, EBF1, CDKN2A and CDKN2B genes. On Day 8, nine of 11 patients were Prednisone Good Responders. On Day 15, nine children had bone marrow control, one M1 and two M3, and on Day 33 only one had M2. Two patients were classified as low risk, 6 as intermediate risk and 3 as high risk. Second remission (CR2) was achieved in 9 children with very very late recurrence. The other 2 died from disease progression. Six of nine patients are still alive and well 6, 8, 10, 11 and 20 years after initial diagnosis. One patient had died from second recurrence and the last two had a second allogeneic BMT and died due to severe infection, 2 and 11 months following that BMT. Interestingly, 3 out of 5 patients who finally died, had the very very late recurrence (10, 10 and 15 years after initial diagnosis) and had been treated with adult type protocols.

**Summary/Conclusions:** The rate of very late B-cell ALL recurrence was only 12.8% of all recurrences. The prognosis is worse in patients, older than 18 years, treated with adult type protocols.
was lower than that of non-mutation (8.53×109/L vs 28.9×109/L, P=0.032). The positive rate of Ph chromosome in patients with R186S was lower than that without the mutant (10.0% vs 31.8%, P=0.018). In addition, the incidence of splenomegaly in patients with R186S and P224 L mutants was lower than that in non-mutant patients (0.0% vs 29.5%, P=0.026; 0.0% vs 29.7%, P=0.034, respectively). The B-ALL patients with L86I mutant had myeloid antigen expression, high white blood cell count (248.4×109/L) and low platelet count (10×109/L), and relapsed in two months after the first induction chemotherapy; and the overall survival was only 2 months. The patient with W255C mutation did not achieve complete remission (CR) with the first induction chemotherapy.

**Summary/Conclusions:** Six novel CRLF2 genetic mutations were identified in adult ALL patients and may associate with clinical outcome, such as CRLF2 R186S indicating favorable, while L86I and W255C indicating poor outcome. Our data indicated that the CRLF2 mutations may be new prognostic markers and play an important role on oncogenesis in ALL.

**Background:** Recently, comprehensive genetic profiling of pediatric and adult core-binding factor (CBF) AML revealed a variety of cooperating events in a cohort of 85 t(8;21) AML patients (Faber et al. Nat Genet 2016). These mutations comprised alterations in genes encoding for proteins in tyrosine kinase (TK) signaling, epigenetic regulation (ER), and in the cohesin complex (CC).

**Aims:** To validate and to further extend our recent findings by comprehensive characterization of the mutational landscape of t(8;21) positive AML using a high-throughput targeted sequencing (HTS) approach.

**Methods:** The HTS panel comprised the entire coding region of 244 genes that are involved in hematological malignancies. Pretreatment blood (n=23) or bone marrow specimens (n=72) of 95 additional t(8;21) positive AML patients (pts) (median age: 51 yrs, range 18-72 yrs) were analyzed. 92/95 pts were enrolled in one of seven prospective AMLSG treatment trials. Libraries (total probe size: 1.359 Mbp) were prepared using SureSelectXT custom solutions (Agilent). Paired-end sequencing was carried out on a HiSeq 2000 (Illumina). The variant allele frequency (VAF) cutoff for reporting mutations was set at ≥0.05.

**Results:** The median coverage per pt was 900x. Mutations were detected with an average of 5.1 (SD: ±2.6) per pt with 99% of all pts harboring at least 1 mutation and 87% ≥ 3 mutations. Consistent with previous studies, mutations in TK signaling pathways were common events: KIT mutations were found in 22/95 pts (23%) followed by mutations affecting NRAS (16/95; 17%), FLT3 (11/95; 12%; point mutations only), and KITAS (4/95; 4%). A significant enrichment of mutations was also observed in genes involved in epigenetic regulation, ASXL1 (15/95; 16%), ASXL2 (12/95; 13%), KDM6A (11/95; 12%), CREBBP (8/95; 8%), SRCAP (8/95; 8%), EZH2 (7/95; 7%), SETD2 (5/95; 5%), TET2 (12/95; 13%) and DNMT3A (5/95; 5%), highlighting their contribution in altering the epigenetic state of this leukemia subtype. Moreover, mutations affecting members of the CC were found with a high frequency: RAD21 (13/95; 14%), SMC1A (5/95; 5%), STAG2 (3/95; 3%), and SMC3 (2/95; 2%). Of note, mutations in CC genes were almost mutually exclusive. We also identified additional mutations in previously detected cooperating genes such as mutations clustering in exon 2 of the ZBTB7A gene (15/95; 16%), encoding for a transcription factor involved in hematopoietic lineage fate. Recurrent mutations were also observed in CCND2 (9/95; 9%), that plays an important role in regulation of hematopoietic cell proliferation, as well as DHX15 (6/95; 6%) being involved in spliceosome function and ribosome biogenesis. With respect to the clonal architecture we found that the median VAF in genes belonging to ER and CC (0.30; range 0.03-0.91; 0.31, range 0.05-0.73, respectively) was higher than in genes associated with TK signaling (0.19, range 0.05-0.53). These data suggest that alterations affecting the epigenetic state and differentiation occur earlier than those in signaling during t(8;21) leukemogenesis.

**Summary/Conclusions:** Using a comprehensive, deep sequencing approach we could further characterize the mutational landscape of t(8;21) positive AML. Here, mutation clusters in genes involved in TK signaling, ER and CC were confirmed as well as novel CBF-associated gene mutations that play an essential role in regulation of hematopoietic cell proliferation and differentiation. Further analyses in terms of sample size extension as well as correlation of findings with clinical parameters are ongoing.
Background: Mixed Lineage Leukemia’s (MLL’s) are characterised cytogenetically by reciprocal translocations of the MLL gene and clinically by unfavourable outcomes. Evidence indicating that MLL leukemias are resistant to apoptosis encourages the identification of novel drug targets.

Aims: Using cord blood (CB) CD34+ cells (control) and CB CD34+ cells expressing MLL-AF9, we sought to determine the potential role of BTK in the development and progression of MLL+ leukemia. We further aimed to uncover possible downstream target/s of BTK, improving the therapeutic efficacy of the drugs used.

Methods: Experiments were performed using control and MA9.3 cells and leukemic blasts from 3 AML (MLL+) patients. Signalling events were evaluated by immunoblotting, p65 mediated BTK expression was determined by promoter assays. Cells were treated with specific inhibitors of BTK (Ibrutinib (IBR): 0.25, 0.5, 1.0 and 2µM) in combination with Daunorubicin (DAU 5nM) or RAC (NSC 23766 (NSC): 5, 10, 15 and 20µM) for 48 hrs and cell viability was assessed using Annexin V Sytox Blue based flow cytometric analysis.

Results: FLT3-ITD driven AML is a therapeutic target in MLL+ AML, we examined the whole cell lysates (WCL) from control cells, two clones of CB expressing MA9 (MA9.3 and 7.6) and leukemic blasts from the 3 AML patients. Active BTK (pY223) was detectable in both the clones of MA9 and MLL+AML samples. Interestingly, the cells demonstrated activation of p65 (p53S6) but not in control cells. To address if activated p65 could potentially drive BTK expression, we performed BTK promoter assays with reporter construct and empty vector. MA9.3 cells electroporated with test construct demonstrated significantly higher transcriptional activity. At the protein level, p65 inhibitor treatment (MG132 or Bay 11-7082) reduced total BTK expression, indicating that p65 stabilized a related p65 mediated creation of BTK-6. Treatment of control and MA9.3 cells with various concentrations of IBR for 48 hrs induced a dose-dependent reduction of cell viability (Annexin V and Sytox blue negative).

We further sought to determine if the use of IBR in combination with Daunorubicin would further sensitize MA9.3 cells. The apoptotic rate of the cells in combination treatment was significantly higher than that of cells treated with IBR or DAU alone. The coefficient of drug interaction (CI) values indicated that IBR-DAU combination synergistically reduced cell viability (CI > 1.0-antagonistic; <1.0 synergistic and =1 additive effect). Recent studies suggested RAC-GTPase signaling may also be a target in AML, particularly in the context of FLT3-ITD. Similar experiments were performed in FLT3-ITD driven AML cell lines and empty vector. MA9.3 cells electroporated with test construct demonstrated significantly higher transcriptional activity. At the protein level, p65 inhibitor treatment (MG132 or Bay 11-7082) reduced total BTK expression, indicating that p65 stabilized a related p65 mediated creation of BTK-6. Treatment of control and MA9.3 cells with various concentrations of IBR for 48 hrs induced a dose-dependent reduction of cell viability (Annexin V and Sytox blue negative).

Summary/Conclusions: Taken together, our data support a biological link between NFκB, BTK and RAC pathways in the modulation of cell survival in MLL-rearranged AML cells. aberrantly active p65 drives the expression of BTK and contributes to the progression of the AML. Combination treatment using IBR-DAU and IBR-NSC might be a promising therapeutic strategy, minimizing high drug dose-related side effects but increasing the therapeutic efficacy.

SECRETION OF SOLUBLE FACTORS BY AML CELLS INFLUENCE CD3/CD3 BITE® ANTIBODY MEDIATED CYTOTOXICITY AND T-CELL PROLIFERATION

M. Costanzi1,2,*, C. Krupka1,2, R. Kischel1, P. Kufer3, T. Köhnke1,2, K. Spiekermann1,2, W. Hiddemann1,4, M. Subklewe1,2, L. Piechaczyk1, M. Costanzi1,2,*, C. Krupka1,2, R. Kischel1, P. Kufer3, T. Köhnke1,2, K. Spiekermann1,2, W. Hiddemann1,4, M. Subklewe1,2

Background: In our previous work, we showed that the CD33/CD3 BiTE® antibody construct (AMG 330) is able to recruit autologous, residual T cells and induce cytotoxicity against primary AML cell lines. However, as described previously (Musaii et al, Blood 2013) primary AML cells are able to secrete soluble factors, which might not only influence T-cell proliferation but also negatively impact AMG 330 mediated cytotoxicity.

Aims: In this study we characterized the influence of soluble factors secreted by primary AML cells on AMG 330 mediated cytotoxicity.

Methods: We used plasma samples (from heparinized serum tubes or after density gradient centrifugation) from newly diagnosed and relapsed AML patients in AMG 330 cocultures of healthy donor (HD) T cells and AML cell lines. In flow cytometry based experiments we determined the influence of AML plasma from bone marrow (BM) on AMG 330 mediated cytotoxicity and T-cell proliferation. In transwell experiments using primary AML cells physically separated from AMG 330 cocultures, we evaluated if AML cells are the source of soluble factor secretion.

Results: The influence of AML plasma from bone marrow (BM) of AML patients on AMG 330 mediated cytotoxicity and T-cell proliferation was heterogeneous: in 15/30 samples, AMG 330 mediated cytotoxicity was significantly reduced compared to cultures containing FCS (mean% specific lysis vs FCS: 78.6 vs 95.0, respectively). In contrast, AMG 330 mediated T-cell proliferation was increased in 14/30 experiments (mean% specific proliferation vs FCS: 78.6 vs 95.0, respectively).

Conclusion: Our results demonstrated long term culture system (Krupka et.al, Leukemia 2016) and HD T cell lines. In flow cytometry based experiments we determined the influence of AML plasma from bone marrow (BM) of AML patients on AMG 330 mediated cytotoxicity and T-cell proliferation. In transwell experiments using primary AML cells physically separated from AMG 330 cocultures, we evaluated if AML cells are the source of soluble factor secretion.

A PRECISION MEDICINE PLATFORM FOR ACUTE MYELOID LEUKEMIA TO HELP UNRAVELING THE MOLECULAR ADDICTIONS OF FLT3-ITD-DRIVEN AML

P. Ayuda-Duran1, B. Zhang1, L. Plechaczky1, M. Popa2, D. Tadele1, A. Rowe2, J. Robertson1, T. Gedde-Dahl 4, E. Mc Cormack2, B.T. Gjertsen2, Y. Fløisand4, T. Köhnke1,2, R. Kischel1, P. Kufer3, T. Köhnke1,2, K. Spiekermann1,2, W. Hiddemann1,4, M. Subklewe1,2

Background: Acute myeloid leukemia (AML) is an aggressive disease with poor prognosis (Tzelepis et al., 2016). No single driver mutation is present in all cases of AML, making its treatment a challenge (The Cancer Genome Atlas Research Network, 2013). Traditional standard of care for AML is an aggressive induction therapy aimed to uncover driver mutations that have remained unchanged for the past 30 years (Longo et al., 2015). Weak or elderly patients might not be eligible for intensive treatment, leading to poor survival rates. Many such patients are labeled as ‘untreatable’, although a portion of them could benefit from specific, individualized treatments. The use of Precision Medicine strategy can help to find the specific treatment for these ‘untreatable’ AML patients.

Aims: Drug-driven personalized medicine aims to directly test the sensitivity of primary cancer cells taken from individual AML patients to a selection of targeted cancer drugs, compare these results with drug sensitivities of healthy donor samples and select the most effective drug for each patient. This approach considers any combination of mutations or epigenetic changes that might not be found in the standard sequencing panels, an advantage when dealing with such a heterogeneous disease. Proof of principle of this strategy was recently demonstrated by FiMM (Helsinki, Finland) (Pernovska et al., 2013), not only providing immediate clinical benefit to leukemia patients, but also identifying drugs that can potentially be repurposed for future treatment of patients.

Methods: We have established a drug-driven personalized medicine platform for AML where we check the ex-vivo drug sensitivity and resistance of bone marrow primary cells to a panel of around 400 drugs and drug combinations covering the standard of care treatments, cancer chemotherapeutics as well as many clinically available and emerging molecularly targeted compounds. We calculate the IC50 values for all the drugs for each individual donor or patient, and then the differential drug sensitivity scores, selecting the drugs that affect preferentially the cancer cells when compared with healthy cells. To date we have successfully processed 6 healthy donors and 68 AML patients, identifying subgroups of patients who respond with a similar dynamic to certain classes of drugs, as the subgroup of cells carrying intrinsic tandem duplications in the receptor tyrosine kinase FLT3 (FLT3-ITD).

Results: FLT3 activating mutations, particularly FLT3-ITD, have been observed in approximately 30% of AML cases (The Cancer Genome Atlas Research 2013), and are associated with increased risk of relapse and poor clinical outcome (Abu-Duhier et al., 2008). The cellular pathways that support FLT3-ITD-expressing AML blasts show an enhanced sensitivity to HSP90 inhibitors such as Ganetespib compared to healthy donors and any other subgroups of leukemia. In addition, HSP90 inhibitors specifically sensitize FLT3-ITD expressing bone marrow-derived cells to TKIs, whereas cells derived from healthy donors are unaffected. HSP90 inhibitors also preferentially eradiate a population of patient-derived FLT3-ITD+ AML cells expressing leucemic stem cell markers.

Summary/Conclusions: In summary, our study reveals a molecular basis for HSP90 addiction of FLT3-ITD-driven AML and provides a rationale for treatment of this form of AML with HSP90 inhibitors.

haematologica | 2017; 102(s2) | 357

Madrid, Spain, June 22 – 25, 2017
Summary/Conclusions: In summary we demonstrated that BM derived plas-
tic cells are sensitive to stromal conditioned medium. Stromal secreted 
proteins mediate AML resistance. In vivo experiments confirmed a role 
for these proteins in AML resistance. These findings suggest that tar-
ted inhibition of stromal proteins may increase the effectiveness of 
existing and novel treatments in AML.

MICROENVIRONMENT SECRETED PROTEINS MEDIATE RESISTANCE TO
TARGETED THERAPY IN PRIMARY AML CELLS

A. Dokal1,2, J. Gribben1, P. Cutillas3

1Haematology- Oncology, Barts Cancer Institute, London, United Kingdom

Background: The bone marrow stromal microenvironment (BMSM) plays an important role in the pathophysiology of acute myeloid leukemia (AML). This is demonstrated by primary AML blasts dependent on stromal conditioned media to survive long-term in culture. Although some of the components of the stromal secreto
me (the totality of secreted proteins by biological cells) that augmented AML survival are known, the precise molecular mechanisms of the stromal-blast interactions are not fully defined.

Aims: To study the clonal evolution of FLT3-ITD-AML and FLT3-TKD-AML in vivo and ex vivo and to investigate the influence of the stromal microenvironment on AML blast protein expression and AML cell signaling.

Methods: We used primary AML cells and established cell lines. Four different human AML cell lines were grown in co-culture with a mouse bone marrow stromal line (MS-5). The resulting conditioned medium from these experiments (4 AML lines alone, 4 AML lines + MS-5, MS-5 alone) was purified to obtain the stromocyte (in triplicate). Proteins from these secreto
mes were quantified using Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS). Peptide sequence searches against both mouse and human proteomes allowed for discrimination between the mouse stromal and human AML prote
ins. Guava EasyCyte Flow Cytometry was used to measure the viability and proliferation of these cell populations, assessing the capabilities of the identified factors above on primary AML cells (n=6) as well as the effects of kinase inhibitors midostaurin and dasatinib on AML cell viability.

Results: We identified 473 secreted proteins that significantly increased AML cell viability/ proliferation. The most prominent factors (top 20) included TGFBL, LIF, IL6, IL8, and GRO. Using a combination of stromal lines and conditioned media, we observed a significant increase in AML cell proliferation and survival.

Conclusions: Our findings suggest that the microenvironment secreted proteins play a critical role in AML cell survival and proliferation. Further studies are needed to determine the specific mechanisms by which these proteins contribute to AML cell resistance to targeted therapy and to identify potential therapeutic targets.
University of Chicago, Chicago, IL, United States; 2Nationalen Centrum für Tumorkrankungen, Universität Heidelberg, Heidelberg, Germany; 3Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, United States

Background: Internal tandem duplications (ITD) and mutations (mut) in the tyrosine kinase domain (TKD) of the receptor tyrosine kinase FLT3 occur in about 25% of acute myeloid leukemia (AML) patients. FLT3-ITD is associated with an unfavorable prognosis in particular in pts with a high allelic mutant to wildtype ratio (AR>0.5) as well as localization of the ITD in the beta1-sheet of the receptor. FLT3is targetable by tyrosine kinase inhibitors (TKI) and the combination of chemotherapy with the TKI midostaurin has been recently investigated within the CALGB 10603 RATIFY trial and is still under investigation within the AMLSG 16-10 trial.

Aims: To study theFLT3mut status at the time of diagnosis (Dx), refractory disease (RD) and relapse (Rel) in AML pts treated within the CALGB 10603 RATIFY trial and is still under investigation within the AMLSG 16-10 trial; one pt had an additional FLT3-ITDmut. Pts entered in the RATIFY trial had either FLT3-ITD (n=22), a FLT3-TKDmut (n=9), or both (n=2). The median AR of FLT3-TKDmut at Dx was 0.82 (0.07-2.66) and the majority of pts showed loss of FLT3-TKDmutat RD or Rel (n=9/12; 75%). In relapsed pts, loss of FLT3-ITD occurred in 14 (36%) pts. There was no significant difference between the median FLT3-ITD-AR at Dx [0.62 (0.10-18.94)] and Rel [0.65 (0.07-38.75); p=0.98]. A fraction of the FLT3-ITD mutations found in 14 (36%) pts at Rel, with switch of the ITD insertion site or length in 8 (21%) pts. 8/14 pts with change of the ITD clone at Rel had multiple ITD clones at Dx. For 35 FLT3-ITDPositive pts with refractory AML, FLT3ITD loss was observed in 17 (49%) pts. The median AR of FLT3-ITD was significantly lower at the time of RD [0.29 (0.05-2.37)] compared to Dx [0.65 (0.08-9.1); p<0.002]. The ITD clone changed in 5 (14%) pts with RD. In pts with shift of the ITD clone at Rd (n=5) or Rel (n=14), no significant difference of the median ITD length was observed (p=0.84).

Summary/Conclusions: Comparing the FLT3-ITD status at Dx, at the time of RD or Rel, we found a lower median AR of FLT3-ITD in pts at RD compared to Dx, whereas no significant change of AR was observed at Rel. In addition, loss of FLT3-ITD was observed in 49% of pts at RD and in 36% of pts at Rel. These findings suggest that the FLT3-ITD clone can be targeted in a significant number of pts and other clones might mediate resistance to treatment. We also observed a switch of the ITD clone in about 20% of pts with Rel, indicating the presence of ITD clones that have the potential to mediate resistance to treatment. Despite the small number of TKD mutations in our study, it was remarkable that most of the TKDs (75%) were lost at the time of RD or Rel.

E871

A NOVEL PML-RARA FUSION IN ACUTE PROMYELOCYTIC LEUKEMIA

Background: Acute promyelocytic leukemia (APL) is a subtype of acute myeloid leukemia (AML) characterized by specific translocation involving retinoic acid receptor alpha (RARA) locus. Retinoic acid receptor (RAR) is a member of nuclear receptor family, and has three types of isoforms such as RARA, retinoic acid receptor beta (RARB) and retinoic acid receptor gamma (RARG). Both RARalpha and RARbeta has a high structural homology (90%). However, RARALPHA and RARBelta have different oncogenic properties of the artificial PML-RARF fusion gene was observed in an in vitro study, there has been no report on the PML-RARF fusion in human APL patients.

Aims: We report here a novel PML-RARF rearrangement in a patient with AML displaying the suitable morphologic and immunophenotypic features of the classic hypergranular APL.

Methods: Whole genome sequencing (WGS) and further analysis of mRNA and gDNA were performed to clarify the atypical gene rearrangement observed by karyotyping and FISH.

Results: Laboratory and immunophenotypic analysis results suggested the classic APL with hypergranular type. A clonal translocation t(12;15)(q13;q22) was identified by karyotyping. No evidence of fusion of PML-RARA was detected by RT-PCR and PML-split was found on FISH analysis using PML-RARA dual color dual fusion probes. WGS analysis performed to clarifying the partner gene of PML located on chromosome 12q13 strongly suggested a PML-RARF fusion. RT-PCR following sanger sequencing were performed to verify the presence of PML-RARF fusion transcript, then two kind of transcripts was detected, one with the fusion of PML exon 3 and the middle part of exon 1 of RARG and the other with the fusion of PML exon 3 and exon 2 of RARG. The breakpoint of DNA was clarified on intron 3 of PML and 5′ region of RARG. Despite of ATRA treatment for 9 days, cell count did not show any response. Then induction chemotherapy composed of idarubicin and cytarabine was combined on ATRA. ATRA was finally stopped after 18 days, then cytokrogenic remission was achieved day 36 after induction therapy.

Summary/Conclusions: We first report the presence of PML-RARF fusion in a human APL patient. This report supports the possibility of a new molecular mechanism involving RARG not RARA in APL and suggests the need of different therapeutic approach for this variant case showing the potential ATRA resistance.
bone marrow microenvironment (BMM). Survival of patients with AML is presently poor: two-thirds of younger adults, and 90% of older adults die of their disease. Even in patients who achieve remission with chemotherapy, relapse is common and occurs from minimal residual disease sequestered in protective niches in the BMM. Reciprocal interactions between that of the AML and bone marrow mesenchymal stromal cells (BM-MSC) are central to the survival and progression of blasts that are protected from the hypoxic microenvironment. Restoration of quiescence in malignant cells as well as the activation of anti-apoptotic and pro-survival pathways.

Aims: To investigate how BM-MSC are programmed by AML to generate a pro-tumoural environment.

Methods: Primary AML and BM-MSC were isolated from the pelvis of AML patients following informed consent and under approval from the UK National Research Ethics Service (LREC/07/H0310/146). Low input RNASeq of 10 AML BM-MSC and 10 healthy BM-MSC (taken from the pelvis of patients undergoing elective hip replacement surgery) was performed following CD271 MicroBead selection. AML blasts co-cultured in confluent primary BM-MSC for 48 hours (h), 72h and 168h. Real-time PCR was used to verify the RNA sequencing data and Western Blot analysis to confirm protein expression. Lentivirus mediated knockdown was used to target gene expression in the BM-MSC. Senescence was assayed by β-Galactosidase staining. Results supported the findings carried out to compare 10 healthy and 10 AML BM-MSC show that 1125 genes were differentially expressed, with 924 down-regulated in AML derived BM-MSC and 201 up-regulated. From this analysis, we found that CDKN1A (p21) is up-regulated in BM-MSC from AML patients (7.406 logFC) compared to BM-MSC from patients with normal bone marrow (0.232 logFC). p21 mRNA and protein expression is increased in BM-MSC compared to normal BM-MSC. In-vitro experimentation showed that p21 mRNA and protein expression is increased in BM-MSC when co-cultured with primary AML. Furthermore, we show that AML increased senescence β-Galactosidase staining in BM-MSC and that p21 knockdown in BM-MSC resulted in increased proliferation and survival. Finally, primary AML cultured on p21 knockdown BM-MSC had reduced survival compared to control BM-MSC.

Summary/Conclusions: We have identified that AML induces a senescent BM-MSC niche via the p21 mediated pathway which in turn promotes survival and proliferation of AML. Silencing of p21 within the BM-MSC reduces AML survival. In identifying this novel microenvironment feedback loop in AML we highlight a potential new target for future AML therapies.

BONE MARROW ECLOGICAL COLAPSE IN ACUTE MYELOID LEUKEMIA IS MEDIATED BY REMODELING OF ENDOSTEAL VESSELS

D. Quansu1,2,*, E.D. Hawkins1, O. Akinduro1, H. Ang1, K. De Filippis3, M. Talalli1, N. Ruivo1, T.S. Weber4, R. Khosrved1, C. Pirillo1, S. Ramasamy5, L.E. Purton6,7, K. Duffy4, R.H. Adams8, L.M. Carlton9, C. Lo Celso1,2

1Department of Life Sciences, Imperial College London, 2The Francis Crick Institute, 3National Heart & Lung Institute, Imperial College London, London, 4Hamilton Institute, Maynooth University, Dublin, Ireland, 5Institute of Clinical Sciences, Imperial College London, London, United Kingdom, 6Stem Cell Regulation Unit, St Vincent’s Institute of Medical Research, 7Department of Medicine, The University of Melbourne, Fitzroy, Australia, 8Max Plank Institute for Molecular Biomedicine, Department of Tissue Morphogenesis, Munster, Germany, 9Cancer Research UK Beatson Institute, Glasgow, United Kingdom

Background: Bone marrow vascular niches have been proposed to support acute myeloid leukemia (AML) growth. However, anti-angiogenic therapies do not improve patient outcome suggesting that a complex relationship between AML cells and the microenvironment influences the disease process.

Aims: We aim to study the complex vascular remodelling occurring during AML progression.

Methods: Using a murine model of AML we performed intravital microscopy to study the remodeling of endosteal vessels in the bone marrow.

Results: We show AML is an invasive species causing highly localized disruption of the endosteal stroma and outcompeting non-malignant cells. Particularly affected are endosteal microenvironments containing osteoblastic cells and type H endothelium, typically associated with hematopoietic stem cells (HSCs). Infiltration of AML expands osteoblastic and HSC niches, suggesting their capacity to support extramedullary hematopoiesis. Intravital microscopy further revealed that the endothelium in AML is more adhesive and permissive to transendothelial migration of hematopoietic cells. Pharmacological intervention known to induce type H endothelium preserved HSC niches in suboptimal areas.

Summary/Conclusions: Together, these data suggest that AML-induced vascular damage contributes to cell egress from the bone marrow, and that new therapeutic approaches aiming to normalize bone marrow vasculature may support normal hematopoiesis.
a preferential engraftment in the presence of FLT3-ITD mutation (9 of 18). Furthermore, we found that the mutational fraction of 3 out of 4 patients harbouring a FLT3-ITD mutation enriched for this mutation in the primary PDX and then remained stable in subsequent xenotransplantations. Similarly, eight PDX with respective primary AML were analysed by next-generation sequencing (NGS) of 27 AML relevant genes. We found stable variant allele frequencies (VAF) among the primary and serial PDX bone marrows and spleens for 50 mutations (6% in healthy pre-treated ALL; patients, reasons for resistance have not been determined. In contrast to classical T-cell activation, BiTE® antibody construct mediated T-cell activation relies solely on binding to the CD3ζ chain of the T-cell receptor (TCR) complex. Recent studies have shown that the mechanism of T-cell activation is a prerequisite for our understanding of mechanisms of resistance. Aims: In the present study we characterized the role of costimulation on intracellular signalling in CD33/CD3 BiTE® antibody construct (AMG 330)-mediated T-cell activation.

Methods: We generated a murine cell line stably expressing human CD33 and devoid of human costimulatory molecules (B33). In intravitro cocultures, cytokoticticy against B33 cells and the AML cell line MOLM-13 was evaluated by flow cytometry. Activation of downstream signalling pathways was assessed by a phospho-flow cytometry protocol for T-cell recruiting antibodies.

Results: Coculture of B33 cells with CD3+ healthy donor T cells (n=4) resulted in AMG 330 mediated mean cytototoxicity of 58.3%. In contrast, MOLM-13 cells were completely lysed (% specific lysis relative to control B33 vs MOLM-13: 58.3±32.9 vs 99.9±0.1, n=4), despite comparable CD33 expression levels (CD33 median fluorescence intensity (MFI) ratio: B33 116.1 vs MOLM-13 67.6). However, through the addition of an anti-CD28 antibody or recombinant human IL-2, cytokoticticy against B33 cells could be restored (% specific lysis AMG 330 vs AMG 330 + anti-CD28 vs AMG 330 + IL-2: 58.3±32.9 vs 82.6±11.1 vs 91.3±9.0). At lower E:T ratios (1:4) the additional costimulatory signal also increased AMG 330 mediated cytototoxicity against MOLM-13 cells (mean MFI Ratio of CD80 and CD86 on MOLM-13 cells: 1.4±1.2 and 3.0±1.0 respectively, n=3) (% specific lysis AMG 330 vs AMG 330 + anti-CD28: 65.1±19.7 vs 80.7±16.1, n=3).

We next analysed intracellular Akt and Erk phosphorylation levels of T cells after stimulation with AMG 330 or a control BiTE® antibody construct (cBiTE®) and MOLM-13 cells. Anti-CD3/anti-CD28 antibodies served as positive control. In the presence of target cells, AMG 330 induced significantly lower Akt and Erk phosphorylation (mean% phosphorylated (p)Akt and pErk 7.9 and 7.6, n=3) compared to crosslinked CD3/CD28 antibodies (mean% pAkt and pErk 43.0 and 34.6). However, the combination of AMG 330 and CD28 increased the amount of phosphorylated proteins (% mean pAkt and pErk 11.6 and 11.1), but not to the level achieved by CD3/CD28 stimulation. In the absence of target cells, no Akt phosphorylation was observed upon incubation with AMG 330, suggesting a highly target cell dependent T-cell activation (mean% pAkt with vs without target cells: 0.8 vs 7.9).

Summary: Our data support the hypothesis that costimulation influences the susceptibility of target cells to lysis by T-cell recruiting antibody constructs. Currently, we are validating our results in a larger cohort using T cells from healthy donors and patients with AML. Furthermore, we will analyse the phosphorylation pattern within different T cell subsets and upon knock out of distinct TCR components. Our results will contribute to the understanding of BiTE® mediated activation of T cells, which is a prerequisite for clinical responses.

E879 RAKF KINASE INHIBITOR PROTEIN IS INVOLVED IN THE DEVELOPMENT OF MYELOID SARCOMA

V. Caraffini1,*, S. Schauer2, K. Kaschofer2, A. Wölfler1, G. Hoefler2, H. Sill1, A. Zebisch1
1Division of Hematology, 2Institute of Pathology, Medical University of Graz, Austria

Background: Myeloid sarcoma (MS) is a subgroup of acute myeloid leukaemia (AML), where leukemic invades non-hematopoietic tissues and form solid tumors. It may occur as isolated event or simultaneously with leukemic infiltration of the bone marrow (BM). Loss of RAKF kinase inhibitor protein (RKIP), a negative regulator of RAS signaling, has recently been described as a frequent event in AML and to be functionally involved in leukemogenesis. Although RKIP has been shown to inhibit the formation of metastases in solid tumors previously, its role in the development of MS is currently unknown.

Aims: In this study, we aimed to delineate the role of the metastasis-suppressor RKIP in the development of MS.

Methods: RKIP protein and mRNA expression was evaluated in formalin-fixed paraffin-embedded biopsies of MS and BM by immunohistochemistry and quantitative real-time PCR (qPCR). Sequence analysis of MS biopsies defined as MS only by histology were carried out by exome sequencing and targeted Next Generation Sequencing (NGS). For functional assays, both RKIP overexpression and knockdown was performed in THP-1 AML cells by lentiviral transduction of a FLAG-tagged RKIP expression construct and by RKIP shRNA, respectively. Subsequently, these cells were tested in migration and invasion assays using transwell methodology.

Results: This study comprised 14 patients with MS (MS-group) and 14 patients with AML without any evidence of extramedullary involvement (BM-AML group). Of the 14 cases within the MS-group, MS occurred as isolated event in three cases and concomitantly with systemic AML in eleven cases. Both groups were analysed in this matched and clinical as well as laboratory values were comparable between them. Most importantly, however, when we measured the protein expression of RKIP in leukemic tissues of these patients (MS biopsies in the MS-group and leukemic BM biopsies in the BM-AML group), we observed a...
significant increase of specimens exhibiting loss of RKIP expression in the MS-group (7/14 vs 1/14, P=0.0339). Interestingly, RKIP loss in MS specimens of cases with concomitant systemic AML was also present in the corresponding leukemic BM samples, thereby excluding a geographical clonal heterogeneity during MS formation in respect to RKIP expression. We then analyzed RKIP mRNA levels by qPCR and observed that RKIP loss correlated with decreased expression of RKIP protein (n=14, P=0.041). To gain more insight into the molecular landscape of MS patients with and without RKIP loss, we performed NGS of 39 genes that are recurrently mutated in AML. Interestingly, five out of six (83%) MS patients with RKIP loss demonstrated mutation(s) affecting the RAS-pathway, suggesting a potential functional synergism between these events. Consequently, we performed double overexpression and knockdown of RKIP in the RAS-mutated THP-1 AML cell line and subsequently studied these cells in functional migration and invasion assays. Importantly, RKIP knockdown increased both migration and invasion, thereby indicating a role of RKIP in the development of this condition.

E880

INHIBITING MIR-10A OVERCOMES CYTARABINE-RESISTANCE IN ACUTE MYELOID LEUKAEMIA
T.T. Vu1,2, K. Wang3, F. Stolz2, G. Ehringer2, T. Molloy4, D. Ma1
1Haematology, Vincent’s Hospital, Sydney, Australia, 2Medical Clinic and Polyclinic I, University Hospital ‘Carl Gustav Carus’, Dresden, Germany

Background: Chemoresistance is the principle cause of treatment failure in acute myeloid leukaemia (AML) despite a promising response to induction chemotherapy. Emerging evidence suggests the roles of autophagy, a self-eating process contributing to chemoresistance of leukaemia cells. We previously demonstrated that miR-10a, highly expressed in a subgroup of AML harboring Nucleophosmin1 mutations, promotes cell survival by inhibiting non-canonical cell death pathway, suggesting its function in autophagy and thus chemoresistance in AML.

Aims: We aim to demonstrate evidence that miR-10a, a regulator of autophagy, plays important roles in chemoresistance in acute myeloid leukaemia.

Methods: Apoptosis and proliferation in miR-10a inhibited and overexpressed leukaemia cells after cytarabine treatment was measured by Annexin V binding and MTT assay. Autophagy was measured by monitoring the levels of LC3I/LC3II proteins, autophagy-related proteins via Western Blotting and monodansyl-cavaradine (MDC) staining (flow cytometry).

Results: First, we observed a decreased expression of miR-10A in the leukaemia cells after the exposure to stress induced by serum starvation. Overexpressing miR-10A in miR-10A low MV4-11 cells decreased apoptosis induced by nutrient starvation and resulted in the resistance to cytarabine. In contrast, its inhibition in OCI-AML3 cells, which express high miR-10A constitutively, resulted in the induction of apoptosis and increased chemosensitivity towards cytarabine. miR-10a was shown to directly downregulate key members of the p53-mediated tumour suppressor gene network, including the CDKN1A (p21) inhibitor Transcript Factor 2 (TGF) gene (TFF2C). The inhibition of either miR-10a itself or CDKN1A by siRNA treatment inhibited autophagy induced by serum starvation, treatment with autophagy inducer, MG132 or p53 stabiliser, Nutlin3a.

Summary/Conclusions: The data suggests miR-10a as an important regulator of autophagy and modulator of the p53-p21 tumour suppressor signaling axis in subtypes of AML. It also emphasizes the significance of autophagy in chemoresistance in AML, supporting the targeting of the autophagy pathway as a potential therapeutic approach for AML.

E881

BY AN MCL-1-DEPENDENT MECHANISM, ALVOCIDIB POTENTIATES THE ACTIVITY OF CYTARABINE AND MITOXANTRONE WHEN ADDED IN A TIME SEQUENTIAL REGIMEN IN AML
H. Haws1, M. Livingston1, W. Kim1, R. Mangelson1, A. Siddiqui-Jain1, P. Peterson1, C. Whatcott1, S. Weitman1, D. Bears1, S. Warner1
1Discovery Biology, Tolero Pharmaceuticals, Inc., LEHI, United States

Background: Treatment with alvocidib has shown significant improvements in the complete remission rates in newly diagnosed acute myeloid leukemia (AML) patients when administered before cytarabine and mitoxantrone (ACM regimen) in a randomized Phase 2 study compared to 7+3. Although the mechanism of alvocidib action as a single agent is documented, the mechanism underlying synergy found in the ACM regimen is not fully understood. The ACM regimen was originally developed based on the perceived benefit of a time-sequential regimen starting with cell-cycle arrest (alvocidib), followed by release of the cells from arrest and inhibition of DNA replication (cytarabine/mitoxantrone) during S-phase. However, recent reports suggest that the transcriptional repression of key anti-apoptotic proteins (e.g., MCL-1) mediated by alvocidib’s CDK9 inhibition, may contribute to the activity in the ACM regimen.

Aims: We hypothesized that MCL-1 transcriptional repression constitutes the primary mechanism for the synergism observed with the ACM treatment regimen.

Methods: Following treatment, cell viability and caspase activation, an indicator of apoptosis, were assessed using CellTitre Glo and Caspase-Glo assays, according to manufacturer protocol. mRNA levels were assessed using RT-PCR. Protein levels were assessed using standard immunoblotting technique.

Results: In this study, we demonstrate that treatment with alvocidib, followed by treatment with cytarabine and mitoxantrone, synergized with the downregulation of MCL-1 protein and mRNA expression. Indeed, the ACM regimen resulted in a 2.4 or 3.4-fold increase in caspase activity relative to any single agent within the combination in MVA-11 or OCI-AML3 cells, respectively. As has been previously reported, we also observed that increased activity of cytarabine in alvocidib-treated cells corresponded with progression into the S-phase of the cell cycle, following the washout of alvocidib. However, this observation accounted for only a small portion of the inhibition of cell proliferation. This was further confirmed by the observation that CDK4/6 (cell cycle) specific inhibitors, such as palbociclib, did not show synergistic increases in caspase activity following treatment in the same setting. In various AML cell lines treated with MCL-1 siRNA, followed by cytarabine and mitoxantrone treatment, we also observed a synergistic increase in the inhibition of cell proliferation.

Summary/Conclusions: Considering our earlier work showing that MCL-1 dependency predicts AML patient response to the ACM regimen, we propose that MCL-1 repression is the primary mechanism of alvocidib’s clinical activity. As MCL-1 also confers resistance to cytarabine, the current study provides additional rationale for the inclusion of alvocidib in the treatment of AML, and in the AML regimen specifically. Taken together, this data suggests that the ACM regimen may be an effective regimen in treating patients with high-risk AML, because of alvocidib’s inhibition MCL-1.

Background: To date, there are no clear evidences if autophagy can lead to therapy resistance or favor apoptosis in cancer. Autophagy can function as a pro-apoptotic mechanism, or can improve stresses survival clearing damaged mitochondria and proteins accumulation. Levels and activity of pro-apoptotic and anti-apoptotic proteins, particularly BCL-2 and p53, high levels of CAMP, and a complex made by PINK/PARK could play as fulcrum of this yin and yang effect of autophagy.

Aims: Our study aims to define the role of PI3P pathways in AML, and to establish if autophagy could reduce the patients’ chance to respond to induction, and to worsen OS.

Methods: We analyzed 148 consecutively newly diagnosed non M3 AML patients treated with induction chemotherapy regimens containing at least one dose of anthracycline. We screened all patients for TP53, FLT3, NPM1 mutations. In all
patients, we perform Microarray-based High-Throughput Technology with Affymetrix SNP array 6.0 or Cytoscan HD. Survival data were collected prospectively from the time of diagnosis, with a median follow-up of 18 months. Survival analysis was performed with Kaplan Meyer method using log rank test. Univariate and multivariative regression and Cox Hazard Ratio (HR) model was performed. Correlation between variables was assessed with Fisher’s exact test. Results: AutoPhagy alteration (gene group 1: 178/311) and myeloid differentiation (gene group 2: 178/311) were considered MSI +. Paired DNAs were separately screened Outlier samples with elevated allele counts were flagged for each locus. Based on the MSs (alleles) each AML sample had was calculated for each of the 18 MS loci. we previously developed (Walker et al, Hum Mutat 2016;37:1004). Briefly, 18 microsatellite loci, called 18 MS loci, were sequenced for 80 genes using amplicon-based next-generation sequencing (NGS). Variants were detected by MuTect and Varscan with variant allele frac- tion. A subset of AML and MDS has been found to have RARs pathway activation characterized by a large enhancer at the RARA locus (RARA-high) and/or upregulation of IKBK, a TF associated with RAS signaling, forming the basis of the SY-1425 sensitive tumor identification. Aims: We sought to understand how SY-1425 agonism of RARa acts to promote maturation and halt proliferation of AML blasts locked into an immature cell state by the cancer circuitry. This characterization could further inform clinical pharmacodynamics markers.

Methods: We analyzed the epigenomic and transcriptional landscape of 66 non-APL AML patients and normal primary myeloid cells by RNA-seq and ChIP-seq for the enhancer marker H3K27ac. AML cell lines were profiled by RNA-seq, ChIP-seq for H3K27ac and RARa, and ATAC-seq with or without SY-1425 treat- ment. Cell surface marker changes were assessed by flow cytometry. Results: A subgroup of the patient samples was defined by an SE driving RARA which co-occurred with SEs driving ROS and JUNB, or IKBK, FOS and JUNB form the AP-1 heterodimeric TF known to promote an immature cell state and the interferon regulatory factor 8 (IRF8) pathway has been implicated in AML pathogenesis. Previously reported crosstalk between INP and retinoic acid signal- ing was supported by the strong induction of interferon gene sets by SY-1425 in IRF8-high AML models. We found that each AML cell line had distinct com- positions of lineage factors consistent with cancer initiation from different stages of myeloid development. SY-1425 induced maturation features associated with monocytic, macrophage, dendritic, and granulocytic cell types. While APL has a monocytic and granulocytic differentiation, we found that RARa/IRF8-high AML could follow multiple differentiation paths depending on the initial state of the AML model, necessitating different marker panels to capture full cell typing. Functional validation confirmed surface marker changes consis- tent with the observed epigenomic alterations including CD11b, CD11c, CD68, and CD38 upregulation. We integrated epigenomic data, DNA accessibility, and SY-1425 response to understand RARa agonist perturbation to cell circuitry.

Enhancer elements directly bound by RARa were associated with greater CR% after induction in univariate and multivariate analyses, to support the differentiation mechanism of action and offering the potential for early biologically relevant data to inform current and future clinical studies.

Summary/Conclusions: A subgroup of the patient samples was defined by a SE driving RARA which co-occurred with SEs driving ROS and JUNB, or IKBK, FOS and JUNB form the AP-1 heterodimeric TF known to promote an immature cell state and the interferon regulatory factor 8 (IRF8) pathway has been implicated in AML pathogenesis. Previously reported crosstalk between INP and retinoic acid signaling was supported by the strong induction of interferon gene sets by SY-1425 in IRF8-high AML models. We found that each AML cell line had distinct compositions of lineage factors consistent with cancer initiation from different stages of myeloid development. AND APOPTOSIS IN ACUTE MYELOID LEUKEMIA (AML)

Background: Mutations in the CEBPA gene are detected in about 10% of patients (pts) with cytogenetically normal (CN) acute myeloid leukemia (AML). CEBPA mutations can either be biallelic (bi) or monoallelic (mo). Only pts with bi CEBPA mutations have favorable outcomes when compared to other CN AML pts. bi CEBPA mutations are rarely associated with other prognostic mutations like internal tandem duplications (ITD) or mutations in the tyrosine kinase domain (TKD) of the FLT3 gene or mutations in NPM1. There is a specific association of bi CEBPA mutations with mutations in the transcription factor GATA2. Aims: In this study we aimed to characterize the mutational spectrum of CN AML pts with mo- and bi CEBPA mutations. We further analyzed the effect of TET2 and GATA2 mutations on outcome in pts with bi CEBPA mutations.

Methods: Targeted amplicon resequencing (Agilent Haloplex, target region: 63kb) was used to analyze 42 target genes or hotspots known to be mutated in AML, or other hematologic neoplasms.

Results: In 48 bi CEBPA and 32 mo CEBPA we found mutations in 20 and 26 different genes respectively. Mo CEBPA pts had significantly more additional mutations compared to bi CEBPA pts (mean: 3.9±1.7 vs 2.2±1.5; p<0.001). We also compared the mutational profile of mo CEBPA and bi CEBPA pts with a cohort of 34 CN AML patients (pts). bi CEBPA pts had a significantly higher percentage of mutations of 5% were significantly associated with one or more groups. We confirmed the mutual exclusiveness of bi CEBPA and NPM1 and the association between GATA2 and bi CEBPA (35.4%). TET2 was frequently mutated in both mo- (43.8%) and bi CEBPA pts (41.7%), but not in wt CEBPA (16.3%). mo- vs wt CEBPA p<.001; bi- vs wt CEBPA p=.004. Mutations in TKD1 or TKD2 of FLT3 were frequently identified in mo CEBPA (25%) and wt CEBPA (17.8%) but not in bi CEBPA pts (2.1%). The FLT3-TKD1/2 mutation frequency in bi CEBPA significantly differs from mo CEBPA (p=0.002) and wt CEBPA (p=0.004). There was a significant difference in the frequency of FLT3-TKD in bi CEBPA (20.8%) vs wt CEBPA (0%) (p<.001). However, mutations in bi CEBPA pts (43.8%) and wt CEBPA (42.6%) were not significantly different. IDH2 was found mutated only in wt CEBPA (21.6%) and mo CEBPA (18.8%). In 48.8% of wt CEBPA pts DNMT3A was mutated, this significantly differs from bi CEBPA pts (14.3%; p<0.001) but not from mo CEBPA patients (28.1%). CSF3R was frequently mutated only in bi CEBPA (10.4%) but not in wt CEBPA (0.35%; p<0.001) or mo CEBPA (3.1%; ns). STAG2 was associated with mo CEBPA (25%), while STAG2 mutations were significantly less frequent in bi CEBPA (6.3%; p<0.001) and wt CEBPA pts (6.27%; p=0.002). TET2 mutations had a negative prognostic impact on overall survival (OS) in bi CEBPA pts, but not in mo CEBPA pts (log-rank test: p=.01; 95% CI: 1.03-3.91). Only bi CEBPA pts' pTET2 was significantly worse in bi CEBPA pts with a TET2 mutation, but relapse free survival (RFS) and cumulative incidence of relapse (CIR) was not different depending on TET2 mutational status. Mo CEBPA pts also evaluated the clinical impact of GATA2 mutations. For 30 of 48 bi CEBPA pts survival data was available, 15 of these patients showed a significant difference with respect to RFS (p=0.216), OS (p=0.479) and CIR (p=0.059). In a combined analysis, the GATA2mut and TET2wt genotype was associated with a lower relapse risk and a trend towards a higher RFS compared to the GATA2wt and TET2mut genotype.

Summary/Conclusions: bi CEBPA, mo CEBPA or wt CEBPA pts show a distinct profile of co-occurring mutations that might explain the biological differences between these groups. TET2 mutations were found in 40% of all CEBPA mutated pts and might have a prognostic impact in bi CEBPA pts.

E887 MUTATIONAL PROFILE OF RELAPSE-RISK GROUPS IN ACUTE PROMYELOCYTIC LEUKEMIA PATIENTS

M. Prieto-Conde1, M. Alcocéba1, C. Jiménez2, M. García-Álvarez1, M.E. Sarasqueta1, A. Balanzañegui1, R. Corral1, L. Marín1, F. Ramos2, A. Gody2, A. Báez4, E. González1, M. González1, R. García3, J. Hernández1, E. Sánchez1,2

Background: Although the fusion oncogene PML-RARA is known to initiate acute promyelocytic leukemia (APL), other cooperating mutations have also been implicated in the disease pathogenesis. However, the spectrum of mutations of APL patients within the relapse-risk groups, based on patient leukocyte and platelet counts at diagnosis, are not yet known.

Aims: 1) To identify genetic alterations that might cooperate with PML-RARA in the leukemogenic process within the three APL relapse-risk groups. 2) To find mutations at diagnosis responsible for poor outcome by comparing patients who experiment relapse vs. patients who do not relapse in each group.

Methods: We performed next generation sequencing (NGS) on bone marrow samples of 91 patients diagnosed with APL (PETHMA LPA09/2005/2012) with a median follow-up of 2.8 years (range 0.2-10) (Table 1). APL patients were classified into relapse-risk groups according to initial leukocyte (WBC) and platelet counts (Score Sanz et al. 2000). Libraries were prepared using the TruSight Myeloid sequencing panel. The gene set analyzed included 54 myeloid related genes. Paired-end sequencing runs were performed on a MiSeq (Illumina) genome sequencer. Minimum depth for reliable analysis was fixed at 100x and minimum variant allele frequency (VAF) in 5%. FLT3-TIT mutations were analyzed by fluorescent PCR and capillary electrophoresis. Sequences obtained were analyzed with the Variant Studio v2.1 software (illumina) and the Integrative Genome Viewer (Genome Browser).

Results: Distribution of 91 patients in the 3 relapse-risk groups was: 28 in low-risk group (31%), 48 in intermediate-risk (53%) and 15 in high-risk (16%). We
found 150 mutations in 31 genes, in 73 out of the 91 patients included (a median of 1 mutation per patient (range: 0-5)) with a mean read depth of 10360x. Eighteen patients remained wild-type for all analyzed genes (Figure 1). Only one of this patients suffered relapse (5%). In the global series, no single mutation or functional category showed an association with clinical variables or prognostic impact in terms of overall survival or relapse free survival (RFS). There were no differences in the mean number of mutations per patient in each risk APL group (p=0.05). Patients who lack mutations belonged to the intermediate (13/48, 27%) and low risk (4/28,14%) groups, except for only one patient (1/15, 6%) in high-risk group. FLT3 was the most frequently affected gene in high risk APL subgroup (10 out of 15); 8 patients carried an FLT3-ITD mutation and 2 patients had amino acid substitutions at codon 835. Seven patients assigned to intermediate-risk relapsed (7/38, 18%). All but one carried mutations that have been reported as unfavorable in AML (FLT3, PTEN, ASXL1, CUX1 and WT1). By contrast, patients who remain in complete remission in this group, lack mutations with a greater frequency (12/31, 39%). Finally, within the low-risk group 3 patients suffered relapse (3/27, 11.5%) and all of them presented missense mutations in the Ras domain of NRAS at diagnosis (p.Qer65Arg & p.Gln61Arg). Therefore, we could identify a small subgroup of patients at a very high risk of relapse (RFS at 5 years, 25% vs 100%, p<0.001).

Figure 1.

| Table 1. |

Summary/Conclusions: In summary, the present study shows that the mutational status of NRAS and FLT3 genes could be used as genetic markers for prognosis in APL, especially in the intermediate and low-risk groups, allowing no differences in the mean number of mutations per patient in each risk APL group (p=0.05). Patients who lack mutations belonged to the intermediate (13/48, 27%) and low risk (4/28,14%) groups, except for only one patient (1/15, 6%) in high-risk group. DISSECTING THE DYNAMICS OF SINGLE-TUMOR-CELL-LINEAGES THAT UNDERPIN RELAPSE OF AML.

F. Caiado1, D. Maia-Silva1, C. Reforço1, R. Faria1, B. Silva-Santos1, H. Norell1,∗

1Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal

Background: Cancers kill primarily via disease recurrences after transient treatment responses. The emergence of therapy-resistant tumor escape variants is fueled by intra-tumor heterogeneity, underpinned by interference and Darwinian evolution across continuously developing sub-clones in the residual tumor. Several non-genetic factors add significant variation, on top of the diversification provided by the often complex landscape, resulting in intra-tumor growth. Such data suggest that each cancer is an extremely heterogeneous and dynamic tumor cell population that can drive disease under many conditions. The relapse of human acute myeloid leukemia (AML) is a prime clinical example of how evolving sub-clonal dynamics can frequently drive treatment-resistant cancer recurrence after initially potent therapeutics.

Aims: We aimed to understand how sub-lineage interference is regulated in AML in response to standard and emerging treatments - and clarify how this impacts the development of therapy resistance. Specifically, we aimed to dissect if relapse from each drug regimen was driven by predetermined or stochastically selected sub-lineages and determine the functional impact of such differences.

Methods: We dissected the intra-tumor population dynamics of relapsing AML, beyond the genetic level, by performing single-cell lineage-tracing through cellular barcoding technology (lentivirus-integrated non-coding DNA-tags). We
second consolidation), and sequenced with high-throughput approach. We and detected at diagnosis and at follow-up (after induction, first consolidation or follow-up: a specific region of the four most frequent alterations at diagnosis (Samples at diagnosis sample; From the 32 genes, we use specific primers to amplify the rent Proton System-Thermo Fisher.

Methods: We developed a custom-targeted sequencing panel of 32 genes at diagnosis. All patients had achieve CR at the moment of MRD assessment.

**Results:**

- Only treatment regimens containing DOX caused marked decreases in HEL cell numbers and barcode architectures diverging strongly from the non-treated control cultures. Replicate AML cultures regrowing after treatment with DOX all converged to a very similar barcode architecture, reflecting that relapse following this mono-therapy was driven by predetermined single-cell lineages. Combination of DOX with CYT increased the degree of overall cell elimination by ~10-fold, while addition of DCT to either chemotherapy regimen had little impact (i.e. yielded similar cell number and re-growth kinetics).
- Interestingly, DCT additions nevertheless qualitatively changed which sub-lineages that regrew - specifically making replications more divergent from each other, indicating a more stochastic selection of the cells emerging when DCT had been added to the respective chemotherapy regimens. Importantly, this cell selection was achieved by the reversion of resistance to chemotherapy re-treatment, which the DOX-containing treatment regimens potently induced in the absence of DCT.

**Summary/Conclusions:** The development of curative treatment combinations requires deep understanding of how non-genetic factors synergize with cancer genetics to drive intra-tumor heterogeneity, which is key for tumor escape/ disease recurrence. Our detailed analyses of the heterogeneous dynamics among single-cell lineages in AML, following different treatment regimens with apparently similar global impact, represent an important step in dissecting kinesis-dependent aspects that go beyond the genetic level. Critically, these studies directly provide the rationale for combining standard chemotherapy with administration of hypomethylating drugs to target AML. The mechanism is prevention of the development of chemotherapy resistance (mediated by selective relapse of a specific set of predetermined sub-lineages) - by partially randomizing which sub-lineages that emerge to drive relapse when DCT is added to the chemotherapy. Maintaining the chemosensitivity of relapsing AML would represent a paradigm shift, turning the currently often lethal recurrences into survivable/ repeatedly clinically manageable episodes of a type of chronic leukemic disease.

**MRD ANALYSIS BY NEXT-GENERATION SEQUENCING APPROACH FOR ACUTE MYELOID LEUKEMIA FOLLOW-UP**

E. Onica De La Fuente1,2, I. Rapado1,2, T. Cedena1,2, M. Llops3, Y. Ruiz-Heredia1, J. A. Garcia Vela1, J. Perez Oteyza1, A. Figueras1, F. J. Peñalver1, E. Barragan1, M. Gallardo1,2, J. Martinez-Lopez1,2, R. Ayala1,2

**Background:** Sensitive detection of molecular marker of minimal residual disease (MRD) in acute myeloid leukemia (AML) can improve prognostic of a possible relapse during the remission. Traditional methods for measuring minimal residual disease (MRD) in AML, such as oncoparametric and multiparametric flow cytometry (MFC) are associated with high technical complexity, low applicability and laborious standardization. However, some patients who achieve a negative MRD become to relapse and several MRD+ patients have a long survival, which indicates that the sensitivity and specificity of traditional methods for MRD are insufficient to detect low residual disease.

**Aims:** To detect minimal residual disease in AML follow-up sample using high-throughput sequencing as a standard and accurate technique.

**Methods:** We studied 54 gDNA bone marrow follow-up samples (27 after induction, 10 after first consolidation, 17 after second consolidation) from 30 AML patients treated according PHEMA AML clinical protocols and with DNA sample at diagnosis. All patients had achieve CR at the moment of MRD assessment. We developed a custom-targeted sequencing panel of 32 genes (Ion Tor rent Proton System-Thermo Fisher) for mutation (SNV and/or InDels) detection at diagnosis sample. From the 32 genes, we use specific primers to amplify the specific region of the four most frequent alterations at diagnosis (Samples at follow-up: FLT3n=10, NPM1n=19, IDH2 n=9 or IDH1 n=7). We analysed and detected at diagnosis and at follow-up (after induction, first consolidation or second consolidation), and sequenced with high-throughput approach. We achieve a technical sensibility around 10^4 for point mutations and 10^5 for Indels mutations according to specificity and sensibility calibration curves.

**Results:** We analyse the results of assessing MRD by NGS, and the presence or absence of MRD was established at a cut-off level of 0.0017 (between 10^-4 and 10^-6) by ROC curve with a sensibility of 0.5 for DFS and 0.571 for OS, and a specificity of 0.92 for DFS and 0.897 for OS; thereby the result above this level was considered as MRD positive. DFS (Disease Free Survival) and OS (Overall Survival) rates in this group were 29.9% and 24.1%, respectively; positive MRD sample was independent marker associated with shorter DFS (p=0.002, HR=0.33, 95% CI:1.60-33.51) and OS (p=0.002, HR=8.33, 95% CI:8.37-37.15) (see figure 1). These results support the usefulness of MRD evaluation in patients with AML by NGS in the context of molecular biology studies.

**GENE RATION OF NEW CELLULAR MODELS FOR THE STUDY OF PEDIATRIC NON DOWN SYNDROME ACUTE MEGAKARYOBLASTIC LEUKAEMA BASED ON HUMAN PLURIPOTENT STEM CELLS**

J. Domingo-Reinel1,1, F. González-Pozas1, L. Morales-Cacho1, M. Vogel-González2, G. Rodríguez-Reali1, J. Olmedo-Pelayo1, R. M. Montes1, V. Ayllón1, V. Ramos-Mejía1

**Background:** Acute megakaryoblastic leukaemia (AMKL) is a rare and complex type of Acute Myeloid Leukaemia (AML), more frequent in children than in adults, characterized by the accumulation of immature megakaryoblasts and thrombocytopenia. Paediatric AMKLs are classified in Down Syndrome AMKL (DS-AMKL) with a good prognosis; and AMKL non-related to Down Syndrome (non-DS-AMKL), a more aggressive disease with a mortality rate close to 80%. There is a limited amount of research done on infant non-DS-AMKL. Due to its low incidence and early human hematopoiesis, we were interested in studying the role of normal hematopoietic cells as model systems. In this project, we aim to use human hPSCs expressing non-DS-AMKL-associated fusion oncogenes as cellular models for this leukaemia, to study the molecular and cellular pathways involved in the development of pediatric non-DS-AMKL.

**Methods:** Generation of human models of non-DS AMKL using hPSCs: 1. Generation of hPSCs with the oncogenic fusion proteins RBBM15-MKL1, CBFAB2-T3-GLIS2 and NUP98-JARID1 using transduction with lentiviral vectors. 2. Generation of hPSCs with the chromosomal translocations t(1;12) and t(11;12), that generate the fusion proteins RBBM15-MKL1 and NUP98-JARID1 respectively, and the inversion of chromosome 16, that originates the fusion protein CBFAB2-T3-GLIS2. 3. Using these hPSC lines, we aim to study the impact of the fusion proteins on the hematopoietic system, the development of the hematopoietic lineage and the potential of these cells to differentiate into the three germ layers forming embryoid bodies. Using an in vitro differentiation system, we aim to study the differentiation of these cells into hematopoietic progenitors and megakaryocyte precursors. We will use colony-forming assays (CFU) to determine the function and specificity of the hematopoietic progenitors.

**Results:** Summary/Conclusions: These models will serve as platforms to discover and understand the cellular and molecular alterations caused by these oncogenes, and their impact in the development of hematopoietic cells during development. With these models, we will have a better understanding of the origin and development of paediatric non-DS AMKL, so we will be able to design new therapeutic approaches for these children.

**ASXL1 MUTATIONS IN AML ARE ASSOCIATED WITH SPECIFIC CLINICAL AND CYTOTGENIC CHARACTERISTICS**

K. Kakosiaou1, F. Fanitsas2, A. Ioannidou3, M. Pagoni2, P. Apostolou2, A. Daraki1, I. Vlachadami4, E. Karamustagi1, T. Marinakis5, C. Giatra2, D. Vasilatou6, C. Sambani1, V. Pappas2, K. Manoli1

**Background:** Acute megakaryoblastic leukaemia (AMKL) is a rare and complex type of Acute Myeloid Leukaemia (AML), more frequent in children than in adults, characterized by the accumulation of immature megakaryoblasts and thrombocytopenia. Paediatric AMKLs are classified in Down Syndrome AMKL (DS-AMKL) with a good prognosis; and AMKL non-related to Down Syndrome (non-DS-AMKL), a more aggressive disease with a mortality rate close to 80%. There is a limited amount of research done on infant non-DS-AMKL. Due to its low incidence and early human hematopoiesis, we were interested in studying the role of normal hematopoietic cells as model systems. In this project, we aim to use human hPSCs expressing non-DS-AMKL-associated fusion oncogenes as cellular models for this leukaemia, to study the molecular and cellular pathways involved in the development of pediatric non-DS-AMKL.

**Methods:** Generation of human models of non-DS AMKL using hPSCs: 1. Generation of hPSCs with the oncogenic fusion proteins RBBM15-MKL1, CBFAB2-T3-GLIS2 and NUP98-JARID1 using transduction with lentiviral vectors. 2. Generation of hPSCs with the chromosomal translocations t(1;12) and t(11;12), that generate the fusion proteins RBBM15-MKL1 and NUP98-JARID1 respectively, and the inversion of chromosome 16, that originates the fusion protein CBFAB2-T3-GLIS2. 3. Using these hPSC lines, we aim to study the impact of the fusion proteins on the hematopoietic system, the development of the hematopoietic lineage and the potential of these cells to differentiate into the three germ layers forming embryoid bodies. Using an in vitro differentiation system, we aim to study the differentiation of these cells into hematopoietic progenitors and megakaryocyte precursors. We will use colony-forming assays (CFU) to determine the function and specificity of the hematopoietic progenitors.

**Results:** Summary/Conclusions: These models will serve as platforms to discover and understand the cellular and molecular alterations caused by these oncogenes, and their impact in the development of hematopoietic cells during development. With these models, we will have a better understanding of the origin and development of paediatric non-DS AMKL, so we will be able to design new therapeutic approaches for these children.

**CHARACTERIZATION OF HEMATOLOGIC MALIGNANCIES WITH ANCHORED MURPLEX PCR AND NEXT-GENERATION SEQUENCING**

L. Vlahadakos1, M. Bausch1, A. Berger1, J. Haines1, D. Fugere1, L. Griffin1, K. Trifilo1, N. Manoj1, H. Wang1, R. Ryan2, M. Hussaini3, B. Kudlow1

**Background:** Hematologic malignancies can be driven by a diversity of mutation types, including single nucleotide variants, copy number variants, gene fusions, insertions and deletions and changes in gene expression profiles. However, comprehensive detection of these mutation types is a challenge, as specific assays are required to detect each mutation type. Next-generation sequencing (NGS) enables comprehensive detection of all mutation types from whole genomes and transcriptomes. However, low detection sensitivity, high input requirements and high costs render these approaches impractical for routine detection of mutations from clinical sample types. Anchored Multiplex PCR (AMP) is a target enrichment strategy for NGS that uses molecular barcoded (MBC) adapters and unidirectional gene-specific primers (GSPs) for amplification.

**Aims:** Our goal was to develop AMP-based NGS assays to simultaneously detect multiple mutation types from DNA and RNA, as well as relative gene expression levels and copy number alterations (CNA).

**Methods:** We developed AMP-based Anchor21* VariantPlex™ and FusionPlex® assays to enable NGS-based detection of mutations from DNA and RNA, respectively. Open-ended amplification permits identification of novel gene fusions with FusionPlex and complex mutation types such as ITDs with VariantPlex assays. MBC adapters ligated to DNA and RNA fragments prior to amplification enable relative gene expression and CNA analysis.

**Results:** We show instances of gene fusion detection from open-ended amplification (AMP), including RNU7-UGA, RUNL1 and RUNL2, and show how this technology can be applied to acute unclassifiable leukemias. Furthermore, unidirectional GSPs provided bidirectional coverage of a BCR-ABL fusion, which was detected with reads originating from BCR1 as well as BCR. Using our optimized bioinformatics algorithm and the VariantPlex assay, we accurately and reliably detected ITDs of varying sizes and insertion points, with simultaneous point mutation detection, in AML-positive blood samples. Furthermore, we show multiple mutations in various AML-positive sample types, including mutations in CEPBP. Finally, MBCs used in AMP enabled NGS-based expression profiling for identification of Diffuse Large B Cell Lymphoma subtypes in a small cohort of samples.

**Summary/Conclusions:** Our data demonstrate that AMP-based NGS enables comprehensive detection of multiple mutation types as well as gene expression levels relevant in hematologic malignancies. Importantly, AMP enables identification of known and novel gene fusions at nucleotide resolution, detection of ITDs and characterization of relative gene expression levels and CNAs.
mutations. Moreover, ASXL1 mutations were detected in 3 of 12 patients with aberrations involving chromosome 8 (25%), 2/9 (22%) with trisomy 13, 2/11 (18%) with t(9;22) and only 1 of 22 patients with t(15;17). Multivariate logistic regression suggested that independent predictors of the presence of ASXL1 mutations were older age (OR 1.43 per decade, 95% CI 1.13-1.79), chromosome 11 aberrations (OR 2.69, 95% CI 1.09-6.63), and sec-AML (OR 4.44, 95% CI 2.3-8.57), whereas del(7q) or -del7q predicted for lower frequency (OR 0.32, 95% CI 0.13-0.75).

Summary/Conclusions: Our results support the association of ASXL1 mutations in AML with advancing age and sec-AML. Association with trisomy 8 did not retain significance in multivariate analysis. Chromosome 11 aberrations emerged as a robust independent predictor. Despite the strong link with secondary AML (majority of cases post MDS), our data show inverse relationship with -7/del(7q) or -del7q. In addition, ASXL1 mutations were not positively associated with MDS-related cytogenetic abnormalities, complex or monosomal karyotypes.

A COMPREHENSIVE DNA TEST FOR THE DETECTION OF TRANSLOCATIONS IN ACUTE LEUKEMIA

E. Van Den Berg-De Ruiter1,*, E. Vellenga5, R.J. Sinke1, R.H. Sijmons1, B. Sikkema-Raddatz1
1Genetics, 2Genetic Coordination Center, UMCG, Groningen, 3Cergentis B.V., Utrecht, 4Laboratory Medicine, 5Hematology, UMCG, Groningen, Netherlands

Background: Patients with acute leukemias carry a wide range of chromosomal abnormalities, which affect their prognosis and treatment options. Currently, over 500 different translocations are reported to be involved in the disease progression. Traditional methods to detect chromosomal abnormalities involve a combination of techniques such as karyotyping, FISH, array and RT-PCR. However, these methods are laborious and at times inadequate. Targeted Locus Amplification (TLA), a new targeted next generation sequencing technology, can overcome these shortcomings. It is based on proximity ligation (crosslinking) of DNA and outward oriented probes for enrichment and can therefore identify chromosomal translocation partners regardless of their identities.

Aims: Here we present a TLA multiplex panel in combination with next generation sequencing as a first tier screening tool in detecting translocations in acute leukemias.

Methods: A multiplex TLA panel was designed using primer sets covering known break-point regions of the 17 most frequently reported genes involved in acute leukemia’s. TLA was performed on five different cell lines carrying translocations detectable by our panel. (t(12;21), t(16;11), t(11;19);t(8;13), t(16;9), t(17;19)). Various combinations of cell line mixtures in multiple dilution series were used to determine the specificity and sensitivity of the panel, and to set sample quality thresholds during analysis. Samples were processed using standard TLA protocol (de Vree et al., 2014). Targets were enriched by PCR amplification with the multiplex panel and subjected for sequencing on Illumina Nextseq 500. To facilitate an easy analysis workflow a semi-automated data analysis was developed. This includes a quality control step, labelling samples with no coverages at the anchor regions after filtering at more than half the number of target regions as failed. These were not interpreted. Only peaks outside other anchor regions were considered as false positive peaks. Peaks present in other anchor regions were interpreted as possible artefacts and labelled as needing extra confirmation. In these series until now, up to 10% aberrant cells were detected with no false positives as no translocations other than expected for cell lines were detected. Bone marrows of 36 patients suspected to carry cytogenetic abnormalities were taken for routine diagnostic (Karyotyping, FISH and or RT-PCR) and TLA. Sample analysis was performed randomized and blinded. TLA outcome was then compared with results from routine genetic tests, can establish whether the TLA panel is applicable as a routine procedure.

Results: From a total of 36 patients three samples did not meet the required sample quality for further analysis. In the remaining 33 patients our TLA multiplex panel confirmed the presence of translocations on 16 samples. This includes a cryptic translocation involving the known break-point regions of the 17 most frequently reported genes involved in acute leukemia’s. TLA was performed on five different cell lines carrying translocations detectable by our panel. (t(12;21), t(16;11), t(11;19);t(8;13), t(16;9), t(17;19)). Various combinations of cell line mixtures in multiple dilution series were used to determine the specificity and sensitivity of the panel, and to set sample quality thresholds during analysis. Samples were processed using standard TLA protocol (de Vree et al., 2014). Targets were enriched by PCR amplification with the multiplex panel and subjected for sequencing on Illumina Nextseq 500. To facilitate an easy analysis workflow a semi-automated data analysis was developed. This includes a quality control step, labelling samples with no coverages at the anchor regions after filtering at more than half the number of target regions as failed. These were not interpreted. Only peaks outside other anchor regions were considered as false positive peaks. Peaks present in other anchor regions were interpreted as possible artefacts and labelled as needing extra confirmation. In these series until now, up to 10% aberrant cells were detected with no false positives as no translocations other than expected for cell lines were detected. Bone marrows of 36 patients suspected to carry cytogenetic abnormalities were taken for routine diagnostic (Karyotyping, FISH and or RT-PCR) and TLA. Sample analysis was performed randomized and blinded. TLA outcome was then compared with results from routine genetic tests, can establish whether the TLA panel is applicable as a routine procedure.

Summary/Conclusions: Our TLA panel showed concordant results for 29 out of the 33 successful sequenced samples. No false positives were found, while an additional translocation was detected. Our panel is able to detect (cryptic) translocations with high sensitivity of the detection partner. Therefore, the TLA multiplex panel is suited as a first tier screening tool in acute leukemia. A prospective study, comparing the diagnostic yield of the TLA panel with current tests, can establish whether the TLA panel is applicable as a routine procedure.

ALTERATIONS IN NECROTOPSIS PATHWAY AFFECT PROGNOSIS OF PATIENTS WITH ACUTE MYELOID LEUKEMIA

S. Lo Monaco1,*, G. Marconi1, M.C. Fontana1, C. Papayanni1, E. Ottaviani1, E. Franchini1, A. Ferrari1, A. Padella1, G. Simonetti1, S. Paolini1, G. Martinelli2
1University of Bologna, Bologna, Italy

Background: Necroptosis is a type of necrotic cell death involving several genes transcription and activation of molecular mechanisms as death receptors, interferon, toll-like receptors, intracellular RNA and DNA sensors. The process is leading by the family of receptor-interacting protein kinase (RIPK3, RIPK2, RIPK1) and the MLKL substrate. Losses of RIPK3 or MLKL, as well as deficiency in apoptosis, could allow tumor cells to escape the immune-mediated cells death (ICD).

Aims: We want to investigate the role of necroptosis deficiency in correlation with chemotherapy resistance and its impact as prognostic factor in AML.

Methods: We performed SNP Arrays (Cytoscan HD and SNP 6.0, Affymetrix) on a cohort of 300 non-M3 AML patients at diagnosis and we analyzed the Overall Survival (OS) of our patients with deficiency on necroptosis pathways. Survival was analyzed with Kaplan-Mayer method and Log-Rank test. We further analyze the relevance of different prognostic factors by the use of COX-Hazard Ratio statistical analysis.

Results: We found that 18 patients presented a loss of RIPK1 or MLKL (nocto-neurotoxic) genes, secondary disease or therapy resistance at diagnosis and we analyzed the Overall Survival (OS) of our patients with alterations in these genes is significantly lower than control group, with a median OS of 3 months vs 27 months in the control group.

Summary/Conclusions: Our study shows that losses in necroptosis pathways are an uncommon alteration in AML, prevalent in old population. Moreover, we hypothesize that the loss of genes involved in necroptosis could be a real mechanism of tumor immune-escape and could be a rational to select patients that high probability to be resistant at chemotherapy promoting ICD mechanism.

Background: A high number of patients with acute myeloid leukemia (AML) present resistance at treatment, which is associated with clonal persistence or evolution. The generation of high-depth sequencing data allowed to quantify variant allelic frequencies (VAF) and permitting estimation of the size of tumor clonal populations in each AML sample, and to perform an estimation of clonal evolution at relapse or refractory case according to diagnostic.

Aims: To evaluate the predictive impact of the fluctuation Variant Allelic Frequency in resistance to treatment cases in AML.

Results: see figure 1.

Figure 1. We performed a custom-targeted sequencing panel of 32 genes (all coding regions) implicated in leukemia prognosis, including ASXL1, CBL, DNMT3A, EPO, ETV6, EZH2, FLT3, HRAS, IDH1, IDH2, JAK2, KDM6A, KIT, KRAS, LNK, MPL, NRAS, PHF6, PRPF40B, PTEN, RUNX1, SF1, SF3A1, SF3B1, SRSF2, TET2, TP53, U2AF35, VHL, ZRSR2, and CALR, by Ion Torrent Proton System-Thermo Fisher. Primary tumor-refractory (n=8) and primary tumor-relapsed (n=17) samples pairs from 25 AML patients treated according PETHEMA AML clinical protocols were sequenced; in addition FLT3-ITD was detected by GENSCAN and NPM1 mutation was detected by PCR. We analyse the evolution of level of VAF, to measure the prevalence of somatic mutations between diagnosis and resistance status (relapse or refractory).

Results: see table.

Methods: see table.

Figure 1. Results: As it is presented in figure 1, ERK1/2 pathway was more activated after TKI treatment in the FLT3-AML patient during sorafenib-resistance development. The same fact was confirmed in MOLM13 sorafenib-resistant culture and in living proliferative cells re-collected after sorafenib treatment. Different doses of trametinib, sorafenib, pazopanib and midostaurin in monotherapy were tested in MOLM13 cell line determining their IC50 values. Synergy effects of combining trametinib with the three TKIs were analyzed with Calcusyn software.

Discussion: see table.

IDENTIFICATION OF NOVEL THERAPEUTIC DRUGS IN DISTINCT PEDIATRIC AML SUBTYPES BY TARGETING EPIGENETIC REGULATORS

C. Wiggers1,2, D. Leleivelde3, D. Egan4, M. Bartels1, H. de Bree1
1Department of Pediatric Hematology/Oncology, 2Center for Developmental Hematology, Radboud University Nijmegen Medical Centre, 3Cell Screening Core, Cell Biology, University Medical Center Utrecht, Utrecht, Netherlands

Background: Treatment protocols for pediatric acute myeloid leukemia (AML) are chemotherapy-based, including high-dose cytarabine. While >90% of patients reach clinical remission, there is still a high relapse rate of ~30%, with overall survival rates of 60-70%. Therefore, better risk-classification at diagnosis and alternative treatment strategies are warranted. There is increasing evidence that epigenetic deregulation is involved in the initiation and progression of cancers, including AML. Epigenetic processes are required for hematopoiesis and epigenetic regulators are frequently translocated (MLL) or mutated (EZH2) in AML. Following this, deregulated epigenetic pathways could be used for targeted therapy and provide an alternative approach to improve pediatric AML therapy.

Aims: To identify new therapeutic drugs in pediatric AML by using an 80-compound screen containing inhibitors of epigenetic regulators, including histone writers (which deposit post-translational modifications (PTMs) on histones), readers (binding of PTMs) and erasers (removal of PTMs).

Methods: Cell lines used in this study are THP-1 (t(9;11)), Kasumi-1 (t(8;21)) and CMK (Down’s syndrome with GATA1 mutation), reflecting distinct pediatric AML entities and a differential response to treatment with cytarabine. Cells were treated for 72hrs followed by analysis of cell viability and apoptosis based on Hoechst, Draq7 and Calcein Green staining. The expression of three candidate compounds were further investigated in triplicates at several concentrations for their effect on cell viability (Annexin V/PI staining), cell cycle, morphology, and apoptosis. As controls, normal myeloid precursor cells derived from Kasumi-1, CMK and THP-1, resp. While inhibition by LMK235 resulted in an increase of cells in S-phase and G2/M. Among the differential effects of the combination of alvocidib, cytarabine, and daunorubicin in Kasumi-1, CMK and THP-1, resp. Inhibition by LMK235 at an IC50 of 0.1µM, 0.13µM and 0.425µM in Kasumi-1, CMK and THP-1, resp. While inhibition by LMK235 resulted in an immediate increase of apoptosis, Bromosporine-treated cells retained in G1 through cell cycle arrest and, interestingly, in vitro, treatment of CMK cells with LMK235 results in a greater increase of cells in S-phase and G2/M. Among the differential effects of the compounds in the cell lines, we also observed differences in sensitivity. In line with previous studies, THP-1 cells were more resistant, indicated by a 10-fold increase in concentration required for NSC3852-induced apoptosis. Interestingly, upon addition of LMK235 to Kasumi-1 and CMK cells showed a similar response, while Kasumi-1 cells were significantly more sensitive to NSC3852-induced effects. These data are currently validated in pediatric AML patient cells.

Summary/Conclusions: Treatment of three distinct pediatric AML cell lines with the epigenetic compounds LMK235, NSC3852 and Bromosporine resulted in cell cycle arrest and reduced cell proliferation. The differential effects, including cell cycle regulation and induction of apoptosis. Our data suggests a potential role for epigenetic compounds, with specificity for molecular subtypes, in the treatment of clinically and biologically distinct pediatric AML subtypes.

ALVOCIDIB SYNERGIZES WITH CYTARABINE AND DAUNORUBICIN (7+3) IN PRECLINICAL MODELS OF ACUTE MYELOID LEUKEMIA

W. Kim1, H. Haws1, R. Mangelson1, P. Peterson1, C. Whatcott1, C. Siddiqui-Jain1, S. Weitman1, D. Bearss1, S. Warner1
1Discovery Biology, Tolero Pharmaceuticals, Inc., LEHI, United States

Background: Although survival of patients with acute myeloid leukemia (AML) has increased in the years 1975-2011, the 5-year, overall survival of patients with AML remains unacceptably low at an estimated 26% (2011). 7+3 treatment (cytarabine 100-200mg/m² + anthracycline [daunorubicin 60-90mg/m²/day or idarubicin 12mg/m²/day]) remains the standard induction therapy for AML patients, and has persisted largely unaltered for more than 30 years. There is a significant unmet clinical need for improved therapeutic options in patients with AML. Alvocidib is a CDK9 inhibitor currently in development for the treatment of patients with AML. Alvocidib has previously been studied as part of the ACM regimen, a combination regimen incorporating the time-to-remission-guided administration of alvocidib, cytarabine, and mitoxantrone, specific in multiple Phase 1 and 2 clinical trials. The ACM regimen has achieved significant improvements in complete response (CR) rates versus 7+3 in previously untreated intermediate and high-risk AML patients. The rationale for time-sequential administration of the ACM regimen was developed with an incomplete understanding of alvocidib’s mechanism of action. TST was based on the expectation that alvocidib would synchronize cells, capitalizing on the S-phase specific activity of cytarabine in the combination. However, rather than cell-cycle inhibition, alvocidib potently induces apoptosis by inhibiting the expression of key anti-apoptotic proteins via CDK9/RNA polymerase II, including MCL1. With this understanding, we reasoned that alvocidib would also enhance the activity of the 7+3 regimen.

Aims: These studies sought to interrogate the preclinical activity of alvocidib in the context of the 7+3 regimen in models for AML.

Methods: CellTiter-Glo and Caspase-Glo assays was used for cell viability and apoptosis, respectively. We used mouse xenograft models in the format of an MV4-11 xenograft mouse model. Following manufacturer’s protocol. We used RT-PCR to measure mRNA expression of MCL1 and other markers in response to drug treatment. Protein levels were interrogated using standard immunoblotting techniques. To determine the efficacy of an alvocidib/7+3 combination on tumor growth in vivo, we performed an MV4-11 xenograft mouse model.

Results: Single agent IC50 values of cytarabide, cytarabine, and daunorubicin range in AML cell lines from 2.2 nm to as high as 567 nm in viability assays. In apoptosis (Caspase-Glo) assays, however, we observed modest induction with single agent cytarabine and no good induction with single agent daunorubicin or cytarabine. In the combination, we observed a very strong synergy with more than two-fold enhanced induction of apoptosis in some treatment groups. As has been previously described, we report here too that alvocidib treatment reduced the expression of MCL1 protein and mRNA in a time and concentration-dependent fashion in AML cells. We observed this in the 7+3 treatment as well. In an MV4-11 xenograft model, we observed 21.1 and 48.5% tumor growth inhibition (%TGI) following single agent treatment of daunorubicin or cytarabine, respectively. 1.25mg/kg alvocidib yielded 60.0%TGI. The combination of alvocidib, cytarabine, and daunorubicin, however, resulted in tumor regression, yielding a 116.2% TGI.

Conclusions: These studies, along with the pan-cancer cellular and mouse xenograft studies, further support the potential of alvocidib as a time-sequential addition to the 7+3 regimen as a means to enhance the activity of the standard of care. In this study, alvocidib demonstrated both preclinical and clinical activity with increased efficacy when added to the 7+3 regimen as a means to enhance the activity of the standard of care.
immunocompetent brown Norwegian myeloid leukemia (BNML) syngeneic rat model. VPA mono-treatment increased survival from a median of 34 days to 38 days in the MOLM-13-cell mouse model, and from 21 days to 50 days in the BNML rat model. Additionally, the IFNα-Le (0.8x10^6 IU/kg) and VPA (400mg/kg) combination treatment indicated a tendency to increased survival in the BNML model. However, IFNα-Le monotherapy (1x10^6 IU/kg) decreased survival in the MOLM-13Luc+ model.

**Figure 1.**

Summary/Conclusions: IFNα does not add beneficial effects to VPA treatment in the two in vivo orthotopic models tested, possibly due to immune constitution and tumor load.

KEVETRIN: PRECLINICAL STUDY OF A NEW COMPOUND IN ACUTE MYELOID LEUKEMIA

R. Napolitano1, S. De Matteis1,1, S. Carloni1, G. Simonetti2, G. Musuraca3, A. Lucchesi3, D. Calisti1, A. Cuneo4, K. Menon5, G. Martinelli6

1Bioscience Laboratory, IRCCS, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST), Meldola, 2Department of Hematology and Oncological Sciences, I, and A. Seragnoli, Bologna, 3Hematology Unit, IRCCS, Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST), Meldola, 4Department of Medical Sciences, University of Ferrara-Arcispedale Sant’Anna, Ferrara, Italy, 5Cellceutix Corporation, Beverly, United States

Background: Acute Myeloid Leukemia (AML) is a heterogenous disorder defined by clonal expansion of immature myeloid cells that infiltrate bone marrow and other tissues. AML therapeutic strategies remain unchanged since 1970 and the majority of patients often eventually relapse and die due to disease progression. Tumor protein p53 transcription factor is a key regulator of several cellular pathways, such as cell cycle, apoptosis and angiogenesis. It is mutated in 8-14% of AML cases and its mutations are commonly associated with a complex karyotype. Kevetrin is a new molecule compound, proposed by Cellceutix, with the ability to target both wild type and mutant p53 tumors.

Aims: The aim of this project is to explore cellular and molecular alterations induced by Kevetrin, focusing on its role in the p53 pathway.

Methods: Kevetrin was kindly provided by Cellceutix, dissolved and stored at 4°C in sterile water in a 600 μg/ml stock solution, and diluted in medium immediately before use [concentration range in use 15-60μg/ml]. Cell lines, MOLM-13 and KASUMI-1, were cultured in RPMI 1640 supplemented with 20% heat inactivated fetal bovine serum, 2mM L-glutamine, 100 U/ml penicillin and 100 μg/ml streptomycin. After 24 and 48 h of treatment MTS, Annexin-V, TUNEL, and transferred to 0.2 μm polyvinylidene fluoride membranes. Quantitative analysis was performed with Quantity One software. Statistical analysis was carried out using the paired and unpaired two-tailed Student’s t tests. p values <0.05 were considered as significant.

Results: Our data indicate that Kevetrin exposure induces cell growth arrest, a great drop of mitochondrial membrane potential and a remarkable increment of Caspase-3 cleaved form, features that contribute to apoptotic cell death in the two cell lines. Cellular changes can be associated with a dose and time-dependent effect in the TP53 mutated cell line (KASUMI-1) but not in the wild type one (MOLM-13), in which we can observe an activity only after 48 h at the higher concentration. Regarding molecular alterations in KASUMI-1 we found a great p53 down-regulation, probably due to Hsp90 reduction, resulting in a less marked formation of the Hsp90-p53 oncogenic complex. We also found a down-regulated p53 active form (Ser15), a reduced expression of p53 targets, p21 and PUMA, and a down-regulation of SIRT-3, that cannot exert its inhibitory activity on p53. The MOLM-13 cell line showed a great p53 reduction, probably related to SIRT-3 up-regulation and Hsp90 down-regulation. Regarding p53 active form, we noticed slight variations in protein expression, suggesting a physiological response of the protein to cellular damage. In accordance with p53 activity, we observed a great deregulated with a drug resistance mechanism; in contrast, PUMA protein was highly down-regulated, suggesting a p53-independent mechanism of action or a feedback regulation of the apoptotic process, after Caspase-3 activation (Figure 1.). In order to better understand drug’s mechanism of action we are performing gene expression profiling after 48h of treatment with Kevetrin 60μg/ml.

CLEARANCE OF ‘DRIVER-COSMIC’ MUTATIONS POST CR1 WITH OPERATING RUNX1 L565 IS UNLIKELY TO CONTRIBUTE TOWARDS DISEASE PROGRESSION IN AML

L. Rai1, T. Boneva2, D. Brazma2, R. Dunn2, C. Grace2, E. Nacheva3

1Onco-Cytogenomics, 2OncoGenomics, HSL Analytics LLP, 3Cancer Research Institute, UCL, LONDON, United Kingdom

Background: Clinical significance of gene variants in AML is well established (Papaemmanuil E, et al, NEJM 2016) and is increasingly being implemented into routine diagnostic algorithms. Although 80% of patients achieve morphological remission after induction chemotherapy, long-term relapse free survival is a meagre 50% (Walter RB et al, JCO 2010). Monitoring of disease kinetics, is therefore, very critical.

Aims: To study the kinetics of gene variants post-induction chemotherapy in AML patients.

Methods: 130 follow-up samples from 45 de novo AML patients [median age-60 yr & median FU period- 18.6 mo] were screened for gene variants using TruSight Myeloid panel (Illumina, CA) covering 54 genes with relevance in myeloid diseases. Gene variants at Variant allele frequency (VAF) of ≥1% at diagnosis and VAF of ≥1.5% during follow-up; both with target coverage of ≥300 reads were considered. Bone marrow (BM) or peripheral blood (PB) was obtained at presentation (BM;44; PB:1) and follow-up (BM;130). Gene variants in 95 samples from 40 MDS patients were also evaluated for progression to secondary AML. Public databases-Catalogue of Somatic Mutations In Cancer (COSMIC), dbsNP and 1000 genome (≥2%) were used to classify gene variants as either Drivers (D), variants of unknown significance (VUS) and germline polymorphisms (SNP).

Results: Of 45 AML patients 19 achieved complete morphological remission (CR), 21 had a relapse and 5 had refractory disease with a median of 4 mutations/patient in each subgroup. Driver mutation was identified in 38 patients; 82% of who had persistence until clinical end-point. While 17 of 18 relapse patients retained a driver only 9 of 15 patients in remission retained it (Table 1). 8 of the 9 patients had a ‘driver with COSMIC and SNP’ (D-CS) reference that persisted, while all ‘driver with COSMIC only’ (D-C) disappeared post-induction. This suggests that drivers with both COSMIC and SNP reference may not always contribute towards disease progression. We also found that D-C mutations persist in 85.7% of relapse patients compared to only 11% of patients in remission (P-value: 0.001). Additionally, D-C mutations were retained in all 13 relapse patients with intermediate risk cytogenetics while complete clearance was observed in all 6 patients who were in sustained remission (P-value: 0.001). Further investigation of genes with D-CS mutation in the remission cohort (8x) revealed that 4 patients had persistent DNTM3A-25457242, 1 had DNTM3A-25457243, 2 had RUNX1-36259324/L565 and 1 had CBL-119149011. As DNTM3A mutations are considered to occur in pre-leukemic disease.
stem cells contributing to clonal haematopoiesis (Askush et al, Nature 2014; Genovese et al, NEJM 2014); this led us to study the distribution of RUNX1 gene variants in an additional 119 AML diagnostic samples. 34 patients (21%) harboured RUNX1 mutation, of which 5 had RUNX1_L56S that were often associated with D-C mutations (4 of 5 cases). Finally, we evaluated kinetics of D-C in 40 MDS cases of which 34 had chronic MDS and 6 had secondary AML (sAML). No significant difference was observed in the number of patients with persistent D-C mutation in the 2 subgroups (chronic MDS: 16 of 19 (84.2%); sAML: 5 of 5 (100%); P-value: 1.000).

Table 1.

Summary/Conclusions: Clearing of ‘Driver-COSMIC only’ mutations while RUNX1_L56S persists is unlikely to contribute towards disease progression in AML.

Acute myeloid leukemia - Clinical

E906

PROGNOSTIC SIGNIFICANCE OF FLT3 STATUS, CYTOGENETIC, ECOG AND 50% BLAST DECREASE IN PRIMARY REFRACTORY OR EARLY RELAPSED AML PATIENTS BEFORE SALVAGE THERAPY

P. Sesques1, S. Bertoli2, M. El-Hamri1, S. Ducastelle1, G. Salles1, C. Recher2, X. Thomas1, E. Paubelle1,2
1hematology, CHU Lyon Sud, Pierre Benite, 2hematology, Oncopole Toulouse, Toulouse, France

Background: Prognosis of relapsed/refractory acute myeloid leukemia (R/R AML) is unfavorable with a long term overall survival around 10%. Thus, management of R/R AML represents one of the most difficult challenges. Because allogeneic-Hematopoietic Stem Cell Transplantation (allo-HSCT) is considered as the best treatment for this category of patients, to determine which patient will benefit from this cumbersome strategy is a crucial issue. A better understanding of the mutational status, cytogenetic, histological and clinical findings of early R/R AML patients and their outcomes could help treatment decisions, particularly for those who allo-HSCT is considered as the best therapeutic option.

Aims: The objective of this study is to determine prognostic factors and develop a prognostic score using usual mutational status, cytogenetic, histological and simple clinical variables in R/R AML patients before salvage treatments.

Methods: In this retrospective study in two hematological departments (Hospices Civils de Lyon and CHU of Toulouse), we evaluated clinical, biological, histological, cytogenetic and current mutational status of early R/R non APL AML patient between age from 18 to 70 years. Univariate and multivariate analysis were performed and we developed a prognostic score based on the independent prognostic parameters from Cox model.

Results: From January 2009 to May 2016, 58 patients presenting early relapse and primary refractory AML were analyzed. Overall Survival (OS) and Progression Free Survival (PFS) median were 9 and 2 months respectively. In univariate analysis, cytogenetic findings (unfavorable groups), unfavorable ECOG (>2), FLT3 positive status and <50% blast decrease (between induction and R/R assessment) independently predicted poor OS and were identified as significant prognostic parameters of OS (p=.037, p=.0084, p=.0452, p=.0071 respectively). In multivariate analysis, these last four criteria confirmed their worst prognostic impacts (p=.015, p=.017, p=.026, p=.015 respectively) and were used to create a five groups prognostic score. Better OS were statistically observed for patient with score 0 or 1 compared to 2, 3 or 4 (2-years OS 48% and Not Reached respectively, p=.0104) (Figure 3).

Summary/Conclusions: Our prognostic score based on simple and usual data: FLT3 status, cytogenetic, ECOG and percentage blast decrease found distinct groups with statistically different outcomes. Basically, the higher is the score, the worst is the OS. This new score is a valuable, simple and useful score for the therapeutic salvage management of AML patients presenting early relapse and primary refractory.
PRELIMINARY RESULTS FROM A PHASE 1 STUDY EXAMINING THE NOVEL BCL-2 INHIBITOR S55746/BCL201 AS SINGLE AGENT IN PATIENTS WITH ACUTE MYELOID LEUKEMIA OR HIGH RISK MYELODYSPLASTIC SYNDROME

A. Wei1, A. Bajel2, N. Boissel3, I. Kloos4, C. Delifer4, S. Banquet4, X. Thomas5, N. Vey6

1Department of Clinical Haematology, The Alfred Hospital and Monash University, 2Department of Haematology & Bone Marrow Transplantation, The Royal Melbourne Hospital, Melbourne, Australia, 3Department of Hematology, Hôpital Saint Louis, Paris, 4Servier, Suresnes, 5Department of Hematology, Centre Hospitalier Lyon Sud, Lyon, 6Department of Hematology, Institut Paoli-Calmettes, Marseille, France

Background: Novel and effective therapeutic options for patients (pts) with advanced acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS) are limited. Targeting the prosurvival molecule BCL-2 is clinically efficacious in various hematological malignancies. S55746/BCL201 is a novel, selective and potent inhibitor of BCL-2, with demonstrated antileukemic activity in preclinical models.

Aims: To evaluate the safety, recommended phase 2 dose (RP2D), pharmacokinetic (PK), pharmacodynamic (PD) and preliminary activity of S55746/BCL201 in patients with AML (relapsed/refractory (R/R) or ≥65 years unfit for intensive chemotherapy (IC)), or MDS failing prior therapies.

Methods: A phase I study (EUDRACT 2014-002559-24, NCT02902541) is underway to investigate S55746/BCL201 as a single agent in 5 European and Australian centers. S55746/BCL201 was initially administered in fasting conditions, once daily (21-day cycles), until disease progression, unacceptable toxicity, or investigator’s or patient’s decision. Pts giving informed consent received S55746/BCL201 at escalating dose levels according to a modified continual reassessment method for dose allocation.

Results: As of 23 February 2017, 34 pts have received S55746/BCL201 at doses ranging from 100 to 1300mg/day (median time on treatment: 43 days, range 1 to >374), 28 pts were R/R AML, 2 pts were elderly AML unfit for IC, and 4 pts had MDS failing prior therapies. Median age was 70 years (range 19-80), median number of prior therapies 2 (range 0-6), ECOG ≤2, and median WBC 3.1 G/L (range 0-30). Among the AML cohort, European LeukemiaNet risk (Döhner 2010) was adverse in 53%, intermediate-I in 20%, and intermediate-II in 27%. 28 pts were R/R AML, 2 pts were elderly AML unfit for IC, or MDS failing prior therapies. Median age was 70 years (range 19-80), median number of prior therapies 2 (range 0-6), ECOG ≤2, and median WBC 3.1 G/L (range 0-30). Among the AML cohort, European LeukemiaNet risk (Döhner 2010) was adverse in 53%, intermediate-I in 20%, and intermediate-II in 27%.

Preliminary PK results in fasting pts showed that exposure increased linearly but with some inter-individual variability. Most common (≥20% of pts) non-hematological adverse events (AEs), all grades, included diarrhea (27%), hypokalemia (27%), nausea (21%), and vomiting (21%). The most frequent grade ≥3 AEs were hematological (anemia (35%), thrombocytopenia (32%), febrile neutropenia (21%), and neutropenia (18%)), hypokalemia (18%), and sepsis (15%). Of 12 pts (38%) with AEs possibly related to study drug, the most frequent were diarrhea (3 pts), muscle spasms, thrombocytopenia, and anemia (2 pts each). One 74-year-old pt had grade 5 cardiac failure considered drug-related after 6 cycles of treatment (900mg). Non-related fatal AEs were reported (2 pts each). One 74-year-old pt had grade 5 cardiac failure considered drug-related after 6 cycles of treatment (900mg). Non-related fatal AEs were reported (2 pts each). One 74-year-old pt had grade 5 cardiac failure considered drug-related after 6 cycles of treatment (900mg). Non-related fatal AEs were reported (2 pts each). One 74-year-old pt had grade 5 cardiac failure considered drug-related after 6 cycles of treatment (900mg). Non-related fatal AEs were reported (2 pts each). One 74-year-old pt had grade 5 cardiac failure considered drug-related after 6 cycles of treatment (900mg). Non-related fatal AEs were reported (2 pts each).

Summary/Conclusions: Initial findings suggest that S55746/BCL201 has acceptable tolerability and clinical activity in advanced AML and MDS. Based on non-compartamental pharmacokinetic food interaction results from another study, demonstrating that S55746/BCL201 Cmax and AUC increased about 6-fold with food, dose escalation has started in patients with drug intake during a meal.

DISSECTING THE CLINICAL HETEROGENEITY OF NUCLEOPHOSMIN-1 (NPM1) MUTATED ADULT ACUTE MYELOID LEUKEMIA: THE CONTRIBUTION OF FLOW-CYTOMETRIC DETERMINATION OF MINIMAL RESIDUAL DISEASE

F. Buccisano1,2, L. Maurillo1, M.I. Del Principe1, A. Di Veroli1, E. De Bellis1, L. Ciconni1, M. Divona1, T. Ottone1, S. Lavorgna1, V. Rossi1, A. Zizzari1, M.A. lno Consalvo1, D. Fraboni1, C. Conti1, G. Del Poeta1, M.T. Vosoi, W. Arcese1, F. Lo Coco1, A. Venditti1

1Biomedicine and Prevention, University Tor Vergata of Rome, Rome, Italy 2Department of Pediatrics, Asan Medical Center Children’s Hospital, University of Ulsan College of Medicine, 3Department of Hematology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: Acute Myeloid Leukemia (AML) with mutations of the gene encoding Nucleophosmin-1 (NPM1) identifies a subgroup of patients with favorable prognosis according to the 2008 WHO classification. However, recent evidences (Papaemmanuil, NEJM 2016) suggest that the coexistence of additional gene mutations (e.g. DNTM3A, IDH1, IDH2R1408 and TET2) may determine an inferior clinical outcome as compared to favorable risk AML and precludes a reliable outcome prediction. The presence of minimal residual disease (MRD), as determined by quantification of NPM1 mutated transcripts, provides powerful prognostic information independent of other risk factors (Ivey, NEJM 2016).

Aims: The aim of our study was to investigate if detection of NPM1 by multiparametric flow cytometry (MFC) might represent an alternative tool to discriminate different prognoses within the NPM1 mutated AML group, in a setting where an extensive gene profiling at diagnosis or a quantitative determination of NPM1 transcripts in remission would not be available.

Methods: We analyzed a series of 69 AML patients with NPM1 mutations; all the patients were in complete remission (CR) after intensive induction cycle of EORTC-GIMEMA protocols. The frequency of NPM1 mutated cases was not different among patients below (48/142, 34%) or above (21/61, 34%) the age of 60 years, respectively. Twenty out of 65 patients (31%) carried a concomitantFLT3-ITD mutation; 51/66 (77%) NPM1 mutated cases had a normal diploid karyotype. Upon full hematological recovery after consolidation cycle, counting, by MFC, ≥3·5×1010·0.0335 residual leukemic cell (RLCs) in the bone marrow (BM) was regarded as a condition of MRD positivity.

Results: Among NPM1 mutated patients, the rate of MRD negative CR was significantly lower (5/69, 7%) as compared to NPM1 WT ones (39/134, 29%), respectively (p<0.001). Although there was not a statistically significant difference, probably due to the low numbers, MRD negative/NPM1 WTs had a lower Cumulative Incidence of Relapse (CIR) as compared to MRD positive/NPM1 mut patients who had a higher Cumulative Incidence of Relapse (CIR) as compared to MRD negative/NPM1 WTs (25% vs 80%). We also evaluated the impact of autologous (AuSCT) or allogeneic (ASCT) transplantation on the outcome of MRD positive/NPM1 mut patients. The overall survival (OS) was significantly higher for patients submitted to ASCT (no=14) as compared to those (no=15) submitted to AuSCT (93% vs 33%, p=0.011). This was confirmed even after excluding from the analysis FLT3-ITD+/patients. When all the meaningful clinical variables were challenged in multivariate analysis (MRD, type of transplant, age >60 yrs, karyotype), the type of transplant (ASCT vs AuSCT) was the only variable that significantly influenced OS and DFS (p=0.001 and 0.003, respectively).

Summary/Conclusions: In conclusion, although quantitative RT-PCR represents the gold standard, MFC determination of MRD also confirms that the quality of remission is critical to discriminate patients with a different outcome among NPM1 mut patients. In fact, these patients have a low chance to become MFC MRD negative and in a situation of MRD positivity, a very poor outcome can be substantially improved only by a timely use of an allogeneic procedure.

EXPRESSION OF IMMUNE CHECKPOINT MOLECULES (PD-1, PD-L1, AND PD-L2) ON BONE MARROW T CELLS IN ACUTE MYELOID LEUKEMIA

1Department of Laboratory Medicine, Asan Medical Center, University of Ulsan College of Medicine, 2Department of Pediatrics, Asan Medical Center Children’s Hospital, University of Ulsan College of Medicine, 3Department of Hematology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic Of

Background: Immune checkpoints constitute a mechanism by which tumors escape from the host immune system and involve the programmed death-1 (PD-1) receptor and its ligands, PD-L1 and PD-L2. In a tumor microenvironment, the expression of PD-1, an inhibitory receptor on the surface of T cells, can lead to dysfunction of antitumor effector cells. Recently, investigators have detected overexpression of PD-1 for patients with acute myeloid leukemia (AML) who experienced relapse following allogeneic stem cell transplantation.
(SCT). However, evidence regarding T cell phenotypes for patients with AML is sparse.

Aims: The authors evaluated patients with AML to determine expression levels of checkpoint molecules (PD-1, PD-L1, and PD-L2) according to diagnosis and treatments (chemotherapy [CTx] and SCT). The purpose of this study was to identify optimal candidates for checkpoint blockade therapy for AML.

Methods: Bone marrow (BM) samples were obtained from 195 AML patients in different stages of the disease. Samples were stratified by time since diagnosis (n=69) and treatment response (complete remission [CR]) after CTx, n=30; persistence after CTx, n=29; relapse after CTx, n=7; normocellular marrow with trilineage regeneration [NMTR] after SCT, n=19; persistence after SCT, n=18; and relapse after SCT, n=23). BM samples also were collected from 23 patients with no evidence of hematologic malignancies (control group). Flow cytometric analysis of PD-1 expression on T cells and PD-L1/PD-L2 expression on leukemic cells was performed by means of a FACSCanto II system (Becton-Dickinson, Sunnyvale, CA, USA).

Results: There were no differences in levels of PD-1 expression on CD8+ and CD4+ T cells at time of AML diagnosis, compared with controls. However, PD-1 expression levels on CD4+ T cells were significantly correlated with time since diagnosis. For patients at time of diagnosis, PD-1 expression on CD8+ and CD4+ T cells was significantly different compared with patients who experienced relapse after SCT (P=0.025 and P<0.0001), persistence after SCT (P=0.0025 and P<0.0001), and NMTR after SCT (P=0.0001 and P<0.0001). In contrast, no difference in PD-1 expression was observed between patients at time of diagnosis and patients after CTx (Figure 1). For CD4+ T cells, a significant difference was found between SCT and CTx groups, and PD-1 expression levels of groups that experienced relapse (P<0.0001) or persistence (P<0.0001) after SCT were significantly higher than those of patients in the CTx groups. PD-L1 and PD-L2 expression on leukemic cells at time of diagnosis was higher in secondary AML transformed from myelodysplastic syndrome than in de novo AML (P=0.0001 and P=0.039). Although PD-L1 and PD-L2 expression levels for patients at time of AML diagnosis did not differ from groups that experienced relapse or persistence after SCT, PD-L1 and PD-L2 levels for diagnosed patients did differ from those of patients who experienced persistence after CTx (P=0.038 and P=0.023).

Summary/Conclusions: Our study shows that HIV status has no prognostic impact on AL patient’s outcome. HIV patient with acute leukemia should thus be included in clinical trials to improve and standardize their therapeutic management.

E910

ACUTE LEUKEMIA IN HIV PATIENTS: EPIDEMIOLOGY, THERAPEUTIC STRATEGY AND PROGNOSIS

F. Rabian1,*, F. Suarez2, T. Cluzeau3, F. Isnard4, C. Recher5, A. Pigneux6, S. Nguyen-Quoc7, S. Chevret8, H. Dombret9, E. Raffoux9

1St Louis Hospital, 2Adult Hematology Unit, Necker Hospital, Paris, 3Adult Hematology Unit, Nice Hospital, Nice, 4Adult Hematology Unit, St Antoine Hospital, Paris, 5Institut universitaire du cancer, oncopole, Toulouse, 6Hematology Unit, Hopital Haut-Lévêque, Pessac, 7Hematology Unit, Pitié Salpetrière Hospital, 8Biostatistics and Medical Information, 9Adult Hematology Unit, St Louis Hospital, Paris, France

Background: Data on HIV patients with acute leukemia (AL, acute myeloid leukemia (AML) or non Burkitt acute lymphoid leukemia (ALL)) are very poor especially on their outcome. Treatment of acute leukemia usually depends of patient-related prognostics factors and disease related prognostic factors. Because HIV patients are considered frail, they are always excluded of therapeutic protocols. There are no guidelines for their treatments.

Aims: Our aim was to precise the epidemiology, the best therapeutic strategies as well as patient’s prognostics, and to compare their outcome to those of seronegative patients with AL.

Methods: We conduct a retrospective national multicentric study. HIV positive patients with a diagnosis of AML or non Burkitt-ALL between January 2000 and February 2016 were included. We compared HIV patients’ outcome to those of seronegative patients with AL after a propensity score matching.

Results: 47 HIV patients with a diagnosis of AL (42 AML and 5 ALL) were included. AL incidence in HIV patients (HIVP) is not different than in general population but AL occurred earlier (49.29 years [44.21 ; 57.47]) and AL are more frequent (42.55%). With a global and multidisciplinary approach these patients can be treated with intensive chemotherapy resulting on good efficiency (complete remission [CR]=84.38%) and tolerance. Based on a multivariable model, only absence of CR was associated with hazard of death (p=0.01). 8 patients (17,02% ; 7 AML and 1 ALL) received a hematopoietic stem cell transplantation. HIVP with AL 2 years overall survival (OS) was 29% C195% [15 ; 54] for AML and 40% C195% [14 ; 100] for ALL. There was no difference in OS between our HIVP and seronegative controls with AL after propensity score matching (HR=1.347 [0.6846-2.796]; p=0.42).

E911

TEN-DAY DECITABINE AS INDUCTION THERAPY FOR OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA FOR INTENSIVE CHEMOTHERAPY

C. Zhou1, H. Wei1, D. Lin1, Y. wang1, B. Liu1, K. Liu1, B. Gong1, Y. Li1, G. Zhang1, S. Qiu1, R. Gu1, S. Wei1, X. Gong1, Y. Mi1, J. Wang1

WITH ACUTE MYELOID LEUKEMIA FIT FOR INTENSIVE CHEMOTHERAPY
Background: Currently, there is no consensus regarding optimal treatment for older patients with acute myeloid leukemia (AML). Decitabine for 5 consecutive days produced a complete remission (CR) rate of 17.8% in older patients with newly diagnosed AML. Ten-day regimen of decitabine induces a higher response in newly diagnosed older patients with AML considered unfit for intensive chemotherapy. But this 10-day regimen has not been tested in older fit AML before.

Aims: To investigate the efficacy and safety of the 10-day decitabine regimen in older fit AML prospectively.

Methods: Twenty-one older patients (>60 years old) with newly diagnosed intermediate or adverse cytogenetic risk group AML, considered fit for intensive chemotherapy, were enrolled in a prospective clinical trial. These patients refused to take intensive chemotherapy. All patients were treated with at least one course of 10-day decitabine consolidation. The primary endpoint was achieved less than 5% bone marrow blasts were subsequently treated with 5-day decitabine courses as maintenance therapy. Median age was 64 (range 60-74) years. There are 5 patients with (23.8%), 10 (47.6%), 6 (28.6%) in favorable, intermediate and poor-risk group, respectively, based on the NCCN guideline. All patients had an Eastern Cooperative Oncology Group performance status of 0-1.

Results: The overall response rate (ORR) was 57.1%, including 52.4% CR. There are no significant differences between responders and non-responders, in the following parameters, including age, LDH, DNMT3A mutation, white blood cells count in peripheral blood, or bone marrow blasts percentage. Nineteen patients achieved negative residual disease (MRD) status, as measured by multi-parametric flow cytometry, in pts with AML who receive indoximod in combination with standard of care (SOC) chemotherapy after completion of the 1st cycle of consolidation, and before maintenance or proceeding to allogeneic stem cell transplantation (allo-HSCT).

Summary/Conclusions: Indoximod is given orally every 8 hours starting on day 8 of induction onward. Indoximod is an inhibitor of the IDO pathway, into conventional remission, and before maintenance or proceeding to allogeneic stem cell transplantation (allo-HSCT). This is a phase 1b / randomized phase 2a trial of indoximod in combination with decitabine for upfront treatment of patients with newly diagnosed acute myeloid leukemia (AML): Phase 1 report.

E912 INDOXIMOD IN COMBINATION WITH IDRACUBYN AND CYTARABINE FOR UPFRONT TREATMENT OF PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML): PHASE 1 REPORT

A. Emadi1,2,3,*, N.G. Holtzman1,2, M. Imran1, F. El Chaer1, M. Koka4, Z. Singh4, A. Shahlaee1,4, E. A. Sausville 1,2,3, J. Law 1,2, S. T. Lee 1,2, A. Banerjee 1,2, A. Rapoport1,2, M. R. Baer1,2, V. H. Duong1,2, D. H. Munn1, M. Loken1, E. Kennedy6, N. Vahanian1, C. Link1

1University of Maryland Greenebaum Comprehensive Cancer Center, 2Medicine, 3Pharmacology, 4Pathology, University of Maryland, Baltimore, 5Institute for Advanced Cancer Care, 6Georgia Cancer Center and Department of Pediatrics, Medical College of Georgia, Augusta, Hematologics Inc., Seattle, 7NewLink Genetics Co., Ames, United States

Background: AML cells can acquire immune evasion and tolerance through overexpression of IDO, which targets immunomodulatory effects through tryptophan (Trp) catabolism and kynurenine production. By degrading Trp, IDO shifts the balance from a Trp-rich environment leading to immune system suppression. We hypothesized that incorporation of indoximod, an inhibitor of the IDO pathway, into conventional remission induction and consolidation would be well tolerated without adding significant toxicity and may improve clinical outcomes of patients (pts) with newly diagnosed AML.

Aims: The primary objective of the phase 1 portion of the trial is to characterize the Asahina and Allergy, Chevy Chase, Maryland, United States, 6Georgia Cancer Center and Department of Pediatrics, Medical College of Georgia, Augusta, Hematologics Inc., Seattle, 7NewLink Genetics Co., Ames, United States

Methods: Twenty-one older patients (>60 years old) with newly diagnosed intermediate or adverse cytogenetic risk group AML, considered fit for intensive chemotherapy, were enrolled in a prospective clinical trial. E913 PHASE III STUDY OF MEK INHIBITOR (MEK-162; BINIMETINIB) IN PATIENTS WITH RELAPSED AND/OR REFRACTORY MYELOID MALIGNANCIES

K. Nadjl1, T. Kadia1, G. Borthakur1, K. Takahashi1, P. Bose1, N. Daver1, Y. Alvarado1, M. Ohanian1, C. DiNardo1, E. Jabbour1, G. Garcia-Manero1, H. Kantarjian1, A. Patel1, F. Ravandi1

1Department of Leukemia, UTMD Anderson Cancer Center, Houston, United States

Background: Activation of the mitogen-activated protein kinase (MAPK) signaling (RAS/RAF/MEK/ERK pathway) promotes growth and inhibits apoptosis of hematopoietic cells. Inhibition of MEK/MAPK pathway has shown antiproliferative effects in acute myeloid leukemia (AML) blasts. MEK-162 is an oral, potent, selective allosteric, ATP-non-competitive inhibitor of MEK1 and 2.

Aims: To study the efficacy and safety of MEK-162 in patients with advanced myeloid malignancies.

Methods: Patients with relapsed/refractory AML, not candidates for intensive chemotherapy, and patients with high risk myelodysplastic syndrome (MDS) who were resistant/intolerant to standard treatment including stem cell transplant were treated with MEK-162 twice daily every 28 days. Patients in the expansion phase had to be RAS mutated. The primary endpoint was overall response rate (ORR=CR+CRI) after 1 cycle of therapy. Survival was estimated using the Kaplan-Meier method. Safety analysis included all patients who had received at least 1 dose of MEK-162. MEK-162 dose escalation followed a 3+3 design; phase 2 had built in futility/toxicity boundaries. 45mg twice daily is the final dose level for expansion phase.

Results: Sixteen patients were treated (escalation=7; expansion=9): 14 AML and 2 MDS. Median age was 62 years (31-85). 56% were male; 94% had a performance status of 1-2. Median number of prior therapies was 4 (1-6). 3/16 (19%) patients had complex karyotype. 11/69 (16%) patients were RAS mutated. All 16 patients completed a minimum of 1 cycle of MEK-162 therapy and were evaluable for response (3 at 30mg and 7 at 45mg dose). ORR was 10% (CRI in 1/10 patients). Median number of cycles administered were 2 (1-4). Median duration on therapy was 1.1 months (0.1-3.4). Median overall survival is 3.2 months (0.3-7.6). Common G3/4 toxicity included neutropenia (56%), fatigue (13%), nausea/vomiting (13%) and electrolyte abnormalities (14%). No dose limiting toxicity was reported.

Summary/Conclusions: MEK-162 shows a tolerable safety profile with an ORR of 10%. The study is currently on-going. Additional studies involving combination of MEK-162 with RAF and PI3 kinase inhibitors are ongoing.

E914 HAPLOIDENTICAL TRANSPLANTATION IS SAFE AND EFFECTIVE FOR OLDER PATIENTS WITH AML/MDS

1Stem Cell Transplantation, The University of Texas MD Anderson Cancer Center, Houston, 2Thomas Jefferson University, Philadelphia, 3Leukemia, The University of Texas MD Anderson Cancer Center, Houston, United States

Background: Acute myeloid leukemia (AML) is more common in the older population. Haploidentical stem cell transplantation (haploSCT) is a potentially cur-
ative treatment option for patients with AML and allows transplantation for patients without an HLA matched donor. Recently, the use of post-transplant cyclophosphamide-based (PTCy) GVHD prophylaxis has improved outcomes of haploSCT; however, outcomes of haploSCT in older patients remain unclear.

Aims: Here we evaluated outcomes of older patients with AML/MDS who underwent haploSCT.

Methods: We retrospectively analyzed outcomes of all 43 patients ≥55 years with AML/MDS who underwent a haploSCT at our institution after year 2009. All patients were treated with fludarabine-melphalan (FM)-based conditioning regimen (melphalan 100 or 140mg/m²) plus thiopeta 5mg/kg or 2GyTBI. Characteristics of these patients are presented in Table 1.

Results: Median age was 61 years (range 55-69), 22 patients (51%) were in CR1/2, 16 patients (37%) had poor-risk cytogenetics, and median HCT-CI was 2 (range 0-11). Reduced melphalan regimen (100mg/m²) was used in 29 pts (67%). Donors were children in 35 (81%) or siblings 10 (19%) patients.

Median follow-up was 19 months (range 6-49). One patient died prior to engraftment. Forty-two patients engrafted the donor cells (100%). Median time to neutrophil and platelet engraftment was 19 (13-28) and 28 (15-117) days. Day 30 chimerism was 100% donor in 38 patients (88%). The cumulative incidence (CI) of grade 2-4 and 3-4 aGvHD at 6 months post-transplant was 35% and 5% while CI of cGvHD at 2 years post-transplant was only 9%. The 2-year overall survival (OS) and progression-free survival (PFS) was 42%, and relapse rate was 24%. Cumulative non-relapse mortality (NRM) was 21%, 30% and 34% at day 100, 1 year, and 2 years post-transplant. Patients in CR1/2 had 2-year NRM and relapse rate of 23% and 14%, and OS was 61%. The 2-year OS for patients in CR1/2 with intermediate/favorable-risk cytogenetics was 73%. In multivariate analysis, favorable predictors for OS were CR1/2 (HR:0.4, p=0.05), good/intermediate cytogenetics (HR:0.2, p=0.01), and donor age greater than 40 (Figure 1).

Figure 1. Results: Median age was 61 years (range 55-69), 22 patients (51%) were in CR1/2, 16 patients (37%) had poor-risk cytogenetics, and median HCT-CI was 2 (range 0-11). Reduced melphalan regimen (100mg/m²) was used in 29 pts (67%). Donors were children in 35 (81%) or siblings 10 (19%) patients.

Summary/Conclusions: Our data show that MRD assessment at different time-point reduces the risk of late relapse by demonstrating the persistence of disease for different populations. The percentage of MFC-MRD negativity is higher than 90%, and patients with MFC-MRD negativity at TP1, TP2, TP3 (NPM-MRD) were more likely to achieve treatment control. The probability of achieving MFC-MRD negativity at TP2 was only influenced by ELN risk group (p<0.05). In the whole cohort, 2 years OS was 60.2% (median not reached). Multivariate Cox-Proportional Hazard model showed that MFC-MRD >0.1% at TP2 was the strongest predictor of higher risk of death, whereas MFC-MRD <0.025 at TP1 was the strongest predictor of long survival (Figure 1). Among Acute Myeloid Leukemia (AML) patients achieving hematological complete remission (CR) the persistence of detectable disease assessed with highly sensitive techniques as Multicolor-Flow-Cytometry (MFC) or PCR-based molecular analysis retains a negative prognostic value. However, a consensus on the most informative time-points (TP) and sensitivity cut-offs for MRD assessment has not been reached.

Aims: The aim of the present study was the evaluation of the prognostic impact of MFC and molecular MRD assessment by identifying TP, MFC positivity cut-off values and molecular MRD markers with the highest prognostic impact.

Methods: One hundred and ten consecutive AML patients treated in our center between 2004 and 2014 were retrospectively analyzed. As previously described, all patients had received a fludarabine-containing induction. Median age was 47 years (range 18-65). Median follow up was 59 months. Three different MRD TP have been considered: TP1, after induction I; TP2, after induction II; TP3, after consolidation therapy for patients who did not undergo hematopoietic stem cells transplantation (HSCT). For patients who underwent HSCT, TP3 coincided with pre-transplant MRD evaluation. MFC-MRD evaluation had been performed through 4-color MFC analysis (and 8-color from 2013). To define the MFC-MRD positivity two cut-offs were considered: 0.2×10−4 residual leukemic cells (>0.025%) or a threshold of 1×10−3 residual leukemic cells (>0.1%). For patients carrying NPM1-gene mutation NPM1 expression levels at TP1, TP2, TP3 (NPM-MRD) were analyzed. A reduction >3.5 log of NPM1 transcript at TP1 was considered optimal as per our published experience. For patients presenting WT1 over-expression at diagnosis WT1-MRD was evaluated at TP1, considering WT1 negativity with a cut-off of WT1 c/b/104 ABL lower than 250.

Results: CR rate after induction I and II was 82.7 and 85.5%, respectively. The percentage of MFC-MRD negativity was >90% and >0.1% increased from TP1 to TP2. The probability of achieving MFC-MRD negativity at TP2 was only influenced by ELN risk group (p<0.05). In the whole cohort, 2 years OS was 60.2% (median not reached). Multivariate Cox-Proportional Hazard model showed that MFC-MRD >0.1% at TP2 was the strongest predictor of higher risk of death, whereas MFC-MRD <0.025 at TP1 was the strongest predictor of long survival (Figure 1). Multivariate Cox-Proportional Hazard model showed that MFC-MRD >0.1% at TP2 was the strongest predictor of higher risk of death, whereas MFC-MRD <0.025 at TP1 was the strongest predictor of long survival (Figure 1). Thirty-five patients carried NPM1-mutation. Two-years OS for NPM1-mut patients showing more or less than 3.5 log reduction at TP1 was 94%, respectively (p=0.039); 2 years OS for patients achieving NPM1-MRD negativity at TP2 was 90.5% vs 42.9% (p=0.003). MFC MRD analysis in the NPM1-mut cohort led to results comparable with the whole cohort. Multivariate analysis showed that NPM1-MRD at TP1 was the strongest predictor for OS in this group.

Summary/Conclusions: Our data show that MRD assessment at different time-points reduces the risk of late relapse by demonstrating the persistence of disease for different populations. The percentage of MFC-MRD negativity is higher than 90%, and patients with MFC-MRD negativity at TP1, TP2, TP3 (NPM-MRD) were more likely to achieve treatment control. The probability of achieving MFC-MRD negativity at TP2 was only influenced by ELN risk group (p<0.05). In the whole cohort, 2 years OS was 60.2% (median not reached). Multivariate Cox-Proportional Hazard model showed that MFC-MRD >0.1% at TP2 was the strongest predictor of higher risk of death, whereas MFC-MRD <0.025 at TP1 was the strongest predictor of long survival (Figure 1). Thirty-five patients carried NPM1-mutation. Two-years OS for NPM1-mut patients showing more or less than 3.5 log reduction at TP1 was 94%, respectively (p=0.039); 2 years OS for patients achieving NPM1-MRD negativity at TP2 was 90.5% vs 42.9% (p=0.003). MFC MRD analysis in the NPM1-mut cohort led to results comparable with the whole cohort. Multivariate analysis showed that NPM1-MRD at TP1 was the strongest predictor for OS in this group.
Background: Hematopoietic recovery is considered to be associated with the number of multipotent hematopoietic stem cells in the bone marrow, as observed in functional assays involving stem cell transplantation. However, there is little evidence related to hematopoietic recovery in non-transplantation settings, which is accomplished by endogenous hematopoietic cells. A recent study suggested that progenitors are the main contributors during this steady-state hematopoiesis, which differs from exogenous transplantation. And our previous data revealed that, CD34+/CD38+/CD117+/HLA-DR+/CD13+CD33+ cells (P cells), a kind of progenitor cell, is significantly decreased in patients with delayed neutrophil recovery after chemotherapy compared with that without delayed count recovery.

Aims: To further examine a potential impact of P cells percentage on hematopoietic recovery.

Methods: The data of 223 patients diagnosed with de novo AML was analyzed retrospectively. All these patients enrolled in our previously registered prospective randomized clinical trial AML 2010-01(201002204). We reviewed the data from bone marrow flowcytometry before the first and second course of consolidation therapy, in which the CD34+/CD38+/CD117+/HLA-DR−/CD13+CD33+ progenitor cell percentage in the bone marrow was analyzed. Plasma recovery time and time of neutrophiia were counted for the evaluation of hematopoietic recovery ability after chemotherapy.

Results: We found that less P cell percentage was significantly associated with prolonged neutrophilia recovery time after the first and second courses of consolidation chemotherapy (p=0.001; p=0.028, respectively). We also observed similar results regarding platelet recovery time after the first course of consolidation chemotherapy (p=0.001). Univariate analysis showed that P cell percentage, rather than gender, age, WHO classification and cytogenetic subgroup, were associated with neutrophil recovery after chemotherapy. Multivariate analysis demonstrated that P cells were an independent negative factor affecting neutrophil recovery capability for both first and second courses (p=0.015; p=0.036, respectively).

Summary/Conclusions: Our results indicate that CD34+/CD38+/CD117+/HLA-DR−/CD13+CD33+ cells before each course of chemotherapy is associated with chemotherapy and hematopoietic reconstitution capacity independently. These findings may help better understand endogenous hematopoietic reconstitution and modify future chemotherapy regimens based on progenitor cell percentages.

E917
MICRONORAS (miRS) IN HIGH RISK PEDIATRIC ACUTE MYELOID LEUKEMIA (AML) AMONG PATIENTS WHO UNDERGO STEM CELL TRANSPLANTATION FOR RELAPSE
P.P. Leoncini1,*, P. Vittulino1, A. Nigita2, D. Veneziano3, P. Fadda3, V. Tocco1, M. Pigazzi2, G. Basso4, R. Rota1, A. Bertaina1
1Oncohaematology, Bambino Gesù Children Hospital, Roma, Italy, 2Medical Genetics, 3Genomic Shared Resources, Ohio State University, Columbus (OH), United States, 4Oncohaematology-Pediatrics, University of Padova, Padova, Italy

Background: Despite recent progresses made in the treatment of acute myeloid leukemia (AML) of childhood, the cure rates of high-risk subtypes remain low. Indeed, patients harboring FLT3-ITD mutations or 11q23 translocations (MLL rearrangements) are still characterized by a poor prognosis, mainly due to leukemia recurrence. Since microRNA (miRs) are small RNA molecules controlling normal hematopoiesis whose deregulation is fundamental in leukemia’s pathogenesis, a possible role as predictors of relapse should be further studied.

Aims: The aim of this study is to evaluate baseline levels of selected cytokines, cytokine receptors and adhesion molecules and their relationship with prognosis in newly diagnosed AML patients.

Methods: A total of 75 AML patients, age 52.9±13.0 years, median 58.5 years, 44 female were, were studied in the period 2010-2015. Only patients with minimal follow-up of 1 year were included. All patients were induced with “3+7” induction chemotherapy consisting of Cytarabine 100mg/m2 per day for 7 consecutive days and Daunorubicin 90mg/m2 for the first 3 days of therapy in younger patients. Since the beginning of 2015, the induction dose of Daunorubicin used has been 60mg/m2 even in younger patients, according to recent evidence-based data modifications. Those who failed to achieve CR were given FLG+ ld savage following by allogeneic stem cell transplantation in younger and fit patients. In CR, the patients were treated either with HI-DAC consolidations and/or allogeneic stem cell transplantation in younger and fit patients. A total of 39 patients underwent allogeneic stem cell transplantation. We evaluated serum levels of the following 29 analytes: interleukins (IL-1α, IL-1β, IL-2, IL-3, IL-4, IL-5, IL-6, IL-7, IL-8, IL-10, IL-12, IL-13, IL-15), IL-1β, Pneumonin Activity, Macrophage Inflammatory Protein-1α, Monocyte Chemotactic Protein-1, Tumor Necrosis Factor-α (TNF-α), Vascular Endothelial Growth Factor, E-selectin (E-SEL), P-selectin (P-SEL), Intercellular Adhesion Molecule-1 (ICAM-1), Vascular Cell Adhesion Molecule-1 (VCAM-1), Matrix Metalloproteinase-9, soluble IL-2 receptor (sIL-2R) and soluble receptors for IL-6 (sIL-6R) and TNF-α type I and II receptors, adhesion molecules: E-selectin (E-SEL) and P-selectin (P-SEL), ICAM-1, VCAM-1, sIL-2Rα and sTNF-α.

Results: IL-1β and sIL-2Rα were significantly higher in patients who failed to achieve CR by induction therapy had higher IL-7 levels, which was not significant after Bonferroni correction (P=0.0913). Inferior PFS was associated with higher sIL-2Rα (P=0.0525). Inferior OS was significantly associated with higher P-SEL (P=0.0003), higher sIL-2Rα (P=0.0029), higher age (P=0.0366) and possibly with higher TNFR-1 (P=0.0611). Age has not correlated with any of the other analyzed analyte. TNFR-1 correlates with TNF-α (P=0.0045), but not with TNF-α. The sIL-2Rα did not correlate with IL-2. Only IL-6 and ICAM-1 were significantly influenced by CRP levels.

Summary/Conclusions: Better understanding of the cancer microenvironment is a sine qua non for development of new treatment approaches. Our results suggest that cytokine levels may be useful markers to predict the treatment outcome and thus should be further investigated as possible therapeutic targets. The work was supported by a long-termorganisation development plan 101 (FMHS) and by MH CZ – DRO (UHKK, 0179908).
MRD-DRIVEN CHOICE OF CONSOLIDATION AND MODULATION OF INDUCTION AND CONSOLIDATION INTENSITY RESULTED IN A SIGNIFICANTLY IMPROVED OUTCOME OF YOUNGER AML PATIENTS IN THE LAST THREE YEARS

M. Clavio1,*, F. Guolo1, P. Minetto1, M. Miglino1, F. Ballerini1, D. Guardo1, E. Covillo1, R.M. Lemoli1, M. Gobbi1
1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genoa, IRCCS AOu San Martino-IST, Genova, Italy

Background: In the last decades no effective new drugs have been introduced and AML induction therapy is still based on an anthracycline and cytarabine. The MRC group has, however, reported a progressive increase of cure rates in younger patients. Our group has recently showed that the outcome can be improved by a fludarabine-containing induction (FLAi5, with fludarabine administration in first course only), followed by a risk- adapted consolidation.

Aims: The aim of the present study was to evaluate if the disease free survival (DFS) and the overall survival (OS) of younger (<65 years) AML patient treated in our center had shown any modification in four consecutive periods of treatment (< 2008; 2008-2010; 2011-2013; 2014-2016) and to recognize factors possibly leading to this result.

Methods: We reviewed the outcome of 145 consecutive AML patients aged 65 or less and uniformly treated according to the above mentioned strategy. Minimal residual disease (MRD) evaluation was performed by flow cytometry (MFC), assessment of WT1 expression levels and, where applicable, evaluation of recurrent abnormalities such as NPM1 mutation.

Results: The cohorts of patients treated in the four periods had a comparable age and risk distribution. Notably, although the median follow up of the 4 cohorts of patients is different, patients treated in the last 3 years showed a significant improvement in DFS (< 2008; 2008-2010; 2011-2013; 2014-2016) and to recognize factors possibly leading to this result. When we reviewed our experience, we found that some changes we introduced in the therapeutic management, possibly contributed to improve outcome. Beside classical risk factors, the time from hematological recovery after the first induction (induction 1) and the start of the second induction course (induction 2) proved to be significantly related to DFS and OS probability. An interval shorter than 15 days resulted in significantly higher toxicity, whereas a time longer than 25 days was associated with an increased relapse probability. Patients being treated in the last three years had a median time from recovery after induction 1 to start of induction 2 of 17 days, compared to 22 days in the other cohorts (p<0.05). Furthermore, after 2013, MRD information after induction 1 was added as a prognostic factor and ELN low and intermediate risk patient with negative MRD after induction 1 were no more scheduled for early deaths. A standard treatment of low dose cytarabine (LD-AraC) or using hypomethylating therapy is not satisfying enough. Polish Adult Leukemia Group’s (PALG) studies showed, that addition of cladribine to daunorubicine and cytarabine increases the complete remission rate and improves overall survival in younger patients with AML. We also proved effectiveness of cladribine combined with high dose AraC and mitoxantrone in relapsed and refractory AML (1, 2). Cladribine, enhances the concentration of Ara-CTP, an active metabolite of Ara-C in leukemic cells (3). Recent data indicate that cladribine has also hypomethylating properties.

Aims: The aim of our study was to evaluate the efficacy and toxicity of cladribine in combination with LD-AraC in older AML patients.

Methods: Patients with newly diagnosed AML (excluding APL), older than 60 years, unfit for standard induction chemotherapy, were enrolled to our study. The patients were given two cycles of cladribine 5mg/m² i.v. on days 1-5 and low-dose cytarabine 40mg/m² s.c. days 1-10 every 28 days followed by two cycles of cladribine 5mg/m² i.v. on days 1-2 with LD-AraC (40mg/m² s.c. 1-10 days). Responding patients were treated with a prolonged maintenance consisting of LD-AraC (40mg/m² 1-10 day). The treatment was continued until progression.

Results: Twenty-four patients have been enrolled with median age 70 years (range 62-84). In our cohort 20 patients had newly diagnosed AML, 3 secondary and 1 therapy related AML. Cytogenetic risk: good risk 5 patients, intermediate 12, poor risk 3 patients, 4 patients were unclassified. The overall response rate (CR+PR) was 84%. 13 out of 24 (54%) patients achieved complete remission (CR) and 7 (30%) achieved partial remission (PR). Median number of cycles to obtain CR was 2 (range 1-3), 16% of patients did not respond to treatment. The regimen was well tolerated without 4-week and 8-week mortality. The main reason of death was: heart failure (n=2), renal failure (n=1) and progressive disease (n=4). We didn’t observe grade 3 and 4 nonhematologic adverse events. With a median time of follow-up 14 months, the median overall survival was 12 months.

Summary/Conclusions: The combination of cladribine plus low dose AraC is effective and well tolerated regimen in elderly AML patients unfit for standard chemotherapy.
Results: DNA from 24 cell lines was assessed using both panels, confirming variants previously detected using other methods. A validation was run on the 3-gene panel using a series of contrived samples generated from cell lines containing between 0.5% and 25% variant allele frequencies for expected variants. Initial validation indicates that these small panel assays can detect mutations down to 0.5% variant allele frequencies. Assay linearity for FLT3/TKD detection from 0.25% to 12.5% or for FLT3/ITD detection from 0.5% to 25% is excellent (R² = 0.996 and 0.998, respectively). Average sequencing coverage was high, ranging from 5,265x to 7,680x. Comparison of FLT3 analysis of the small panel to amplicon based NGS assay and CE, FLT3-ITD showed complete concordance in clinical samples - and showed a strong linear relationship between the two methodologies, indicating feasibility of the assay using the international ISO13485 design control standards makes them suitable for regulatory approval worldwide.

E922
EFFICACY BY OUTPATIENT VS INPATIENT ADMINISTRATION OF CONSOLIDATION: SUBGROUP ANALYSIS OF A PHASE 3 STUDY OF CPX-351 IN OLDER ADULTS WITH NEWLY DIAGNOSED HIGH-RISK ACUTE MYELOID LEUKEMIA

1Moffett Cancer Center, Northwell Health System, Lake Success, NY, 2Van derbilt-Ingram Cancer Center, Nashville, TN, 3MD Anderson Cancer Center, Houston, TX, United States, 4Gordon and Leslie Diamond Health Care Centre, Vancouver, British Columbia, Canada, 5Lee Moffitt Cancer Center & Research Institute, Tampa, FL, 6John Theruer Cancer Center at Hackensack University Medical Center, Hackensack, NJ, 7Jazz Pharmaceuticals, Palo Alto, CA, 8Medical Univ. of South Carolina & Hollings Cancer Center, Charleston, SC, 9Stanford University School of Medicine, Stanford, CA, United States

Background: The CPX-351 liposomal formulation delivers a synergistic 5:1 molar ratio of cytarabine and daunorubicin preferentially to leukemia cells. CPX-351 has demonstrated significantly improved overall survival (OS) versus cytarabine/daunorubicin (7+3) in a randomized, open-label, phase 3 study in patients aged 60 to 75 years with newly diagnosed, high-risk AML (Lancet, et al. ASCO 2016). In contrast to the 7+3 regimen, which includes cytarabine continuous infusion for 7 days, CPX-351 is administered as a 90-minute infusion and thus has the potential to be given in the outpatient setting.

Aims: The current analysis of the phase 3 trial assessed the number of patients getting treated in the outpatient setting and their outcomes.

Methods: Enrolled patients were randomized 1:1 to receive 1 to 2 induction cycles of CPX-351 or 7+3; patients with complete remission (CR) or CR with incomplete platelet or neutrophil recovery (CRi) could receive up to 2 consolidation cycles (CPX-351: 65 units/m² [cytarabine 65mg/m² + daunorubicin 28.6mg/m²] on Days 1 and 3; 7+3: cytarabine 100mg/m²/day x 5 days + daunorubicin 60mg/m² on Days 1 and 2). The site of administration was not protocol defined.

Results: Few patients received induction as outpatient therapy (CPX-351 n=3/153 and 7+3 n=1/151 in each cycle). A total of 49/153 patients in the CPX-351 arm and 32/151 patients in the 7+3 arm received consolidation. In contrast to the induction cycles, a substantial proportion of patients received CPX-351 in the outpatient setting (consolidation 1: n=25/49 [51%]; consolidation 2: n=2/12 [17%]). Consolidation was associated with numerical improvement in median OS versus 7+3, irrespective of administra-

MOLECULAR GENETIC TESTING PATTERNS FOR PATIENTS WITH NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML) ENROLLED IN THE CONNECT® MDS/AML DISEASE REGISTRY

1University of Colorado Cancer Center, Aurora, 2University of New Mexico, Albuquerque, 3University of Alabama at Birmingham, Birmingham, 4Aurora Research Institute, Aurora Health Care, Milwaukee, 5Weill Cornell Medical of New York, 6University of Florida Health Cancer Center-Orlando Health, Orlando, 7Swedish Cancer Institute, Seattle, 8New York Medical College, Valhalla, 9University of Florida, Gainesville, 10Celgene Corporation, Summit, United States

Background: Recurrent mutations in AML-associated genes have prognostic value and may help guide treatment decisions. Molecular genetic testing pat-

Methods: The CONNECT MDS/AML Disease Registry (NCT01688801) is a comprehensive, observational cohort study of patients with newly diagnosed AML (≥25 years) or myelodysplastic syndrome (MDS). All clinical decisions are made by the treating clinicians. Data are collected, using an electronic data capture system, at screening, enrollment, and approximately quarterly throughout the duration of the patient’s participation in the registry. All patients provided informed consent. Enrollment is ongoing. The current analysis evaluated the percentage of patients with AML who had undergone molecular genetic testing recommended by NCCN guidelines (NPM1, FLT3-ITD, CEPBA, IDH1, IDH2, DNMT3A, and KIT). Chi-square tests evaluated effects of several variables on likelihood of molecular genetic testing.

Results: Between 12 Dec 2013 and 8 Dec 2016 (data cutoff), 259 patients with AML were enrolled at 86 sites. Molecular genetic testing was reported in 67% (173/259) of patients. Likelihood of testing varied, respectively, for academic vs community settings (76% [70/92] vs 62% [103/167], P=.018), normal vs acute myeloid leukemia (AML) types (77% [79/103] vs 59% [77/133], P=.006), age ≤65 vs >65 years (83% [85/103] vs 65% [108/181], P=0.003), and Medicare vs ACA (83% [65/78] vs 77% [77/99], P=.018). In patients who had undergone molecular genetic testing (n=173), the mutations tested varied substantially. All of the NCCN-recommended molecular genetic tests were reported in 9% (15/173) of patients, including 8% (6/77) of patients with normal karyotype. Of the seven NCCN-recommended tests, NPM1 (77%) and FLT3-ITD (76%) were most often reported and DNMT3A least often (16%).

Summary/Conclusions: Early data from the CONNECT MDS/AML Disease Registry reveal that despite molecular testing reported in 67% of patients with newly diagnosed AML, a majority of patients did not undergo guideline-recommended testing. This prospective registry is uniquely positioned to capture changes in testing patterns as guidelines are established.

E924
PHASE 1, OPEN-LABEL, RANDOMIZED STUDY TO EVALUATE THE EFFECT OF CYTOCHROME P450 (CYP) 3A4 INHIBITION ON THE PHARMACOKINETICS (PK) AND SAFETY OF QUIZARTINIB (Q) AND ITS ACTIVE METABOLITE, AC886

J. Levis1, 2, M. Kankam2, D. Trome3, G. Gammon3
1Daichi Sankyo, San Diego, CA, 2Vince & Associates, Overland Park, KA, 3Formerly Daichi Sankyo, San Diego, CA, United States

Background: Q is a potent, selective FMS-like tyrosine kinase 3 (FLT3) inhibitor currently being investigated in Phase 3 studies in AML patients (pt) with FLT3 internal tandem duplication (ITD) mutations. Early studies showed concentration (c) and c dependent adverse events (AE) in pts and identified the c of Q, but not its active metabolite, AC886, was a significant predictor of the Qc prolonging effect(Levis, et al. ASH 2016). Q and AC886 are both primarily metabolized by CYP3A4. Because CYP3A4 inhibiting drugs are frequently required in the
course of AML treatment, a drug interaction study was performed to assess PK when Q is co-administered with CYP3A4 inhibitors.

**Aims:** The primary aim was to determine the effect of ketoconazole (K), a strong CYP3A4 inhibitor, and fluconazole (F), a moderate CYP3A4 inhibitor, on PK of Q and AC886. The secondary aim was to assess the tolerability and safety of Q co-administered with K or F.

**Methods:** This was an open-label, randomized, parallel-group study. Healthy subjects (HS) age 18–55 years (yr) who provided informed consent were randomized 1:1:1 to receive K 200mg twice daily (BID), F 200mg BID, or placebo (P) BID on Days(D) 1-28. A single 30mg dose of Q was administered to all HS on D8. Plasma Q and AC886 conc were measured D8-28, using a validated liquid chromatography–tandem mass spectrometry method. PK parameters were determined using noncompartmental analysis. Steady-state (SS) drug conc, following repeated once daily dosing, were predicted using non-parametric superposition. An analysis of variance (ANOVA) was performed to assess the CYP3A4 inhibitory effect of K and F on the PK.

**Results:** 93 subjects (31 per arm) and 88 received Q. 75% were male, median age 32 yr (18-53). Relative to Q+P, co-administration of Q+K or Q+F increased the geometric mean (GeoMean) Cmax of Q by 17% and 11%, and GeoMean AUC0-inf by 94% and 20%, respectively (Table 1 below). The GeoMean Cmax and AUC0-inf of AC886 were decreased by 60% and 15%, respectively, for Q+K, and were increased by 3% and 14%, respectively, for Q+F. Apparent clearance (CL/F) of Q was 50% lower and t1/2 of Q and AC886 were 46% and 96% longer, respectively in Q+K vs Q+F. CL/F of Q was 17% lower and t1/2 of Q and AC886 were 10% and 28% longer, respectively, in Q+F vs Q+P. AC886 is a minor component in circulation relative to Q (approximately 25%). An increase of 86% in simulated SS Q Cmax and 96% in SS Q AUC0-inf was predicted following repeat daily dosing of 30mg Q+K vs Q+F, while a modest decrease in AC886 exposure (<20%) was predicted. The most common adverse events were headache (7.5%) and diarrhea (5.4%), with the majority being Grade 1/2. There were no clinically significant hematological, clinical chemistry, QTc, or vital sign observations, and no deaths or serious adverse events.

**Summary/Conclusions:** Co-administration of Q with K or F was well tolerated and safe. Overall, there was an approximate 2-fold increase in Q exposure when Q was co-administered with K, which is considered clinically significant. The increase in Q exposure when Q was co-administered with F was within 20% and is not considered clinically relevant. Given the relationship between Q conc and QTc prolongation, these results support reducing Q doses by approximately one-half when taken concomitantly with a strong CYP3A4 inhibitor. No dose reduction is needed when Q is co-administered with a moderate or weak CYP3A4 inhibitor. This approach has been implemented in two ongoing Phase 3 trials of Q in FLT3-ITD mutated AML.

**CLINICAL OUTCOMES OF CHILDHOOD ACUTE MEGAKARYOBlastic LEUKEMIA: THE CHILDREN CANCER HOSPITAL EGYPT 57357 EXPERIENCE**

**Background:** Acute megakaryoblastic leukemia is a rare subtype of pediatric AML occurring in both Down and non-Down syndrome patients. Down syndrome patients with M7 subtype have an excellent prognosis while non-Down syndrome patients have poor outcomes. Heterogenous cyto genetic abnormalities have been described with M7 AML and the impact of different prognostic factors on outcomes is yet to be determined.

**Aims:** To evaluate the prognostic significance of various cytogenetic abnormalities and minimal residual disease (MRD) by flow cytometry after induction I and correlate them with clinical outcomes of patients with acute megakaryoblastic leukemia.

**Methods:** We retrospectively analyzed the data of 80 non-Down syndrome patients diagnosed with M7 AML treated at CCHE between January 2007 through December 2016. Three treatment protocols were used.

**Results:** The median age at diagnosis was 1.7 years (range 0.2-15). The median time to diagnosis was 1 month. The overall (OS), event free survival (EFS) and cumulative incidence of relapse at 2 years were 53.4%, 42.9% and 28.4% respectively. Sixty one patients had abnormal cytogenetic abnormalities including Trisomy 19 (n=20), 13q (n=3), Trisomy 8 (n=12), Complex karyotype (n=28), t(1;22) (n=12), MLL gene rearrangement (n=9), Trisomy 21 (n=24) but none of these had an impact on outcomes. Out of the 80 patients 56 were in complete remission post induction I. Twenty two patients had MRD<0.1% after induction I. In the univariate analysis patients with MRD <0.1% post induction I had a better OS and EFS with a lower cumulative incidence of relapse however these findings did not reach a statistical significance.

**Summary/Conclusions:** Acute megakaryoblastic leukemia in non-Down syndrome patients have poor outcomes irrespective of any cytogenetic abnormalities. Future direction to determining tumor biology based on molecular pathways in this disease is being considered.

E927

**IDENTIFICATION OF RESISTANCE ASSOCIATED CPG METHYLATION CHANGES IN ACUTE MYELOID LEUKEMIA PATIENTS UNDERGOING INDUCTION CHEMOTHERAPY**

C. Niederwieser1, C. Rohde1, H. Servé2, W. Berde3, G. Eiringer4, S. Göllner1, L. Müller1, C. Müller-Tidow1

**Background:** Methylation of DNA contributes to the development of cancer and correlates with clinical outcome. The epigenetic alteration of DNA methylation is recognized as an important mechanism in leukemia pathogenesis. Understanding the DNA methylation patterns in hematological malignancies provides insights into the epigenetic events in leukemia. The identification of resistance associated DNA methylation changes is important for treatment optimization and novel therapy development.
Background: Acute myeloid leukemia (AML) is a heterogeneous disease associated with epigenetic alterations that can be targeted with demethylating agents to induce CR in a subgroup of patients. However, there are currently no predictive markers that reliably distinguish responder from non-responder patients. In this analysis we assessed DNA methylation changes in a group of refractory patients with AML treated either with the hypomethylating agent azacitidine followed by intensive chemotherapy or with intensive chemotherapy alone in order to identify the alterations and genes involved.

Aims: The exploration of whole genome methylation changes of azacitidine and chemotherapy treatment in refractory patients with AML guides treatment refinement.

Methods: Patients from the AML- AZA trial of the Study Alliance Leukemia were randomized to receive either azacitidine followed by chemotherapy or chemotherapy alone. Cells were harvested at baseline and 15 days after chemotherapy from 16 of the 105 patients receiving the combination and from four of the 109 patients randomized to receive chemotherapy only. Genome wide DNA methylation was analysed using a 450K Illumina array (Illumina, San Diego, USA). With a signature derived by differential blasts within diagnosis to day 15, patients with a reduction of blasts clustered together by methylation of all the selected CpG sites, as did those with an increase of blasts on both day 0 and day 15, and those paired samples of day 0 and day 15 frequently clustering together as well. This led us to refine blast independent analyses. We excluded methylation changes correlating with the percentage of blasts (p=0.14, exploratory regression among blast change and median methylation change change day 0 to day 15, each), since these are likely to reflect the increased lymphocyte counts in patients with the most strongly impacted by methylation changes were detected using the Homer software (Salk institute, San Diego, USA). Methylation changes were compared between the two groups to identify the changes associated with the use of azacitidine prior to treatment.

Results: In the Azacytidine plus Chemotherapy treated group, a total of 389 differentially methylated regions (DMRs), most of which were single CpGs, were identified, 176 of which were hypermethylated and 213 hypomethylated. The most highly represented hypermethylated loci were INSM1 (p=1e-17, 6.25% of 176 DMRs), KLF13 (p=1e-14, 7.95%), HIC2 (p=1e-11, 5.11%), while those most commonly hypomethylated were ARID5B (p=1e-15, 2.82% of 213 DMRs), MYB (p=1e-14, 3.76%) and STAT1 (p=1e-14, 1.88%). The chemotherapy alone group yielded 7181 DMRs, 5752 of which were hypermethylated and 1429 hypomethylated. The genes most commonly hypermethylated in these patients were EHF (ETS) (p=1e-226, 32.79% of 5752), CEBPE (p=1e-90, 10.34%), and Jun-AP1 (p=1e-45, 6.10%), while those most commonly hypomethylated were RUNX1 (p=1e-24, 28.34% of 1429 DMRs), TCF4 (p=1e-21, 8.40%) and SNAI3 (p=1e-17, 1.05%). Median overall survival did not differ between the two treatment groups, with 153 days for chemotherapy and 143 days for the combination chemotherapy patients.

Summary/Conclusions: Methylation changes associated with azacitidine and chemotherapy of refractory patients were particularly found in genes previously associated with cancer and AML. DNA hypermethylation was more common after chemotherapy alone. This finding suggests that DNA hypermethylation of specific loci may be associated with therapy resistance. Hence, the methylation levels were detected from the most resistant cells. Of note, upon Azacitidine treatment more hypomethylated loci were observed. This potentially indicates DNA hypomethylation in vivo.

E928
OVER-EXPRESSION OF ZEB2-AS1 LNCRNA PREDICTS POOR OUTCOMES IN PATIENTS WITH ACUTE MYELOID LEUKAEMIA
X. Shi1,2, J. Li1, L. Ma1, L. Wen1, Q. Wang1, H. Yao1, C. Ruam1, D. Wu1,2, S. Chen1
1The First Affiliated Hospital of Soocho University, Jiangsu University of Hema-tology. 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soocho University, Suzhou, China

Background: Acute myeloid leukemia (AML) is a fatal hematopoietic malignancy with poor clinical outcomes characterized by blasts infiltrated in tissues. Aims: To determine whether the antisense lncRNA namely ZEB2-AS1 would be associated with clinical outcomes, we assessed its expression in retrospectively collected AML cases.

Methods: Relative quantitative real-time PCR analysis was employed for detecting levels of ZEB2-AS1. SYBR Green RT-PCR was performed, followed by obtaining relative threshold cycle normalized to reference GAPDH gene. Cell migration, invasion, proliferation and apoptosis tests were used to analyze biological phenotypes of AML cells after knocking down ZEB2-AS1 IncRNA by small interfering RNAs.

Results: Results showed that expression of ZEB2-AS1 IncRNA was prominently high and closely correlated with adverse clinical outcomes in AML patients, based on either modified MRC or ELN risk stratification system. Univariate analyses indicated that patients with higher expression of ZEB2-AS1 IncRNA had significant shorter 3-year overall survival (OS) (0% vs 68.2%, p=0.036) and disease-free survival (DFS) (25.0% vs 69.8%, p=0.039). In addition, Patients with higher expression of ZEB2-AS1 IncRNA had significant lower complete remission (CR) rate in response to induction chemotherapy (75.0% vs 27.3%, p=0.031). In patients with low levels of ZEB2-AS1 IncRNA, patients treated by allogeneic hematopoietic stem cell transplantation had significant longer OS (3-year OS, 75.8% vs 28.6%, p=0.037) and DFS (3-year DFS, 81.8% vs 26.8%, p=0.049) compared to that of chemotherapy.

Summary/Conclusions: Moreover, knockdown of ZEB2-AS1 IncRNA could effectively inhibit invasion and migration in AML cells, which was closely associated with down-regulation of ZEB2 and up-regulation of E-cadherin. Collectively, although independent prognostic value for survivals was not rigorously determined, ZEB2-AS1 IncRNA may serve as candidate to improve conventional risk stratification system and contribute to evaluating therapeutic responses.

RESULTS

CONSOLIDATION IS SAFE AND WELL TOLERATED IN OLDER PATIENTS WITH ACUTE MYELOID LEUKAEMIA
J. Loh1, S. Avery1, S. Patil1, P. Walker1, A. Spencer1,2, A. Wei1,2, S. Fleming1,2
1Department of Haematology, Alfred Hospital, 2Australian Centre for Blood Diseases, Monash University, Melbourne, Australia

Background: AML in the elderly is more susceptible to treatment failure. Treatment related mortality in elderly patients with AML is decreasing over time, and receiving chemotherapy of adequate intensity is important in treating AML in these patients. The optimal induction and consolidation approach for patients in this age group is yet to be established, however data from the HOVON group has demonstrated the benefit of anthracycline intensification during induction in patients aged 60-65 years, while locally the Australian AML12 study demonstrated the value of anthracycline intensification during consolidation in younger adults. We have implemented a novel combination of intensified anthracycline in combination with infusional cytarabine (AraC) during induction and in combination with intermediate-dose AraC during consolidation.

Aims: To demonstrate the safety and tolerability and provide preliminary efficacy evidence for anthracycline intensification during induction and consolidation in older adults with Acute Myeloid Leukaemia.

Methods: A retrospective pilot study was done on 76 consecutive patients above the age of 55 years with newly diagnosed AML between January 2010 to June 2016 at Alfred Hospital, Melbourne, Australia. All received the 7+3 induction regime (AraC continuous infusion at dose of 100mg/m2/day on days 1 to 7, and idarubicin at a dose of 12mg/m2/day on days 1 to 3), with a planned consolidation with AraC (AraC 100mg/m2 twice daily Day 1, 3, 5, and idarubicin 12mg/m2/day Day 1-2). Outcomes were assessed according the Cheson criteria with cytogenetic risk assessed by the refined Grimwade MRC criteria.

</tbody>
</table>

Results: 76 patients, with a median age of 62 years (range 55.4-70.6 years) received the 7+3 induction with a median overall survival of 590 (range 6-1996) days and overall response rate was 52 patients (68.4%). The event-free survival median is 109 days (range 6-1988) and the relapse-free survival median is 314 days (range 6-4197). There were 7 treatment-related deaths (11.8%) within 30 days following 7+3 induction. Of 41 patients who attained complete morphological remission after induction, 29 patients (70.7%) received the planned IDAC+2 consolidation with 17 (41.5%) receiving two consolidation cycles. Of those not receiving IDAC+2, 10 patients (24.4%) received an alternative consolidation regimen and 2 patients (4.9%) did not receive consolidation. Of those receiving IDAC+2 25 (86.2%) were intermediate cytogenetic risk and 3 (10.7%) were unfavorable. No treatment related deaths occurred following IDAC+2. 20 patients (26.3%) from the whole cohort received an allogeneic stem cell transplant (SCT), and 8 patients (27.6%) of those who received the IDAC+2 consolidation regime proceeded to an allogeneic SCT. In all IDAC+2
consolidation cycles, the median days to neutrophil recovery was 26 days (range 18-72), platelet recovery 32 days (range 17-75), and the ICU admission rate was 12.8% (range 2-10 days). 18 patients (62.1%) receiving IDAC+2 consolidation suffered disease relapse. For patients receiving IDAC+2 consolidation the median OS was 727 days (range 113-1614 days) with an EFS of 388 days (range 109-1614 days). For patients aged 60-65 years the remission rate and overall survival were similar to those published by Lowenberg et al.

Summary/Conclusions: Anthracycline intensification was well tolerated with low treatment related mortality and rates of ICU admission along with acceptable time to count recovery. In patients aged 60-65 outcomes were similar to published data with high-dose daunorubicin. Despite this intensive post-remission therapy approach rates of disease relapse were high highlighting the need for novel therapeutic approaches in this patient group.

E930

PROGNOSTIC IMPACT OF IDH1 AND IDH2 MUTATIONS IN LOW AND INTERMEDIATE RISK AML: A MULTICENTER RETROSPECTIVE STUDY

F. Lessi1, M. Riva 1,*, M. Gottardi 2, F. Mosna 2, B. Luca 3, C. Minotto 4, R. Bertorellle5, G. Semenzato1

1Department of Medicine, University of Padua, Hematology and Clinical Immunology Unit, Padova, 2Hematology, Department of Speciality Medicine, Ospedale Santa Maria di Ca’ Foncello, Treviso, 3Education and Training Department, Azienda Ospedaliera di Padova, Padova, 4Division of Oncology, Ospedale di Mirano, Mirano, Venice, 5Department of Surgery, Oncology and Gastroenterology, University of Padova, Istituto Oncologico Veneto, Padova, Italy

Background: Mutations in the isocitrate dehydrogenase 1 and 2 (IDH1 and IDH2) genes are common in acute myeloid leukemia (AML) but, although investigated in several studies, their prognostic significance still remains controversial.

Aims: To evaluate the prevalence and prognostic impact of IDH1 and IDH2 mutations in adult AML patients with low and intermediate-1 and 2 risk (European Leukemia Net, ELN 2013).

Methods: We retrospectively evaluated IDH1 and IDH2 mutations in 99 low and intermediate risk patients with new diagnosed AML who underwent intensive induction chemotherapy in three Italian centers.

Results: Median age for all patients was 60 years. IDH mutations were detected in 25% of our patients. 7% were IDH1 R132, 16% were IDH2 R140 and 2% R172. Median WBC count was 12.66x10⁹/L in IDH wild-type, and 24.71 x10⁹/L in IDH mutated. Absolute neutrophil count was 3.1x10⁹/L in IDH wild-type and 0.9x10⁹/L in IDH mutated, and the difference was statistically significant (p<0.001). Median bone marrow blasts, platelets count, and LDH did not differ significantly. Cytogenetic risk group according to ELN 2010 showed favorable risk in 31.4%, and intermediate (I and II) risk in 68.6%. In favorable risk group IDH mutated patients were 12%, and 13% in the intermediate risk group. IDH expression was significantly correlated neither with NPM1 mutation nor with FLT3 mutation. There were no significant differences between induction therapy and IDH status.

Summary/Conclusions: Our study demonstrated that IDH1 and IDH2 mutations showed no impact on OS and DFS.
markers. Results were given overall and stratified by age (<60/60 years) and sex. Kaplan Meier curves and Cox regression (Hazard ratios; HRs) was used to compare survival by cohabitation (living with someone, living alone) and marital status (married, divorced, widowed, unmarried).

**Results:** The study included 3243 AML patients. Patients living with someone (n=2050) were younger, more likely to be married, male, to be working, and to have a higher education than patients living alone. Comorbidity, white blood cell count, lactate dehydrogenase, and blast counts did not differ between groups, however patients living with someone tended to have better performance status at time of diagnosis. Patients living with someone were more likely to receive intensive chemotherapy than patients living alone when aged 60 years or older (41.2% versus 22.8%, adjusted OR 0.81 (CI=0.66-0.81)). In patients <60 years, never-married patients were less likely to receive intensive therapy (adjusted OR 0.43 (CI=0.19-0.99)) than married patients. In patients <70 years achieving CR, the chance of alloHCT was reduced when living alone (11.8%, adjusted OR 0.47 (CI=0.28-0.78), versus 19.0% in patients living with someone). In divorced/widowed, the chance was also reduced (7.6% adjusted OR 0.38 (CI=0.20-0.74)) compared to married patients (19.3%). Crude survival by cohabitation is shown in Figure 1. Overall survival was inferior in patients <60 years living alone (adjusted HR 1.21 (CI=1.09-1.33)) and unmarried patients (never-married: adjusted HR 1.29 (CI=1.08-1.57), divorced/widowed: adjusted HR 1.11 (CI=1.00-1.23)) compared to married patients. In contrast, cohabitation and marital status did not affect treatment response (living with someone: CR 70.6%, living alone: CR 72.8%) or overall survival (adjusted HR 1.08 (CI=0.81-1.23)) in intensive therapy patients only.

**Summary/Conclusions:** Our study results indicate, that the effect of cohabitation and marital status on outcome, especially in patients <60 years, is explained by social support rather than by differences in income and occupation. Patients living alone do not present with more advanced disease or higher comorbidity burden than patients living with someone. Still, patients living alone and never-married patients are less likely to receive intensive chemotherapy affecting overall survival. Increased focus on what drives treatment decisions in patients lacking social support is important to improve survival in these patients.

**E933**

**TREATMENT OF MOLECULAR RELAPSE IN ACUTE MYELOID LEUKEMIA WITH DIRECTED THERAPY REDUCES TOXICITY OF SALVAGE TREATMENT AND IMPROVES DISEASE CLEARANCE**

F. Guolo1,*, P. Minetto1, M. Clavio1, D. Guardo1, E. Covilli1, N. Colomb1, F. Balerini2, M. Miglioli1, R.M. Lemoi1, E. Gobbi1
1Clinic of Hematology, Department of Internal Medicine (DIMI), University of Genoa, IRCCS AOI San Martino-IST, Genova, Italy

**Background:** Acute Myeloid Leukemia with mutated NPM1 (NPM-AML) is characterized by a favorable prognosis. Most patients achieve hematological complete remission (CR) and are not considered eligible for an early allo stem cell transplantation. The important minimal residual disease (MRD) detection by multicolor flow cytometry (MFC) in acute myeloid leukemia (AML) is widely explored by different researchers and it is an additional independent factor in clinical outcomes. The prognostic value of leukemic associated immunophenotype (LAIP) changes during chemotherapy and post-therapy disease burden, assessed by NPM levels, was explained by social support rather than by differences in income and occupation.

**Aim:** To investigate the announcement and clearance of MRD reduction and LAIP changes in de novo AML during chemotherapy and compare the results with clinical outcomes.

**Methods:** In clinical prospective study since March 2016 till February 2017 50 patients (pts) were included in the study. 14 pts by this moment completed basic chemotherapy (ChT) courses: 7+3 and 2 consolidation. Among them favorable cytogenetics was in 4pts (t(16;21)-1, 16q22-1, 8-21-2 pts), intermediate-7 (6-with normal cytotype, t(17;22)), poor-3 (complex karyotype-2, 11q23-1pt). Bone marrow samples were studied in standardized panel with most common antibodies by 6-color MFC (BD FACSCanto II, USA) before the treatment, after 1st and 2nd cycles of induction and after 2nd consolidation. Among patients that MRD >0 was assumed as MRD positivity. Besides MRD status we also explored LAIP changes in patients with CR after 2nd ChT. Two early relapses were also detected: both with persistent MRD during all period of ChT and CMR after the second ChT. All pts with MRD-negative status after first course are alive and in CMR (8 months from diagnosis). While monitoring, LAIP changes were distinguished in 7 pts. One from two with resistant AML lost CD65, another one acquired CD11b. 5 pts were in complete morphological remission (CMR) after the second course and during ChT one of them gained CD56 and CD13, 2nd lost CD65 and CD11b, 3rd – gained CD65, 4th gained CD11b after 2nd ChT, the last one didn’t change LAIP. We detected relapse in 3 pts from this group and one – with increasing MRD after 4th course and cytopenic syndrome. We may suggest that LAIP changes during ChT reflect selection of more chemoresistant leukemia clone, followed by subsequent relapse.

**Summary/Conclusions:** 1. The most favorable group of patients consisted of MRD negative pts after 1st course. LAIP changes are common in pts with less favorable prognosis.

**E934**

**MINIMAL RESIDUAL DISEASE AND LAIP CHANGES BY FLOW CYTOMETRY IN DE NOVO ACUTE MYELOID LEUKEMIA DURING CHEMOTHERAPY AND CLINICAL OUTCOMES**

T. Lobanova1,1, I. Galtseva1, Y. Dayvova1, N. Kapranov2, V. Troitskaya1, E. Parovichnikova1
1Hematologic Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation

**Background:** Minimal residual disease (MRD) detection by multicolor flow cytometry (MFC) in acute myeloid leukemia (AML) is widely explored by different researchers and it is an additional independent factor in clinical outcomes. The prognostic value of leukemic associated immunophenotype (LAIP) changes during chemotherapy and post-therapy disease burden, assessed by NPM levels, was explained by social support rather than by differences in income and occupation.

**LENALIDOMIDE MAINTENANCE IN PATIENTS WITH HIGH RISK ACUTE MYELOID LEUKEMIA IN CR1**

T. Kadia1,*, J. Cortes1, F. Ravandi1, N. Daver1, E. Jabbour1, A. Ferrajoli1, N. Pemmaraju1, K. Naqvi1, S. Pelletier1, M. Brandt1, Z. Estrov1, H. Kantarjian1
1Leukemia, MD Anderson Cancer Center, Houston, United States

**Background:** Minimal residual disease (MRD) detection by multicolor flow cytometry (MFC) in acute myeloid leukemia (AML) is widely explored by different researchers and it is an additional independent factor in clinical outcomes. The prognostic value of leukemic associated immunophenotype (LAIP) changes during chemotherapy and post-therapy disease burden, assessed by NPM levels, was explained by social support rather than by differences in income and occupation.

**Aim:** To investigate the announcement and clearance of MRD reduction and LAIP changes in de novo AML during chemotherapy and compare the results with clinical outcomes.

**Methods:** In clinical prospective study since March 2016 till February 2017 50 patients (pts) were included in the study. 14 pts by this moment completed basic chemotherapy (ChT) courses: 7+3 and 2 consolidation. Among them favorable cytogenetics was in 4pts (t(16;21)-1, 16q22-1, 8-21-2 pts), intermediate-7 (6-with normal cytotype, t(17;22)), poor-3 (complex karyotype-2, 11q23-1pt). Bone marrow samples were studied in standardized panel with most common antibodies by 6-color MFC (BD FACSCanto II, USA) before the treatment, after 1st and 2nd cycles of induction and after 2nd consolidation. Among patients that MRD >0 was assumed as MRD positivity. Besides MRD status we also explored LAIP changes in patients with CR after 2nd ChT. Two early relapses were also detected: both with persistent MRD during all period of ChT and CMR after the second ChT. All pts with MRD-negative status after first course are alive and in CMR (8 months from diagnosis). While monitoring, LAIP changes were distinguished in 7 pts. One from two with resistant AML lost CD65, another one acquired CD11b. 5 pts were in complete morphological remission (CMR) after the second course and during ChT one of them gained CD56 and CD13, 2nd lost CD65 and CD11b, 3rd – gained CD65, 4th gained CD11b after 2nd ChT, the last one didn’t change LAIP. We detected relapse in 3 pts from this group and one – with increasing MRD after 4th course and cytopenic syndrome. We may suggest that LAIP changes during ChT reflect selection of more chemoresistant leukemia clone, followed by subsequent relapse.
Background: New drug combinations and higher intensity therapy have led to significant improvements in complete remission (CR) rates for patients with acute myeloid leukemia (AML). However, relapsed disease remains a major source of failure. With the exception of allogeneic stem cell transplant (SCT), there are few options for post-consolidation maintenance of remission in high-risk patients. NK cells as part of the immune microenvironment are important mediators of immune surveillance in AML. Lenalidomide has demonstrated single-agent activity in AML and enhances NK cell activity and immune synapse formation in leukemia.

Aims: We designed a phase II clinical trial studying the efficacy of lenalidomide as maintenance therapy in AML patients with high-risk disease in remission, who were not being considered for SCT.

Methods: AML patients ≥18 years with a high-risk feature in 1st CR (CR1) or any patient in 2nd CR (CR2) who had received induction and at least 1 consolidation cycle were eligible for enrollment. Patients should be within 12 months of achieving CR, have PS ≤3, adequate kidney/liver function, ANC >0.5 and platelets ≥100. Patients were treated continuously with lenalidomide 10mg PO daily on D1-28 of a 28 day cycle up to 24 cycles. All pts had baseline cytogenetic and molecular testing, and minimal residual disease (MRD) assessment by flow cytometry. After cycle 1, stepwise dose escalations were allowed to 20mg daily in pts who were tolerating their dose and have presence of minimal residual or morphologically detectable disease.

Results: A total of 14 patients have been enrolled with a median age of 57.5 years (range, 23-67). All pts were in CR at the time of enrollment, with 12 pts (86%) in CR1 and 2 (14%) in CR2. Baseline pt characteristics are outlined in Table 1. AML-related mutations detected at start of therapy included: CEBPA(n=5), NPM1 (3), FLT3 (3), IDH2 (2), NRAS (2), DNMT3a (2), and 1 each of JAK2, TET2, and EZH2. High risk features at the time of enrollment were as follows (some are overlapping): S (36%) with history of prior myeloid neoplasm or therapy related AML, 4 (29%) persist MRD, 4 (29%) adverse mutational profile, 2 (14%) adverse karyotype, 1 (7%) primary refractory disease, and 2 (14%) CR2 status. Patients have received a median of 9 cycles (1-24) cycles of therapy. With a median followup of 19+ months (8.5-39), the 6- and 12-month estimated RFS were 100% and 89%, respectively. The 6- and 12-month estimated OS were 100% and 90%, respectively (Figure 1). The regimen was well tolerated. Cytopenias were mild and managed with dose adjustments. The most common grade 3 (no grade 4 toxicity) non-hematotoxic toxicities were 1 each of rash, fatigue, cough, and nausea, vomiting, and stroke.

Summary/Conclusions: Lenalidomide is a safe and feasible maintenance strategy in high-risk AML patients who are not candidates for SCT. The study continues to surpass the pre-specified expected rate of relapse-free survival of high-risk patients based on a historical cohort. Studies evaluating dynamics of MRD on study are ongoing.

E936 POSTREMISSION THERAPY FOR AML WITH INTERMEDIATE RISK CYTOGENETICS IN FIRST COMPLETE REMISSION

1Institute of Hematology and Blood Transfusion, Prague, 24th Department of Internal Medicine - hematology, Charles University, University Hospital Hradec Králové, Hradec Králové, 3Dept. of Hematology, Charles University, University Hospital Královské Vinohrady, Prague, 4Department of Internal Medicine/Haematology-Oncology, University Hospital Brno, Brno, Czech Republic

Background: Postremission therapy of AML with intermediate risk cytogenetics in first CR is based on chemotherapy with high dose cytarabine (HIDAC) or hematopoietic cell transplantation (HCT). Evidence from single trials with regards to optimal postremission therapy has been inconclusive, metaanalyses suggest a survival benefit of allogeneic HCT in first CR, except for patients with mutation of NPM1 without concomitant FLT3/ITD.

Aims: We analyzed retrospectively data from patients with AML with intermediate risk cytogenetics in CR1 with the aim to determine rates of completion of postremission therapy, rates and risk factors for early relapse and non relapse mortality (NRM), overall survival (OS) and relapse free survival (RFS) according to postremission treatment and describe causes of and risk factors for treatment failure.

Methods: Data on 304 patients in CR1 treated with curative intent between 2007 and 2016 in four centers participating in Czech Leukemia Study Group for Life were analyzed. All patients signed informed consent with data collection, analysis and publication. Cox regression was used to determine risk factors for OS and RFS, using time dependent covariates for postremission therapy. Age, WBC count, number of induction cycles, NPM1 mutation, FLT3/ITD, performance status, BMI, previous malignancy and extramedullary disease were included in models. Postremission therapy was completed after HCT or after three cycles of HIDAC without HCT in patients <60 years and two cycles of intermediate dose cytarabine (IDAC) in patients ≥60 years. Competing risk cumulative incidence estimates were calculated for NRM and relapse. Early relapse and NRM were defined as relapse/NRM before completion of postremission therapy.

Results: Median age was 52 (18-74) years. Median follow up time was 481 (31-3384) days. Early relapse rate (RR) and NRM were 11.01% and 5.29%, respectively. Median OS after early relapse was 128 days. Presence of FLT3/ITD mutation and high body mass index were associated with increased risk of early relapse on multivariate analysis (HR 14.88, 95%CI 3.24-68.43 and 2.34, 95%CI 1.3-4.2, respectively). Age increased risk of early NRM (HR 5.13, 95%CI 1.5-17.58 for age 55-55 years). 76% of patients completed therapy: 42% received allogeneic HCT in CR1, 21% completed three cycles of HIDAC and 13% completed two cycles of IDAC. 3-year OS and RFS of the whole cohort were 53.68% and 40.26%, respectively. OS was 67% in a group of patients who completed HIDAC, 34% in IDAC group and 64% in HCT group (p=0.28469). Cumulative incidence of NRM and RR 3 years after completion of therapy were 23% and 20% after HCT, 7.1% and 51% after HIDAC and 16.8% and 66.4% after IDAC, respectively, differences among groups were significant (p=0.00947 and p<0.00001). HCT reduced the risk of relapse in comparison to chemotherapy (HR 0.51, 95%CI 0.3-0.85). RFS was adversely influenced by concomitant FLT3/ITD/NPM1 mutation (HR 2.17, 95%CI 1.06-4.45). Increasing age had negative effect on OS (HR 1.65, 95%CI 1.13-2.42 for age 55-35 years). After HCT, HLA mismatch and TBI based myeloablative conditioning were associated with increased NRM (HR 6.32 (95%CI 1.89-21.14) and 6 (95%CI 1.86-19.2), respectively) in comparison to transplantation from HLA matched donors and busulphan based myeloablative conditioning.

Summary/Conclusions: The majority of patients within intermediate cytogenetic group in our analysis received allogeneic HCT. Patients who relapsed before completion of treatment had dismal outcome with very short OS. Allogeneic HCT decreased risk of relapse but led to increased NRM, reducing positive effect of HCT on OS. Risk of NRM was increased after TBI based myeloablative conditioning and after HCT in mismatched unrelated donors.

LONG TERM FOLLOW UP OF PATIENTS OVER 60 YEARS TREATED WITH INTENSIVE CHEMOTHERAPY FOR ACUTE MYELOID LEUKAEMIA AND MYELODYSPLASTIC SYNDROMES

Background: More and more data on patients over the age of 60 years treated with intensive chemotherapy are emerging, however, long term data with patient outcomes following treatment in 2-5 years are lacking. In 2007, we published a single center study on patients over the age of 60 years, suffering from acute myeloid leukemia (AML) or high risk myelodysplastic syndrome (MDS), treated with intensive chemotherapy (Knipp et al. Cancer 2007, 110:345-52). We now present long term follow up data of these patients, the first patient being treated in 1991, meaning 26 years ago.

Aims: To characterize the long term outcome of elderly AML and high risk MDS patients treated with intensive chemotherapy after the usual 2-5 year follow up period.

Methods: We treated 160 patients aged 60 years or more suffering from high risk MDS and AML with intensive chemotherapy regimen between 1991 and 2004. None of the patients underwent allogeneic stem cell transplantation afterwards. We now performed a follow up of the surviving patients 10 years after publication of the initial study.

Results: In the initial study median survival from the start of induction therapy was 9.5 months (10 days to 157 months), with the median survival from diagnosis of 14 months (1 day to 157 months). At publication of the study in the year 2007, 20 patients were still alive, 18 of them presented with a low risk karyotype. 13 of these patients were in complete remission and 7 patients had relapsed. Since then 11 of the 13 patients who were in CR relapsed and died of their leukemia. One patient died of other causes and only one patient is still alive and well, currently at the age of 84. This patient initially presented with a normal karyotype, too. As a result the rate of long term survivors 5 years after treatment is 5.6% only.

Summary/Conclusions: Long term follow up data of elderly patients treated for AML and MDS with intensive chemotherapy is scarce. Our data show, that induction chemotherapy not followed by allogeneic stem cell transplantation does not result in a meaningful improvement of outcome. In addition, morbidity and lack of quality of life has to be taken into account. More data and studies on this subject are urgently needed in an aging population. In our population of 160 treated patients, 158 died of their leukaemia, only one patient died of another cause and only one single patient is still alive and well over a decade later.

E938

FLAG-IDA FOR RELapsed/REFractory ACUTE MYELOLeUKAEMIA: A SINGLE CENTRE 5-YEAR STUDY

Background: The treatment of relapsed/refractory Acute Myeloid Leukaemia (AML) remains a formidable challenge as the therapeutic options are limited. The regimen most commonly used in this setting, FLAG-Ida (Fludarabine, cytarabine, G-CSF and idarubicin) is considered more toxic than standard Daunorubicin plus Cytarabine (DA) regimen, often associated with prolonged periods of bone marrow suppression and predisposition to severe infections.

Aims: In this study, we present a single tertiary centre experience in the use of this regimen with a view to identifying predictive factors for survival following FLAG-Ida chemotherapy. The secondary aim of this project was to assess its efficacy in an elderly patient profile in the routine clinical setting.

Methods: We conducted a retrospective chart review of patients treated with FLAG/FLAG-ida chemotherapy regimen for relapsed or refractory acute myeloid leukemia (including secondary AML) between 2011 and 2016 in a large tertiary hospital. Patients treated with FLAG/FLAG-ida as first line therapy were excluded.

Results: Of 80 patients eligible for the analysis, 95% (95% CI 2.4-6.4), 13.4 months, from first line therapy was associated with an inferior survival following FLAG-ida compared to best supportive care or intensive chemotherapy. (Int J Hematol 2014; 100: 141-151).

Summary/Conclusions: FLAG-ida is an effective salvage regimen in patients with refractory or relapsed AML allowing the achievement of complete remission in the majority of cases. In this single-centre cohort, early relapse, within 12 months, from first line therapy was associated with an inferior survival following salvage therapy with FLAG-ida.

E939

A MULTICENTER, RETROSPECTIVE ANALYSIS OF ELDERLY PATIENTS WITH ACUTE MYELOID LEUKAEMIA WHO WERE TREATED WITH DECITABINE

Background: While acute myeloid leukemia (AML) is the disease of the elderly, treatment options has been limited for elderly patients. Decitabine is widely accepted as the treatment options for them. However, the efficacy has yet been evaluated in Asian population where difference of clinical manifestation or cytogenetics had been noted.

Aims: In the current study, we conducted a multicenter, retrospective analysis on elderly AML patients from 8 tertiary institutes in Korea who were treated with decitabine in order to confirm whether the clinical outcomes of this agent are also acceptable in this population, and to provide further understanding of the disease nature of AML arise in elderly patients.

Methods: Patients diagnosed with AML from 2013 to 2016 were included in the analysis. The inclusion criteria were as follows: (1) 65 or older patients with newly diagnosed, histologically confirmed AML (myeloid blast ≥20% either in the bone marrow or peripheral blood); (2) Treated with decitabine in a schedule of 20mg/m² for five days every 4 weeks in patients. The primary end-point of the study was OS. We compared our data to the data from another Korean retrospective analysis, in which elderly patients with AML were treated with best supportive care or intensive chemotherapy. (Int J Hematol 2014; 100: 141-151).

Results: A total of 80 patients were eligible for the analysis. The median age of patients was 74 years (range, 64 to 86 years) and 49 patients (61.3%) were male. According to the risk group, 6 (7.5%), 49 (61.2%), and 25 (31.3%) cases were classified as favorable, intermediate, and poor risk group, respectively. The patients had received median 3 (range 1-27) cycles of treatment and the median OS for all patients was 10.2 months. The median OS durations according to the cytogenetic risk group are as follows: 12.4 months (95% CI 11.4-13.4) for favorable risk group (N=6), 13.6 months (95% CI 8.7-18.5) for intermediate risk group (N=49), and 5.5 months (95% CI 1.4-9.6) for poor risk group (N=25) (p< 0.01). And when we categorized our cohort into two groups, that is, ECOG-PS 0-2 vs. ECOG-PS 3 & 4, those with good performance status demonstrated improved survival (11.5 months (95% CI 6.6-16.4) vs 4.4 months (95% CI 2.4-6.4), p=0.04). The OS curves according to prognostic factors are provided in figure 1.

Summary/Conclusions: Compared to intensive treatment, decitabine is widely accepted as the treatment options for elderly AML patients. However, the efficacy has yet been evaluated in Asian population where difference of clinical manifestation or cytogenetics had been noted. In this study, we present a single tertiary centre experience in the use of this regimen with a view to identifying predictive factors for survival following FLAG-ida chemotherapy. The secondary aim of this project was to assess its efficacy in an elderly patient profile in the routine clinical setting. In the current study, we conducted a multicenter, retrospective analysis on elderly AML patients from 8 tertiary institutes in Korea who were treated with decitabine in order to confirm whether the clinical outcomes of this agent are also acceptable in this population, and to provide further understanding of the disease nature of AML arise in elderly patients.

Methods: Patients diagnosed with AML from 2013 to 2016 were included in the analysis. The inclusion criteria were as follows: (1) 65 or older patients with newly diagnosed, histologically confirmed AML (myeloid blast ≥20% either in the bone marrow or peripheral blood); (2) Treated with decitabine in a schedule of 20mg/m² for five days every 4 weeks in patients. The primary end-point of the study was OS. We compared our data to the data from another Korean retrospective analysis, in which elderly patients with AML were treated with best supportive care or intensive chemotherapy. (Int J Hematol 2014; 100: 141-151).

Results: A total of 80 patients were eligible for the analysis. The median age of patients was 74 years (range, 64 to 86 years) and 49 patients (61.3%) were male. According to the risk group, 6 (7.5%), 49 (61.2%), and 25 (31.3%) cases were classified as favorable, intermediate, and poor risk group, respectively. The patients had received median 3 (range 1-27) cycles of treatment and the median OS for all patients was 10.2 months. E940

**DRUG-DRUG INTERACTION POTENTIAL OF GILTERITINIB IN HEALTHY SUBJECTS AND PATIENTS WITH RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA**

San Francisco, 3Mayo Clinic, Rochester, 4University of Pennsylvania-Abramson Comprehensive Cancer Center of Northwestern University, Chicago, 6Astellas Pharma

*Background:* Gilteritinib (ASP2215), a highly selective FLT3/AXL tyrosine kinase inhibitor with activity against both FLT3-ITD and FLT3-D835 mutations, was administered as a single 20-mg dose on Day 8. Additionally, the potential effects of CYP3A4 inhibitors (itraconazole [ITZ] and fluconazole [FLZ]) on the gilteritinib pharmacokinetic (PK) profile were assessed in an open-label, parallel-group study conducted in 81 healthy subjects. Gilteritinib was administered as a single 10mg dose alone on Day 6, or in combination with 200mg ITZ administered twice daily on Day 1 and once daily on Days 2–28, or in combination with once daily 400mg FLZ on Day 1 and 200mg FLZ on Days 2–28. When given concomitantly with ITZ or FLZ, gilteritinib was administered on Day 6. In an additional cohort, RIF 600mg was administered on Days 1–21 and gilteritinib was administered on Day 6. In an additional cohort, RIF 600mg was administered on Days 1–21 and gilteritinib was administered as a single 20-mg dose on Day 8. Additionally, the potential inhibitory effects of gilteritinib on the PK profile of a CYP3A4 substrate (midazolam) was assessed in a cohort of patients with R/R AML (n=9) in the Phase 1/2 CHRYSSALIS study (NCT020144585). Patients received oral gilteritinib (300mg/d) and single oral midazolam (2mg) doses. Gilteritinib was administered on Cycle 1 Day 1 and continued once daily in 28-day cycles; midazolam was administered on Day -1 and Cycle 1 Day 15. Furthermore, in patients with R/R AML, gilteritinib trough concentration data for patients on strong (eg, voriconazole or posaconazole) or moderate (eg, FLZ) CYP3A4 inhibitors were compared with those for patients not using CYP3A4 inhibitors.

*Results:* In healthy subjects, gilteritinib exposure (expressed as Cmax and AUC0-24) was higher (2-fold increase) in subjects who were coadministered gilteritinib with a strong CYP3A4 inhibitor (ITZ) than in subjects who were administered gilteritinib alone. Coadministration of gilteritinib with RIF, a strong CYP3A4 inducer, resulted in an approximate 70% decrease in gilteritinib exposure in healthy adult subjects (Figure 1). In patients with R/R AML, midazolam exposure was approximately 10% higher when administered with gilteritinib compared to midazolam alone as reflected by the geometric mean ratio and 90% confidence intervals of midazolam Cmax (111.64%; 69.54%–179.25%) and AUC0-24 (109.46%; 49.82%–240.48%). Additionally, a 2-fold increase in gilteritinib exposure was observed in patients who were taking concomitant medications that were moderate or strong CYP3A4 inhibitors relative to patients who did not use a CYP3A4 inhibitor. The increased exposure in these patients, however, did not translate to differences in the incidence of drug-related safety events when compared across groups.

*Summary/Conclusions:* These data suggest coadministration of CYP3A substrates with gilteritinib is unrestricted. A comprehensive review of safety data in patients with R/R AML did not suggest that dose adjustment is warranted when gilteritinib is coadministered with strong CYP3A4 inhibitors. Although concomitant use of gilteritinib with strong CYP3A inhibitors (eg, ITZ or FLZ) may be permissible, precaution is warranted.

---

**A FLUDARABINE-BASED ACUTE MYELOID LEUKEMIA INDUCTION IS WELL TOLERATED UP TO 75Y OF AGE ALLOWS EARLY CONSOLIDATION AND LONG TERM SURVIVAL. A SINGLE CENTRE EXPERIENCE OF 136 CONSECUTIVE PATIENTS**

E. Zappone1, L. Aprile1, M. Defina1, G. Papini1, V. Cardi1, G. Bartalucci1, C. Zuanelli Brambilla1, S. Ciofini1, M. Bocchia1

1Hematology Unit, University of Siena, Siena, Italy

*Background:* For decades no effective new drugs or better anthracyclin cytara- bin combinations other than the standard 3 + 7 regimen have been available for AML induction treatment. Fludarabine-based regimens have shown good efficacy in relapsed patients but raised concern about toxicity in the induction setting (Burnett JCO 2013, PMID 23940227) a modified regimen has shown better tolerance and good results in patients younger than 60 years (ys) (Guolo AJH 2016, PMID 27084986)

*Methods:* Patients were treated with the FLAIE or FLAI regimen followed by Idarubicin or Fludarabine. Aracytin, Idarubicin or with or without Etoposide: FLAIE up to 65ys or FLAI up to 75ys.

*Results:* Median age at diagnosis was 55ys (18-75ys), median follow up was 18 months (range 3-172 months), 75% of patients (102/136) had de novo AML with strong (34/136) had strong (34/136), 9% of patients (12/136) had secondary AML mostly from myelodisplastic syndrome, 19% of patients (26/136) had good CMR risk disease. 45% of patients (61/136) had intermediate risk and 36% of patients (50/136) had high risk disease. Complete remission (CR) rate was 68% and was comparable to the majority of pub-
lished trial data, considering the proportion of high CMR risk (36%) and leukemia of secondary origin (25%) and the relatively high median age: 36% of patients (49/136) were above the 60s old age limit of most AML protocols. In multivariate analysis CR rate was significantly affected by age below 50ys: p=0.011; good/intermediate CMR risk: p=0.011 and de novo AML: p=0.008. The induction death rate was 4% in line or slightly lower than published results, showing that when patients are well selected, low CMR groups had a significant difference in terms of survival and factors significantly affecting OS were age below 50ys p<0.0001; good/intermediate CMR risk p<0.0002; intensive consolidation with Allo or Auto transplant p<0.0001 compared to chemotherapy alone. The mean probability of Leukemia free survival (LFS) was 88 months (median not reached). Patients above 50ys and patients with karyotype profile (NPM1/FLT3-ITD) the median probability of OS and LFS were 16.4 and 23.4 months respectively, this compares favorably with many published results. Chen Medicine 2016 PMID: 27472687 reported a median OS of 10.3 months in a large cohort of patients of similar age treated with intensive induction. Moreover we did not found a significant difference between the 50-59ys and 60-75-ys age groups: median OS was 20.8 and 14 months (p=0,12) and median LFS was 15.9 and 23.6 months (p=0,71) respectively.

Summary/Conclusions: In our real life experience the FLAIE/FLAI regimen combined with intensive consolidation demonstrated good long term results both in terms of OS and LFS in patients younger than 50ys, this regimen was also very feasible and manageble in patients beyond age of 60ys a difficult population to treat with a curative intention mainly because of concern of high toxicity of intensive induction regimens and higher incidence of poor risk prognostic factors.

E942
OVEREXPRESSSION OF SOX4 CORRELATES WITH POOR PROGNOSIS OF ACUTE MYELOID LEUKEMIA
1Clinical Laboratory Sciences And Medical Biotechnology, National Taiwan University, Taiwan, Taiwan; 2Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan, Republic of China

Background: The SOX4 belongs to the SOX (Sry-related high-mobility group box) family and has been characterized as a transcription factor. Over the past decade, multiple functions of SOX4 have been unveiled, and the protein is now known to play important roles in embryonic development, cell fate decision, and cellular differentiation. Overexpression and amplification of SOX4 have been implicated in various cancers and are correlated with poor prognosis. In mouse models, previous studies demonstrated that the upregulation of Sox4 can be induced by and then cooperate with the aberrant expression of AML-1, ETO, NUP98-DDX10, and MLN-RARA; the overexpression of HOXA9, CREB, and Evl1, and the haplosufficiency of PU.1 to trigger leukemogenesis. Furthermore, a previous study that employed retroviral transduction of Sox4 and bone marrow transplantation techniques revealed that increased Sox4 expression may cooperate with the deregulation of Mef2c expression to induce myeloid leukemia in recipient mice. Sox4 gene was also reported to be as a direct target of C/EBPα. C/EBPα is known to inhibit the self-renewal of leukemic cells and to restore cellular differentiation. The overexpression of Sox4 that results from C/EBPα inactivation contributes to the development of a type of leukemia that is characterized by a distinct leukemia-initiating cell (LIC) phenotype. This work further indicated that Sox4 is a key oncogenic target and critical mediator of C/EBPα mutants in acute myeloid leukemia (AML), which suggests a potential novel therapeutic approach to the treatment of this disease. However, the clinical implications of SOX4 expression and its role of AML leukemogenesis are not well understood.

Aims: To evaluate the relationship between bone marrow (BM) SOX4 expression and clinicopathological parameters of de novo AML and to evaluate the prognostic value of SOX4 expression for AML patients.

Methods: From Mar 2009 to Dec 2011, a total number of 112 adult AML patients were enrolled in this study. This study was approved by the Institutional Review Board (IRB) of the National Taiwan University Hospital (NTUH) and written informed consent was obtained from all participants in accordance with the Declaration of Helsinki. Immunocytochemical staining was used to assess SOX4 expression in bone marrow leukemic cells. All statistical analyses performed for this study involved two-tailed Student’s t-tests and non-parametric analysis with Cox proportional hazards regression models. Kaplan-Meier estimation techniques were used to plot survival curves and log-rank tests.

Results: We divided AML patients into two groups according to the intensity and extent of SOX4 expression as follows: low expression group (score 0-2, n=50) and high expression group (score 3, n=50), respectively. The variance in clinical manifestations of AML did not show significant differences in terms of SOX4 expression. However, AML patients with low SOX4 expression tended to have favorable-risk cytogenetic (P=0.0866). We did not observe significant differences between the high and low expression groups in terms of age, gender, hemogams, NPM1 mutation and FLT3/ITD. Additionally, of the 112 AML patients that underwent conventional intensive induction chemotherapy, 85 (75.9%) achieved complete remission (CR), and the high and low expression groups showed similar probabilities of achieving first CR (36/50, 72% vs 49/62, 79%, P=0.3219). However, high SOX4 expression were associated with increased relapse rates compared to low SOX4 expression (19/36, 52.8% vs 13/49, 26.5%, P=0.028). Furthermore, with a median follow-up period of 46.7 months (range: 0.3 to 70.9 months), SOX4 expression was associated with overall survival (OS) and disease-free survival (DFS) in all patients with de novo AML (P=0.008 and P=0.013, respectively), patients with non-M3 subtypes (P=0.001 and P=0.011, respectively), patients with intermediate-risk cytogenetics, (P=0.001 and P=0.005 respectively), or even in those with normal karyotype profile (P=0.022 and P=0.111, respectively). In multivariate analysis, high SOX4 expression was found to be an independent poor prognostic factor for OS (RR 1.924, 95% CI 1.020-3.628, P=0.043) irrespective of age, WBC count at diagnosis, karyotype profile and NPM1/FLT3-ITD status. Our results also reveal that SOX4 is an independent prognostic factor of AML. In conclusion, we reveal that BM SOX4 expression could serve as an informative new biomarker for the clinical prognosis of AML patients.

E943
AN OPEN-LABEL, MULTICENTER, PROSPECTIVE, RANDOMIZED STUDY OF RECOMBINANT HUMAN THROMBOPOETIN AS A ADJUNCT AFTER INTENSIVE CONSOLIDATION CHEMOTHERAPY IN ACUTE MYELOID LEUKEMIA
X.-H. Sui1,*, Y. Li1, X. Wang2
1Hematology department of Shandong provincial hospital affiliated to Shandong University. 2Hematology department ofShandong provincial hospital affiliated to Shandong University, Shandong University school of medicine, Jinan, China

Background: Thrombocytopenia is a common problem in the management of patients with acute myeloid leukemia (AML) receiving induction and consolidation therapy. AML patients with platelet count of less than 20×10^9/L might have a high risk of bleeding complications and had to take dose modifications instead of intensive chemotherapy leading to increased disease-free survival and overall survival. Platelet transfusions have a short therapeutic effect and are associated with all types of transfusion reactions. Recombinant human thrombopoietin (rhTPO) has been shown to improve the megakaryocyte and platelet development in solid tumor patients and immune thrombocytopenia (ITP) patients refractory to corticosteroids. We conducted this study to determine the availability of rhTPO in the platelet recovery after intensive consolidation chemotherapy with AML patients.

Aims: The aims of this study were to identify the effectiveness and safety of rhTPO in supportive care in patients with AML receiving consolidation chemotherapy.

Methods: Patients: Patients were eligible if they were 15–70 years of age who achieved complete remission after one course of IA induction therapy, and had platelet counts of less than 50×10^9/L after induction therapy, with an Eastern Cooperative Oncology Group (ECOG) performance status of 0–3. Patients with FAB M3 (acute promagranulocytic leukemia) and FAB M7 (acute myelomonoblastic leukemia) were excluded from the study. All patients provided written informed consent according to protocol guidelines approved by the institutional review boards at their individual institutions. Study design: Patients received consolidation chemotherapy with DA, MA and intermediated-dose arabinosyl cytosine (Ara-C), et al. When the platelet count was less than 50×10^9/L, patients in study group received 15000u/day of rhTPO (trade name: TPIAO) administration subcutaneously and patients in control group not received rhTPO therapy. The administration of rhTPO continued until the platelet count was more than 100×10^9/L or for the maximum of 21 days. Statistical analysis: Baseline characteristics were compared using chi-squared test or independent samples test and chi-square test. Other statistical data analyses were performed using the two-tailed Student’s t test and were represented as means±SD of values. All differences were considered to be statistically significant when the p-value was less than 0.05.

Results: The rhTPO was no statistically significant difference was observed in the main characteristics between study group (n=49) and control group (n=36), including age, gender and other baseline characteristics. No patient withdrew. Platelet transfusion and time required for platelet recovery were shown in Table 1. Platelet transfusions: The mean number and days of platelet transfusions for the study group were less than those in the control group, but there were no significant differences of statistical status between the patients. Platelet recovery: 1. rhTPO might reduce the duration of platelet count less than or equal to 20×10^9/L and 30×10^9/L after chemotherapy. 2. rhTPO could increase the maxi
mal and minimal platelet count after chemotherapy. 3. rhTPO might shorten the days of platelet count recover to at least 20×10^9/L from its nadir. The incidence of side effects were similar in both groups of the study.

Summary/Conclusions: rhTPO, administered as dose of 15000u/day when platelet count less than or equal to 50×10^9/L, might improve the recovery of thrombocytopenia of patients with acute myeloid leukemia in CR after consolidation chemotherapy. While there was no significant difference between study group and control group, there was a decreasing trend of platelet transusion number and shorter time required for platelet transfusion for patients in study group.

E944

TREATMENT-ASSOCIATED SURVIVAL RATES IN OLDER PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML): A SYSTEMATIC LITERATURE REVIEW

J. Bell^1, A. Galaznik^2, R. Huelin^3, M. Stokes^4, D. Faller^5, R. Fram^6

1Global Outcomes Research, 2Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 3Meta Research, Evidera Inc., Waltham, United States, 4Retrospective Observational Studies, Evidera Inc., Dorval, Quebec, Canada, 5Oncology Clinical Research, 6Takeda Oncology, Cambridge, United States

Background: AML patients ≤60 years old are more likely to experience complications following intensive induction chemotherapy and are at higher risk of unfavorable outcomes compared with younger patients. Information regarding optimal treatment approaches for older AML patients is limited.

Aims: Summarize outcomes associated with therapies among older AML patients, with a focus on treatment patterns and overall survival (OS) as reported in the literature.

Methods: Searches were conducted in Medline and Embase (Jan 2014–May 2016) and supplemented by conference abstracts (2015–2016). Eligibility included studies in English reporting on treatment regimens and outcomes associated with older AML patients or subgroups thereof, and conducted in the US, EU 5 (United Kingdom, Germany, France, Spain, Italy), or Japan. Only studies enrolling ≥50 patients were included.

Results: Twelve studies (19 publications) reporting on OS among older AML patients were included. Participants in most studies were newly diagnosed with AML; ages ranged from 60 to 93 years. Five non-comparative studies examining the effects of various treatment modalities were identified. Median OS in studies examining azacitidine (AZA) ranged from 10 to 12 months, whereas in studies examining induction chemotherapy or reduced intensity conditioning-hematopoietic stem cell transplantation, the median OS ranged from 6.85 months (95% CI: 3.7–13.5) to 16.4 months (95% CI: 12.6–24.6), respectively. Six comparative observational studies assessed the efficacy of different treatment regimens. Intensive chemotherapy (IC) was generally associated with longer median OS compared to other regimens. In one study, median OS for patients receiving IC, lower-intensity therapy (low dose cytarabine [LD-AraC]- (AZA, decitabine), or best supportive care (BSC) was 12.4 months (95% CI: 8.5–17.4), 11.5 months (95% CI: 9.2–13.9), and 2.6 months (95% CI: 1.9–3.1), with 3-year OS rates at 27%, 17% and 6% (p<0.0001), respectively. Another study assessed the efficacy of LD-AraC relative to IC, hypomethylating agents (HMA), and BSC. Patients appeared to have longer OS when receiving IC compared to LD-AraC (median OS: 12.4 vs 9.6 months; 3-year OS: 27% vs 21%, p=0.07), and those receiving LD-AraC compared to BSC had significantly improved OS (median: 9.6 vs 3.4 months, p<0.001). In this same study, while OS was longer with HMA than LD-AraC, this difference was not significant (median OS 16.1 vs 9.6 months; 3-year OS 22% vs 12%, respectively; p=0.1). Two studies assessed the efficacy of AZA vs moderate-IC, LD-AraC, or palliative therapy, alone or in combination. AZA had a significantly better survival rate vs LD-AraC in poor prognosis patients (p=0.015). Furthermore, 1-year survival was higher for AZA-treated patients (67.8%) compared to those not treated with AZA (36.9%) (p=0.004). The efficacy of AZA relative to other conventional care regimens (CCRs) including BSC, LD-AraC, or standard IC was also examined in a randomized clinical trial (n=488). Median OS at 1-year was significantly higher for AZA relative to CCR (10.4 vs 6.5 months). Results also showed that 1-year median OS was higher with AZA than CCR in all cytogenetic risk groups, normal risk (14.1 vs 10.0), intermediate risk (13.0 vs 10.1), and high risk (6.4 vs 3.2), respectively.

Summary/Conclusions: Among older AML patients, IC tended to be associated with improved OS compared with other CCRs. However, evidence from this review indicates that AZA could be an alternative treatment option for older AML patients, whether fit or unfit for IC.

E945

SYSTEMATIC REVIEW OF HEALTH STATE UTILITY VALUES FOR ECONOMIC EVALUATION OF ACUTE MYELOID LEUKEMIA

A. Forsythe^1, V. Bal^2, M. Dolph^3, S. Patel^4, G. Tremblay^5

1Purple Squirrel Economics, New York, 2Novartis Pharma, East Hanover, United States, 3Purple Squirrel Economics, Montreal, Canada, 4Novartis Pharmaceuticals UK Limited, Surrey, United Kingdom, 5Purple Squirrel Economics, Quebec city, Canada

Background: Cost-utility analyses undertaken to inform decision making regarding acute myeloid leukemia (AML) require a set of health state utility values (HSUVs) so that the time AML patients spend in different health states can be aggregated into quality-adjusted life-years (QALY).

Aims: This study reviews AML-related HSUVs that could be used in economic evaluation and assesses their advantages and disadvantages with respect to valuation methods used and AML clinical pathways.

Methods: Embase, MEDLINE, Cochrane database, and conference abstracts (ASCO, ESMO and ASH) were systematically searched from Jan 2000 through Nov 2016 for relevant studies that reported quality of life (QOL) and HSUV in AML. Identified relevant EORTC Quality of Life Core Questionnaire QLQ-C30 values were mapped to HDUV using previously published algorithm by Crott, et al. 2010. HSUV for induction, consolidation, complete remission (CR), relapse, stem cell therapy (SCT) treatment, SCT recovery and CR post SCT were identified.

Results: Ten relevant studies were identified. Six were cost effectiveness analyses utilizing HSUVs for calculation of Quality Adjusted Life years (QALY), one effectiveness analysis (incremental QALY). Two QOL studies reporting specific AML utilities (either collected or mapped from QLQ-C30). An additional study reported QOL for patients undergoing SCT. Since no study reported HSUV for relapse, values from study of secondary AML patients who failed prior treatment for Myelodysplastic Syndrome, were used. While multiple HSUVs were available, prioritized clinical trials were used to identify HSUV are presented in Figure. AML treatment (both induction, consolidation and SCT) was associated with decreased HSUV, while post-treatment CR lead to increased HSUV.
Summary/Conclusions: This interim analysis of the use of decitabine in real life showed a superiorimposable OS to controlled international clinical trials. Safety profile was acceptable considering setting of pts and incidence of important comorbidities. Despite a similar OS, the comparison between our data and Cashen study (56 vs 55 pts) showed in our cohort, a poorer rate of CR+CRi compared to decitabine therapy. WBC >10000/µL as well as high cytogenetic risk. This apparent contradiction supports the idea that in elderly pts recovery of peripheral blood cells counts (PR+hematological improvement) is probably the most important factor influencing OS (Ferrara, Hemat 2016).

E947

ASPARAGINASE ERWINIA CHRYSVANTHEMI EFFECTIVELY DEPLETES PLASMA GLUTAMINE, HAS CLINICAL ACTIVITY, AND IS WELL TOLERATED IN ADULT PATIENTS WITH RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA

A. Emadi1,2,3,*, E.T. Strovel4, B.A. Carter-Cooper1, D. Sewell2, I. Van Der Merwe1, M. Imran1, S.L. Yu1, H. Li1, P.C. Amrein6, V.H. Duong2, E.A. Sausville1,2,3, A.T. Fathi6, Z. Singh6, M.R. Baer1,2, S.M. Bentzen1,2

1University of Maryland Greenebaum Comprehensive Cancer Center, 2Medicine, 3Pharmacology, 4Pediatrics, 5Pathology, University of Maryland, Baltimore, 6Massachusetts General Hospital Harvard Medical School, Boston, 7Epidemiology and Public Health, University of Maryland, Baltimore, United States

Background: Asparaginase-induced glutamine (Gln) depletion demonstrates anti-leukemic activity in preclinical studies of AML. We hypothesized that administration of asparaginase Erwinia chrysanthemi (Erwinaze) would lead to effective plasma Gln reduction and may be a feasible therapeutic approach for AML, because myeloblasts may be addicted to Gln.

Aims: The primary aim was to determine the dose of Erwinaze inducing plasma Gln levels <120 μmol/L with an acceptable safety profile, 48 hours (h) after the first intravenous (IV) dose and before each subsequent dose administered thrice weekly for 2 weeks in patients (pts) with relapsed or refractory (R/R) AML.

Methods: This was a phase 1, single-arm, pharmacokinetic investigator-initiated trial (NCT02283190, funded by Jazz Pharmaceuticals), with a 3+3 design with dose de-escalation/escalation rules that incorporate both safety and biochemical activity (nadir plasma Gln levels) of IV Erwinaze. There was no intrapatient dose adjustment. For safety, a 3rd cohort of three pts was to be added if 2 of 6 pts in the 1st and 2nd cohorts experience a dose limiting toxicity (DLT) at a certain dose level. If ≤3 of 9 pts experienced DLT, the trial was to be terminated. To evaluate Gln reduction ability of Erwinaze, the dose could be increased based on 48h trough plasma Gln in cohorts of 3, 6, or 9 pts per dose level. Correlative studies measured plasma Gln, glutamate (Glu) and asparagine (Asn) levels, plasma asparaginase activity and plasma and urine 2-hydroxylgluturate (2-HG) levels.

Results: Five pts were enrolled on study. Enrolment was then halted due to Erwinaze supply manufacturing complexities. Median age was 69 (range 20-83) years, 4 were male, 2 had prior MDS or CML, 3 had high risk abnormal karyotype, 3 had isocitrate dehydrogenase (2 IDH1, 1 IDH2) mutations, and 3 had been treated with ≥2 lines of prior treatment. Erwinaze was administered IV (25,000 IU/m2, dose level 0) for 6 doses MWF for 2 weeks to all pts. No DLT was observed. Anemia and electrolyte abnormalities were the most common adverse events. Plasma asparaginase activity ≥0.1 IU/mL was achieved in all pts at 48h trough, but in 3 pts it decreased to zero on day 8 (72h trough). Median trough plasma Gln, Asn and peak Glu levels (μmol/L) at 28h were 27.6 (range <12.5-227), 0 (range 0-0), and 704 (range 474-754), respectively. Asn remained undetectable for the entire 2 weeks. Gln levels increased significantly on day 8 (72h trough) compared to day 5, p<0.001. Four of 5 pts (80%, lower limit of 1-sided 95% CI: 34%) achieved at least one nadir Gln value <120 μmol/L. The fold reduction (FR) in Gln level at 3 days, relative to baseline, was 2.44 (1.78-3.42) (p<0.001). One achieved partial remission (PR) and one achieved hematologic improvement (HI) after 6 doses of single agent Erwinaze. Both pts had plasma Gln levels <65 μmol/L on days 5, 10 and 12. Off study, after completion of Erwinaze, they were treated with azacitidine. Both pts are still alive in complete remission (CR) and CR with incomplete count recovery (CRi) 13.3 and 13.4 months after the on-study date. Plasma and urine 2-HG levels did not change significantly. The 3 pts with IDH mutations tended to have higher plasma 2-HG levels (p=0.10).
Summary/Conclusions: To the best of our knowledge, this is the first clinical report demonstrating that an asparaginase product is capable of not only decreasing plasma Glu level to ≤120μmol/L but also depleting it to undetectable (i.e. <12.5μmol/L) levels in pts with AML. Two of 5 patients with R/R AML had clinical responses and are alive in remission. Given clinical activity of asparaginase in AML, we are to investigate mechanistically-designed asparaginase combination therapies.

E948
PROGNOSTIC SIGNIFICANCE OF SOX2, SOX3, SOX11, SOX14 AND SOX18 GENE EXPRESSION IN DE NOVO ACUTE MYELOID LEUKEMIA (AML) PATIENTS
N. Tosic1,*, M. Virijevic2, I. Petrovic3, N. Kovacevic Gruijic3, S. Davidovic3, N. Stojadinovic Vukovic3, S. Pavlovic1, M. Stevanovic3
1Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia, 2Clinic of Hematology Clinical Centre of Serbia, University of Belgrade Faculty of Medicine, 3Laboratory for Human Molecular Genetics, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia

Background: Members of the SOX (SRY-related high mobility group (HMG) box) gene family encode a group of transcriptional factors with important functions in embryonic development. Also, SOX genes are aberrantly expressed in different types of cancer. However, their role in hematological malignancies, especially in acute myeloid leukemia (AML), remains elusive.

Aims: The aim of this study was to investigate the expression level of SOX2, SOX3, SOX11, SOX14 and SOX18 genes in de novo AML patients, and to evaluate their potential as prognostic markers.

Methods: Fresh bone marrow (BM) samples were collected from 50 non-APL AML patients at diagnosis (27 male, 23 female, median age 52.5 years, range 22-73) and from 8 healthy donors. Relative quantification analysis of SOX genes expression level was performed by RQ-PCR methodology, with GAPDH gene as endogenous control, and using comparative ddCt method with healthy controls as calibrator.

Results: The median expression level of SOX2, SOX3, SOX11, SOX14 and SOX18 in AML patients was 0.46 (0.01-226.13), 0.81 (0.01-1210.00), 0.35 (0.01-177.29), 0.98 (0.02-469.51) and 3.53 (0.18-332.00), respectively. This was not significantly different from the levels detected in healthy controls where the median expression levels were 0.01 (0.32-2.54), 1.00 (0.45-5.73), 1.00 (0.19-2.54), 1.04 (0.38-2.38) and 1.00 (0.48-12.29), respectively. As a cut-off value above which the patients were considered to be positive for SOX2/3/11/14/18 gene expression was used median expression level of each SOX gene in healthy controls + 2SD. The percentage of patients who were positive for the expression of the studied genes ranged from 14% (SOX2+ and SOX11+), 20% (SOX3+ and SOX18+) to 28% (SOX14+). A significant association with the presence of FLT3-ITD and NPM1 mutations was detected in all but SOX14+ patients. The same result was found concerning association with higher leukocyte count. There were no significant associations with any other presenting clinical parameters. As far as the impact that SOX expression positive status has on the analyzed genes had on the prognosis and outcome of the disease, we detected higher relapse rate in SOX14+ patients (p=0.045). Significantly shorter disease-free-survival (DFS) was detected among SOX2+, SOX11+ and SOX18+ patients (p<0.001; p=0.017; p=0.017, respectively). Although all of the SOX+ patients had shorter overall survival (OS) time compared to SOX- patients, the most prominent influence has been detected for the SOX2+ patients (p=0.034).

Summary/Conclusions: This is the first study focused on examining the expression level of SOX2/3/11/14/18 in AML patients. We have found that these genes are significantly overexpressed among patients in comparison with normal BM. However, in some patients, the expression of these genes is highly increased, and associated with a negative prognostic factors such as the presence of FLT3-ITD mutations and higher leukocyte count. Also, increased expression of these genes has been clearly associated with shorter DFS and OS. As for the exact function of these genes in the pathogenesis of AML is not yet known, our preliminary results show that their overexpression can have prominent prognostic significance in AML patients and therefore should be the subject of further investigation.

E949
ACUTE ANTHRACYCLINE INDUCED CARDIOTOXICITY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA
O. Pasvolsky1,*, O. morelli1, U. rozovski1, M. vaturi1, I. amitai1, I. vaxman1, R. ratzon1, M. yeshurun1, Z. Iakobishvilli1, R. kornowski1, P. raanani1
1Beilinson Hospital, Petach Tikva, Israel

Background: Chemotherapeutic agents are associated with a wide range of cardiotoxic adverse effects. Anthracyclines and related drugs are some of the most implicated agents, with a well-recognized potential for the development of cardiomyopathy and heart failure. Chronic anthracycline induced cardiotoxicity can lead to cardiomyopathy, which may develop several years after treatment. Acute and subacute anthracycline induced cardiotoxicity is considered relatively uncommon, described mostly in patients treated for solid tumors or lymphomas. While anthracycline based regimens have been used to induce remission in newly diagnosed patients with acute myeloid leukemia (AML) for more than four decades, relatively little is known about the acute cardiotoxic effect of anthracyclines in this setting. Since many of these patients were candidates for hematopoietic stem cell transplantation (HSCT), an intensive intervention usually reserved for fit patients, even transient decrease in cardiac function might render them ineligible for this intervention, or might increase their transplant related morbidity.

Aims: To study the short-term outcomes of anthracycline exposure on cardiac function in patients with AML who are candidates for allogeneic HSCT. Because current AML-induction regimes use anthracyclines (most commonly daunorubicin) at a relatively high dose between 45 and 90mg/m2/day for three consecutive days, we hypothesized that the incidence of post-induction cardiac injury in these patients is high.

Methods: The medical records of 55 consecutive patients who had received induction chemotherapy and had undergone HSCT in our medical center were reviewed. Patients included in the study were those with echocardiographic data both prior to and post induction therapy. Median age at diagnosis was 59 years (range: 19-73) and 49% were males. Approximately half of the patients had de novo AML (N=29, 53%). 26 patients (47%) had either therapy related AML or AML secondary to a previous hematological disorder. Induction treatment included 7 days of cytarabine at a dose of 100mg/m2/day and 3 days of daunorubicin at a dose of 45mg/m2/day (N=2, 3.6%), 60mg/m2/day (N=34, 6.1%) and 90mg/m2/day (N=15, 27%).

Results: Selected patient characteristics are summarized in Table1. Post-induction echocardiogram studies demonstrated a significant cardiac deterioration in left ventricular ejection fraction (EF) (defined as 10% or more absolute decrease from baseline EF) in 25.5% of the patients (N=14). Higher doses (90mg/m2/day) of anthracyclines were associated with higher rates of cardiac function deterioration (odds ratio: 4.1, 95%, confidence Interval: 1.06 to 15.7). Patients with cardiovascular risk factors and male patients tended to develop cardiotoxicity at higher rates, whereas age, white blood cell counts at diagnosis and AML type (de novo vs. secondary) had no impact on cardiotoxicity. The decrease in cardiac function was temporary in 10.9% of the patients (N=6) with subsequent normalization of left ventricular EF in those patients.

| Table 1. |
AN INTEGER WEIGHTED GENOMIC MUTATION SCORING (IWGMS) USING THE TRUSIGHT MYELOID SEQUENCING PANEL SHOWS HIGHER MORTALITY IN PATIENTS WITH INTERMEDIATE RISK ACUTE MYELOID LEUKAEMIA: A RETROSPECTIVE STUDY

1Internal Medicine, Houston Methodist Hospital, Weill Cornell Medical College, New York, United States, 2Department of Laboratory Medicine, Houston Methodist Hospital, Houston, Texas, 3Hematology, Houston Methodist Cancer Center, 4Baylor Miraca Genetics Laboratories, Baylor College of Medicine, Houston, United States

Background: AML is currently classified by European LeukemiaNet into favorable, unfavorable, and intermediate prognosis based on cytogenetic aberrations. Although favorable and unfavorable categories have good prognostic values, the intermediate category encompasses the majority of patients and offers unclear prognosis. The development of Cancer Genome Atlas (TCGA) opens new windows for the incorporation of next generation sequencing (NGS) into cytogenetics to enhance prognostic risk stratification. However, few studies explore the combination of cytogenetics and NGS in prognostic predictions.

Aims: Here we have developed a system of Integer Weights for the Genomic Mutation Score (IWGMS) for a quantifiable stratification of the prognostic risks associated with a combination of cytogenic aberrations and genomic mutations. Our next step is validating the scoring system through its application to data obtained from other institutions.

Methods: Patient data at Houston Methodist Hospital was queried from the Methodist Environment for Translational Enhancement and Outcomes Research (METEOR), a clinical data warehouse that integrates research data-bases and national registries. The diagnosis of AML was queried along with patient demographics, cytogenetics, NGS and OS. The resultants patients were divided into three categories based on their MRC cytogenetic risks: favorable, intermediate, and poor. Using the TruSight Myeloid Sequencing Panel (Illumina), mutations in 54 genes associated with myeloid disorders were tested in NGS. A scoring system was developed that assigned each of the nine TCGA mutation categories (Transcription- Factor Mutation, Nucleophosmin (NPM1), Tumor Suppressor Genes, DNA-Methylation related genes, Signaling Genes, Chromatin Modifying Genes, Myeloid Transcription Factor Genes, Cohesion complex Genes and Spliceosome-complex genes) a score between -2 (good risk) and +2 (poor risk). The IWGMS for each patient was calculated by the sum of the individual mutation scores. A IWGMS score greater than 3 was considered significant as a poor prognostic factor. Statistical analysis was done using Chi-Square, Mann Whitney U test and multivariate logistic regression analysis. Data from other institutions will be analyzed in a similar fashion for the confirmatory portion of the project.

Results: A hundred of the 1200 AML patients met the criteria for having both cytogenetic and NGS data availability. The two-year mortality rates were 43%, 52%, and 51% respectively for the favorable, intermediate, and poor cytogenetic groups. In the intermediate cytogenetic group, high IWGMS score (>3) was associated with higher mortality when compared to low IWGMS score (80% vs 44%, p=0.045, Fig 1). A look at the gene mutation distribution in the intermediate risk cytogenetic group also showed a general correlation between known favorable gene mutations with low IWGMS scores and unfavorable ones with high IWGMS scores. We thus hypothesize the IWGMS scoring system can be utilized to divide patients into higher and lower mortality subgroups based on a combination of cytogenetic and genetic mutations. We expect similar results with data from other institutions.

Summary/Conclusions: Most studies in current literature focuses on the individual contributions of cytogenetic aberrations or genetic mutations to risk stratification and treatments risk stratification and treatment response. However, prognosis varies widely in the heterogeneous, intermediate cytogenetic class, where 60% of the AML patients belongs. We propose a systematic approach that correlates cytogenetic and genetic mutations in stratifying prognostic outcomes with a focus on the intermediate cytogenetics group. The ability to differentiate in this specific group opens great potentials for targeted therapies and improving outcomes.

---

SUCCESSFUL IDENTIFICATION OF SPECIFIC AMINO ACID-DEPENDENCE IN ADULT T-CELL LEUKAEMIA / LYMPHOMA (ATL) AND PRECLINICAL APPLICATION FOR NEW THERAPY

M. Ibañez-Santos1,2, M. Cabezas-Cruz1, A. Ucchimaru1, N. Vázquez1, C. Landing1, A. Lázaro1, A. García-Mascarós1, S. Yamanaka1, K. Uchimaru1, A. Topi1, H. Nakaoch1,6
1Division of Stem Cell Therapy, 2Department of Laboratory Medicine, Research Hospital, 3Project Division of Advanced Regenerative Medicine, The Institute of Medical Science, The University of Tokyo, 4Laboratory of Tumor Cell Biology, The University of Tokyo, 5Department of Hematology and Oncology, Research Hospital, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan, 6Institute for Stem Cell Biology and Regenerative Medicine, Stanford University, California, United States

Background: Adult T-cell leukemia / lymphoma (ATL) is highly aggressive malignancy caused by human T-cell leukemia virus type 1 (HTLV-1). As leukemia/lymphoma cells are often resistant to combination chemotherapy and recent antibody therapy, new strategies should be developed. Our laboratory recently found that proliferation and survival of hematopoietic stem cells are critically dependent on the amino acid valine (Science, 2016).

Aims: We here aimed to assess amino acid-dependence of lymphoma and leukemic stem cells, and tried to establish a novel therapy by utilizing the differences in amino acid-dependence between normal and leukemic stem cells.

Methods: First, primary ATL cells were sorted from samples of 7 typical acute-type ATL patients by 12-color flow cytometry, and serially passaged on stromal cells. Then passageable ATL cells from 3 patients were transduced with GFP-expressing lentivirus for tracking and counting by image cytometry. Using complete medium and twenty different culture media each lacking a single amino acid, we examined amino acid dependency of ATL cells. Amino acids vital for ATL cells were screened by co-culture with stromal cells. Effects of these media on normal lympocytes of healthy volunteers were also examined. Finally, the effectiveness of amino acid restriction was evaluated in vivo by xenotransplantation of ATL cells into NOD mice. Mice were fed with different diets lacking specific amino acids at 6 weeks after transplantation, and sacrificed at 10 weeks for analysis of peripheral blood, organs, and lymphoma size.

Results: In vitro studies revealed that ATL cells have dependency on specific amino acids: cysteine, methionine, and valine. As 2-weeks restriction of the former two amino acids damaged stromal cells or normal lymphocytes, valine was picked up for further analysis. Proliferation of ATL cells was dramatically inhibited by valine restriction while the influence on normal cells was limited. Interestingly, valine restriction did not effect a significant change in the proportion of normal CD4+ populations, such as Treg, naive, central memory, effector memory, and effector T-cells. Moreover, 4-week restriction of valine succeeded in eradicating ATL cells in vitro and no recurrence was observed after refilling valine although 2-weeks restriction was insufficient for extermination. In-vivo model also showed that 4-weeks restriction of valine could dramatically reduce ATL tumor size. Valine-depleted diet did not significantly reduce hemoglobin or platelet count, and there were no significant organ damages as far as examined macroscopically.

Summary/Conclusions: We discovered that proliferation and survival of adult T-cell leukemia / lymphoma cells were dependent on valine. ATL cells could be eradicated by 4-weeks of valine in vitro. In-vivo model also showed that the growth of ATL cells was significantly inhibited by dietary restriction of valine. Massive lymphoma cells, which are known to be resistant to antibody therapy, were also vulnerable to the valine restriction. There were no severe complications such as anemia, thrombocytopenia, and organ damages which are often seen in chemotherapy recipients. These data demonstrate that valine restriction may potentially provide a new option for leukemia/lymphoma therapy.

---

VEGF AND VEGFR2 POLYMORPHISMS ARE INVOLVED IN AGGRESSIVENESS AND PROGNOSIS OF DIFFUSE LARGE B-CELL LYMPHOMA

A. Borsarelli Carvalho Brnto1, M. Torresan Delamain2, C. Antonio de Souza2, J. Vassallo2, C. Silva Passos Lima4, 1Department of Internal Medicine, 2Haematology and Haemotherapy Centre, 3Laboratory of Molecular and Investigative Pathology, University of Campinas, Campinas, Brazil

Background: Angiogenesis (AG), with participation of the vascular endothelial growth factor (VEGF) and its receptor (VEGFR2), plays a key role in clinical features and outcome of patients with diffuse large B cell lymphoma (DLBCL).

The ability to induce AG is variable in humans, once that VEGF and VEGFR2 genes have several single nucleotide polymorphisms (SNPs) described with distinct proteins production. The wild-type alleles of VEGF -2578 C/A (rs699947), -2489 C/T (rs1005230) -117 C/G (rs1570360), -634 G/C (rs2010963), -460 C/T (rs833081), 936 C/T (rs3025039) and VEGFR2 -2710 G/A (7667289) and -604 T/C (rs2071559) SNPs determine higher production, transcriptional activity or binding efficiency of VEGF/VEGFR2.
Aims: Since the roles of these SNPs in clinical aspects, response to therapy and prognosis of DLBCL treated with R-CHOP- are still unknown, these were the aims of the present study.

Methods: Our analysis included 168 consecutive DLBCL patients at diagnosis seen at University Hospital from July 2009 to September 2014. Genotypes were identified through DNA of peripheral blood by real-time polymerase chain reaction using a Taqman SNP Genotyping Assay. Replicates were performed in 10% of the reactions, achieving 100% of concordance. Chi-Square test, Fisher’s Exact test, and multivariate analysis, using the logistic regression model, served to assess associations between genotypes and clinical aspects. Kaplan-Meier analysis was used to evaluate the effect of clinical features and genotypes on the progression free survival (PFS) of BMI at baseline, assessed by means of BMB and PET/CT. Results were considered statistically significant when P<0.05.

Results: Concerning clinical features, the frequency of the wild-type VEGF -634GG genotype was more common in stage II or IV patients. The wild-type VEGFR2 -604TT genotype was more common in high intermediate and high international prognostic index (IPI) patients. Concerning response rate, patients with the wild-type VEGF 936CC genotype was associated with higher complete response (CR). These patients had a high proportion of achieving CR to therapy than others. The median follow-up time of 168 DLBCL patients enrolled in the study was 43 months (range: 1-105). The estimated probabilities of 60-months EFS and OS were 58% and 66%, respectively. At 60 months of follow-up, patients with the variant VEGF 1154 A allele and 936 T allele had 1.52 and 1.52 more chances of presenting disease relapse or progression, and 1.47 and 1.60 more chances of evolving to death in univariate analysis, respectively. After correction with other classical prognostic factors in DLBCL (IPI and GCB subtype), only the VEGF 1154 A/G A SNP was associated with PFS and OS: patients with the variant VEGF 1154 A allele had 1.88 and 1.83 more chances of having an event.

Summary/Conclusions: Our data present, for the first time, preliminary evidence that inherited abnormalities in AG pathway, related to the VEGF -1154A/G, -634GG and 936CT/C, and VEGFR2 -604TT/C, influence clinical features, response to R-CHOP and outcome of DLBCL patients.

E954

THE PROGNOSTIC SIGNIFICANCE OF CD11b+CX3CR1+ MONOCYTES IN PATIENTS WITH NEWLY DIAGNOSED DIFFUSE LARGE B-CELL LYMPHOMA

1Internal Medicine, Chonbuk National University Hospital, Jeonju, 2Internal Medicine, Catholic University of Korea, Seoul, 3Mckusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, Korea, Republic Of

Background: Interest in the role of myeloid-lineage cells, including monocytes and their precursors, has been increasing in prognosis of lymphoma. It has been shown that the circulating monocyte count at the time of diagnosis shows prognostic significance in diffuse large B-cell lymphoma (DLBCL), suggesting the role of specific subset of monocyte in prognosis of DLBCL. Recent studies suggest CD11b+ monocytes expressing CX3CR1 promote angiogenesis and suppress anti-tumor immunity through the interaction with fractalkine (CX3CL1), the only ligand for CX3CR1. However, limited data is available regarding the prognostic significance of CD11b+CX3CR1+ monocytes in DLBCL patients.

Aims: The study investigates the prognostic significance of peripheral blood (PB)- and bone marrow (BM)- CD11b+CX3CR1+ monocytes on progression-free survival (PFS) and overall survival (OS) in newly diagnosed DLBCL patients.

Methods: This is a retrospective multicenter study including patients older than 17 years, with a BM and/or PET/CT performed simultaneously as part of the routine pre-therapy staging for newly diagnosed DLBCL. Patients who had not received chemotherapy or corticosteroids and no concomitant malignancy was known to be present at the time of both procedures. Only patients treated with R-CHOP as first line therapeutic strategy were included. Only variables that are independent of analysis were included in the multivariate Cox regression for outcome predictors.

Results: A total of 271 DLBCL patients were initially identified; we excluded: 31 patients who received low intensity chemotherapy regimens (R-COP, Mini-CHOP-R, monotherapy with steroids) due to advanced age, comorbidities or detainees and 46 clinical trials including standard regimens plus new agents (Bortezomib, Lenalidomide, Ibrutinib) or non-standard regimens (R-CHOP/14, Da-EPOCH-R, MACOP-B, Mega-CHOP, Hyper-CVAD). In the homogeneously treated (R-CHOP/21) 205 DLBCL patients subset, the median age at diagnosis was 61 y.o. (range: 18-85), with a balanced gender distribution (113 females and 92 males). Twenty-one of these patients (10.3%) had BMI on BMB, whereas 43 (21%) had BMI according to PET/CT finding. Fifty-three patients (25.9%) had BMI according to either BM or PET/CT. Concordant BMI by means of both techniques was present in 16 (7.8%) patients. With a median follow-up of 25 months (15-47 months, p25-p75), 50 patients (24.4%) progressed or relapsed and 41 (20%) died. The 3-year estimated progression-free survival (PFS) and overall survival (OS) were 70%, and 78%, respectively. By univariate analysis, factors associated with a shorter PFS, with a p<0.150, were: female gender; IPH3, abnormally elevated B2-microglobulin levels, PET/CT-BMI(+) and BMB-BMI(+). In multivariate analysis only two factors were retained: age +IPI (HR: 3.15, 95%CI 1.92-5.1; p<0.001). The four patients with a worse survival. In this cohort, BMI by PET/CT could not independently predict a shorter PFS and/or OS.

Conclusion: Our data indicate that the circulating monocyte count at the time of diagnosis shows prognostic significance in diffuse large B-cell lymphoma (DLBCL), suggesting the role of specific subset of monocyte in prognosis of DLBCL. Recent studies suggest CD11b+ monocytes expressing CX3CR1 promote angiogenesis and suppress anti-tumor immunity through the interaction with fractalkine (CX3CL1), the only ligand for CX3CR1. However, limited data is available regarding the prognostic significance of CD11b+CX3CR1+ monocytes on progression-free survival (PFS) and overall survival (OS) in newly diagnosed DLBCL patients.

Results: Eighty-nine patients (male, 52) were enrolled. The median age was 65 years (range, 19-88). 37 patients (41.6%) were classified as high-intermediate (HI) or high risk according to National Comprehensive Cancer Network International Prognostic Index (NCCN-IPI). CD11b+CX3CR1+ monocytes were enumerated in the study. The results are summarized in the table. The expression level of CD11b+CX3CR1+ cells was 3.31% (range, 0.21 to 21.66%) in PB and 3.09% (range, 0.20-20.01%) in BM. Patients were categorized into high (PB- or BM-CD11b+CX3CR1+ cells >median) and low (<median) groups. High PB-CD11b+CX3CR1+ cell group was significantly associated with unfavorable features, including age >60 years, advanced stage, elevated serum LDH level, and extranodal involvement (P<0.05), which were clinical factors associated with higher risk NCCN-IPI (P<0.004). However, BM-CD11b+CX3CR1+ cells were not associated with clinical variables. With a median follow-up of...
27.7 months (IQR, 14.6–46.1), low PB-CD11b+CX3CR1+ cell group had significantly better PFS (3-year, 77.1% vs 58.7%; P=0.006) and OS (3-year, 86.6% vs 58.4%; P=0.004) than high PB group. No significant survival differences were observed between high and low BM-CD11b+CX3CR1+ cell groups. Uni-variate analyses demonstrated that age, ECOG performance status, B symptoms, extranodal involvement, NCCN-IPI, and PB-CD11b+CX3CR1+ cell group were significantly associated with OS. However, HI or high risk NCCN-IPI was an only independent prognostic factor for reduced OS (hazard ratio, 4.41; 95% confidence interval, 1.17-16.59) in the multivariate analysis. In subgroup analysis according to the NCCN-IPI, 3-year OS of high PB-CD11b+CX3CR1+ monocytes was significantly inferior to that of low group (34.0% vs 77.9%; P=0.026) in B-NHL, but not in T/NK-NHL. In contrast, PB-CD11b+CX3CR1+ monocytes failed to predict OS (3-year, 91.7% vs 96.7%; P=0.878) in the low to low-intermediate risk NCCN-IPI subgroup.

Summary/Conclusions: Our study represents PB-CD11b+CX3CR1+ monocytes can be used in differential patients with high risk for early death and are associated with risk stratification by the NCCN-IPI, possibility of potential therapeutic target in DLBCL.

Background: Clinical management of pediatric rare non-Hodgkin lymphomas (r-NHL) (<1 case/1million) is unclear.

Aims: To characterize children with r-NHLs in AIEOP centers. Performing a retrospective analysis of r-NHLs AIEOP case records, describing main epidemiological, clinical and histopathological parameters. To review the histopathological case records according to WHO 2008 classification. Evaluation of treatment response - chemotherapy or watch and see (W&S) in terms of overall survival (OS) and of complete remission (CR), relapse and resistance cases, secondary neoplasias and deaths.

Methods: Data from the AIEOP database were collected between 1997 and 2015.

Results: The incidence of r-NHL in AIEOP registry was 6.5% (67 pts). Forty-eight were male and 19 female, median age was 11 years (0.3-21 years). Classification according to St.Jude stage was: stage I n=36; II n=13; III n=11; IV n=7. Bone marrow (BM) involvement was diagnosed in 7 cases; central nervous system (CNS) in 1 case. Patients who presented LDH >500 UI were 18. B-NHLs accounted for approximately 49% (33 pts) of the entire population analyzed. BM-NHL accounted for other 40% (27 pts), the remaining 11% (7 pts) of the population under study being categorized as “others” (other than those deriving from B or T/NK-cells). The most common histological subtypes were: follicular lymphoma (FL) amongst B-NHLs; peripheral T-cell lymphoma (PTCL) n.o.s., mycosis fungoides (MF), subcutaneous panniculitis T-cell lymphoma (SPTCL) and lymphomatoid papulosis (LP) amongst T-NHLs; histiocytic sarcoma (HS) amongst “others” category. A similar proportion for both B and T/NK NHL underwent either W&S approach only or active treatment (AT): 45% and 55% were W&S and AT approach, respectively. Patients in “others” category were almost completely treated (71%). Therapy was based on AIEOP B-, T/NK-NHLs and ALCCL protocols and / or immunotherapy. Surgical resection has been performed in case of localized disease B-NHLs only, followed by a W&S strategy, with 100% 3-yr OS. It has been seen that B-NHLs have a more favorable prognosis and very few events (development of resistance to therapy, relapse, secondary malignancy, death). Amongst T/NK-NHLs-related events, death remained the most common event. In case of B-NHL, the most common cause of relapses; as for the category “others”, no relative preponderance has been registered for any of the above-mentioned events. The 3-year OS has shown to be significantly higher for B-NHLs than for T/NK-NHL (94% vs 69%, p-value 0.024), as illustrated in Figure 1. Regarding the treatment, the 3-year OS was 100% for the patients underwent a W&S approach whereas 75% for treated patients (p-value 0.037). FLs show favourable clinical course and outcome, limited stage at diagnosis. Differently from adults, pFLs have a higher 3-years OS with respect to that of other histological pediatric NHLs subtypes (100% vs 75%, p-value 0.049).

Figure 1.

Summary/Conclusions: The incidence of AIEOP pediatric rNHLs is in line with the literature. In case of localized disease, a W&S approach was successfully applied; of these, the T/NK rNHLs being most often registered and with best prognosis are the cutaneous lymphomas (i.e. LyP, MF). Patients’ prognosis varies greatly depending on the histological subtype. The better survival was observed in the B-NHLs compared to other categories. An international collaboration is warranted, in order to create new guidelines or protocols for an appropriate management of pediatric rNHLs.

E956
PRIMARY ANALYSIS OF THE EFFECT OF HEMATOPOIETIC STEM CELL TRANSPLANTATION IN THE TREATMENT OF 110 CASES OF T CELL LYMPHOMA
C. Li1,2, D. Yang1, X. Chen1, J. Chen1, T. Wang1, Q. Zou1, C. Gu1, D. Wu1,2
1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology, 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: T cell lymphoma(T-NHL) is a rare and heterogeneous group of lymphoid malignancies with mostly poor outcome with conventional treatment. Recent studies have suggested that Hematopoietic stem cell transplantation(HSCT) has a better curative effect and is superior to traditional chemotherapy.

Aims: To investigate the effect of HSCT in the treatment of T cell lymphoma.

Methods: The clinical data of 110 patients with T cell lymphoma treated by HSCT from January 2006 to August 2016 in our center were retrospectively analyzed.

Results: (1)110 T-NHL patients, 70 males and 40 females, aged 7-64 years (median age 26 years). Disease subtypes: 35 cases of T-cell lymphoblastic lymphoma(T-LBL), 23 cases of NK / T cell lymphoma(NK/TCL), 24 cases of peripheral T-cell lymphoma (PTCL, NOS), 24 cases of peripheral ALCL, 1 case of hepatosplenic T cell lymphoma(HSTCL) and 1 case of histiocytic lymphoma(HLCL). Transplantation type: 56 cases of autologous hematopoietic stem cell transplantation (auto-HSCT), 54 cases of allogeneic hematopoietic stem cell transplantation (allo-HSCT). The follow-up was ended in December 2016, the duration of follow-up ranged from 2 to 130 months (median follow-up time was 22 months). (2)56/110 patients with auto-HSCT, 3 year overall survival (OS) and disease-free survival (DFS) were 76.5% and 60.9%, respectively. (3)54/110 patients with allo-HSCT, 3 year DFS and OS of allo-HSCT were 61.7% and 58.9%, respectively. (4)36/56 patients with CR1 status before auto-HSCT, 3 year OS and EFS were 87.3% and 68.7% respectively. (5)56/110 patients with non-CR1 status before auto-HSCT, 3 year OS and EFS were 60.6% and 40.2%. The OS and EFS of the two groups were significantly different (P=0.001). (5)45/110 cases were young and high-risk patients (age<60 years, IPI score ≥3). 20/56 patients with non-CR1 status before auto-HSCT, the 3 year OS and EFS were 47.6% and 36.9%. The OS and EFS of the two groups were also significantly different (P=0.001).

Summary/Conclusions: HSCT can improve the efficacy of T cell lymphoma. Auto-HSCT in first complete remission (CR1) enables T-NHL patients with
greater benefit. Allo-HSCT can cure some t-NHL patients, which can be considered for the treatment of young and high-risk T-NHL patients.

E957 SHORT COURSE OF R-HYPERCVAD/MTX/ARA-C FOLLOWED BY ASCT AS FIRST-LINE THERAPY IN MANTLE CELL LYMPHOMA PATIENTS PROLONGS PROGRESSION FREE SURVIVAL TO MORE THAN 9 YEARS. SINGLE CENTER EXPERIENCE

M. Aranda-Campos1,2, S. Mercadal1, E. Domingo Domenech1, V. Paredes Henao1, C. Aguilara Gomez1, A. Oliveira Ramos1, E. de la Band1, F. Ciliento3, R. Parody Porras1, A. Fernandez de Sevilla1,4, A. Sureda1, E. Gonzalez Barca1,2
1Department of Hematology, Institut Català d’Oncologia Hospitalet, IDIBELL, Barcelona, 2ICIBER de Enfermedades Raras, CIBERER, IIS Ciutat, Zaragoza, 3Pathology Department, Hospital Universitario de Bellvitge, IDIBELL, 4Department of Clinical Sciences, University of Barcelona, Barcelona, Spain

Background: Mantle cell lymphoma (MCL) is considered an incurable disease with an historical median overall survival around 3-4 years with short progres-

sion free survival (PFS) periods. Regimens that include high dose cytotoxicare and consolidation with autologous stem cell transplant (ASCT) have become

standard therapy for fit patients. The median PFS reported after 4-6 cycles HyperCVAD followed by ASCT consolidation is 4.5 years (Ahmadi et al, BMT 2012). Nevertheless, toxicity is high and many patients cannot obtain stem
cells for transplant. In this setting, some groups use 6-8 cycles R-HyperCVAD
without ASCT consolidation, achieving the same median PFS of 4.6 years (Romaguera et al, Br J Hematol 2010). Based on this we have review our expe-
rience using a short course of HyperCVAD followed by transplant consolidation.

Aims: To analyze our experience treating fit patients with MCL in first line with a short course of 2 cycles of R-HyperCVAD followed by consolidation with ASCT.

Methods: from January 2002 to August 2016, the patients diagnosed with MCL treated in first line with a short course of 2 cycles of R-HyperCVAD and ASCT were included in this retrospective analysis. International working group response assessment criteria were used, PFS was calculated from the date of start therapy until date of relapse/progression or last contact.

Results: During the study period 85 MCL patients were registered: 7 (8.2%) did not receive immediate therapy, 44 (52.4%) were not eligible for intensive therapy due to comorbidities or age and 33 (39.3%) were treated with R-Hyper-
CVAD. Clinical characteristics at diagnosis of these 33 patients were: MiP ratio: 26/7 (78.8%/21.2%), median age: 63 y.o. (limits: 40-73), ECOG 0-1; 26 (86.7%), Ann Arbor stage III-IV 28/31 (90.3%), MiPi score: low risk: 5 (16.7%), interme-
diate risk: 17 (56.7%), high risk: 8 (26.7%). Thirty (90.9%) patients completed the 2 cycles of R-HyperCVAD. Reasons for discontinuation were: 2 deaths for sepsis and 1 CNS progression. Intention to treat response rate was: CR 26 (78.8%), PR 2 (6.0%), progressive disease 3 (9.0%), not evaluable 2 (6.0%). Among the 28 patients in CR / PR considered eligible for consolidation with ASCT, 8 patients were not transplanted: 4 (14.3%) had harvest failure (all before plerixafor availability), 2 had persistent toxicity (prolonged neutropenia and severe mucositis) and were not longer considered for ASCT, 1 rejected, 1 unknown cause. Conditioning regimen was BEAM/LACE in 18 (90%) patients and cyclophosphamide-TBI in 2 (10%). One patient died 10 days after infusion for sepsis. With a median follow-up of 35 months (1-315) months, the median PFS was 73.0 (95%IC 38.2-107.8) months (8.08 years) for the whole group, 114 (47.3-180.7) months for the transplanted patients vs 21 (3.1-38.9) months (1.8 years) for the not transplanted group. The median OS was 123 (31.9-214.1) months, median OS was not reached for transplanted group vs 31.0 (7.5-54.6) months for not transplanted.

Figure 1.

Summary/Conclusions: A short course of R-HyperCVAD achieves a very high remission rate in fit patients with MCL. Stem cells could not be obtained in a small proportion of patients, all of them before the use of plerixafor. Two thirds of the patients could complete the planned therapy with ASCT consolidation, and those patients have an excellent outcome, with a PFS of more than 9 years.

E958 THE FREQUENCY OF INCIDENTAL MALIGNANCIES DETECTED BY PET/CT SCANS IN PATIENTS WITH LYMPHOMA AND THE ASSOCIATED CLINICAL IMPLICATIONS

J. Falconer1, G. Kidston-Gerber2, E. Wegner2
1Haematology, Concord Repatriation General Hospital, 2Haematology, The Prince of Wales Hospital, Sydney, Australia

Background: PET/CT imaging has a well-established role in the investigation of malignant lymphoma. Given the widespread clinical applications, unexpected findings are occasionally identified. Whilst there is substantial information pertaining to additional primary cancers identified on PET/CT in patients with solid organ malignancy, there is a relative paucity of data in patients with lymphoma.

Aims: The primary aim was to identify the frequency of incidental second malignancies identified by PET/CT imaging in patients with lymphoma. Qualitative data related to histological diagnosis and staging, interruptions or obstacles to lym-
phoma therapy, therapy for the second malignancy and the overall impact upon prognosis were also reviewed.

Methods: A total of 550 PET/CT images were performed in 298 patients at The Prince of Wales Hospital, Sydney Australia between January 2013 – March 2016. Patients with both Hodgkin’s and Non-Hodgkin’s lymphoma, with PET/CT imaging performed for all medicare-allowed indications were included. All PET/CT reports suggest of an incidental second malignancy prompted further review of electronic medical records, MOSAIC cancer database and paper medical records. Where a clear diagnosis of second malignancy was confirmed, information regarding histological findings and staging, as well as the implica-
tions of this diagnosis related to treatment of the underlying lymphoma and impact on overall prognosis was collected.

Results: 510 PET/CT scans in 259 patients had confirmed diagnoses of lym-
phoma. Patients aged 17 to 96 were included in the study, with a median age of 62 years. Of the 259 patients included (M=155; F =104), 55 patients had a diagnosis of Hodgkin’s lymphoma and 204 patients a diagnosis of Non-
Hodgkin’s lymphoma. A total of 33 out of 295 patients with a diagnosis of malign-
nant lymphoma had PET/CT findings suspicious for an underlying second malignancy (12.7%). Of the 33 patients, 19 underwent further invasive inves-
tigation, with a total of 8 patients having a biopsy proven pathological diagnosis of a second malignancy (3.1%). Qualitative information was gathered regarding the patients who did not have further investigation.

Summary/Conclusions: The frequency of incidental malignancies detected by PET/CT imaging in patients with lymphoma was found to be comparable to other similar international retrospective studies. The majority of incidental sec-
ond malignancies were early stage and gastrointestinal in origin. Further ret-
rospective as well as prospective data may assist in the establishment of guide-
lines, to address a standardized diagnostic approach to investigating incidental lesions discovered on PET/CT imaging that are suggestive of a second malignance.
and was approved by the institutional review boards of all participating institutes.

Results: Among the 465 DLBCL cases, karyotypic analyses by G-banding were performed on biopsied tumor specimens before the start of treatment in 181 patients. Among the 181 patients, metaphase spreads were available for G-banding in 120 patients. Neither overall survival (OS) nor progression-free survival (PFS) was statistically significantly different between the patients with available metaphase and no available metaphase spreads. Based on the result of G-banding, we next divided the 120 patients with available metaphase spreads into two groups, i.e., patients with karyotypic abnormalities accompanied by ≥2 subclones and patients with 0-1 subclones. We found that the presence of ≥2 subclones was significantly associated with poor OS (3 year OS rates of patients with ≥2 subclones and 0-1 subclones were 67.6% and 82.8%, respectively (p=0.035), and tended to associate with a shorter PFS. Among the 120 patients with available metaphase spreads, the R-IPI-defined high-risk patients and KPI-defined high-risk patients were significantly more frequent in the group of patients with ≥2 subclones. Ages and genders were not significantly different between patients with ≥2 and with 1-2 subclones.

Summary/Conclusions: DLBCL is a cytogenetically and molecularly heterogeneous disease entity. No specific chromosomal abnormality has been associated with the shorter survival, except double or triple hit lymphomas. However, in this study, it was possible to divide DLBCLs into two groups based on karyotypic evolution, i.e., DLBCL with 0-1 subclones and with ≥2 subclones, because the OS was the most markedly different between these two groups. In our study, more subclones were associated with poor prognosis, suggesting the significance of karyotypic evolution in DLBCL. In conclusion, our study suggests that more advanced cytogenetic clonal evolution underlies the development of high-risk disease feature in DLBCL.

E960
REGIMENT INTENSIFICATION MAY IMPROVE OUTCOMES IN PATIENTS WITH HIGHER RISK HUMAN IMMUNODEFICIENCY VIRUS (HIV) RELATED AGGRESSIVE B-CELL LYMPHOMAS
1Department of Internal Medicine, University of South Florida Morsani College of Medicine, Tampa, 2Hematology Oncology, Mercy Clinic Oncology and Hematology, Joplin, 3Malignant Hematology, 4Bone Marrow Transplant, H.Lee Moffitt Cancer Center & Research Institute, Tampa, 5Malignant Hematology, George Washington Cancer Center, Washington D.C., United States

Background: Despite effective combination antiretroviral therapy for HIV, there remains an increased incidence of HIV related B-cell Non-Hodgkin lymphomas (NHL). The introduction of early antiviral therapy and effective chemotherapy have led to improved outcomes overall. Regimen intensification (RI) in HIV associated B-cell NHLs has shown improved survival, especially in the rituximab era (Barta et al, Blood 2013).

Aims: To examine the effect of RI on the overall survival (OS) and progression free survival (PFS) compared to CHOP based chemotherapy according standard risk stratification.

Methods: Patients with HIV associated aggressive B-cell NHL were identified between 2001- 2015 at Moffitt Cancer Center. Patients with primary central nervous system lymphoma, T-cell NHL and indolent NHLs were excluded. Patients received R-CHOP or intensive chemotherapy (IC) including DA-EPOCH, hyperCVAD or CODOX/IVAC as initial treatment. Data collected included patient demographics, disease baseline characteristics, CD4 count, HIV viral load, treatment regimen, response, and outcomes including relapse and OS. The IPI score was calculated, and patients were divided into two groups: lower risk group (low and intermediate IPI risk) and higher risk group (high-intermediate and high).

Results: A total of 83 patients were included. The M:F ratio was 9.4. Median age was 65 years (y) (range 25-86). Two thirds of patients were Caucasian. The median time from HIV to NHL diagnosis was 29 months (90 – 284). Eighty two percent presented with stage III/IV disease. Bulky disease was present in 27%, elevated LDH in 66%, and CD4 count<100/mL at diagnosis in 22% patients. Fifty percent of patients were on HAART therapy at time of lymphoma diagnosis (PFDS). Chemotherapy regimens included: R-CHOP (n=30, 36%), CHOP (n=12, 15%), DA-EPOCH-R (n=27, 33%), DA-EPOCH (n=1, 1%), hyperCVAD (n=11, 13%) and CODOX/IVAC (n=2, 2%). The median follow up was 2.7 y (95% CI 1.2-3.0 y). The median OS and PFS for the whole cohort was 5.9 and 1.4 y, respectively. The median OS was 4 y (95% CI 1.5-6.5) for patients who received CHOP, the median OS for those with lower risk disease was NR (p=0.05). For patients who received IC, the median PFS was NR among lower and 1.4 y higher risk groups (p=0.34).

Summary/Conclusions: The IPI score remains prognostic in HIV related B-cell NHLs. There was a trend for improved OS and PFS using IC regimens. CHOP treatment remained associated with worse outcome among higher risk patients while IC regimens may overcome the higher risk features based on the IPI.

E961
EPSTEIN-BARR VIRUS LATENT MEMBRANE PROTEIN 1-MEDIATED OVEREXPRESSION OF MYC AND BCL2 CAN PREDICT POOR PROGNOSIS IN PATIENTS WITH EXTRANODAL NK/T-CELL LYMPHOMA, NASAL TYPE
J.-H. Wang1, X.-W. Bi2, Z.-J. Xia1, W.-Q. Jiang2, H.-Q. Huang2, L. Wang1
1Hematologic Oncology, 2Medical Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Recently double-hit lymphoma or double protein expression lymphoma has been identified as a distinct group of diffuse large B cell lymphoma with poor prognosis. However, the expression status, clinical and prognostic effect of combined overexpression of MYC and BCL2 in extranodal NK/T-cell lymphoma, nasal type (ENKTL) are not known.

Aims: This study aims to explore the clinical and prognostic effect of combined overexpression of MYC and BCL2 in ENKTL.

Methods: Paraffin-embedded lymphoma samples from 53 patients with newly diagnosed ENKTL were studied using immunohistochemistry for MYC and BCL2, and fluorescent in situ hybridization (FISH) for MYC and BCL2 were done on 5 tissue sections with highest percentages of both MYC and BCL2 positive lymphoma cells.

Results: The median percentage of MYC-positive lymphoma cells and BCL2-positive lymphoma cells were 20% (range, 5% >45%) and 70% (10% >95%), respectively. Using median scores as cutoffs, we assigned each patient an IHC double-hit score (DHS) that ranged from 0 to 2. Using this DHS, 15 patients (28.3%) had a DHS of 0, 24 patients (45.3%) had a DHS of 1, and the remaining 14 patients (26.4%) had a DHS of 2. FISH analysis was performed on 5 tissue sections with DHS of 2, and none of them had MYC or BCL2 rearrangement. The DHS was not associated with patients’ age, gender, disease stage, LDH level, B symptoms, performance status, or local tumor invasiveness. However,
patients with tumor localized in extranodal sites seemed to have higher expression of BCL2 and higher DNH than nasal lesions (p=0.014 and 0.042, respectively). In univariate survival analysis, either high expression of MYC or BCL2 was significantly correlated with inferior PFS and OS (p<0.05). According to the DNH, patients with ENKTL could be divided into three significantly different risk groups for PFS and OS (3-year PFS rate for DNH of 0, 1, and 2 was 60%, 41%, and 21%, respectively, p=0.008; 3-year OS rate for DNH of 0, 1, and 2 was 79%, 49%, and 33%, respectively, p=0.015). In multivariate survival analysis, it was found that DNH was an independent prognostic factor for both PFS and OS (p=0.006 and 0.011, respectively).

Summary/Conclusions: Our study demonstrated that DNH can help identify patients with newly diagnosed ENKTL who are at a high risk for a poor clinical outcome, which needs to be validated in prospective clinical trials with patients treated uniformly.

SOLUBLE INTERLEUKIN-2 RECEPTOR AS A PREDICTIVE MARKER FOR SPONTANEOUS REGRESSION OF OTHER IATROGENIC IMMUNODEFICIENCY-ASSOCIATED LYMPHOPROLIFERATIVE DISORDERS: A RETROSPECTIVE STUDY

Y. Nakajima1, S. Fujiwara2, C. Nogari3, A. Matsumura1, T. Ando2, T. Suzuki3, E. Ogusa1, Y. Ishii2, K. Miyashita3, H. Takahashi1, T. Miyazaki1, K. Motohashi2, M. Hagiwara1, K. Matsumoto1, E. Yamazaki1, H. Nakajima1
1Department of hematology and Clinical Immunology, Yokohama City University Graduate School of Medicine, 2Department of Hematology, Yokohama City University Medical Center, 3Clinical Laboratory Department, Yokohama City University Graduate School of Medicine, Yokohama, Japan

Background: Patients treated with immunosuppressive drugs (ISD) for autoimmune diseases are at an increased risk of developing other iatrogenic immunodeficiency-associated lymphoproliferative disorders (OI-LPD). Some patients with OI-LPD shows spontaneous regression after withdrawal of ISD, but some require chemotherapy. The factors that are associated with spontaneous regression and outcomes of chemotherapy remain uncertain.

Aims: The aims of our retrospective study are to assess the clinical factors that predict spontaneous regression of lymphoma after ISD withdrawal in patients with OI-LPD and to evaluate the outcomes of patients who underwent chemotherapy without spontaneous regression.

Methods: We collected data from all patients with autoimmune disease who were pathologically diagnosed with OI-LPD between January 2002 to October 2016 at Yokohama City University Hospital, and Yokohama City University Medical Center.

Results: The patients included 12 males and 28 females, with a median age at diagnosis of 65 years (range 30-81). Methotrexate (MTX) was administered to all patients at any point of the clinical course before OI-LPD. The median time from diagnosis of autoimmune disease to OI-LPD development, and the median duration of MTX administration were 120 months (range 1-584), and 89 months (range 4-297), respectively. The histological findings of OI-LPD were diffuse large B-cell lymphoma (DLBCL) in 26 patients, follicular lymphoma in 1, MALT in 2, peripheral T-cell lymphoma, not otherwise specified in 3, Hodgkin lymphoma in 4, and LPD in 4. EBER in situ was examined in 30 patients with 7 patients. The median observation period in the surviving patients was 34 months (range 3-119). The 2-year progression-free survival (PFS) and overall survival (OS) rates for all 40 patients were 69% and 79%, respectively. A total of 18 patients (45%) had spontaneous regression after ISD withdrawal. The median time from ISD withdrawal to spontaneous regression was 4 months (range 1-13). Among the 18 patients with spontaneous regression, 3 relapsed. Of the 22 patients without spontaneous regression, 20 subsequently underwent chemotherapy; 18 underwent CHOP/CHOP-like ± rituximab, and 2 underwent other regimens. In total, 7 patients died: all died from lymphoma progression. Compared to those without spontaneous regression, patients with spontaneous regression had clinical stages I-II (P=0.021), performance status of 1-2 (P=0.028), normal levels of LDH (P=0.026), and lower levels of sIL-2R (P=0.005). The ROC curve analysis showed the appropriate cut-off of sIL-2R levels to be 2400 U/mL for predicting spontaneous regression (AUC, 0.74; sensitivity, 0.81; specificity, 0.67). On multivariate analysis, only advanced stages of OI-LPD was associated with spontaneous regression (odds ratio, 0.03; 95% CI, 0.002-0.39; P=0.007). Thirteen patients with DLBCL who did not have spontaneous regression received CHOP/CHOP like ± Ritux. The CR rates, and 2-year PFS and OS of these 13 patients were 38%, 68.3%, and 82.1%, respectively.

Summary/Conclusions: Our study revealed that an sIL-2R level of <2,400 U/mL was significantly associated with spontaneous regression in patients with OI-LPD. Because CR rates with chemotherapy in patients without spontaneous regression are low, evaluation of sIL-2R in patients with OI-LPD may be useful for an early withdrawal of ISD, resulting in a higher chance of spontaneous regression.
CIRCULATING MICRORNAS AS BIOMARKERS IN DIFFUSE LARGE B-CELL LYMPHOMA: A PILOT PROSPECTIVE LONGITUDINAL CLINICAL STUDY

C. Bouvy1,*, A. Wannez12, C. Chatelain1, J.-M. Dogne1
1Department of Pharmacy, University of Namur, Namur, 2CHU UCL Namur, Université Catholique de Louvain, Yvoir, Belgium

Background: Diffuse large B-cell lymphoma (DLBCL) is highly heterogeneous in terms of phenotype and treatment response in patients. These characteristics make tumor progression difficult to establish and hinder the use of new personalized treatments in clinical practice. In this context, there is currently a necessity to define new biomarkers enabling a better definition of DLBCL subtypes, prognosis evaluation and an overview of the resistance to chemotherapeutics. We decided here to focus on circulating microRNAs that are found in all biological fluids. This accessibility makes them good candidates for biomarkers studies.

Aims: This research aims at studying microRNAs found in plasma from DLBCL patients and at investigating their potential as biomarkers of survival in these patients. For this purpose, a plasma biobank was created with samples from DLBCL patients at different times of their treatment. This follow-up of microRNAs level during the course of treatment is particularly innovative in this study.

Methods: A plasma biobank from DLBCL patients was set up at the Centre Hospitalier Universitaire (CHU) UCL Namur Yvoir, Belgium (ethical agreement number BO39201419613). Informed consents of all patients were obtained. In this way, blood samples from patients were taken before any treatment (C0), at the administration of the second and the fourth chemotherapeutic course (C2 and C4) and at the remission review (Cf). In the case of an autograft, a sample was taken at the post-graft review (Cpgr). The first step of this study was the selection of the microRNAs that will be quantified in all the samples of the biobank and that would potentially be used as biomarkers. To this end, a quantification of 377 microRNAs was performed by TaqMan® Low Density Array on the plasma samples of two selected DLBCL patients and one healthy donor with no history of cancer. These DLBCL patients were selected based on their highly different response to treatment. One of them obtained a complete remission after a R-CHOP treatment, while the other presented a refractory disease to the same treatment. Thereafter, we determined some criteria to use in a scoring system to evaluate their potential as biomarkers. In this way, one point was given to a microRNA each time it meets the criteria enabling it to be defined as a potential diagnostic, prognostic and/or remission biomarker, biomarker of a disease progress, biomarker of an inherent resistance to treatment, and/or biomarker of an acquired resistance to treatment.

Results: On the 377 microRNAs quantified into the plasma of the 3 selected donors (2 DLBCL patients and 1 healthy donor), 81 microRNAs were detected. Three microRNAs obtained the highest score of 5 points: miR-197, miR-20a and miR-451. Four points were attributed to miR-122, miR-19b and miR-19a. Two additional microRNAs were also selected: let-7e, for its prognostic value at C0, C2 and C4 and miR-21, for its numerous citations in the literature.

Summary/Conclusions: miR-197, miR-20a, miR-451, miR-122, miR-19b, miR-19a, let-7e and miR-21 have been selected in this study and are currently quantified in the plasma of the entire biobank. Since then, 19 patients have been included in the study and the potential of these microRNAs as biomarker are statistically evaluated.
OVERALL SURVIVAL IN YOUNGER NEWLY DIAGNOSED HIGH-RISK INTENSIFIED TREATMENT REGIMENS IMPROVE EVENT-FREE AND OVERALL SURVIVAL IN PATIENTS WITH DLBCL. More prognostic information can be obtained from sarcopenia, which is related to intolerance to R-CHOP therapy and to worse survival.

Results: Patients who showed complete (CR) or partial response (PR) after the fourth induction cycle of RD-BENDA started a consolidation course with four weekly doses of rituximab (375mg/m^2 i.v.) followed, in the case of persisting evidence of CR or PR, by a maintenance treatment with monthly courses of lenalidomide (10mg/m^2, days 1-21). All patients performed G-CSF prophylaxis to avoid febrile neutropenia. Patients with progressive disease after RD-BENDA started maintenance therapy with monthly courses of full dose lenalidomide. PD-ESR was performed for the assessment of therapy response after RD-BENDA induction course and after rituximab consolidation. After a median follow-up of 6 months (range 2-18), the overall response rate was 81%, with CR and PR of partial response rates of 63 (n=71) and 21% (n=22) respectively. Two patients died due to multiple organ failure and disease progression after 1 and 8 months from diagnosis, respectively. In our frail 80-year-old patient cohort, the sequential treatment strategy was well-tolerated. After R-BENDA cycles, grade II infectious disease was observed in 2/11 patients (18%) and DNA-CMV reactivation was detected in other 2 additional patients (18%). However, 2 out of five patients who started maintenance lenalidomide treatment discontinued therapy for renal and hematological grade 3 toxicity. At the time of analysis, the estimated median 18-month progression free survival (PFS) and overall survival (OS) were 75 and 66%, respectively.

Summary/Conclusions: Our preliminary data show that sequential treatment with RD-BENDA followed by four weekly doses of rituximab and finally by lenalidomide maintenance is a feasible and safe therapy option in frail elderly a-B-NHL patients, but needs to be assessed in a larger subsequent trial.

E968 CLINICAL RELEVANCE OF SARCOPENIA IN DIFFUSE LARGE B-CELL LYMPHOMA - TWO ARE BETTER THAN ONE S.-I. Go1, M.-J. Park2, G.-W. Lee1 1Internal Medicine, 2Radiology, Gyeongsang National University School of Medicine, Jinju, Korea, Republic Of

Background: Sarcopenia is known to be associated with poor clinical outcome in patients with diffuse large B-cell lymphoma (DLBCL). There is no consensus concerning the optimal method to define sarcopenia in DLBCL patients.

Aims: In this study, given the uncertainty about the optimal SM1 to define clinically meaningful sarcopenia in DLBCL, we compared the characteristics and clinical outcome between sarcopenic patients determined by L3 skeletal muscle index (L3-SMI) and those determined by pectoralis muscle SMl (PM-SMI) who were treated with standard line R-CHOP therapy. Furthermore, the synergistic role of L3- and PM-SMIs as prognostic markers was also investigated.

Methods: We retrospectively reviewed 193 DLBCL patients treated with rituximab plus cyclophosphamide, doxorubicin, vincristine, and prednisone (R-CHOP) therapy. Sarcopenia was classified by the region where the pretreatment skeletal muscle index (SMI) was measured.

Results: Both the sarcopenia-L3 and sarcopenia-pectoral muscles (PM) groups had increased incidences of severe treatment-related toxicities and treatment discontinuation compared with the non-sarcopenia-L3 and non-sarcopenia-PM groups, respectively. The sarcopenia-L3 and non-sarcopenia-L3 groups had 5-year overall survival (OS) rates of 40.5% and 67.8% (p=0.001), respectively. The sarcopenia-PM and non-sarcopenia-PM groups had 5-year OS rates of 35.9% and 69.0% (p<0.001), respectively. When the sarcopenia-L3 alone and sarcopenia-PM alone groups were compared, there were no differences in baseline characteristics, treatment toxicity, or survival. In multivariate analysis, when compared with the non-sarcopenia-both group, OS was significantly worse in the sarcopenia-both group (HR, 2.480; 95% CI, 1.284-4.792; p=0.007), but not in patients with either sarcopenia-L3 alone or sarcopenia-PM alone (p=0.151).

Summary/Conclusions: L3- and PM-SMIs are equally useful to define sarcopenia, which is related to intolerance to R-CHOP therapy and to worse survival in patients with DLBCL. More prognostic information can be obtained when these two SMIs are combined to define sarcopenia.
**Summary/Conclusions:** Our data suggests that the addition of etoposide to R-CHOP and increase in dose-intensity improves EFS and OS of younger patients with newly diagnosed high-risk B-LCL. R-CHOEP/14 and DA-R-EPOCH seem to be similarly effective in this setting.

**HIGH COMORBIDITY INDEX ALONG WITH HIGH NCCN-IPI STRONGLY INFLUENCE SURVIVAL OF Diffuse Large B CELL LYMPHOMA PATIENTS: SERBIAN Lymphoma Group EXPERIENCE**

J. Jelicic,1,2 D. Antic,2 M. Todorovic Balint,3 B. Andjelic2 O. Markovic3 I. Petkovic4 V. Nikolic2 J. Bilja2 V. Djurasicovic2 A. Sretenovic1 V. Vukovic1 M. Smiljanic1 S. Sretenovic1 B. Minajevic1 1Clinical Center Kragujevac, Kragujevac, Serbia 2Clinical Center of Serbia, Belgrade, Serbia 3Clinical Center of Serbia, University of Belgrade, Clinic of Hematology, 4Clinical Hospital Center “Bezanijska Kosa”, University of Belgrade, Belgrade, 5Clinic of Oncology, University Clinical Center Nis, 6Clinic of Hematology, Clinical Center Kragujevac, Kragujevac, Serbia

**Background:** A few studies have validated the prognostic significance of the NCCN International Prognostic Index (NCCN-IPI) so far. However, some patients with low risk according to NCCN-IPI have poor survival, and thus clinical parameters, that might better characterized patients within risk groups, need to be explored.

**Aims:** The aim of this study was to evaluate prognostic significance of current indexes such as International Prognostic Index (IPI), NCCN-IPI, and the influence of comorbidities on the overall survival (OS) of patients with newly diagnosed diffuse large B cell lymphoma (DLBCL).

**Methods:** A total of 708 patients (383 males/345 females) with the median age of 58 years (range 18-89) were included in the study. Majority of patients received R-CHOP (Rituximab, Cyclophosphamide, Doxorubicine, Vincristine, Prednisone) protocol, 652 (92.1%), while 29 (4.1%) received R-EPOCH (Rituximab, Etoposide, Cyclophosphamide, Doxorubicine, Vincristine, Prednisone), and 27 (3.8%) received R-CVP (Rituximab, Cyclophosphamide, Vincristine, Prednisone).

**Results:** According to the Ann Arbor classification, stage I and II had 332 patients (46.9%), while stage III and IV had 376 patients (53.1%). Bulky disease was present in 201 patients (28.4%), and B symptoms in 437 patients (61.7%). Majority of patients had cardiovascular disorders (223, 31.5%), endocrinological (63, 8.9%), neuropathological (132, 18.6%), and other (13, 1.8%). According to IPI, low, low intermediate, high intermediate and high risk had 332 patients (46.9%), 174 (24.6%), 132 (18.6%), and 70 (9.5%), respectively, while according to NCCN-IPI, 133 (19.6%) patients had low risk, 335 (47.3%) low intermediate, 198 (28.0%) high intermediate, and 36 (5.1%) high risk. Overall treatment response (ORR) was achieved in 615 patients (86.9%). Disease relapse was confirmed in 116/615 patients (18.9%). The patients with B symptoms (Log Rank=18.50, p<0.0001) and bulky disease (Log Rank=14.79, p=0.0001) had inferior OS compared to those without B symptoms or bulky disease. All parameters incorporated in IPI, as well as in NCCN-IPI, were significantly associated with OS (p<0.01). Moreover, the patients with at least one comorbidity had inferior OS (Log Rank=5.41, p=0.20), as well as those with high CCI ≥2 (Log Rank =7.59, p=0.006). Regarding OS, IPI (Log Rank=97.36, p<0.0001), and NCCN-IPI (Log Rank=102.29, p<0.0001) confirmed its prognostic significance. Furthermore, the patients with high CCI had significantly inferior median OS in the high risk group according to IPI (19 months vs 37 months), and NCCN-IPI (12 months vs 19 months).

**Summary/Conclusions:** NCCN-IPI represents useful prognostic index in DLBCL patients. It can be used in the clinical practice to better describe patients within risk groups, compared to IPI. Moreover, comorbidities contribute to inferior survival through frailty, drug dose reduction and poorer tolerability.

**SUBSTITUTING DOxorubicin WITH ETOPoside IN r-CHOP RESULTS IN A REGIMEN WITH SIMILAR EFFICACY FOR TREATMENT OF NEWLY DIAGNOSED ELDERLY PATIENTS WITH B-LARGE CELL LYMPHOMA (B-LCL)**

I. Hude1,2, S. Basic-Kindla1, I. Radman1, S. Dotlic1, M. Kralik3, M. Vodanovic1, P. Reifsan1, L. Galunic-Bilic4, M. Dobrenic5, A. Ostojic1, D. Dujmovic1, I. Aurer1 1Department of Hematology, Department of Internal Medicine, 2Department of Pathology and Cytology, 3Department of Radiology, 4Department of Oncology, 5Department of Nuclear Medicine, University Hospital Centre Zagreb, 6Medical School, University of Zagreb, Zagreb, Croatia

**Background:** R-CHOP is standard front-line treatment for B-LCL. However, anthracycline-induced cardiac toxicity limits its use in elderly and patients with preexisting heart disease. R-CEOP, in which doxorubicin is substituted with etoposide, has been suggested as a potential solution of this problem, but reports on the efficacy of this regimen vary substantially, especially in patients with non-GC DLBCL. We have been using this regimen regularly for front-line treatment of patients with B-LCL and preexisting heart disease and present here our experience.

**Methods:** We performed a retrospective analysis of all newly diagnosed B-LCL patients treated with R-CEOP at our centre from 2011 to 2016 and compared them to patients 60 years or older treated during the same period with R-CHOOP, the standard regimen used at our centre for non-frail elderly without significant cardiac comorbidities. The dose of etoposide in R-CEOP was 50 mg/m2 iv or 100 mg/m2 orally daily for 3 days. Both regimens were given every 3 weeks for 6-8 cycles. Patients with initial bulky disease or in PR after systemic treatment were irradiated.

**Results:** 31 patients, 15 male and 16 female, received R-CEOP and 48, 25 male and 23 female, R-CHOOP. Patients in the former group were older (median age 77 y, range 58-87 vs median age 66 y, range 60-83), had more often low performance status (81% vs 31%) and advanced disease (84% vs 54% stage 3 and 4) resulting in a significantly higher proportion of patients with IPI 3-5 (74% vs 40%, p=0.019). Proportions of patients with increased LDH were similar between the groups. There were no significant differences in frequency of grade 3-4 toxicity between the regimens; 48% of patients in both groups required emergency hospitalization; thrombocytopenia or anemia occurred in 16% of R-CEOP and 23% R-CHOOP treated patients, infections in 32% and 31% and cardiovascular events in 16% and 21%. However, 7 patients (23%) in the R-CEOP group died during treatment due to adverse effects in comparison to 4 (8%) in the R-CHOOP group. Efficacy was similar, 65% responded to R-CEOP and 79% to R-CHOOP. After a median follow-up of survivors of 27 mo, 3-y OS was 55% in the R-CEOP group and 52% in the R-CHOOP group, 3-y EFS was 50% and 50%, respectively (figure). Outcomes of patients with GC and non-GC DLBCL categorized according to Han’s algorithm were similar irrespective of treatment.

![Figure 1](image_url)

**Summary/Conclusions:** Long-term outcomes of newly diagnosed B-LCL patients treated with R-CEOP seem as good as those achieved with R-CHOOP irrespective of cell of origin. Observed differences in treatment-related mortality were most probably caused by differences in age, comorbidities and performance status. R-CEOP should be considered as a regimen of choice for B-LCL patients with cardiac contraindications for anthracycline treatment.
E972
POST-TRANSPLANT LYMPHOPROLIFERATIVE DISORDERS: A SINGLE-CENTER CASE SERIES
C. De Miguel1, B. Navarro1, J. Martín2, P. Martín2, G. Anze1, A. Alarcón1, R. Fores1, C. Bellas2, J.R. Cabrera1
1Hematology, 2Pathology, Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda, Spain

Background: Post-transplantation lymphoproliferative disease (PTLD) is a complication of both solid organ transplant (SOT) and haematopoietic cell transplant (HCT) and represent a very heterogeneous group.

Aims: The objective of this study is to evaluate the epidemiology, clinical features, characterization and therapeutic management of this disease.

Methods: We evaluated a total of 52 patients diagnosed between May 1995 and February 2017. We analyzed the following data: type of transplantation, immunosuppression time from transplantation to lymphoma diagnosis, clinical stage, response to treatment and survival. We classified them morphologically according to the WHO criteria (2016 revision), using immunohistochemical and molecular techniques and their relationship with the Epstein-Barr virus (EBV) by studying the expression of EBERs. We correlated clinical data with morphological, immunohistochemical and molecular results.

Results: Among the 52 patients, 31 were men (59.6%) and 21 women. PTLD after SOT were 45 (86.5%), of which 16 were after liver transplant (35.6%), 14 cardiac (31.1%), 9 pulmonary (20%), 4 renal (8.9%) and 2 double (cardiac-pulmonary and cardiac-renal) (4.4%). There were 7 PTLD after HCT, 2 identical HLA family donor, 2 unrelated donor, 2 double umbilical cord blood and 1 autologous. Of the 52 PTLD, 48 were B lymphomas (92.3%), of which 26 were diffuse large B-cell lymphomas (DLBCL) (54.2%), 7 polymorphic (14.6%), 7 low-grade (14.6%), 4 Burkitt lymphomas (8.3%), 1 Hodgkin’s lymphoma (2.1%) and 1 T/NK lymphoma, 1 gamma/delta T lymphocytosis. 35/52 PTLD were EBV + (67.3%). The median time of immunosuppression was 123 months in renal transplant, 93 months in liver, 85.5 months in cardiac, 51 months in lung and 3 months in HCT. Histologically, it was 96 months in T lymphomas, 80 months in B lymphomas, being 51 months in EBV + and 124 months in EBV-. Fifty percent of Burkitt lymphomas were diagnosed after lung transplant, while 85% of low-grade lymphomas were diagnosed after liver transplant. Clinical stage was III/IV in 73% of the patients (38). Among the 52, 45 received treatment (86.5%), 37 with immunochemotherapy (82.2%) and 8 with Rituxin + Rituxin (17.8%). Three patients responded to reduction of immunosuppression (5.8%) and 3 did not receive any treatment for early death (5.8%). At the time of writing, 19 patients remain alive (36.5%) and 33 have died. The median survival of these patients was 19.5 months (0-198).

Summary/Conclusions: PTLD constitute a very heterogeneous group. Its appearance is much earlier in the HCT than in the SOT and, within this latter group, it is earlier after lung transplant and later after renal transplant. The most common type in our series is DLBCL. The majority are related to EBV, so post-transplant monitoring is essential, and its diagnosis is earlier than in EBV-.

Most low-grade lymphomas appear post-liver transplant, either in relation to viral infections or autoimmune diseases. Survival is significantly lower than in other primary LPS. -AR-SA-We analyzed the following data: type of transplantation, immunosuppression used in both induction and maintenance, immunosuppression time from transplantation to lymphoma diagnosis, clinical stage, response to treatment and survival. We classified them morphologically according to the WHO criteria (2016 revision), using immunohistochemical and molecular techniques and their relationship with the Epstein-Barr virus (EBV) by studying the expression of EBERs. We correlated clinical data with morphological, immunohistochemical and molecular results.

SURVIVAL OUTCOMES AFTER FIRST-LINE THERAPY IN DIFFUSE LARGE B-CELL LYMPHOMA (DLBCL) USING A UNITED STATES (US) ELECTRONIC MEDICAL RECORD (EMR)-BASED COHORT
A. Galaznik1, J. Bell1, L. Hamilton2, A. Ogbonnaya2, A. Raju2, K. Hennenfent2, M. Eady1, Y. Shou1
1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, 2Xcenda LLC, Palm Harbor, United States

Background: In the rituximab era, the recommended first-line therapy (1LT) in DLBCL patients who can tolerate combination therapy is rituximab combined with chemotherapy. For refractory/relapsed disease, high-dose chemotherapy with stem cell transplant, combination chemotherapy, or single-agent rituximab are considered. While the efficacy of rituximab has been shown in clinical trials, few studies have evaluated survival outcomes in patients seen in routine clinical care.

Aims: We evaluated survival outcomes in a US population of newly diagnosed DLBCL patients seen in routine clinical care.

Methods: In this retrospective study, adult patients ≥18 years old with newly diagnosed DLBCL were identified from the Humedica, a large US electronic medical record database, between 01/01/08 and 07/31/15. DLBCL diagnosis was determined by the presence of ≥1 inpatient record or ≥2 outpatient records with DLBCL diagnosis codes; the first DLBCL record served as the index date. Following the index date, initiation of 1LT for DLBCL was required. For the assessment of the survival outcomes, patients were evaluated from the date of treatment initiation until death, loss to follow-up, or end of study (09/30/15).

Median progression-free survival (PFS) (defined as initiation of second-line therapy, evidence of supportive care >30 days after the end of a line of therapy, or death), median overall survival (OS), and PFS and OS rates at 2 years following initiation of 1LT were evaluated using unadjusted Kaplan-Meier analyses.

Results: 1,436 newly diagnosed DLBCL patients who initiated 1LT met the patient selection criteria. 54.0% were male, and the mean age was 66.4 years (SD: 13.7) At baseline, 27.4% of patients had a Charlson Comorbidity Index of ≥2, and the most common comorbidities were diabetes (20.3%), chronic pulmonary disease (15.5%), and moderate to severe renal disease (9.5%). In 1LT, 92.1% of patients received combination therapy, with R-CHOP (63.5%) being the most common combination therapy. 7.9% of patients received monotherapy upfront, with rituximab (77.2%) being the most commonly used single agent. At 2 years following initiation of 1LT, the Kaplan-Meier OS and PFS were 79.2% and 67.3%, respectively. Median OS was not reached, and median PFS was 53.9 months (95% confidence interval: 45.2, 61.5). OS and PFS were also compared among patients receiving monotherapy vs combination therapy in unadjusted analysis. At 2 years, OS was 80.2% for patients receiving combination therapy vs 67.4% (P=0.0093) for patients receiving monotherapy. Also at 2 years, PFS was 68.3% for patients receiving combination therapy vs 55.1% (P=0.0051) for patients receiving monotherapy.

Summary/Conclusions: In this population of patients with newly diagnosed DLBCL receiving 1LT survival outcomes at 2 years were significantly improved for patients treated with combination therapy vs monotherapy. Future analysis will explore the differences in clinical characteristics of patients treated with monotherapy vs combination therapy in the 1LT setting.

**AN EXPERIENCE WITH LONG ACTING FACTOR VII PROPHYLAXIS IN PAEDIATIC AND YOUNG ADULT PATIENTS WITH HAEMOPHILIA A**

S. Verma1, A. Tripathi1,2, G. Suni1, N. Kumar1, R. Kushwaha1, A. Kumar1, P. Kumar1

1K G. Medical University Lucknow, Lucknow, India

**Background:** Hemophilia is an X linked inherited bleeding disorder. Recurrent joint bleeds and muscle bleeds are the common manifestations leading to long term comorbidities in hemophilia. High dose factor prophylaxis has been proven to be very effective in preventing joint problems in western world. We look for a cost effective and feasible way for Indian patients in terms of reduced dose and frequency of factor infusion. Data on prophylaxis with low dose long acting factor infusion on twice weekly dosing schedule is limited.

**Aims:** To study the efficacy and safety of long acting factor VII (Eloctate) for tertiary prophylaxis in pediatric and young adult patients with moderate and severe haemophilia A.

**Methods:** Thirty eight patients with moderate and severe haemophilia A without inhibitors and age range from 1 to 25 years were included in this study. Patients were initially observed for 4 months during which they received therapeutic doses of long acting factor VII, ELOCTATE (Factor VII with Fc Fusion Protein) on episodic basis after clinical bleed. In next 4 months they received prophylactic ELOCTATE, given intravenously at doses of 20 unit/kg body weight on twice weekly schedule. Annual bleeding rates, school absenteeism, emergency visits, aspects of quality of life and joint scores were compared during observation and prophylaxis period.

**Results:** Total number of bleeds during observation and prophylaxis period was 607 and 90 respectively. Annual bleeding rate was 47.9 during observation period and 7.1 during prophylaxis. There was 85.1% reduction in bleeding rates on prophylaxis. School/college absenteeism was 3.1 days/ month and 0.84 days/month during observation and prophylaxis respectively. Emergency visits were significantly more during observation. None of the patients developed inhibitors and two patients had superficial thrombophlebitis during prophylaxis.

**Quality of life assessment using KIDSCREEN QOL questionnaire showed moderate to marked improvement in quality of life domains during prophylaxis.**

**Summary/Conclusions:** Low dose, twice a week, long acting factor VIII prophylaxis can be a reasonable option for patients with haemophilia A in developing countries. It significantly reduces joint bleeds, school absenteeism, Joint scores significantly without risk of inhibitor formation and also improves all domains of quality of life.

**E975**

**NOVEL MUTATIONS IN THAI CHILDREN WITH CONGENITAL FACTOR VII DEFICIENCY**

D. Sopothikul1,2, T. Fungchaintai3, R. Ittwu1, P. Komvilaissak2, C. traivaree3, K. Supaphol3

1Department of Pediatrics, Chulalongkorn University, Bangkok, 2Department of Pediatrics, Khon Kaen University, Khon Kaen, 3Department of Pediatrics, Phramongkutklao Hospital and College of Medicine, Bangkok, Thailand

**Background:** Congenital factor VII (FVII) deficiency is a rare autosomal recessive coagulopathy disorder resulted from mutations in the FVII gene (F7). The disease severity is not correlated with FVII levels but might be determined by molecular effects in F7.

**Aims:** To delineate the phenotypic and genotypic characteristics of patients with congenital FVII deficiency.

**Methods:** We described demographic data, clinical manifestations, and outcome of patients with congenital FVII deficiency. F7 mutation analysis was performed by PCR-direct sequencing.

**Results:** Of the ten patients diagnosed with FVII deficiency, five (50%) were males. The median age (range) at diagnosis was 19 days old (1-730). Consanguinity was found in 50% of the patients. Of the nine patients (90%) classified as severe, six patients presented with intracerebral hemorrhage within the first month of life, two presented with gastrointestinal bleeding and one presented with hemarthrosis. There were eight different alterations identified. Four have been previously reported (c.1091G>A (p.R364Q), c.1238G>A (p.R413Q), c.1256C>T (p.T419M), and c.681G>T (IVS6+1T)). Four were novel (c.1192G>T (p.D398Y), c.1313G>T (p.G420V), c.291+2T>C (IVS3+2T>C), and IVS6-2A>G) that have been previously reported (c.1091G>A (p.R364Q), c.1238G>A (p.R413Q), c.1256C>T (p.T419M), and c.681G>T (IVS6+1T)). Four were novel (c.1192G>T (p.D398Y), c.1313G>T (p.G420V), c.291+2T>C (IVS3+2T>C), and IVS6-2A>G) and associated with major bleeding especially during infancy.

**Summary/Conclusions:** This study reported Thai children with congenital FVII deficiency presented with life-threatening bleeding especially in the first year of life. Pathogenic including newly identified variants in the F7 gene were detected in all cases. Genetic counseling can be appropriately provided to reduce the risk of disease recurrence in the families at risk.
E978

AUDIT ON MANAGEMENT OF HIGH INTERNATIONAL NORMALIZED RATIO (INR) IN WARFARINISED INPATIENTS

H. Hendra1, V. Gorur1,*, W. Nagi1

1Haematology, Broomfield Hospital, Chelmsford, United Kingdom

Background: Warfarin is the commonest used oral anticoagulant with an effective antidote. The British Committee for Standards in Haematology guidelines recommend administration of 25-50µg of four factor Prothrombin Complex Concentrate (PCC) and intravenous (IV) Vitamin K 5mg for patients with major bleeding, 1-3mg of Vitamin K intravenously for those with minor bleeding and 1-5mg of Vitamin K orally for patients with INR >8 and who have no signs of bleeding.

Aims: The aim of this audit was to compare our hospital’s performance against the above guidelines.

Methods: A total of 76 patients admitted between 01/08/2015-31/01/2016 were analysed retrospectively.

Results: There were 103 incidents with INR level 5-8 and 24 with INR >8 in these 76 inpatients. Bleeding was documented in 18/127 cases, which included 6 incidents of major and 12 incidents of minor bleeding. In major bleeding, warfarin was withheld and Vitamin K administered. However, 4/6 (66.7%) of these patients got a dose different to 5mg advocated. Also, PCC was prescribed in only 50% of these patients. While 9/12 (75%) patients with minor bleeding received Vitamin K, only 3 of these 9 patients received the recommended dose of 1-3mg IV. Vitamin K was unnecessarily given to 9/16 (56.25%) patients with INR >8 and who have no signs of bleeding.

Summary/Conclusions: Our audit highlighted that there is less than 100% compliance in the recommended dose and route of vitamin K administration. A flowchart containing the guidelines will be designed to improve the management of high INR. To increase the awareness of this issue, teaching sessions for junior doctors and nursing staff are planned. A re-audit will be conducted once these steps are in place.

E979

NOVEL AND RECURRENT F7 MUTATIONS IN KOREAN PATIENTS WITH COAGULATION FACTOR VII DEFICIENCY

H. Kim1,*, K.-Y. Yoo2, K.-O. Lee3, S.-H. Kim1, H.-J. Kim1

1Laboratory Medicine & Genetics, Samsung Medical Center, Sungkyunkwan University School of Medicine; 2Korea Hemophilia Foundation; 3Samsung Biomedical Research Institute, Seoul, Korea, Republic Of

Background: Coagulation factor VII deficiency is one of the rare hereditary bleeding disorders with relatively limited clinical and genetic data.

Aims: This study aimed to characterize F7 gene mutational patterns of Korean patients with coagulation Factor VII deficiency including their clinical and laboratory variability.

Methods: F7 gene mutations of total 16 unrelated Korean patients with Factor VII deficiency were identified by direct sequencing analyses of all exons and flanking intronic sequences. Variants were assigned according to the recently released criteria of 2015 ACMG standards and guidelines.

Results: A total of 14 mutations (pathogenic or likely pathogenic) were detected including four novel mutations (Glu66Lys, c.681+3A>T, Glu66Alafs, Ile290del). Six (38%) patients have 2 mutant alleles and three mutations were recurrently identified. The most frequent mutation detected in this study was Cys89Gly detected in 37% (11/30) patients, validating the data of our previous patient cohort.

Summary/Conclusions: Correlation of genetic data with coagulation laboratory and clinical findings suggested the presence of modifiers, which warrants further investigation in a larger cohort of patients for better clinical prediction and management in this rare bleeding disorder.

UTILITY OF CD157 IN A FLAER BASED SINGLE TUBE FIVE COLOR COMBINATION FOR SCREENING OF PAROXYSMAL NOCTURNAL HEMOGLOBINURIA CLONE

K. Rahman1,2, R. Gupta1, S. Harankhedkar1, T. Gupta1, M. Sarkar1, S. Nityanand1

1Hematology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

Background: Fluorescent Aerolysin (FLAER) based flow cytometric analysis of polymorphs and monocytes is the gold standard for the screening of paroxysmal nocturnal hemoglobinuria (PNH) clone. In recent years CD157 has been identified as a PNH marker which targets both polymorphs and monocytes. It can be used in a single tube five color combination to screen polymorphs and monocytes simultaneously.

Aims: The objective of this study was to analyse the utility and advantage of CD157 in the PNH screening along with its ability to replace CD24 and CD14.

Methods: Our routine protocol for PNH screening included single tube six color antibody cocktail in following combination: FLAER-AF488, CD24-PE, CD15-PerCP-Cy5.5, CD14-PerC7, CD64-APC, CD45-APC H7. We assessed the utility of single tube 5 color combination of FLAER-AF488, CD15-PE, CD15-PerCP-Cy5.5, CD64-APC, CD45-APC H7 for PNH screening and compared the results with the routinely used 6 color panel.

Figure 1.

Summary/Conclusions: CD157 is a robust, reliable and potentially useful universal marker for PNH screening. Its inclusion in a single tube five color FLAER based panel is a cost effective approach which is ready to replace CD24/CD14 from routine PNH screening.

E982

IMMUNOPHENOTYPIC DYSPLASTIC FEATURES IN PATIENTS WITH APLASTIC ANEMIA

Y. Davydova1,*, E. Parovichnikova1, I. Galtseva1, E. Mikhaylova1, N. Kapranov1, A. Kohn1, L. Kuzmina1, V. Troitakaya1, Z. Fidarova1, T. Moiseeva1, V. Savchenko1

1Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Multicolor flow cytometry (MFC) of bone marrow (BM) is a promising additional approach to the diagnosis of myelodysplastic syndromes (MDS). Aplastic anemia (AA) as MDS characterizes by cytopenias and dysplastic features in BM by morphology are absent. It is well known that up to 15% of AA transformed in MDS over time. It is possible to suggest that in some cases of AA immunophenotypic abnormalities can also be identified.

Aims: To study and compare the presence of dysplastic features by MFC in AA and MDS without excess of blasts.

Methods: The study included 14 patients with AA (8m, 6f, median age 33), 28 patients with MDS de novo without excess of blasts by morphology (13m, 15f, median age 59). MDS group included 3 patients with 5q-syndrome, 4 - RCUD, 3 - RARS, 18 - RCMD. 20 patients with cytopenias constituted the control group (4m, 16f, median age 42) due to B-12 deficiency anemia, iron-deficiency anemia, Fanconi anemia, hereditary anemia, 8-thalassemia, ITP; hepatitis C, multiple myeloma, Burkitt’s lymphoma. BM of 33 healthy donors was used as reference. FLAER was used for the reference values. MFC was performed according to International Leukemia-Net by 6-color cytometer BD FACSCanto II. We enumerated the proportion of CD34+ myeloid cells from CD45+ cells (normally <2%), the proportion of CD19+ (B-cell progenitors) from CD45+ cells (normally <5%), the expression of CD34, CD45, CD117, CD7, CD56 on CD34+ myeloblasts. Among granulocytes we analyzed: their proportion, granularity, CD14, CD64, CD45 expression and patterns CD16vsCD13, CD16vsCD11b, CD13vsCD11b. The final MFC conclusion was done by scale Ogata/Wells (van de Loosdrecht, 2013): A - does not correspond to MDS; B - reveals some features which commonly appears in MDS; C - results are consistent with MDS.

Results: Among MDS patients without excess of blasts assessment “B” and “C” scores were obtained in 78.6% (sensitivity). Increased proportion of CD34+ myeloblasts was in 35.7% of cases, increased CD56 and CD7 - in 42.9%. The most common abnormalities were: increased CD64 (53.6%), abnormal patterns (39.3%), low granularity (35.7%) in granulocytes; increased proportion (21.4%) and abnormal patterns (28.6%) in monocytes. 64.3% (n=9) patients with AA (CD157 was assessed as “A”, 21.4% (n=3) - “B” and 14.3% (n=2) - “C”. All “C” abnormal expression of CD117 and expression of CD56 on CD34+ cells were seen. AA patients with “B” and “C” showed increased expression of CD56, CD64 and decrease CD10 expression on granulocytes. Abnormal patterns were less common than in MDS patients. The increased proportion and CD56 expression in monocytes were more frequent than in MDS patients. All patients not diagnosed with AA, MDS were assessed as “A” (specificity 100%). But some MFC abnormalities were found in them: abnormal expression of CD34 (35%) and CD45 (30%) on CD34+ myeloblasts, and increased CD64 expression (20%) on granulocytes (pic.).

Table 1.

Summary/Conclusions: Flow cytometry MDS study with Ogata/Wells scale has a high sensitivity and specificity. Immunophenotypic abnormalities characterizing dysplastic features can also be found in AA patients up to 35% of cases. Increased expression of CD56 on CD34+ myeloblasts, granulocytes and monocytes is commonly found in AA patients. Perhaps the appearance of MFC dysplastic features foreshadows the MDS-transformation of AA, but requires further prospective studies.

E983

SURGICAL MANAGEMENT OF PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA (PNH) – DATA FROM THE SPANISH PNH REGISTRY

S. De La Iglesia1,*, C. Notario McDonell 2, A. Gaya Valls 3, M.T. Cedena4

1Madrid, Spain, June 22 – 25, 2017

Aims: Here we report data on the clinical management and treatment results of patients with PNH undergoing surgery.

Methods: We collected data on 14 surgical interventions of 11 patients (8 males; age, 25-76 years). All patients had a high prevalence of PNH clone cells (55-95% in PMPN) and were receiving eculizumab (ECU). Types of surgery were: 6 laparoscopic cholecystectomies, a transjugular intrahepatic portosystemic shunt, a distal splenorenal shunt, a laparoscopic Achilles allograft ligationoplasty, a gastrectomy, an emergency appendectomy, and 3 urologic interventions. Ten patients received ECU 900mg, while one patient surgery 6 received 1200mg since he had developed hemolysis at a previous surgical intervention (surgery 5). In two cases (patient G surgery 8; patient H surgery 11), an additional dose of ECU was administered before surgery. Patient H (surgery 11) had developed hemolysis at previous surgical interventions (surgery 9 and 10). In most cases, either the date of the ECU dose was taken into account when scheduling surgery or the ECU dose was moved forward to coincide with the date of surgery. The time between the last ECU dose and surgery was normally one day (range, 1-8).

Results: In nine cases, transfusions were required due to hemorrhagic complications. Patient I (surgery 12) had a thrombotic event leading to acute myocardial infarction one week after surgery. Increased hemolysis was observed (increased LDH and/or presence of hemoglobinuria) in five cases (patients E, H, I and K; surgeries 5, 9, 10, 12 and 14) during the week following surgery. Two of these patients (patients E and H) later underwent additional surgery (surgery 6 and surgeries 10 and 11, respectively). The pre-surgical ECU dose was increased in surgery 6 (patient E) and an extra dose was administered in surgery 11 (patient H) and no hemolysis was observed. (See Table 1).

Summary/Conclusions: Our findings lead us to recommend to perform the intervention within 24 hours of the administration of Ecu in programmed surgery for which it is necessary to program the dose. While in urgent surgical interventions put a new dose on the day of the intervention independently of the previous dose. Also the normal ECU dose could be increased or an extra dose be administered in order to minimize the risk of hemolysis in high-risk patients or in those with a previous history of surgery-related hemolysis.

Figure 1.

Results: The median age of the study population was 49 years (range, 18-73 years) at eculizumab initiation and the median duration of eculizumab treatment was 34 months (range, 6-44 months). Median LDH fold x upper limit of normal was 7.29 (range 2.4-23.7) and GFI-deficient granulocytes was 92.8% (range, 15.7-100%) at the time of eculizumab treatment. PNH-related signs and symptoms were thromboembolism (TE, n=19), renal failure (n=20), pulmonary hypertension (n=5), and severe/recurrent abdominal pain requiring opioids (n=17). Of 46 total patients, 12 (26%) were classified as having PNH/AA and 34 with classic PNH. There were no substantial differences in laboratory findings, transfusion requirement, or clinical findings and symptoms between the two groups. Treatment with eculizumab induced a rapid inhibition of hemolysis. At the time of 6 month follow-up, LDH level decreased to near normal levels in all patients and this effect was maintained until 36 months follow-up regardless of concomitant AA. Mean hemoglobin level significantly increased from the first 6 months of eculizumab treatment and the effect (hemoglobin above 10 g/dL) was sustained throughout 36 months in both groups. Transfusion-independence was achieved by 54.3% within the first 6 months of treatment and 86.4% by the last 36 months (83.3% in PNH/AA vs 87.5% in classic PNH). The mean number of RBC units transfused was significantly reduced from 8.5 units during the previous 6 months to 1.6 units for the first 6 months in total PNH patients (Fig). There were no significant differences in clinical outcomes (ie, LDH and transfusion unit per every 6 months) with eculizumab between the two groups. All TE (n=19) patients in whom 6 received concomitant anticoagulation therapy were resolved on the eculizumab; one classic PNH patient had recurrence of TE at the same site after discontinuation of anticoagulation therapy while on eculizumab. Among 9 patients who had baseline eGFR less than 60 ml/min/1.73m², 5 patients (56%) showed improvement of eGFR during the eculizumab treatment and 4 patients stabilized eGFR.
Summary/Conclusions: Clinical outcomes with eculizumab were significantly improved compared with the baseline in patients with both PNH/AA and classic PNH. This study demonstrated that eculizumab has a beneficial role in the management of patients with PNH/AA, similar to that of classic PNH, by inhibiting hemolysis and reducing transfusion requirements, thus resulting in the improvement of clinical signs and symptoms.

E985
DIAGNOSIS AND FOLLOW-UP OF THE CLONES OF PAROXYMAL NOCTURNAL HEMOGLOBINURIA BY FLOW CYTOMETRY
S. Oukid1*, S. Taoussi1, N. Rekab1, M.T. Abad1
1Hematology, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a very rare chronic disease associated with a clonal expansion of one or several hematopoietic stem cells carrying acquired somatic mutations of PIG-A gene resulting in GPI-AP deficient blood cells and great susceptibility to complement mediated cell lysis. Diagnosis of PNH is of importance and flow cytometry (FC) is a required tool for this. We report 33 cases of PNH diagnosed and monitored by FC.

Aims: To show the interest of flow cytometry for the diagnosis and follow-up of PNH clones in some risky haemopathies.

Methods: A PNH clone has been researched in 234 patients since August 2008 to January 2017. The PNH clone was investigated for bone marrow aspira- sion with or without haemolysis, regenerative hemolytic anemia with negative direct coombs test (DCT), myelodysplasia (MDS), unexplained cytopenia and thrombosis. The search for the PNH clone by FC is based on the analysis of the following monoclonal antibodies: Fcar and CD59 with gating on CD45 for neutrophils and CD14 for monocytes with gating on Glycophorin A for red blood cells. We judged that the patient has a PNH clone when the deficiency is >50% on at least two markers highlighted on two different lines. FC surveillance is provided in the absence of a deficit or in the case of a very moderate or single-line deficit.

Results: Out of 234 cases analyzed, 201 cases (85%) showed absence of PNH clone and 33 cases (14%) had a PNH clone. There are 14 women and 19 men; Sex ratio (M/F) = 1.35, mean age = 42.27 years (17-73). Among patients that should be screened for positive PNH clone we have bone marrow failure: 25 positive (21.9%) of 114 cases screened, hemolytic anemia with negative direct coombs test: 4 positive/63 cases (6.34%), thrombosis: 2 positive/28 (7.14%), one negative case of AML2, myelodysplasia with 02 (11.2%) positive/18 cases and cytopenias: 0 positive/13 cases. The types of PNH were type II in 3 cases (9%), type III in 24 cases (72.9%) and mixed deficits in 6 cases (19%). The mean degree of CD14 deficiency was 29.4% (5-82) on red blood cells 48.21% (5-95) on neutrophil (N); the mean degree of Fcar was 55.33% (9-59) on lymphocytes (

Table 1. NK T cell level (%) in patients with AA in remission according to subgroups.

Summary/Conclusions: Thus, in patients with AA the decrease of NK-cell level was observed along with recovery of hemopoiesis in all the subgroup vari- ants. Previously we have shown that the decrease of NK-T cells accompanies the increase of TNF and IL-6, but there was no correlation between the degree of all subgroups.

E986
ASSOCIATION OF T-, B-, NK AND NKT CELLS WITH THE DURATION, COMPLETENESS AND OTHER CHARACTERISTICS OF REMISSION IN PATIENTS WITH APLASTIC ANEMIA
O. Rozanova1, T. Glazanova1, E. Shilova2, L. Bubnova1
1Hematology, EHS ELCC CAC, Bilda, Algeria

Background: Immune-mediated dysregulation of hemopoiesis is the basis for pathogenesis of aplastic anemia (AA). Dysbalance of T cell subsets, especially Th1 and Th2, plays a significant role in the pathogenesis of this phenomenon. It is suggested, that NKT cells play an important role in the regulation of T lymphocyte subsets, and, especially NK-T cells during stable and prolonged remission are not characterized yet.

Aims: To evaluate the association of T-, B-, NK and NKT cells in AA patients with the duration of remission, its completeness, duration of period free of immunosuppressive therapy (IST) and the size of PNH-clone.

Methods: The studied group included 36 patients with AA in remission, reference group – 20 patients with primary diagnosed AA. Level of T-, B-, NK and NKT cells in peripheral blood (PB) and bone marrow (BM) was evaluated using 5-color flow cytometry (Beckman Coulter, FC-500).

Results: Group of AA patients in remission was divided into subgroups in four variants: 1) according to the remission duration (<12 months, 12-24 months, 24-36 months, >36 months); 2) according to completeness of remission (CR); 3) duration of IST-free period (<1 year, ≥1 year); 4) PNH-clone size (0.1-1%, 1-10%, >10%). Levels of T-, B- and NK cells in AA patients with remission varied broadly in different subgroups, but there were not revealed any clear tendency in their dynamics in all assigned subgroups, except for NK- and NKT cells in CR. NK cells in 10% of AA patients the level of NK-T cells in PB and BM exceeded normal level 1.8- and 2.2-fold, respectively. In patients with remission ≥36 months it significantly decreased both in PB and BM (data presented in table 1). In patients with PR, as compared with patients with primary AA, NK-T cells decreased 2.8- and 1.9-fold, respectively, and in patients with remission ≥36 months it significantly decreased both in PB and BM (data presented in table 1).

Table 1. NK T cell level (%) in patients with AA in remission according to subgroups.

Summary/Conclusions: Thus, we have shown that the decrease of NK-T cells accompanies the increase of TNF and IL-6, but there was no correlation between the degree of all subgroups.

E987
A NOVEL DUAL-REAGENT SINGLE TUBE FLOW CYTOMETRY ASSAY TO SCREEN PAROXYMAL NOCTURNAL HEMOGLOBINURIA
Bormann1, I. M. U. S. Sachdeva2, A. Ahluwalia1, B. Bose1, N. Varma1
1Hematology, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired hematopoietic stem cell disorder resulting from loss of membrane-bound glycosylphosphatidyl inositol (GPI) anchor protein. The disease is characterized by heterogeneous clinical phenotypes including intravascular hemolysis, cytopenias, bone marrow hypoplasia and atypical site thrombosis. Screening guidelines recommend documentation of the lack of at least two GPI-liked anti- gens on at least two cell lineages. Alexa fluor 488 conjugated fluorescent Aerolysin (FLAER-AF488) has become a mandatory component in FCM based PNH assays.

Aims: We have analyzed the feasibility of a novel dual-reagent assay for screening PNH, by a single tube, cost-effective approach for PNH screening.

Methods: EDTA anti-coagulated peripheral blood of patients referred to department of Hematology with clinical suspicion of classical-PNH/ aplastic anemia, was tested with a single tube panel of FLAER-AF488/CD33APC. Simultaneously, the routine two tube flow cytometry assay (established sensitivity of 0.1%) for screening for PNH was performed. The panel (FLAER-AF488, CD59 and FLAER-AF488 and FLAER/CD33/CD14 for monococytes) was performed in the same sample. Each tube was run till a minimum of 50,000 granulocytes were acquired or till the tube ran dry. A cluster of at least 20 FLAER negative events was considered for reporting PNH-clone positivity in both granulocytes and monococytes. The granulocytes and monococytes were considered positive and the respective clone sizes detected by both the strategies were compared.

Results: A total of 33 patients and 7 healthy controls were analyzed by both dual-reagent and conventional strategies. Among the thirty-three patients, twelve patients concurrently showed the presence of PNH clones by both methods. The rest twenty-one patients were negative for PNH clones in granulocytes and monococytes by both strategies, indicating complete concordance at a sensitivity of 0.2% (Chi Square p=0.000). Of the PNH positive cases, the mean PNH clone sizes among the granulocytes by dual-reagent and conven-
tional methods were 3.78% (range, 0.2-18.2) and 3.60% (range, 0.1-18.6), respectively. The mean PNH clone sizes among the monocytes by dual-reactant and conventional methods were 7.30% (range 0.2-29.4) and 7.32% (range 0.1-28.8), respectively. There was no significant difference in the granulocyte and monocyte PNH clone sizes determined by both the methodologies (p=0.000). There were significant correlations between the granulocyte PNH clone sizes (Pearson’s r=0.991, p=0.000) and the monocyte PNH clone sizes (Pearson’s r=0.991, p=0.000) detected by both the analysis strategies.

Summary/Conclusions: This pilot study demonstrates the practical feasibility of a simple, cost-effective and widely applicable dual-reactant, single tube PNH-screening assay at a sensitivity of 0.2%. The study needs to recruit patients of various hematological disorders besides healthy controls, and although seems effective for analyzing classic and subclinical PNH, the strategy has to be further standardized to achieve a sensitivity of 0.01%.

E988 TREATMENT OF REFRACTORY APLASTIC ANEMIA WITH ELTROMBOPAG: EXPERIENCE OF A CENTER
M. Gomes1,*, M.J. Teles2, F. Ferreira1, J.E. Guimarães1
1Clinical Hematology, 2Clinical Pathology, São João Hospital Centre, Porto, Portugal

Background: Eltrombopag, a thrombopoietin receptor agonist, was approved in 2008 for the treatment of immune thrombocytopenic purpura. More recently, benefits demonstrated in the proliferation and maintenance of hematopoietic stem and progenitor cells (HSTC) led to its use and approval in the treatment of severe aplastic anemia (AA) refractory to immunosuppressive therapy.

Aims: In this report, we evaluated response to eltrombopag in patients with refractory AA and associated side effects.

Methods: Retrospective analysis of six patients with a diagnosis of aplastic anemia and thrombocytopenia (platelet count ≤30,000/μL), refractory to immunosuppressive therapy and ineligible for allograft transplantation, treated with eltrombopag. Patients characteristics, response, clinical evolution and adverse effects were evaluated.

Results: Four patients were female and median age at diagnosis was 66 years (36-76). Previous treatments included horse antithymocyte globulin (1), cyclosporine (4), intravenous immunoglobulin (1), corticosteroids (4) and dexamethasone (1). Median duration of treatment with eltrombopag at the time of this analysis was 7 months (3-12). At 3 months, all patients had platelet counts >30,000/μL (median increase, 16,500/μL). Five patients improved hemoglobin levels (median increase, 2.2g/dL); 3 of them were previously dependent on red cell transfusions, and no longer needed transfusions. Four patients had increased neutrophil counts (median increase, 1110/μL). All but one patient received a maximum dose of 150mg per day. Only one patient needed temporary discontinuation due to hematological abnormalities, that were rapidly resolved. One other patient had mild elevation of liver enzyme levels. No other relevant side effects occurred.

Summary/Conclusions: Treatment with eltrombopag was associated with hematologic response of one or more hematopoietic lineage, independence of side effects occurred. The median duration of treatment with eltrombopag at the time of this analysis was 7 months (3-12). At 3 months, all patients had platelet counts >30,000/μL (median increase, 16,500/μL). Five patients improved hemoglobin levels (median increase, 2.2g/dL); 3 of them were previously dependent on red cell transfusions, and no longer needed transfusions. Four patients had increased neutrophil counts (median increase, 1110/μL). All but one patient received a maximum dose of 150mg per day. Only one patient needed temporary discontinuation due to hematological abnormalities, that were rapidly resolved. One other patient had mild elevation of liver enzyme levels. No other relevant side effects occurred.

Summary/Conclusions: Treatment with eltrombopag was associated with hematologic response of one or more hematopoietic lineage, independence of side effects occurred. Inhibiting Arginine Uptake in Chronic Lymphocytic Leukemia (CLL) Cells

**Background:** The gene expression profile of chronic lymphocytic leukemia (CLL) cells revealed a homogeneous phenotype related to memory B cells accompanied by an aberrant expression of several proteins. For example, lipoprotein lipase (LPL), typically expressed in adipocytes, is readily detected in CLL cells. However, unlike their normal counterparts which are resting cells, CLL cells do proliferate. What energy source CLL cells use and which metabolic pathway they recruit is currently unknown. Because the gene expression profile of CLL cells is skewed towards that of adipocytes, and because they proliferate at similar rates, we hypothesized that like adipocytes CLL cells utilize free fatty acids (FFA).

**Aim:** Determine whether CLL cells are capable of utilizing FFA for energy production. (B) Determine whether lipid metabolism in CLL is LPL dependent. (C) Determine why LPL is aberrantly expressed in CLL cells.

**Methods:** Peripheral blood (PB) and bone-marrow derived lymphocytes were obtained from previously untreated patients with CLL. Imaging of CLL cells was done by electron microscopy, and PB lymphocytes were stained for Oil red O. Confocal microscopy studies helped in determining the cellular localization of LPL. To study the capacity of CLL cells to utilize FFA we developed an assay that measured the oxygen concentration in the sera of cultured CLL cells prior to and after adding FFA. In addition we measured the oxygen consumption of CLL cells derived from ibrutinib-treated patients. We used immunofluorescence precipitation (CHIP) and luciferase assays to study the binding of STAT3 to the LPL promoter.

**Results:** To study whether CLL cells are capable of utilizing FFA we cultured cells with or without FFA for 20 hours to measure the consumption of cultured media-dissolved O2 (dO2) prior to and after adding FFA, assuming that if the cells oxidize the acid, dO2 levels will drop. Indeed, after 48 hours incubation with FFA dO2 levels were markedly reduced as compared with the dO2 media levels of CLL cell incubated without FFA. Remarkably, unlike cultured normal B cells, dO2 levels of cultured CLL cells did not change. Intriguingly, the levels of dO2 remained unchanged if CLL cells were incubated in the presence of FFA and ibrutinib. Similarly, the dO2 levels of CLL cells obtained from ibrutinib-treated patients remained constant, suggesting that ibrutinib disrupts the capacity of CLL cells to utilize FFA. Oil red O staining of CLL bone marrow smears detected lipid deposits and electron microscopy confirmed the presence of lipid vacuoles in the cytoplasm of peripheral blood CLL cells but not in normal B cells, suggesting that like adipocytes, CLL cells store lipids in intracytoplasmic lipid vacuoles. Similar to adipocytes, CLL cells express LPL which mediates the uptake of lipid particles into the cells and catalyzes the hydrolysis of lipids into FFA. Indeed, we detected LPL in the cytosol of CLL cells and in the cytoplasm of CLL cells. Furthermore, using small interfering RNA (siRNA) we knocked-down LPL mRNA levels and found that LPL-siRNA reduced the capacity of CLL cells to utilize FFA, suggesting that the lipid metabolism in CLL is LPL dependent. Because STAT3 is constitutively active in CLL cells, and because the LPL gene harbors STAT3 binding sites, we sought to determine whether STAT3 activates the LPL gene. Indeed, transfection of luciferase reporter gene constructs driven by LPL promoter fragments into MM1 cells revealed that STAT3 activates the LPL promoter. In addition, CHIP confirmed the binding of STAT3 to the LPL promoter. Furthermore, transfection of CLL cells with STAT3-shRNA downregulated LPL transcripts and protein levels, confirming that STAT3 activates the LPL gene.

**Summary/Conclusions:** Our data suggest that CLL cells undergo metabolic reprogramming and use strategies normally utilized by adipocytes. This process is driven by constitutively activated STAT3 and is inhibited by ibrutinib.
ence or absence of IL-4. Most of the investigated samples in this series showed reduced surface FcγR expression and increased surface IgM expression after IL-4 treatment, but a few cases showed only reduced FcγR expression and no change in IgM expression. Interestingly, these samples also showed greater anti-IgM induced phosphorylation of SYK, PLCγ2, AKT and ERK, suggesting that downregulation of FcγR is the primary mechanism through which IL-4 regulates the BCR signaling capacity of CLL cells. FcγR is downregulated by IL-4 and shows reduced expression in LN CLL cells, which could represent a mechanism to allow CLL cells to respond more effectively to stimulation with antigen encountered in the appropriate context.

Summary/Conclusions: These data show that FcγR is a negative regulator of BCR signaling in CLL cells. Overexpression of FcγR could be at least in part responsible for the reduced BCR signaling capacity of PB CLL cells. FcγR is downregulated by IL-4 and shows reduced expression in LN CLL cells, which could represent a mechanism to allow CLL cells to respond more effectively to stimulation with antigen encountered in the appropriate context.

E994 TRANSCRIPTION FACTORS AND CHECKPOINT INHIBITORS EXPRESSION WITH AGE: MARKERS OF IMMUNOSENESCENCE? L. Dong1, K. Williard-Clay2, S. Garaud2, H. Duvillier1, J.-N. Lodewyckx2, C. Solinas2, C. Gu-Trantien2, B. Stamatopoulou1, C. Sibile3, D. Bron1,7 1Clinical and Experimental Hematology, 2Molecular Immunology, 3Anatomopathology, INSTITUT JULES BORDET, ULB, Brussels, Belgium Background: Aging is characterized by a progressive decline in immune surveillance that favors tumor development in older patients. One mechanism used by malignant cells to escape immune surveillance is the upregulation of immune checkpoint inhibitors. Another process associated with aging is genetic or epigenetic modifications of tumor suppressor genes (TSGs).

Aim: To evaluate the correlation and potential role of BACH2 down-regulation and progression into a T cell lymphoproliferative disease, identifying the BACH2 gene as a candidate TSG. We thus examined the expression of specific transcription factors (BACH2 and PRDM1) and checkpoint inhibitors (PD-1 and PD-L1) in the major lymphocytes subsets for their potential role in immunosenescence.

Methods: Peripheral blood mononuclear cells were isolated from whole blood using Lymphoprep (Stemcell Technologies) density gradient centrifugation. Lymphocyte subsets (CD19+, CD3+CD4+; CD3+CD8+) were isolated for subsequent molecular analyses using the MACS Technology (Miltenyi), with the purity of each lymphocyte subpopulation between 95%-99%. PD-1 (PDCD1), PD-L1 (CD274), IL4, IFNG, BACH2 and PRDM1 mRNA transcripts were quantified using qRT-PCR. BACH2 and BLIMP1 (PRDM1) protein expression were examined by Western blotting.

Results: Blood samples were obtained from 60 healthy volunteers and 41 untreated B-cell lymphocytic leukemia (B-CLL) patients (median: 67yo). Healthy donors (HD) between the ages of 20 to 90 years subdivided into <50 yrs (median: 36yo) and >50 yrs (median: 65yo). BACH2 mRNA expression in the HD groups is significantly down-regulated in CD4+, CD8+ T cells and CD19+ B cells from the older HD group (P=0.0012; 0.0045 and 0.0067, respectively). BACH2 expression was further reduced in CD4+, CD8+ T cells and CD19+ B cells from CLL patients compared to HD well balanced for age (P=0.001; <0.0001 and 0.0043). PRDM1 mRNA expression was inversely correlated with BACH2 in CD4+, CD8+ T cells and CD19+ B cells (r=0.61; 0.71 and 0.85, respectively). Curiously, PRDM1 was – as expected – significantly upregulated in CD4+ T cells and CD8+ T cells (P=0.0034; P=0.0017) from B-CLL patients but not in their leukemic B. Western blotting analysis demonstrated that BACH2 and BLIMP1 (PRDM1) protein expressions in the T and B cell subpopulations were significantly correlated with transcript expression. BACH2 down-regulation was correlated with increased IL-4 mRNA expression (r=0.67) but not IFNγ in CD4+ T cells. These observations suggest that BACH2 down-regulation in CD4+ T cells could enhance the expression of effector memory-related genes, particularly Th2 such as IL-4 and PRDM1, PD-1 mRNA expression was up-regulated in CD4+, CD8+ T cells (P=0.0153 and 0.0214) in the older HD group and also up-regulated in the T cells from B-CLL patients (P=0.0014 and 0.0023) when compared to age-matched HD population. High PD-L1 mRNA expression was correlated with increased age in HD B cells (P=0.04) with a further increase detected in HD PB (p=0.001). We also observed an inverse correlation between BACH2 and PD-1 in CD4+, CD8+ T cells (r=0.62 and 0.68); and between BACH2 and PD-L1 in CD19+ B cells (r=0.66).

Summary/Conclusions: These data suggest that down-regulation of BACH2/PRDM1 and up-regulation of PD1/PD-L1 mRNA expression in major lymphocytes subsets from CLL patients and older healthy controls are significantly correlated with the aging immune cells and could be part of the immunosenescence process.

E995 T-CELL EXHAUSTED PHENOTYPE IS ENHANCED DURING DISEASE PROGRESSION IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) I. Jiménez1,2, S. Bobillo3, P. Abrisquetta2, C. Palacios2, J. Carabia1, M.J. Terol1, M. Crespo1, F. Bosch1 1Experimental Hematology, 2Hematology, Vall de Hebron Institute of Oncology, Barcelona, 3Hematology, INCLIVA Biomedical Research Institute, Valencia, Spain Background: The different biological mechanisms leading the clinical progression of CLL from early stages are currently not fully elucidated. Different progression factors that decades a higher probability of progression, such as the presence of mutated IGHV genes, 6q deletion and positivity of CD38 and ZAP70. However, we are still not able to identify an important proportion of patients that eventually progress. Clinical progression from early stages to an advanced CLL is associated with a certainly reduced acquisition of molecular changes that are not able to explain the fifty percent of the CLL cases progressing. CLL cells are dependent on survival and proliferative signals from the microenvironment and are able to evade immune anti-tumoral responses using different mechanisms, which is a crucial feature for cancer development. T-cell dysfunction is one of the main sources of impaired anti-tumor immunity. In CLL, T cells show functional defects and have increased expression of the exhaustion markers PD1, CD244 and CD160 compared to T cells from healthy individuals. Taking this into account, we hypothesize that changes in the microenvironment, and particularly in T-cell exhaustion component, are contributing to the clinical progression of CLL.

Aims: In order to explore the role of the immune system in the progression of CLL we studied the immunophenotype of T cells from CLL patients using paired samples at diagnosis and progression.

Methods: A total of 14 CLL patients (median age, 69 years; median time to progression of 29.5 months) and 6 patients diagnosed with CLL that did not experience clinical progression during a median follow up of 34 months were included in the study. Multicolor flow cytometry was performed in matched samples at two time-points: diagnosis and progression before treatment or diagnosis and follow-up. We studied T-cell differentiation status based on CD45RA and CD69 expression and the inhibitory receptors PD1, CD244, CD160, LA53, TIM3 and CTLA4. We also analyzed the expression of the transcription factors BACH2 and TIM3.

Results: We observed a significant increase in CD8+ absolute numbers (P=0.0107) and a significant decrease of the CD4:CD8 ratio (P=0.0012) with progression. T cells increased their effector memory (EM) (CD45RA-CCR7- phenotype during progression (EM CD4+ = P=0.0353; EM CD8+ = P=0.0223), PD-1 expression was significantly increased during progression in absolute numbers and up-regulated in CD8+ T cells (P=0.0161), as well as in the PD1+ EM subset (EM PD1+CD4+; EM PD1+CD8+ = P=0.0024). Interestingly, we did not observe these changes in CLL patients that did not progress where the absolute numbers of cells expressing PD1 were either diminished or maintained during the follow-up, pointing out an important role of PD1 in regard to CLL progression. We also observed that the percentages of CD38+ cells expressing CD244 and CD160 were higher at the time of progression, especially for CD244 (P=0.0078). Moreover, the co-expression of these markers with PD1 was found on CD8+ T cells and its percentage was increased during progression (P=0.0578). Among the differentiation subsets, the EM and EM CD45RA+ (TEMRA) CD8+ T cells expressed the highest percentages of CD244 and CD160. We did not observe changes in LA53, TIM3 and CTLA4. T-bet and Eomes are essential to regulate T-cell differentiation and their expression has also been associated with a progenitor (T-bethi PD1int) or a terminal (Eomeshi PD1hi) phenotype. The percentage of TEMRA CD8+ T cells expressing Eomes and PD1 were significantly increased during progression (P=0.0186 and P=0.0286, respectively) whereas T-bet expression was more stable.

Summary/Conclusions: T cells from patients with progressed CLL show a more severe exhausted phenotype compared to diagnosis, which is characterized by an effector memory subset with higher expression and co-expression of PD1, CD244 and CD160, as well as higher levels of the transcription factor Eomes, indicating that the terminal exhausted phenotype (Eomeshi PD1hi) is predominant. These changes may contribute to the immune evasion that facilitates the progression and to the immunosuppressive scenario that dominates advanced CLL stages. Functional assays to explain why this T cell subset is enhanced during progression are currently ongoing.

E996 EARLY SPECIFIC INCREASED EXPRESSION OF SURFACE IGm BUT NOT OF OTHER ASSOCIATED MOLECULES APPEARS TO REFLECT ANTIGEN STIMULATION IN CLL PATIENTS ON IBRUTINIB THERAPY S. Drennan1, G. Chioldi1, A. D’Avola1, P.W. Johnson3, L. Trentini2, G. Packham3, A.J. Steele3, F.K. Stevenson3, F. Corfoni1,4 1Haematology Oncology Group, Cancer Sciences Unit, University of Southampton, Southampton, United Kingdom, 2Cancer Sciences Unit, University of Southampton, 3Paola University School of Medicine and Department of Hematology and Clinical Immunology, Bambino Gesù Children’s Hospital, Rome, Italy, 4Haematology Branch, University of Padua, Padua, Italy, 3Cancer Sciences Unit, University of Southampton, 4Haematology Department, University Hospital Southampton NHS Trust, Southampton, United Kingdom Background: B cell receptor (BCR) signaling through surface IgM (slgM) is key to the survival and proliferation of normal and chronic lymphocytic leukemia (CLL) cells, and can be targeted effectively by the BTK inhibitor ibrutinib. Chronic exposure of the BCR to (super)antigen leads to downmodulation of slgM,
but not of slgD, levels and signaling capacity. This is evident in the circulating CLL B-cells which are characterized by variably reduced slgM levels/signaling. The variability influences outcome and cases with relatively higher slgM levels/signaling capacity, but not slgD, have more rapid progression, likely due to a proliferative component.

Aims: The aim of this study was to investigate the effect of ibrutinib in vivo on the expression and function of slgM and of other surface molecules associated with the BCR complex on the circulating CLL cells of patients during the early phases of therapy (first 3 months).

Methods: Peripheral blood mononuclear cells were collected from 12 CLL patients prior to (pre-) and at 1 week, 1 month and 3 months following commencement of single agent ibrutinib therapy. Expression of BCR-complex associated slgM, slgD, CD19 and other surface markers was assessed by flow cytometry. Signaling capacity following slgM stimulation was measured by immunoblotting. Following biotinylation of cell surface proteins, the N-glycosylation pattern of the µ chain was assessed by immunoblotting as a readout of slgM expression. Flow cytometry was performed on patients (REC: H228/02/01).

Results: At week 1 of ibrutinib therapy, there was a dramatic increase in the expression of slgM on the circulating CLL cells (mean fold increase 1.6, P<0.001), while expression of slgD and CD19 remained constant. At this time point, increased slgM expression associated with full N-glycan maturation of slgM heavy-chain, indicative of retrieval from antigen engagement at tissue sites. Also, the slgM levels correlated with increased anti-ιgM mediated SYK phosphorylation (r=0.64, P<0.03), to indicate functionality upstream of BTK. Sequential assessment at month 1 and 3 revealed that slgM levels were similar to that observed prior to therapy, with preserved upstream signaling ability. In marked contrast, the other BCR complex associated molecules slgD, CD19 and CD20 all reduced expression (P<0.001). Reduction of these markers was also accompanied by reduction of cell size and of other surface markers while overexpression of autophagy marker LC3B2 was documented.

Summary/Conclusions: Our data point to two major events dissociating slgM expression from other BCR-complex associated molecules. In the initial phase, the increased slgM expression and maturation, with no changes in other BCR-associated molecules, appears consequent to lack of antigen encounter, likely due to inhibition of chemokine-mediated entry to tissue sites. In the later phases the circulating CLL cells will suffer lack of tissue derived proliferation stimuli. In their absence, CLL cells will reduce expression of several markers and cell size, possibly explained by autophagocytic mechanisms aiming to protect the circulating CLL cells from death unless ibrutinib therapy is withheld.

ROLE OF THE COMBINATION MEK1/2 INHIBITOR BINIMETINIB AND AKT INHIBITOR MK2206 IN CLL
S. Sandhu1,2,*, S. Mulligan2,3, G. Best2
1Acute Medical Unit, Royal Melbourne Hospital, Parkville, 2Northern Blood Research Centre, Kolling Institute of Medical Research, 3Haematology, Royal North Shore Hospital, St Leonards, Australia

Background: Clinical trials of ibrutinib and idelisib demonstrate the efficacy of B-cell receptor-targeted therapies for CLL. We sought to investigate the efficacy of targeting both the BCR and the MAPK-ERK1/2 signaling pathways.

Aims: To evaluate the role of targeting the Ras-Raf-MEK1/2-ERK1/2/2 together with the PI3K-AKT pathways as a potential novel approach in treating chronic lymphocytic leukemia. In particular, assessing the efficacy of MEK1/2 inhibitor, binimetinib (MEK162), in combination with either a PI3K inhibitor, idelisib or an AKT inhibitor, M2206.

Methods: All experiments conducted on primary CLL cells were co-cultured with CD40L-expressing stroma which mimics the support conferred by the tumour environment. Firstly, the effects of MK2206 and idelalisib at doses varying from 1 to 40µM were tested on primary CLL cells. Secondly, binimetinib and MK2206 were tested as single agents and in combination at 20µM against primary CLL cells. Thirdly, binimetinib at 20µM combined with varying doses of idelisib on primary CLL cells. The mechanisms underlying the effects of binimetinib in combination with MK2206 in primary CLL cells were investigated by western blotting with changes in the expression of phosphorylated and total forms of AKT, MCL-1, and ERK1/2 assessed. Expression of B-actin was used as a loading control.
were observed while the combination with MK2206 was significantly more effective than either drug alone, suggestive of synergy between the two drugs (Figure 1B). The analysis of binimetinib at 20μM with idelalisib failed to demonstrate any additive effects or suggestion of synergy between the two drugs (Figure 1C). Binimetinib treatment led to an increase in the activity of AKT and a decrease in ERK1/2 phosphorylation. MK2206 completely abrogated the activity of AKT and MCL-1 phosphorylation when combined with binimetinib (Figure 2A). Although we observed a reduction in AKT phosphorylation following idelalisib alone, it had no effect on the levels of AKT activity induced by binimetinib or the levels of phosphorylated MCL-1 protein. This result was irrespective of the dose of idelalisib used (Figure 2B). We explored the possibility that protein kinase C (PKC) may be involved in binimetinib-induced AKT phosphorylation. Using the pan-PKC inhibitor GF109203X (GFX), we demonstrated that inhibition of PKC significantly reduces binimetinib-induced phosphorylation of AKT with no effect on the activity of ERK1/2-MAPK (Figure 2C). These data suggest a role for PKC in the regulation of AKT activity in CLL cells.

Summary/Conclusions: The combination of binimetinib and MK2206 in vitro has been shown to be an effective strategy to treat primary CLL cells. The western blot data reinforce that the increased activity observed in AKT activity in CLL cells following binimetinib treatment is independent of the idelalisib and totally abrogated by MK2206. This PIS kinase-independent regulation may be regulated by PKC, which may play a significant role.

Dual inhibition of MAPK-ERK1/2 and AKT signaling may be effective at targeting the proliferative drug-resistant compartment of CLL that resides in the tumour microenvironment.

E999
TARGETING HIF-1A AND ITS REGULATORY PATHWAYS AS A STRATEGY TO HAMPER LEUKEMIA-MICROENVIRONMENT INTERACTIONS IN CHRONIC LYMPHOCYTIC LEUKEMIA
C. Vitale1,2, V. Griggio1,2, M. Todaro1,2, C. Riganiti1, I. C. Salaroglio3, C. Salvetti1,2, M. Rigoni1,2, M. Foglietta1, B. Castella2, M. Boccadoro1,2, M. Massaia2,4, M. Coscia1,2

Background: The CXCL12/CXCR4 axis has a fundamental role in the microenvironment-mediated protection of chronic lymphocytic leukemia (CLL) cells from spontaneous and drug-induced cell death. The binding of CXCL12 with CXCR4 activates multiple intracellular pathways, including RhoA- and Ras-dependent signaling. We have previously shown that co-culture with stromal cells (SC) induces in CLL cells the activation of RhoA/RhoA kinase and Ras/ERK1-2 signaling, the upregulation of Akt, and an increased activity of the transcription factor HIF-1α (Rigoni et al., Oncotarget 2015).

Aims: The purpose of this study was to identify new potential pharmacological targets involved in the CXCL12/CXCR4 axis in order to impair the protection exerted by SC towards spontaneous and fludarabine-induced apoptosis in CLL cells.

Methods: Peripheral blood was collected from 62 patients with CLL. In selected experiments, the M2-10B4 murine SC line and the HS-5 human SC line were used. Patient-derived bone marrow SC were generated from 12 patients with CLL. Where indicated, cell cultures were treated with recombinant CXCL12 (100 ng/ml), CXCR4 inhibitor AMD3100 (5 μg/ml), fludarabine (F-ara-A, 10 μM), simvastatin (1 μM), ERK1-2 kinase inhibitor PD98059 (10 μM), HIF-1α inhibitor BAY87-2243 (1 μM), and PI3K inhibitor idelalisib (10 μM). RhoA and Ras activities were evaluated by an ELISA-based assay and by pull-down assay, respectively. ERK1-2, HIF-1α amount in whole cell extracts and in nuclear fraction, and HIF-1α phosphorylation were evaluated by Western Blot. RhoA kinase, Akt and HIF-1α activities were measured with specific immunoassay kits. CXCL12 was quantified by ELISA. Cell viability was determined by Annexin-V-propidium iodide immunostaining and flow cytometry analysis.

Results: In the exposure of CLL cells to recombinant CXCL12 led to the activation of RhoA- and Ras-dependent signaling, and to the downstream upregulation of HIF-1α. The CXCR4 antagonist AMD3100 completely abrogated the positive regulation exerted by both CXCL12 and SC, thus unveiling the key role of the CXCL12/CXCR4 axis in the SC-induced modulation of these signaling pathways. The inhibition of Ras and RhoA activity by simvastatin, and the inhibition of ERK1-2 and HIF-1α by PD98059 and BAY87-2243 effectively blocked the SC-induced expression and activity of HIF-1α, significantly impairing the SC-mediated protection of CLL cells, both in absence and presence of fludarabine. Similar effects were observed by targeting the PI3K/Akt pathway with idelalisib. We then investigated whether targeting RhoA- and Ras-dependent signaling could modulate HIF-1α also at the SC level. Simvastatin and BAY87-2243 effectively inhibited HIF-1α expression both in SC lines and in patient-derived SC. Moreover, simvastatin significantly reduced the secretion of CXCL12, which is a known transcriptional target of HIF-1α.

Summary: Our data demonstrate that the targeting of HIF-1α and its regulatory pathways, both at the tumor cell and at the SC level is an appealing strategy to overcome the microenvironment-mediated protection toward spontaneous and fludarabine-induced apoptosis in CLL cells.

Anna Hospital, Ferrara, 5Department Medical Sciences, University of Milan, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Chemomunotherapy with fludarabine, cyclophosphamide and rituximab (FCO) is the optimal front-line treatment for fit chronic lymphocytic leukemia (CLL) patients. IGHV mutations and FISH lesions are predictive markers of response and progression-free survival after FCR. Minimal residual disease (MRD) is the single best post-treatment predictor of long-term outcome after FCR, independent of biologic prognostic markers.

Aims: To explore whether conventional biologic markers (i.e. IGHV mutations, FISH lesions) and TP53, NOTCH1, BIRC3 and SF3B1 mutations can predict the attainment of a MRD negativity after first-line treatment of CLL patients with FC and ofatumumab (FOC).

Methods: Eighty young (≤65 yrs) and fit CLL patients from 15 Italian centers were enrolled in the GIMEMA LLC0911 first-line trial and treated with 6 cycles of FCO. CLL diagnosis, treatment requirement and response were defined according to the 2008 iwCLL guidelines. MRD was evaluated in responding patients by 8-color flow cytometry in the peripheral blood (PB) and bone marrow (BM) 2 months after the end of induction (month +8), and every 6 months thereafter: flow negative cases were analyzed by RQ-PCR, according to the guidelines. The association between CLL biologic markers and MRD clearance after FCR was tested by Fisher’s exact test. Logistic regression models were used to estimate the risk values in univariate and multivariate analyses.

Table 1.

Results: Sixty-five responding patients underwent MRD evaluation at month +8; their biologic features are reported in the Table. By flow cytometry, 25/65 (38%) resulted MRD+ in the PB and/or BM, while the remaining 40 (62%) showed no residual CLL cells. The absence of del17p+TP53mut/del11q was associated with the achievement of MRD negativity: 37 MRD- (74%) vs 13 MRD+ among patients with trisomy 12/negative FISH/del13q/TP53WT vs 2 MRD- (14%) vs 12 MRD+ among del17p+/TP53mut/del11q+ (p=0.0001). Interestingly, when patients were stratified into high (n=6), intermediate (n=22), low (n=21) and very-low risk (n=15) groups by integrating FISH and gene mutations (Rossi et al., Leukemia 2010), 18/22 (82%) vs 16/39 (41%) vs 10/21 (48%) vs 5/15 (33%) resulted MRD- (Fisher’s exact test p<0.05).

410 | haematologica | 2017; 102(s2)
et al., 2013), the high and intermediate risk groups (del17p/TP53/BIRC3+) or del11q/NOTCH1/538F+) showed a significantly lower probability of achieving a MRD negativity (36%, 10/28) than the low and very low risk groups (+12/ negative FISH/del13q/WT for 4 genes: 81%, 29/36) (p=0.0003). The 40 flow cytometry MRD- cases were also evaluated by ROC-PCR: 22 (55%) were reclassified as MRD+. By combining the two methods, 47/65 cases (72%) were MRD+ and 18/65 (28%) MRD- at the end of FCO. Mutated (M)-IGHV status was signifi-
cantly associated to a molecular MRD- (12 MRD-15 MRD+, 44%) compared to unmutated (UM)-IGHV cases (5 MRD-/32 MRD+, 13%) (p=0.0092). Moreover, when M-IGHV status is reinforced by the absence of del17p/ TP53/ndel11q, the association with a deeper MRD negativity got stronger (12 MRD-15 MRD+, 44% vs 5 MRD-/32 MRD+, 13%; p=0.0038). A multivariable model including FISH lesions, gene and IGHV mutations supports the inde-
pendent role of FISH and IGHV profile in predicting MRD negativity by flow and ROC-PCR, respectively.

### Summary/Conclusions:

In CLL patients treated with the FCO combination (L3), the Gata regulation of MRD negativity by flow cytometry (82%) can be predicted by the FISH profile: 74% in patients without del17p/ndel11q vs 14% in del17p+/del11q+ cases. A deeper MRD negativity by ROC-PCR (28%) can be anticipated by the IGHV status (44% M vs 13% UM) or by combining IGHV and FISH. A longer follow-up will determine whether these parameters can identify patients who maintain over time a good quality of response.

**ISOCROMOSOME 17q, UNBALANCED TRANSLocations AND 8q GAIN REPRESENT adverse prognostic factors in chronic lymphocytic leukemia (CLL)**

**Summary/Conclusions:** The type of chromosomal abnormality leading to 17p- is a prognostic factor, especially del17p+. However, the remaining allele being generally mutated. The presence of additional gene abnormalities accompanying the 17p- unbalanced translocations were found in 121/195 (63%) of patients. Combining FISH and K, del13q was detected in 71/118 (60%) of cases, del8p in 40/189 (21%), tril2 in 30/195 (15%), gain8q in 13/105 (12%), and del11q in 20/161 (12%). By univariate analysis, the parameters which were associated with significantly shorter follow-up were: age ≥65 years (p=0.0092); and gain8q-17p+ (p=0.0003). The 40 flow cytometry MRD- cases were also evaluated by ROC-PCR: 22 (55%) were reclassified as MRD+. By combining the two methods, 47/65 cases (72%) were MRD+ and 18/65 (28%) MRD- at the end of FCO. Mutated (M)-IGHV status was significantly associated to a molecular MRD- (12 MRD-15 MRD+, 44%) compared to unmutated (UM)-IGHV cases (5 MRD-/32 MRD+, 13%) (p=0.0092). Moreover, when M-IGHV status is reinforced by the absence of del17p/ TP53/ndel11q, the association with a deeper MRD negativity got stronger (12 MRD-15 MRD+, 44% vs 5 MRD-/32 MRD+, 13%; p=0.0038). A multivariable model including FISH lesions, gene and IGHV mutations supports the inde-
pendent role of FISH and IGHV profile in predicting MRD negativity by flow and ROC-PCR, respectively.

pendent role of FISH and IGHV profile in predicting MRD negativity by flow and ROC-PCR, respectively.

---

**Background:** Microenvironment found in bone marrow and lymph nodes supports survival, proliferation and drug resistance in chronic lymphocytic leukemia (CLL). Indeed, CLL cells are highly dependent on interactions with the microen-
vironment. The BCR is one of the key players involved in the crosstalk between CLL cells and the microenvironment. Furthermore, it has a critical role in patho-
genesis and prognosis of CLL. Accordingly, different factors related to increased BCR signaling are adverse prognostic factors in CLL, such as IGHV genes, high expression of ZAP-70 and increased serum levels of CCL3. Expression of ZAP-70 in CLL cells has been related to enhanced response to BCR stimu-
lation, as well as to increased response to diverse migrative and survival stimuli from the microenvironment. MiR-21 is an oncogenic microRNA that has been found to be overexpressed in a wide variety of neoplasms where it participates in oncogenic events such as proliferation, resistance to treatment, and meta-
tasis; its overexpression in CLL has been associated to refractoriness to flu-
conazole and to shorter overall survival and higher probability of progression. Aims: In order to further elucidate the molecular mechanisms defining bad prognosis CLL by further elucidation of the role of ZAP-70 in the crosstalk between CLL cells and the microenvironment, we studied the relationship between ZAP-70 protein and miR-21 and how it is influenced by the microen-
vironment. From this, we can hypothesize a model of chromosomal abnormalities that may be involved in the crosstalk between CLL cells and the microenvironment.

**Methods:** Peripheral blood mononuclear cells (PBMC) from 48 patients diagnosed with CLL were isolated by Ficoll-Paque Plus density gradient centrifugation. Ramos B-cells stably transfected with a vector encoding for ZAP-70 protein fused with Green fluorescent protein (GFP) or GFP only as a control were treated with Akt (LY294002) and MAPK (PD98059) and STAT3 (USI-124) inhibitors for 1 hour. BCR was stimulated with F(ab)2 anti-IgM. PBMC were co-cultured with bone marrow stromal cells with CD40L and CpG to mimic the microen-
vironment found in proliferation centers. After 48 hours CLL cells were harvested to analyze cell viability, cell proliferation and mRNA expression. Expression levels of miR-21 were evaluated by primary miR-21, miR-21, PTEN, PDCD4 and PIA33 were measured by QRT-PCR.

**Results:** First, we observed that miR-21 expression was significantly higher in patients with high expression of ZAP-70. Subsequently, using stably transfected Ramos B-cells with ZAP-70 protein we found that pri-miR-21 and mature miR-
-21 were significantly increased upon ZAP-70 stimulation, as well as enhanced by ectopic expression of ZAP-70. We also observed that inhibition of both MAPK and STAT3 pathways impairs the regulation of miR-21 expression after ZAP-70 activation. Moreover, the induction of miR-21 expression after ZAP-70 activation also induced downregulation of the tumor suppressor gene PTEN, as well as increased expression of miR-21. Moreover, we observed that miR-21 was up-regulated in the microenviron-
ture of primary CLL cells induced ZAP-70 and miR-21 expression, as well as downregulation of the putative miR-21 targets. Interestingly, the increase in miR-21 after co-culture was significantly impaired by ibrutinib, indicating that miR-21 expression was modulated by the microenviron-
ment. From this, we can hypothesize a model of chromosomal abnormalities that may be involved in the crosstalk between CLL cells and the microenvironment.

**Summary/Conclusions:** In conclusion, stimuli from the microenvironment are capable of regulating expression of miR-21 and tumor suppressor genes
E1003 IMPACT OF RECURRENT MUTATIONS ON PROGRESSION-FREE SURVIVAL IN CLL PATIENTS TREATED WITH FRONT LINE RITUXIMAB-BASED REGIMENS

G. Pavlasova1,2,*, M. Borsky2, V. Svobodova1,2, K. Musilova1,2, K. Cerna1,2, V. Seda1,2, J. Osickova 2, Y. Brychtova 2, M. Doubek 2, S. Pospisilova 1,2, 1Molecular Medicine, CEITEC MU, 2Department of Internal Medicine - Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Brno, Czech Republic

Background: Regimens consisting of rituximab and DNA-damaging drugs represent an important therapeutic option for patients with chronic lymphocytic leukemia (CLL). Up-to-date studies including clinical trials agreed upon the advantage of TKP53-defective patients that should be provided alternative treatment approaches. Additionally, mutations in NOTCH1 gene were connected with a lack of benefit from rituximab added to chemotherapy. A potential impact of other mutations commonly occurring in CLL patients remains less clear, namely regarding a role in relapse development.

Aims: (a) to assess impact of mutations in ATM, SF3B1, NOTCH1 and BIRC3 genes on progression-free survival (PFS) in CLL patients treated with front line rituximab-based regimens, and (b) to analyze clonal evolution of mutations in relapse.

Methods: We analyzed 53 CLL patients administered first line regimens FCR (fludarabine, cyclophosphamide, rituximab) or F-Q-FCR (FCR with reduced doses) or BR (bendamustine, rituximab); all harbored intact TP53 gene as assessed by FISH and the yeast functional analysis; 46/53 (87%) had unmethylated IGHV. The next generation sequencing using MiSeq (Illumina) was done in 53 CLL patients, with 41 relapsed samples using three different panel sets: ATM (exons 2-63; median coverage (MC) 6100), SF3B1/NOTCH1/BIRC3 (exons 14-16, part of 34, and 7-10, respectively, MC 11200), and TP53 (exons 2-11; MC 31500). Functional impact of ATM mutations was verified by SIFT and PolyPhen online tools. Only mutations present in >10% of reads were considered for the PFS analysis (log-rank (Mantel-Cox) test); the interval was calculated from therapy completion to clinical progression (as defined by the iwCLL recommendations).

Results: In the pre-treatment analysis, we identified 23 patients with one disrupted gene and 7 patients with two disrupted genes; the rest of the cohort (n=23) harbored all the mutations (wt). The most frequently affected gene was ATM (15 cases; only mutations with predicted functional impact considered), followed by SF3B1 (10 cases; hot-spot mutations), NOTCH1 (7 cases; all deletion c.7541-7542) and BIRC3 (5 cases; frame-shift mutations). We did not observe significant differences in PFS among the employed regimens: the median PFS was 30.5 months and the PFS rates at 5 years were 42.2% (SD 18.7; P=0.96) in the ASCT arm versus 44.0% (SD 18.5; P=0.96) in the chemotherapy arm. Our pilot analysis with limited number of samples (n=13) demonstrated that patients with mutated TP53 have significantly shorter median survival (15.5 m; P=0.041). Analysis of clonal evolution in patients who relapsed (41 paired samples) showed that: (i) only one sample showed no significant change in the number of mutated clones (n=13); (ii) in a more detailed analysis, we observed that the frequency of mutations in ATM gene was higher in late relapse (3% vs 18%) and in patients who relapsed at different timepoints (9% vs 16%); (iii) overall, we observed that the number of mutations in ATM gene as well as their frequency in early relapse (20% vs 42%) and late relapse (5% vs 13%) was significantly higher in patients who relapsed (P<0.05).

Summary/Conclusions: Our pilot analysis with limited number of samples does not indicate an adverse impact of mutations in ATM gene on PFS. In the ongoing analysis, we aim to evaluate impact of mutations in ATM, SF3B1, NOTCH1 and BIRC3 genes on PFS in a larger number of patients treated with front line rituximab-based regimens. We also plan to analyze clonal evolution of mutations in relapse, as well as their impact on survival.

E1004 BCR SIGNALLING PROFOUND CHRONIC LYMPHOCYTIC LEUKAEMIA B CELLS ARE PRONE TO RITUIMAX MEDIATED ELIMINATION IN VIVO

G. Pavlasova1,2,*, M. Borsky2, V. Svobodova1,2, K. Musilova1,2, K. Cerna1,2, V. Seda1,2, J. Osickova 2, Y. Brychtova 2, M. Doubek 2, S. Pospisilova 1,2, 1Molecular Medicine, CEITEC MU, 2Department of Internal Medicine - Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Brno, Czech Republic

Background: Anti-CD20 monoclonal antibody rituximab (RTX) has improved clinical outcome of patients with CD20-positive B-cell malignancies, including chronic lymphocytic leukemia (CLL). However, despite the fact that RTX has been clinically used for 20 years, the exact mechanism of its action remains largely unclear.

Aims: The aim of this study was to determine susceptibility of CLL cells’ subpopulations to RTX.

Methods: Peripheral blood samples from CLL patients (N=17) were obtained and analysed before (day 0) and 24 hours (day 1) after RTX administration (375mg/m2, single agent).

Results: It was described that CLL cells that interacted with stromal cells in vivo can be characterised by relatively weak cell-surface expression of chemokine receptor CXCR4 and high expression of activation marker CD56. In our study, RTX-treated and untreated CLL cells were co-cultured in the presence of fibroblasts. We showed that RTX significantly increased CXCR4 expression (~2-fold, P<0.005) which was coupled with higher responsiveness of the CXCR4+CD56+CD20- subpopulation, since CD20 was proposed to play a role in BCR signalling. We observed that CXCR4+CD56+CLL cells have higher immunoglobulin (IgM) expression (~2-fold, P<0.005) which was coupled with higher responsiveness to BCR crosslinking with anti-IgM (P<0.005). Moreover, CXCR4+CD56+CLL cells also have higher levels of CD19 (1.8-fold, P=0.001), which is an important component of BCR complex that augments signal transduction. Furthermore, we demonstrated that CXCR4+CD56+CLL cells have higher phosphorylation of several proteins involved in PI3K/BCR/NFkB signalling pathway (P<0.05) compared to CXCR4+CD56+CLL cells obtained from the same patient. This led us to hypothesize that the regulation of BCR signalling is likely of physiological importance for PI3K/BCR signalling. Indeed, we observed significant reduction in phosphorylation of tyrosine-protein kinases associated with PI3K/BCR signalling after silencing of CD20 by siRNA in B cells.

Summary/Conclusions: We showed that CXCR4+CD56+CLL subpopulations in peripheral blood of CLL patients has the highest surface levels of CD20 and is therefore preferentially and effectively eliminated by RTX. These CLL cells likely represent the most “aggressive” subclone of CLL cells since they have relatively high proliferative and BCR signalling capacity.

E1005 REGULATION OF BCR SIGNALLING IN CHRONIC LYMPHOCYTIC LEUKAEMIA: ROLE OF E3 UBQUITIN LIGASE C-CBL

V. Martinelli1,2, R. Molfetta3, F. Severini1,2, V. Trimarco1,2, F. Raggi1,2, L. Martiniello1, A. Visentin1, E. Scomazzon1, M. Facco1,2, G. Semenzato1,2, R. Padini2, L. Trentin1,2, 1Department of Medicine, University of Padua, 2VIMM, Venetian Institute of Molecular Medicine, Padua, 3Department of Molecular Medicine, University of Sapienza, Rome, Italy

Background: in normal B cells, the E3 ubiquitin ligase Cbl (c-Casitas B-lineage lymphoma) is involved in the ubiquitin-dependent Lyn degradation and in the down-regulation of BCR signalling. c-Cbl is activated by phosphorylation that releases c-Cbl from its autoinhibited structure by triggering a conformational change that leads to an enhanced transfer of ubiquitin from the E2 enzyme to the substrate proteins. Mutations in this RING/Linker region result in the loss of ubiquitin E3 ligase activity thus prohibiting lysosomal or ubiquitin/proteasome-mediated degradation of tyrosine kinases and thereby unleashing tyrosine kinase signalling. We reported that in Chronic Lymphocytic Leukemia (CLL) Lyn is over-expressed and is in an active conformation as integral component of an aberrant cytosolic multicomponent complex, associated with several proteins, (CXCR4, SDF1, HS1 and Calpain I among others) that can contribute to cytosolic Lyn, thus stabilizing the aberrant complex and converting individual transient interactions into stable ones. Aims: The accumulation of clonal B lymphocytes in CLL is mostly due to apoptosis resistance but also to proliferative activity. Abnormalities of molecules involved in signal transduction associated with lymphoid cells and a strongly reduced and a critical role has already been ascribed to B-cell receptor (BCR)-Lyn axis. Here, we investigated the expression and the role of c-Cbl in CLL B cells since in normal B cells it is involved in the ubiquitin-dependent Lyn degradation and in the down-regulation of BCR signalling.

Methods: Peripheral blood samples were collected from 30 CLL patients and 15 controls. Untouched peripheral blood B cells were purified using the RosetteSep isolation kit for human B cells. We characterized c-Cbl total protein level and c-Cbl(Y700) by Western blotting. To evaluate the interaction between c-Cbl and Lyn in CLL...
B cells we performed a co-immunoprecipitation assay, followed by Western blotting analysis, at steady state and after IgM (10µg/ml) stimulus. We also evaluated the interaction between c-Cbl and Lyn after treatment with 17-DMAG (500nM), a potent HSP90 inhibitor.

**Results:** We demonstrated that c-Cbl is overexpressed (p<0.001, Student’s t test) in CLL B lymphocytes with respect to normal B cells. We found that in neoplastic B cells c-Cbl did not co-immunoprecipitate with Lyn neither after BCR trigger. We obtained similar results when we treated neoplastic B lymphocytes with 17-DMAG to dissociate the Lyn-Hsp90 complex: after 1h, 2h and 4h of treatment we immunoprecipitated Lyn demonstrating that neither before nor after IgM stimulation c-Cbl interacts with this kinase. These results support the hypothesis that c-Cbl is not involved in Lyn turnover. Data obtained from 10 independent experiments showed that in CLL neoplastic cells the phosphorylation on Y700 increased after 5’ and 10’ of IgM stimulus, highlighting the involvement of c-Cbl in BCR signaling.

**Summary/Conclusions:** These preliminary results prompt us to investigate the role of c-Cbl in the development of neoplastic clone. In CLL cells c-Cbl is overexpressed with respect to normal B cells, and upon BCR engagement it undergoes Y700 phosphorylation. However, c-Cbl is unable to stably interact with Lyn suggesting an altered c-Cbl function that contribute to cell homeostasis.

**ACTIVATION OF SHP-1/PP2A PATHWAYS TRIGGERS APOPTOSIS IN CHRONIC LYMPHOCYTIC LEUKEMIA CELLS**

F. Severin1,2, E. Tubăl2, M.A. Pagano4, F. Frezzato2, V. Trimmer1,2, V. Martin1,2, F. Raggi1, L. Martino1, M. Faccio1,2, G. Zagotto4, G. Ribaudo1, V. Pavan4, L. Bordin3, L. Trenni1,2.

1Department of Medicine, University of Padua, 2Venetian Institute of Molecular Medicine (VIMM), 3Department of Molecular Medicine, 4Department of Pharmaceutical and Pharmacological Sciences, 5Department of Biomedical Sciences, University of Padova, Padova, Italy

**Background:** CLL B cells inability to reach programmed cell death is due to intrinsic defect and extrinsic factors. Among the intrinsic fault there is the mis-regulation of the phosphorylation pattern. Reversible protein phosphorylation is a fundamental post-translational modification by which virtually all cellular events are regulated. The crucial players involved in this dynamic process are protein kinases and protein phosphatases, which are placed at the different levels of cellular signaling. The Src Family Kinase (SFK) Lyn is a key factor in the dysregulation of survival and apoptotic pathways of malignant B cells in CLL. One of the effects of Lyn’s action is the spatial and functional segregation of the tyrosine phosphatase SHP-1 into two pools, one beneath the plasma membrane and an active pool in the cytosol which is dependent on Lyn activation, after 24 and 48 hours with/without a layer of Mesenchymal Stromal Cells (MSCs). Caspase dependence was demonstrated using the pan-caspase inhibitor z-VADfmk.

**Methods:** B cells were isolated from 37 CLL patients. Freshly isolated CLL cells incubated with increasing concentrations of nintedanib (0-24 µM) and MP07-66 (2,2-diethoxyethyl[f4-(3-hexyloxy)phenyl]methyl]amine) for 24 and 48 hours with/without a layer of Mesenchymal Stromal Cells (MSCs). Caspase dependence was demonstrated using the pan-caspase inhibitor z-VADfmk.

**Results:** We performed in vitro phosphatase activity assays on the cytosolic pool of SHP-1 in the presence of increasing concentrations of nintedanib, a receptor tyrosine kinase inhibitor recently shown to trigger SHP-1 activity. Nintedanib treatment could activate the phosphatase (at Ser951), and inhibited, form of SHP-1 and to induce apoptosis, depending on the caspase activation, after 24h and 48h at marked level. Interestingly, we recently demonstrated that Ser91 phosphorylation of SHP-1 could be dephosphorylated by MP07-66. In this scenario, the restoration of PP2A activity by a fingolimod analogue devoid of immunosuppressive action, called MP07-66, and the subsequent dephosphorylation of PP2A substrates, was shown to trigger apoptosis, like nintedanib, in a caspase-dependent manner. Since our data suggest that the activation of either PP2A or SHP-1 is triggered by specific small molecules caused stimulation of each one or activity, we treated CLL cells with nintedanib and MP07-66 together demonstrating an improved effect when used in combination. Similar results, in all the conditions, were obtained in presence of a MSC layer, showing the capability of these treatments to counteract the protective action of tumour microenvironment.

**Summary/Conclusions:** In conclusion, our findings indicate that phosphatase activators may represent a new weapon against this form of leukaemia. Overall, these data corroborate the hypothesis that the inhibition of PP2A is central to CLL cell viability and that its activation is facilitated by the supportive action of SHP-1, as demonstrated by the effect produced by the simultaneous use of the respective activators.

**TARGETING NANOPARTICLES TO CHRONIC LYMPHOCYTIC LEUKAEMIA: EXPLOITING THE PROPERTIES OF CXCR4**

1School of Chemistry, University of Manchester, Manchester, 2School of Chemistry, University of Leeds, Leeds, 3Institute of Cancer Sciences, 4School of Pharmacy, University of Manchester, Manchester, United Kingdom

**Background:** Nanoparticle carriers of therapeutic agents (‘drug delivery vehicles’) can be used to deliver drugs to specific cells through the incorporation of a ‘targeting ligand’. Targeting provides the therapeutic benefit of achieving high local drug concentrations while reducing off-target effects against other cells; the combined ligand/delivery system can also be manipulated to determine the uptake pathway or modulate biological effects. The CXCR4 chemokine-receptor is an attractive target for drug delivery vehicles. It is over-expressed in cancers including chronic lymphocytic leukaemia (CLL) (Doman ska et al., 2013) and binding to its ligand (CXCL12) may induce proliferation, survival or entry into protective cellular niches (Ganju et al., 1998). Targeted nanoparticles that can bind and antagonise CXCR4 could therefore allow specific drug delivery to cancer cells while simultaneously blocking CXCL12-induced chemoprotection.

**Aims:** A drug-design strategy was developed to synthesise and evaluate a novel CXCR4 targeting motif (BAT1) with structural similarity to Plerixafor, a CXCR4-antagonist in clinical use. A key design principle was to incorporate a polyethylene glycol (PEG) tether with a functional end-group to provide an attachment point for cargoes, particularly liposomes. The evaluation aim was to assess the effectiveness of BAT1 to deliver a chemotherapy cargo to CLL cells within an in vivo culture system.

**Methods:** A three-step synthesis was used to generate BAT1 (Figure 1A); its structure and purity was confirmed using NMR, MS and HPLC. Bioactivity testing employed primary CLL lymphocytes. Assessments tested: CXCR4 binding-affinity (flow cytometric competition assays), cell-binding characteristics (immunocytotoxic fluorescence) and blockade of CXCL12-induced signalling (immunoblotting). Initial targeting assessment used a fluorescent label (Cy5) conjugated to the functional PEG tether. Cholesteryl chloroformate was then selected to conjugate BAT1 to PEGylated liposomes.

**Results:** The binding affinity of BAT1 (Figure 1B) was demonstrated using competition assays (CXCL12, anti-CXCR4 ab, and the bis(cyc)lam drug Plerixafor). The studies confirmed BAT1 had high affinity for CXCR4 receptors expressed on primary CLL cells. Immunocytotoxic fluorescence comparison with its native ligand confirmed binding of BAT1 to the CLL cell surface, while immunoblotting demonstrated binding of CXCL12-induced downstream signalling (Figure 1C and 1D). The fluorescent moiety Cy5 was covalently linked to the PEG moiety as a test-cargo, demonstrating that binding affinity was retained in the presence of a cargo and that the drug competed for CXCR4 binding with related bis(cyc)lam drugs. This work has been extended to attach BAT1 to liposomes, with present work optimising liposome characteristics for binding and uptake by CLL and the delivery of cytotoxic payload.

**Figure 1.**

**Summary/Conclusions:** A novel bis(cyc)lam CXCR4 antagonist and targeting agent (BAT1) – has been synthesised. BAT1 demonstrates high affinity for the CXCR4 receptor, supporting targeted delivery to CLL cells. Receptor binding is associated with simultaneous blockade of CXCL12-mediated signal initiation and effect, and therefore biological modulation of target cell behaviour. BAT1

THE ROLE OF THROMBOPOIETIN AS A TOOL OF IMMUNE MODULATION IN CHRONIC LYMPHOCYTIC LEUKEMIA
S. Ringelstein-Harlev1,*, M. Fanadka2, N. A. Horowitz1, T. Katz1
1Department of Hematology and Bone Marrow Transplantation, Rambam Health Care Campus, 2Bruce Rappaport Faculty of Medicine, Technion, Israel Institute of Technology, Haifa, Israel

Background: Thrombopoietin (TPO) is the major regulator of platelet production, synthesized mainly by liver cells. The TPO receptor (TPO-R) is known to be expressed on platelets, megakaryocytes and CD34+ cells. It has been reported that patients with immune thrombocytopenic purpura, treated with TPO-R agonists, developed alterations in the T-cell repertoire and pattern of cytokine secretion from B- and T-cells. Thus, clinical activity of these agents could be attributed in part to immune modulation. In chronic lymphocytic leukemia (CLL), characterized by aberrant T-cell responses, high TPO serum levels coexist with low levels of TPO gene transcripts in the malignant cells. These observations could imply that TPO acts as an immune modulator in CLL.

Aims: The aim of the current study was to explore the role of TPO in T-cell modulation in CLL.

Methods: B-cells and CD4+ T-cells were isolated from peripheral blood mononuclear cells (PBMCs) of untreated CLL patients (Rai stages 0-IV) and healthy donors. TPO-R (CD110) expression on CD4+ T-cells was estimated by flow cytometry. CD4+ T-cells were incubated with low-dose IL2 and TPO for 5 days. Percentage of cells retained in G0 (non-proliferating pool) was determined. CLL B-cells were co-cultured with a TLR9 agonist (ODN) and TPO expression was assessed by Q-PCR.

Results: CD4+ T-cells of CLL patients expressed significantly higher levels of TPO-R (CD110) compared to T-cells of healthy donors, with a mean fluorescent intensity of 764±148 and 498±206, respectively (p<0.05; n=6). Stimulation of patient T-cells with TPO induced an increase in the number of cells retaining in G0 (from 75±5.4% to 86±5.6%; p<0.05; n=8), whereas proliferation of healthy donor T-cells remained unaffected by TPO (11.5%±5.7% and 11.4%±5.7% of G0; p=NS; n=6). Additionally, TPO stimulation resulted in a 24% increase of Treg levels in patient T-cells (from 2.1±1.7 to 2.6±1.7%; p<0.05; n=8). However, the Treg levels were not altered in healthy donor T-cells subjected to TPO (0.74%±0.7 and 0.74%±0.8; p=NS; n=5), which is similar to their proliferation response to this growth factor. To determine whether CLL cells could be the TPO source in this disease, TPO mRNA expression in the malignant cells was assessed, demonstrating a baseline ct value of 72±1296, which significantly increased to 1033±342 (p<0.05; n=6) upon ODN activation.

Summary/Conclusions: In the current study, TPO is found to affect immune properties of CLL patient T-cells, inhibiting their proliferation and increasing Treg levels. These effects have been observed in patient T-cells only, which could be partly explained by higher levels of TPO-R expression revealed on patient T-cells compared to healthy donor T-cells. The elevated TPO mRNA expression in CLL B-cells could point to them as one of the possible sources of this growth factor in patient serum. Activation of TPO-R may represent a novel mechanism of T-cell inhibition in CLL.

TREATMENT WITH BCR INHIBITORS INCREASES ROR1 EXPRESSION IN B-CELLS
J. Kotaskova1,2,*, S. Pavlova1, K. Plevova1, J. Malickova1, O. Stehlikova1, L. Poppova1, H. Kockova1, M. Doubek2,3, V. Bryja4, S. Pospisilova1,2
1CMGBT, Department of Internal Medicine – Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, 2Central European Institute of Technology (CEITEC), Masaryk University, 3Department of Internal Medicine – Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, 4Institute of Experimental Biology, Faculty of Science, Masaryk University, Brno, Czech Republic

Background: Receptor Tyrosine Kinase-Like Orphan Receptor-1 (ROR1) expression on malignant B-cells is considered a promising target for therapy of CLL and other lymphoproliferative disorders. Recently published data suggest that combination of BCR inhibitor ibrutinib with ROR1 antibody cirtumzumab can enhance treatment efficacy in CLL. Nevertheless, the variability in ROR1 expression during disease progression, therapy administration and relapse remains unknown.

Aims: In our study we aimed to i) detect ROR1 in CLL cells during different stages of the disease using flow cytometry and qRT-PCR with focus on patients undergoing therapy; ii) analyze changes in ROR1 expression within individual patients during the disease course.

Methods: CLL cohort consisted of 96 CLL patients (152 samples); 23 patients with stable disease, 16 patients with active disease prior first therapy intervention, 6 patients during first therapy, 13 patients in progression before second line treatment, 3 patients in complete remission, 10 refractory patients, 9 patients treated with ibrutinib, 13 patients treated with idelalisib. To monitor changes in ROR1 expression we tested serial samples from 5 CLL patients (median follow up 76 months (66-131), median number of sampling points 12 (5-18)). For surface ROR1 protein analysis we used 8-color flow cytometry (modified MRD protocol: CD45/CD3/CD19/CD5/CD8/CD79b/CD22/ROR1) in all patients. To quantify ROR1 mRNA expression changes within individual patients we performed qRT-PCR in separated CLL cells (>95% CD19+CD5+). CLL cells from samples in remission were separated immunomagnetically (Whole Blood Anti-ROR1 MicroBead, Miltenyi Biotec).

Results: Using multicolour flow cytometry we confirmed ROR1 antigen/protein expression in CLL cells in all studied samples. ROR1 antigen was detectable on residual CLL cells during disease remission with the ability to distinguish malignant population from healthy B-cells. Using qRT-PCR we detected significantly higher levels of ROR1 mRNA in samples of treated patients (p<0.01). This observation was supported by analysis of ROR1 mRNA expression in five patients tested consecutively in several time-points. We detected ROR1 mRNA expression increase in disease progression before therapy and further increase during therapy administration. In case of remission induction we observed decrease of ROR1 mRNA level. In patients treated with ibrutinib or idelalisib we observed steep increase of ROR1 expression compared to patients treated with other regimens.

Summary/Conclusions: ROR1 protein remains detectable on CLL cells during disease course even in complete remission. ROR1 mRNA levels are highly influenced by therapy administration especially in the case of treatment with Bcr inhibitors.

mediated TFS of 4 years (log rank test: p=0.0003). Thus, patients with normal SPE and IGHV mutated status constitute a group with excellent prognosis.

Summary/Conclusions: In conclusion, normal SPE was associated with good outcome with decreased accumulation of side genetic events (in particular, SF3B1 mutations). This analysis shows a bias in IGHV repertoire according to SPE status. These results also clearly suggest that patients with a normal SPE and mutated IGHV have an extremely quiet CLL natural history. This could be either due to the weaker activity of the disease and/or to the absence of adverse consequences of a concomitant paraprotein.

HS70 EXPRESSION IS MODULATED BY ITS MASTER REGULATOR HSF1 VIA MAPKS AND PI3K/AKT/MTOR PATHWAYS IN CHRONIC LYMPHOCYTIC LEUKAEMIA

F. Frezzato1, F. Raggi1, B. Accordi1, S. Bresolin1, F. Severin1,2, V. Martini1,2, V. Trimarco1,2, L. Martellino1, A. Visentini1,2, S. Imbargemo1, E. Sciammazzoni1, M. Faccoli1,2, F. Piazza1,2, G. Bassi1,2, G. Semenzato1,2, L. Trentin1,2,4

1Department of Medicine, University of Padua, 2Venetian Institute of Molecular Medicine (VIMM), 3Department of Women’s and Children’s Health, University of Padua, Padova, Italy

Background: The search for molecules involved in apoptosis resistance/ increased survival of B cells from Chronic Lymphocytic Leukemia (CLL) is still ongoing since this disease remains not definitively understood. We recently found that the Heat Shock Protein of 70kDa (HS70), expressed in response to a wide variety of stress signals and allowing cells to survive to lethal conditions, was particularly overexpressed in neoplastic B cells from CLL. Moreover, the Heat Shock Factor 1 (HSF1), the main responsible for the transcription of HS70, is itself overexpressed in CLL and strictly correlated to HS70. In response to stress, HSF1 becomes phosphorylated, forms homotrimers, binds DNA and activates heat shock gene transcription. HSF1 is regulated by a finely tuned balance of activatory/inhibitory phosphorylations mediated by kinases belonging to pathways triggered by RAS (i.e. PI3K/AKT/mTOR and RAF/MEK/ERK).

Aims: Since HS70 is overexpressed in CLL neoplastic B cells and most of ‘HSF1-phosphorylating actors’ belong to signalling pathways taking part from RAS, being the PI3K/AKT/mTOR and the RAF/MEK/ERK pathways, we are herein aimed at gaining information and dissecting this network in CLL B cells.

Methods: In a Reverse Phase Protein Array (RPPA) study, previously performed from 57 CLL patients and 11 healthy subjects, we assessed the activation/expression of key signalling proteins. Herein, we focused on HS70, AKT-Ser473, mTOR-Ser244, GSK3α/b-Ser21/9, CDK2, CREB-Ser133, Ser217/221 and ERK-Thr202/Tyr204, known to negatively regulate HSF1. RPPA and demonstrated that the examined proteins behave in a different way as cut-off the value of the median of HS70 expression levels calculated by RPPA and demonstrated that the examined proteins behave in a different way between patients expressing high or low levels of HS70. HS70-high patients present high Akt-Ser473, an inhibitor of GSK3a/b that, in the inhibited form, prevents HSF1 inhibition. By contrast, HS70-low patients have high MEK1/2-Ser217/221 and ERK-Thr202/Tyr204, known to negatively regulate HSF1. Intriguingly, p38MAPK-Thr180/Tyr182, SAPK-JNK-Thr183/Tyr185 and PDK1-Ser241. Cluster and separated analyses have been performed.

Results: We divided our patients in HS70-high and HS70-low considering as cut-off the value of the median of HS70 expression levels calculated by RPPA and demonstrated that the examined proteins behave in a different way between patients expressing high or low levels of HS70. HS70-high patients present high Akt-Ser473, a regulator of GSK3a/b that, in the inhibited form, prevents HSF1 inhibition. By contrast, HS70-low patients have high MEK1/2-Ser217/221 and ERK-Thr202/Tyr204, known to negatively regulate HSF1. Intriguingly, p38MAPK-Thr180/Tyr182, SAPK-JNK-Thr183/Tyr185 and PDK1-Ser241. Cluster and separated analyses have been performed.

Summary/Conclusions: These data would suggest that, in CLL, HS70 expression is regulated by the modulation of HSF1 activity through the activation of one or the other way triggered by RAS. In particular, an activation of the PI3K/AKT/mTOR pathway leads, as result, to a higher expression of HS70 while an activation of the RAF/MEK/ERK signalling rather results in HS70 down regulation. The dissection of signalling pathways connected to HS70-HSF1 axis in CLL will contribute to define the biology and understand the pathogenesis of this disease.

THE INTERPLAY BETWEEN TH17 AND TREGS: A NEW IMMUNOSUPPRESSIVE INSIGHT IN CHRONIC LYMPHOCYTIC LEUKAEMIA

S. De Matteis1,2, R. Napolitano1, A. Lucchesi2, D. Cancini2, A. Cuneo3, G.M. Rigolin3, E. Volta3, G. Musuraca2

1Bioscience Laboratory, 2Haematology Unit, IRCCS Istituto Scientifico Romagnolo per lo Studio e la Curca dei Tumori (IRST), Meldola, 3Medical Sciences, University of Sassari, Sassari, Italy

Background: Chronic lymphocytic leukemia (CLL) is the most frequent leukemia in the Western world and it is characterized by the clonal expansion of CD5 positive B cells. In CLL, different T cells dysfunctions have been described, probably related to the interaction with malignant B cells. TH17 and regulatory T cells (Tregs) are subpopulations of T lymphocytes which play a fundamental part in inflammatory response and immune tolerance. However, their role in the immunopathogenesis of CLL has not yet been fully clarified.

Aims: The aim of this study is to clarify the interplay between TH17 and Tregs in the pathogenesis of CLL.

Methods: After obtaining the patient’s informed consent, peripheral blood was collected from 30 untreated CLL patients and 30 age-matched healthy volunteers (HV). Cytokine production was evaluated before and after a 48 h culture of CD4+ T cells in complete medium with IL-6 (o/n), followed by a 5 h stimulation with PMA, ionomycin and Monensin (PIM), or with anti-CD4 FITC, anti-CD25 APC-Cy7, anti-FoxP3 APC and anti-Tbet PE or anti-ROTYt PE or anti-GATA-3 PE. Statistical analysis were carried out using the paired and unpaired two-tailed Student’s t tests and confirmed with the non-parametric Wilcoxon signed-rank test.

Results: In CLL patients we observed a reduced production of IFN-γ and IL-4, respectively from TH1 and TH2 and an increase of IL-17A from TH17, compared to HV. All the observed differences were statistically significant. We also evaluated the ability of CD4+ T cells to secrete IL-17A, IL-10 or both. We reported a statistically significant increase in the frequency of CD4+ IL-17A-producing cells in CLL patients compared to HV, whereas the percentage of IL-17A+/IL-10+ cells remained unchanged. In order to evaluate the functional effects of the observed alterations, we analyzed IFN-γ+/CD4+ T cells-mediated response after stimulation with C. Albicans for 48 h, with or without depletion of IL-17A-secreting cells. The frequency of IFN-γ-producing T cells resulted statistically significant increased in patients than HV before IL-17A-secreting T cells depletion. Conversely, after IL-17A+ CD4+ T cells depletion, we didn’t observe significant differences in term of IFN-γ production. We also observed increased IL-23 plasma levels in patients compared to HV. In addition our data highlighted a significantly higher frequency of CD4+ CD25+IL-10+FoxP3+ cells (Tregs) in CLL samples, with a statistically significant increase in Th17, Th1, Th2, and Th17/Treg subsets in CLL patients, probably trying to overcome the deficit of effector T cells. In order to study regulatory T cells, we evaluated the ability of CD4+ T cells to secrete IL-10 or both. We observed a statistically significant increase in the frequency of CD4+ IL-10-producing cells in patients than HV, whereas the percentage of IL-17A+/IL-10- cells remained unchanged.

Summary/Conclusions: Our results highlighted the importance of the Th1/Th2/Th17/Treg network in the immune modulation of CLL. The observed modifications in CD4+ T cells may represent an adaptive mechanism to avoid the presence of TH17 cells and to maintain a Th2 response in order to downregulate the immune system.

E103

LOW EXPRESSION OF CD25 IN CHRONIC LYMPHOCYTIC LEUKEMIA NOTCH1-MUTATED CASES INDEPENDENT OF CDK4/6 MISREGULATION

T.H. Chen Liang1, A.M. Hurtado1, M. Castillio1, J. Muñoz-Ballester1, B. Przychodzen2, M.D. García-Malo1, F. De Arriba1, F.J. Ortuño1, J.P. Maciejewski2

1Hematology and Oncology Department, Hospital Morales Meseguer, Centro Regional de Hemodonación. Universidad de Murcia, IMIB, Murcia, Spain, 2Translational Hematology and Oncology Research Department, Cleveland Clinic, Cleveland, United States

Background: Recently, it has been shown that CDK6-mediated repression of CD25 is required for induction and maintenance of NOTCH1-induced T-cell acute lymphoblastic leukemia.

Aims: The aim of this study was to identify the NOTCH1 mutant status detected by deep sequencing in a cohort of 138 patients, and to correlate it with the immunophenotypic profile and CDK4 and CDK6 expression.

Methods: We performed targeted NGS sequencing of blood samples, collected at diagnosis, from 138 CLL patients. We designed a TruSeq Custom Amplicon sample preparation kit, with a list of~51 target regions of the genome that include~1100 genes. We performed un-parametric Wilcoxon signed-rank test.

Results: The aim of this study is to clarify the interplay between TH17 and Tregs in the pathogenesis of CLL.
containing 13 genes and evaluating 28,099 bases. Paired-end sequencing was performed with MiSeq v2 chemistry, and a mean depth of 96x across the targeted region was obtained. Every patient underwent, at baseline, a flow cytometry characterization with a panel including (slg)k, (slg)λ, CD19, CD11b, CD81, CD10, CD79b, CD29, CD38, FMC7, CD22, CD45, CD103, CD11c, CD25, ZAP70, CD11a, and CD24. CDK4 and CD6K expression levels were quantified by RT-qPCR.

**Results:** With a median age of 66 y.o. (range, 31-89) and a slight male predominance, the median follow up time of our cohort was 43 months (24-104). We found that 38/138 (28%) patients harbored at least one mutation, with NOTCH1 (n=16, 12%), ATM (n=12, 9%), TP53 (n=9, 7%), and SF3B1 (n=8, 6%) among the most commonly mutated genes. Those patients with a NOTCH1 mutation showed a lower CD25 expression (24 mean fluorescence intensity units (MFIu)) than those without a mutation (43 MFIu), *p*=0.03. We could not validate the recently reported association between the presence of NOTCH1 mutations and a low expression of CD25. In our cohort, the MFI in NOTCH1 mutated and non-mutated patients was 163 and 146 units, respectively (*p*=0.05). We measured CDK4 and CD6K expression in the CD19+ sorted fraction RNA of 7 NOTCH1 mutated cases and 11 non mutated cases, without finding significant differences (0.26 vs 0.27 for CDK6, 0.025 vs 0.022 for CDK4; *p*>0.5). We noted a significant inferior expression of CD25 when activating NOTCH1 mutations are present in CLL patients. The relationship found between these two variables, with an inverted direction to that found in physiological conditions, has also been shown to be present in the setting of NOTCH1 mutated T acute lymphoblastic leukemia. In CLL cases, it seems to be independent of CDK4/6 expression, prompting further studies assessing CD4K and CD6K regulators.

**Summary/Conclusions:** We found a significant inferior expression of CD25 when activating NOTCH1 mutations are present in CLL patients. The relationship found between these two variables, with an inverted direction to that found in physiological conditions, has also been shown to be present in the setting of NOTCH1 mutated T acute lymphoblastic leukemia. In CLL cases, it seems to be independent of CDK4/6 expression, prompting further studies assessing CD4K and CD6K regulators.

**GENE MUTATIONS ANALYZED BY NEXT-GENERATION SEQUENCING ALLOW US TO DEFINE THE PROGNOSIS OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS WITH EARLY-STAGE DISEASE AND 13Q DELETION**

M. de Miguel1, M. Leal-Aguilera2, A. Sánchez3, A. Delgado1, A. Rodríguez-Arribas1, J.-A. Queizán5, I. De la Fuente6, C. Aguilar7, A. García de Coca8, C. Hernandez-Rivas9, J.-Á. Hernández-Rivas12, M. González1, J.-M. Hernández-Rivas1
1Cancer Research Center/Hospital Universitario de Salamanca, SALAMANCA, 2Hospital Virgen Blanca, LEÓN, 3Hospital del Bierzo, PONFERRADA, 4Hospital Río Carrión, PALENCIA, 5Hospital General, SEGOVIA, 6Hospital Río Hortega, Valladolid, 7Hospital Santa Bárbara, SORIA, 8Hospital Clínico Universitario, VALLADOLID, 9Hospital Juan Ramón Jiménez, HUELVA, 10Hospital Miguel Servet, ZARAGOZA, 11Hospital Virgen del Puerto, PLASENCIA, 12Hospital Universitario Infanta Leonor/Universidad Complutense de Madrid, MADRID, SPAIN

**Background:** Next-Generation sequencing (NGS) studies have revealed a number of recurrently mutated genes in chronic lymphocytic leukemia (CLL). It is reasonable to argue that evaluating the newly gene mutations as prognostic markers would help to improve prognostic counseling of CLL patients. Interestingly, gene mutations could help us to refine the prognosis in the group of CLL patients with other prognostic markers associated with good prognosis.

**Aims:** To analyze the presence of mutations of a panel of genes by NGS and its prognostic impact in patients with CLL, focusing in the groups of patients with good prognosis characteristics.

**Methods:** Amplionc-based-NGS was performed using 454 platform in 147 CLL patients to evaluate the mutational status of 6genes (TP53, NOTCH1, SF3B1, XPO1, FBXW7 and MYD88). Samples were obtained at diagnosis or before treatment in all cases. 70.1% were Binet A and 53% had 13q deletion (13q-). A cut-off 2% was applied to define variants. All the mutations were validated.

**Results:** 1. NGS analysis showed that 37.4% of CLL patients (55/147) showed mutations in any of the analyzed genes. The frequency of mutations was 16.3% for NOTCH1, 10.2% for SF3B1, 6.8% for TP53, 4.8% for XPO1, 3.4% for FBXW7, and 1.4% for MYD88. The presence of mutations in any of these genes except to MYD88 (mutated CLL) was significantly associated with clinical progression (60.0% for mutated CLL vs. 38.2% for unmutated CLL, *p*=0.05). Interestingly, mutated CLL patients showed a shorter time to first treatment (TFT) than unmutated CLL patients (30 months vs. 88 months; *p*=0.006). By contrast, MYD88 mutations were detected in CLL with mutated IGHV and 13q-. Of note, 23.6% of the mutations had a mutational load of ≤15% and thus would not have been detected by capillary Sanger sequencing. CLls with mutations in MYD88 had an inferior TFT than those without mutations (18 vs 88 months; *p*=0.018), and similar to CLL patients with mutations >15% of cells (*p*=0.370). In addition, 14.5% of mutated CLL patients showed 2mutations. Patients with more than one mutation had a shorter TFT than CLL patients with one mutation (7 months vs 31 months). 3. In the group of CLL patients with Binet A and 13q-, 32.8% of them showed mutations in any of the analyzed genes. Interestingly, CLL patients Binet A with mutations (except to MYD88) showed a shorter TFT than CLL patients without mutations (31 vs 131 months, *p*=0.001). Besides this, CLL with 13q- as the sole cytogenetic alteration and gene mutations had also a shorter TFT that unmutated 13q- CLL patients (22 vs 88 months, *p*=0.002).

**Summary/Conclusions:** 1) CLL patients with mutations in TP53, NOTCH1, SF3B1, XPO1 and FBXW7 show a worse prognosis than CLL patients without mutations. 2) Gene mutations in TP53, NOTCH1, SF3B1, XPO1 and FBXW7 in a low percentage of the cells are associated with a shorter TFT. 3) Among CLL patients with good prognostic characteristics (Binet A and 13q-), gene mutations help us to define the prognosis of the patients.

**ALTERED COMPLEX C5 IS ASSOCIATED WITH COMPROMISED COMPLEMENT ACTIVITY IN CHRONIC LYMPHOCYTIC LEUKEMIA**

A. Braester1,2,*, M. Barhoum1, R. Michelis3
1Haematology, Galilee Medical Center, Naharya, 2Faculty of Medicine, Bar- Ilan University, Safed, Israel

**Background:** The therapeutic monoclonal antibodies used for the treatment of Chronic lymphocytic leukemia (CLL) mediate anti-tumor effects through several mechanisms: complement cell-mediated cytotoxicity (ADCC), and phagocytosis. CDC efficacy thus depends on the expression level of the target B-cell antigen, the integrity of apoptotic cascades within tumor cells, the functional capacity of effector cells, and the availability and activity of the complement (C) system. Published data indicate deficiency of one C protein or more in most CLL patients, as well as additional factors that may affect C activity. The role of structural abnormalities of C complexes in affecting C function has not been investigated.

**Aims:** To study the structural integrity of circulating C complexes, focusing mainly on C5, and to establish its importance for C activity in CLL. **Methods:** Blood samples were collected from 35 (20) Binet A and 10 healthy controls (HC). Biochemical and haematological parameters, and CLL staging were recorded. The isoforms of two C components, C3 and C5 were studied by Western blot analysis. The activity of the C system before and after in-vitro activation via the classical or alternative pathways was followed by the levels of C5b-9, the terminal product of C activation. C activation was also studied in vitro on normal and CLL sera. The differences in C5 pattern were noted in some of the CLL patients. Specifically, the C5 complex that exists as a single protein band in all HC and in 56% of CLL patients appeared in 44% of the patients as a clear double-band. No clear differences were observed in C3 pattern in the patients. Higher basal levels of C5b-9 were found in CLL patients with abnormal pattern of C5 (394±6758 SFM g/mL) compared with both HC (50±158 SFM g/mL) and CLL patients presenting normal C5 pattern (236±655 SFM g/mL). In-vitro C activation via the classical pathway was inversely correlated with basal activity, and was significantly lower (*p*<0.03) in the CLL patients with altered C5 compared to HC and CLL patients with normal C5. In-vitro activation via the alternative pathway was similar in all subjects’ groups. C activity in C5-deficient serum supplemented with 33% sera from patients with abnormal C5 was significantly lower compared to the activity observed after supplementation with serum from HC or from patients with normal C5. Activity after supplementation with normal C5 (commercial) was significantly lower in sera from CLL patients compared to sera from the other subjects’ groups.

**Summary/Conclusions:** The data indicate a possible link between the activation potential of the C system in CLL patients and alterations in the complex structure of C5. The differences in C activation via the classical and alternative pathways may indicate disturbance in the classical pathway in patients with abnormal C5. The exact mechanisms by which abnormal C5 distracts the C activity need further clarification. Yet, the appearance of abnormal C5 in CLL patients with disturbed C activity bears the potential to develop a marker which will assist in identifying patients who are likely to be less responsive to future immunotherapy treatment due to compromised CDC. Development of such a marker may assist clinicians in refining and personalizing the immunotherapeutic approach, improving CDC and consequently the therapy results.
Chronic lymphocytic leukemia and related disorders - Clinical

ASSOCIATION OF CGP-STIMULATED KARYOTYPE WITH TIME-TO-FIRST TREATMENT FOR CLL
1Bone Marrow Transplantation, Ospedale Pausilipon, Napoli, Italy, 2Leukemia, MD Anderson Cancer Center, Houston, United States, 3Ematologia, PO San Giuseppe Moscati, Aversa, Italy, 4Chao Family Comprehensive Cancer Center, California, United States

Background: Prognostic factors correlate with clinical outcomes, independent of treatment. B cell receptor (BCR) signaling pathway inhibitors can nullify the prognostic impact of some markers, such as IGHV mutation status. CpG-stimulated metaphase karyotype can identify clonal cytogenetic abnormalities in CLL that may not be seen with standard non-stimulated karyotype or by FISH. Complex cytogenetics, defined as 3 or more chromosome abnormalities in 2 or more metaphases was the highest-risk feature for shorter progression-free and overall survival in patients receiving ibrutinib for relapsed/refractory CLL. Complex karyotype is not uncommon among relapsed/refractory CLL cases, particularly those who previously received genotoxic chemotherapy.

Figure 1.

Aims: The aim of this study is to report the incidence and the impact of CpG-stimulated karyotype in the treatment of naive CLL.

Methods: We evaluated 501 treatment-naive patients with CLL at MDACC between July 2013 and June 2016. CpG-stimulated metaphase karyotype of CLL cells from blood or bone marrow was performed by culture of mononuclear cells for 72 hrs in media containing CpG-685 (20ug/ml), phorbol 12-myristate 13-acetate (PMA; 0.04ug/ml) and Pokeweed mitogen (PWM; 0.1ug/ml). Banding and analyses were by standard laboratory procedures. Twenty metaphases were analyzed per culture and patients were categorized as having diploid karyotype, a single, 2 or 3 or more(complex) clonal chromosome abnormalities present in more than 1 metaphase by CpG-stimulated karyotype. The frequency and distribution of chromosome abnormalities with other prognostic factors and time-to-first treatment from diagnosis (TTFT) were analyzed (Table + Figure). Results: The majority (69%) of patients had diploid cytogenetics. Higher-risk prognostic features such as de17p, del11q, unmutatedIGHV and ZAP70 expression were associated with presence of complex karyotype abnormalities. Shorter TTFT from diagnosis was associated with 1, 2, and complex clonal chromosome abnormalities compared to diploid karyotype (p<0.0001). A model was developed, which identified patient characteristics independently associated with shorter TTFT including: 1 or more clonal chromosome abnormality by CpG stimulated karyotype; unmutatedIGHV; 3 involved lymph node sites; and CD38 expression (>30%). Study conclusions: In conclusion, CpG-stimulated karyotype identified 1 or more clonal chromosome abnormalities in nearly a third of untreated patients and was a significant independent prognostic factor for TTFT. Models for TTFT may be useful in identifying patients at high-risk for needing treatment sooner and thereby useful for early intervention clinical trials.

COMPARISON OF THE CHRONIC LYMPHOCYTIC LEUKEMIA INTERNATIONAL PROGNOSTIC INDEX (CLL-IPI) WITH THE BARCELONA-BRNO PROGNOSTIC MODEL: ANALYSIS OF 1299 NEWLY DIAGNOSED CASES
1Hematology, Hospital Anna Zanella, Modena, Italy, 2Hematology, Mayo Clinic, Rochester, United States, 3Oncoology, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland, 4Hematology, Catholic University Hospital “A. Gemelli”, 5Hematology, Università La Sapienza, Rome, 6Hematology, Pugliese-Ciaccio Hospital, Catanzaro, 7Hematology, 7SS Molecular Diagnostics IRCCS S. Martino-IST, Genova, 8Hematology, Hospital Anna Zanella, Modena, Italy, 9Hematology, Università La Sapienza, Roma, 10Immunology, Consiglio Nazionale delle Ricerche, Istituto di Biomedicina ed Immunologia Molecolare, Reggio Calabria, Italy, 11Divisione di Biomedicina ed Informatiche, Mayo Clinic, Rochester, United States, 12Biotechnology Research Unit, Azienda Sanitaria Provinciale di Cosenza, Aprigliano, Italy, 13Hematology, University of Milano and Hematology CTMO, Foundation IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milano, 14Direzione Scientifica IRCCS-, San Martino IST, Genova, 15Hematology, Department of Translational Medicine, PO, Novara, Italy

Background: In the last two decades, a plethora of clinical, serological and biological markers have been identified that are significantly associated with the prognosis of chronic lymphocytic leukemia (CLL) patients. A recent prognostic index called CLL International Prognostic Index (CLL-IPI), built on clinical, serological, and biological parameters (TP53 deletion and/or mutation, IGHV mutational status, β2M, clinical stage) was proposed for evaluating. Recently, Beijing and Barcelona-Breno CLL group, with the aim of simplifying the CLL-IPI, proposed a prognostic model comprising only two biomarkers (IGHV mutational status and FISH cytogenetics).

Aims: We performed a comparison of the CLL-IPI with the Barcelona-Brno prognostic model in an independent series of Italian and United States (U.S.) patients.

Methods: Databases from 4 Italian and 1 U.S. centers including roughly 3700 newly diagnosed CLL patients were used to compare the CLL-IPI with the Barcelona-Brno prognostic model. Baseline data regarding age, Rai stage, IGHV mutational status, β2M and fluorescence in situ hybridization (FISH)-detected cytogenetic abnormalities were available for 1299 cases. Del17p was used as the sole marker of TP53 status. The CLL-IPI and the Barcelona-Brno prognostic model were calculated using the methods proposed. The accuracy of the prognostic models was assessed by the Harrell C index (an index of discrimination), the explained variation in mortality (an index combining discrimination and calibration), and the Akaike information criterion (AIC, an index comparing two non-nested prognostic models). The lower the AIC, the higher the prognostic accuracy of a predictive model.

Results: The median age of the 1299 patients was 63 years (range 27-92) with 61.3% males. The majority of patients had Rai stage 0 (57.9%). Among the 1299 patients, according to the CLL-IPI, 51.3% of patients were classified as low-, 28.7% as intermediate-, 16.2% as high-, and 3.8% as very high-risk. The 5-year OS probabilities were: 95% for low-risk, 89.9% for intermediate-risk, 70.1% for high-risk, and 32.8% for very high-risk cases (P<0.0001; Harrell C index=73%, P<0.001) (Figure 1). In comparison to the Barcelona-Brno prognostic model, 58.1% of the 1299 patients were classified as low-, 31.8% as intermediate-, and 10.1% as high-risk. The 5-year OS probabilities were: 92.2% for low-risk, 83.6% for intermediate-risk, and 68.2% for high-risk cases (P<0.0001; Harrell C index=65%); P<0.001 (Figure 1B). The AIC showed the superiority of the CLL-IPI compared to the Barcelona-Brno prognostic model in predicting OS (CLL-IPI, AIC=3432.167 versus Barcelona-Brno prognostic model, AIC=3549.492). Accordingly, the explained variation in mortality provided by the CLL-IPI was 42% (P<0.001), a figure higher than that due to the Barcelona-Brno prognostic model.
(21%, P<0.001), indicating that the CLL-IPI had a higher prognostic accuracy for mortality compared to that of the biomarkers-only prognostic model. Then, we also compared the ability of the two scores to predict TTFT in newly diagnosed patients. The Harrell C-index of the Barceloña-Brno prognostic model was 0.70 (P<0.001), lower than that of the CLL-IPI score (0.73, P<0.001). The AIC showed the superiority of the CLL-IPI compared to the Barceloña-Brno prognostic model in predicting TTFT (CLL-IPI, AIC=6010.929 versus biomarkers-only prognostic model, AIC=6010.929). Accordingly, the explained variation provided by the CLL-IPI was 33% (P<0.001), a figure higher than that achieved by the Barceloña-Brno prognostic model (28%, P<0.001), indicating that the CLL-IPI had a higher prognostic accuracy for predicting TTFT as compared to that of the Barceloña-Brno prognostic model.

Summary/Conclusions: Our results confirm the validity of both scores (CLL-IPI and biomarkers-only prognostic model) to predict survival and TTFT among patients with previously untreated CLL. Moreover, we have demonstrated that the CLL-IPI which combines clinical and serological data with biological parameters has a higher accuracy for predicting prognosis and TTFT of CLL patients than the Barceloña-Brno biomarkers-only prognostic model.

E1018
PRELIMINARY RESULTS OF S55746/BCL2L201 (A NEW BCL2 INHIBITOR) IN RELAPSED OR REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS AND EFFECT OF CALIBRATED MODERATE MEAL ON THE PHARMACOKINETICS

Methods: S55746/BCL2L201 as single agent is being investigated in a phase I (EUDRACT NCT02920697), open-label, multiple-dose, international dose escalation trial. S55746/BCL2L201 was initially administered in fasting condition, once daily (in 21-day cycle) until progressive disease (PD) or unacceptable toxicity. A tumor lysis syndrome (TLS) prevention protocol was implemented. After giving informed consent pts could receive 50 to 2000mg according to a modified version of the Continual Reassessment Method for dose allocation process. In the food effect part of the study, 7 non-Hodgkin’s lymphoma patients received a film coated 200mg tablet under fasting condition (i.e. after 10-hour fasting period) and after a calibrated moderate meal the day after.

Results: As of February 2017, 12 CLL pts have been treated (median age 67 years [range 52-82]). On these 12 pts, 5 presented a bulky disease, 1 a 17p deletion, 4 a 11q deletion, and 1 a p53 mutation. CLL pts were dosed up to 700mg, with a median duration on treatment of 79 days. Median number of prior regimens in CLL pts was 4 (range 2-5). Preliminary PK results in fasting pts showed that exposure increased linearly but with some inter-individual variability. The most frequent (≥2 pts) grade 3/4 adverse events (AEs) were neutropenia (n=2) and thrombocytopenia (n=2). AEs possibly related to the study drug were reported in 4 pts: neutropenia (n=2), neutrophil count decrease (n=1), fatigue (n=1), dyspnea (n=1), gingival bleeding (n=1) and left ventricular ejection fraction (LVEF) decrease (n=1). No clinical or laboratory TLS were reported. One patient in the 700mg cohort experienced a DLT (asymptomatic LVEF decrease grade 2 recovered within 2 weeks). At 700mg, a decrease in lymphocytes count from baseline (≥50%) was observed in 3 out of 4 patients associated with a decrease in the sum of the product of the diameters of lymph nodes (from 23% to 40%). This decrease in lymphocytes count, started from cycle 1, and may be correlated with an induction of apoptosis in CLL cells (4 hours post first dose), detected by flow cytometry in CD19+AnnexinV+ cells. Two CLL pts are ongoing after having completed their 3rd cycle; 10 pts have withdrawn from the study: 7 due to PD, 1 for lack of efficacy and 2 due to AE. The non-comparative pharmacokinetic analysis of the food effect cohort (5 assessable pts) demonstrated that S55746/BCL2L201 PK is modified by the ingestion of a moderate meal (400-500 kcal with fat contributing to 150 kcal). The median Tmax was delayed from 1.5h to 4h when administered with food. Compared with fasting condition, Cmax and AUC increased by approximately 6-fold following a moderate meal. Based on these results, a protocol amendment to the clinical trial has been implemented in order to further investigate the administration with food in a new dose escalation.

Summary/Conclusions: S55746/BCL2L201 monotherapy showed first signs of activity across the tested dose levels with an acceptable safety profile so far. Based on PK food interaction results, dose escalation in the fed state has started.

E1019
INCREASED VIRUS-SPECIFIC IMMUNE RESPONSES PARALLELED BY A PNEUMOCOCCUS-SPECIFIC IMMUNODEFICIENCY STATE AND HYPOGAMMAGLOBULINEMIA: ALREADY EMERGE IN HIGH-COUNT MONOCL. B LYMPHOCYTOSIS PRIOR TO CLL

Methods: A total of 249 subjects (119 males/130 females; aged 68±11y) including 91 healthy donors, 71 CLL-like MBL, 29 CLL-like MBL and 58 CLL cases (32 Binet A, and 26 Binet B/C patients) were studied. Detection of clonal CLL-like B cells was performed by high-sensitive 8-color flow cytometry. Quantification of plasma antibody-antibodies and specific immunoglobulins against CMV (cytomegalovirus), EBV (Epstein Barr Virus), influenza virus and S.pneumoniae were performed by nephelometry and commercial ELISA kits, respectively. Individuals who had received vaccination against Influenza and/or Pneumococcus were excluded from the analysis of the immunoglobulin-specific titers against the corresponding pathogen, respectively. Plasma CMV and EBV DNA load were determined by real-time qPCR using commercially available kits.

Results: Total immunoglobulin (Ig) titers tended to decrease with disease progression, independently of the isotype. In contrast, specific IgM and IgG titers against CMV, EBV and Influenza virus did not vary among groups, with the...
exception of VCA-EBV IgG titer, that were higher in CLL vs the other groups. Strikingly, the IgG levels for the three viruses tended to gradually increase, from healthy individuals to stage B/C CLL. These findings were more pronounced (<0.05) for IgG and to a lesser extend also for IgM, when the ratios between the virus-specific IgG/total IgG titer of the same isotype were calculated, except for Influenza-specific IgG, that showed the same trend but without statistical significance. Replicating CMV DNA load, only 3/177 individuals, 1 MBL and 2 CLL, were found to be positive (below the limit of quantitation), while EBV DNA load was detected in plasma from 7/191 (all being Binet A CLL) at median levels of 3.6 copies/μl. In contrast to the virus-specific IgG, IgG plasma levels against S. pneumoniae progressively diminished through progression of the disease, in contrast to the overall lower gammaglobulin levels.

**Summary/Conclusions:** Both MBL and CLL patients present relatively high levels of specific Ig against human host viruses in parallel to progressively lower levels of anti-S. pneumoniae antibodies, which might reflect (asymptomatic) chronic reactivation of humoral immune responses against host viruses and thereby negatively decreased protection against other microorganisms, denoting a severe pathogen-specific humoral immunodeficiency state not reflected by the overall plasma immunoglobulin levels. Alternatively, these results might point out a potential role of ubiquitous viruses in the pathogenesis of the disease. Further analyses are necessary to establish the potential relevance of such asymptomatic humoral immune responses against host viruses in the expansion of the tumor B-cell clone and progression from MBL to CLL.

---

**E1020**

**AN EXTENSIVE MOLECULAR CYTOGENETIC CHARACTERIZATION IN HIGH-RISK CHRONIC LYMPHOCYTIC LEUKEMIA IDENTIFIES KARYOTYPIC ABNORMALITIES AND TP53 DISRUPTION AS PREDICTORS OF OUTCOME AND CHEMOREFRACTORYNESS**

G.M. Rigolin1,*, L. Formigaro1, M. Cavalli1, F.M. Quaglia1, E. Lista1, A. Urslo1, E. Guardalben1, S. Martinelli1, E. Saccenti1, C. Bassi2, A. Bardil2, E. Volta1, E. Tammolo1, M. Melandri1, N. Megrini2, F. Cavazzoni2, A. Cuneo1, Science Medicine, Azienda Ospedaliera Universitaria Arcispedale S. Anna, 2Department of Morphology, Azienda Ospedaliera Universitaria Arcispedale S. Anna, Italy, 3Laboratorio per le Tecnologie delle Terapie Avanzate (LTTA), University of Ferrara, Ferrara, Italy

**Background:** Chronic lymphocytic leukemia (CLL) is a heterogeneous disease, running an indolent course in some patients and a clinically aggressive course in others. Risk assessment is important in clinical practice and prediction of outcome and response to treatment is very useful in an era in which several chemomunotherapy combinations and effective mechanism-driven treatments are available.

**Aims:** We investigated whether an extended genetic characterization including mutational screening by next generation sequencing (NGS) and karyotype analysis could allow for a refinement of our capability to predict outcome in newly diagnosed CLL patients with high-risk features, as defined by the presence of unmutated IGHV gene and/or 11q22/17p13 deletion by FISH and/or TP53 mutations.

**Methods:** 101 patients were included in this study. TP53 disruption was defined by the presence of 17p13 deletion by FISH and/or TP53 mutation by NGS. Cytogenetic analysis was performed using CpG-oligonucleotide DSP30. Each patient was categorized according to the following classification: favorable group (isolated 13q14 deletion or normal karyotype), unfavorable group (deletions of 11q22 or 17p13, or complex karyotype, i.e., at least 3 chromosome aberrations); intermediate group (all other karyotypic abnormalities). A cut-off of 98% homology to the germline sequence to discriminate between IGHV mutated and unmutated cases. Mutational screening was performed with Ion Torrent PGM NGS platform on 20 CLL-related genes by using a 5% cut off.

**Results:** Cytogenetic analysis showed favorable findings in 30 patients, unfavorable in 34 cases and intermediate in 36 cases. A complex karyotype was present in 21 patients. By NGS, 95 somatic mutations were observed in 56/101 (55.4%) cases, 80 nonsense mutations, 5 nonsense mutations and 10 frameshit deletions. 16 cases (15.8%) showed mutations in the TP53 gene, 11 (10.9%) in the NOTCH1 gene, 10 (9.9%) in the SF3B1 gene, 8 (7.9%) in the ATM gene, 5 (4.9%) in the BIRC3 gene, 5 (4.9%) in the PTEN gene, 4 (4.0%) in the MYD88 gene, 4 (4.0%) in the POT1 gene, and 18 (17.8%) cases in the remaining 11 genes. 26/56 (46.4%) mutated patients presented two or more mutations. The presence of mutations was associated with unmutated IGHV status (p=0.040) and the complex karyotype (p=0.047). TP53 disruption correlated with the presence of ≥2 mutations by NGS (p=0.001) and a complex karyotype (p=0.012). By multivariate analysis an advanced Binet stage (p=0.01) and an unfavorable karyotype (p=0.01) predicted for a shorter time to first treatment (TTFT), while TP53 disruption (p=0.019) and unfavorable karyotype (p=0.028) predicted for a worse overall survival (OS). A shorter time to chemorefractoriness (TTCR) was associated with TP53 disruption (p=0.001) and unfavorable karyotype (p=0.025). Patients with both unfavorable karyotype and TP53 disruption presented a dismal outcome (median OS and TTCR of 28.7 and 15.0 months respectively).

**Summary/Conclusions:** A comprehensive analysis of chromosomal aberrations and gene somatic mutations in high-risk CLL showed that the cytogenetic profile was independently associated with a shorter TTFT, OS and TTCR. Since karyotyping using novel mitigogens may contribute to the refinement of prognosis in high-risk CLL patients, the introduction of this technique in future CLL trials seems warranted to identify those patients that could be ideal candidates for consolidation treatment or novel treatment combinations.

---

**E1021**

**SHOULD CLL-IPI BE USED TO ASSESS OVERALL SURVIVAL OF EVERY CLL PATIENT? A SYSTEMATIC REVIEW AND META-ANALYSIS**

S. Molica1,*, D. Giannarelli2, R. Mirabelli3, L. Levato3
1Hematology-Oncology Department, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, 2Biostatistic Unit, IRCCS Regina Elena, Roma, 3Hematology-Oncology, Azienda Ospedaliera Pugliese-Ciaccio, Catanzaro, Italy

**Background:** A weighted grading approach based on five independent prognostic factors (i.e., TP53 status, IGHV mutational status, 8-loc microglobulin, clinical stage and age) has been used by an international Working Group to generate the chronic lymphocytic leukemia international prognostic index (CLL-IPI). Although the robustness of CLL-IPI has been confirmed in external validation studies it remains unclear whether CLL-IPI has the greatest validity and should be preferred to guide clinical decision in CLL.

**Aims:** To shed light on this important research question, we conducted a systematic review which includes all published studies which used CLL-IPI to prognosticate overall survival (OS) in CLL.

**Methods:** A comprehensive MEDLINE search using “CLL-IPI” as Medical Subject Headings (MESH) allowed to identify at the cut-off time of February the 28, 2017 “seven hits” with only “four” citations considered pertinent. The search was extended to the conference proceedings of annual meetings of ASH, EHA and ASCO of last two years recognized “three” additional citations.

**Results:** Overall 6720 patients from seven evaluable studies were suitable for the present analysis aimed at assessing the impact of CLL-IPI on OS. The majority of patients (4563 or 67.7%) came from studies of external validation of CLL-IPI while 17% (1192) and 8.5% (576) had been used to generate (train- and validation phases) and to internally validate the model. Patient distribution in the four risk categories of CLL-IPI was heterogeneous thus reflecting the CLL phase (i.e., at diagnosis, at time of first treatment and at relapse) of patients within different studies. According, patients diagnosed as having low-, intermediate-, high- and very high-risk CLL-IPI ranged respectively between 9% and 58%, 25% and 39%, 14% and 52% and 2% to 9%. Next we evaluated the 5-year OS of patients stratified into each of the four CLL-IPI risk groups using either “Q” or “I2” test to assess the heterogeneity across different studies. The 5-year survival probability was 91% for low-risk group (95% CI, 90-91%; Q=55.2; P= 0.00; I2, 87%), 85% for intermediate group (95% CI, 79-82%; Q=49.36; P<0.00; I2, 86%), 60% for high-risk group (95% CI, 57-62%; Q=42.78; P<0.00; I2, 84%) and 32% for very high-risk group (95% CI, 27-38%; Q=18.1; P=0.01; I2, 67%).

**Figure 1.**

**Summary/Conclusions:** In this comprehensive review and meta-analysis of studies thus far published on CLL-IPI we confirmed the value of this novel model to predict OS whatever the CLL phase (fig 1). The prognostic impact of CLL-IPI seems warranted to identify those patients that could be ideal candidates for consolidation treatment or novel treatment combinations.
TREATMENT AND 17P DELETION TESTING PATTERNS IN COMMUNITY E1023
T. Kapustyan1,*, H. Keim1, B. Meissner1, L. Zhang1, D. Jiang1
Background: Oral anticancer medications (OAMs) present several advantages compared with intravenous cytotoxic chemotherapy, including greater convenience for the patient. However, OAMs require that a patient be actively involved in regular drug administration over an extended period of time (Schneider SM, et al. Semin Oncol Nurs. 2011;27(2):133-141). Adherence to OAMs significantly impacts patient outcomes; poor adherence may result in inferior survival and outcomes, higher hospitalization rates, treatment resistance, and increased healthcare costs (McCue DA, et al. Pharmacotherapy. 2014;34(5):481-494). The Canadian YOU&i™ patient support program (PSP) was developed to improve adherence to long-term ibrutinib therapy using research-proven techniques for promoting positive behavioral changes, i.e. cognitive behavioral therapy, psycho-social support, and a nurse coaching component. Results from the program are presented below. Aims: To evaluate patient adherence to ibrutinib, and patient and physician satisfaction with the YOU&i™ PSP Methods: Using evidence-based literature reviews and global/local market research, various patient-centered barriers to treatment adherence were identified. A questionnaire was developed using the Morsky Medication Adherence Scale® score, which informed nurse coaching frequency. Adherence was delineated by prescription refill compliance. Patient and physician questionnaires were used to gauge satisfaction with the YOU&i™ PSP. Results: As of 20 January 2016, a total of 903 patients with CLL were enrolled in the YOU&i™ PSP. A total of 552 patients were included in the adherence analysis. Of these, 86% opted in to receive the nurse coaching component. At 2 months from treatment initiation, patients who received nurse coaching demonstrated an adherence rate of 92.3%, as compared with 63.5% for patients who did not receive nurse coaching (95% CI, 17.5±41.0; p <0.0001). At 3 months the adherence rates were 89.9% vs 60.8% (95% CI, 17.5±41.4; p <0.0001). By 9 months, adherence rates were 81.7% vs 71.1% (95% CI, -4.4 to 28.4; p=0.141). At study conclusion, 12 month adherence rates were 76.6% vs 72.2% (95% CI, -18.9 to 32.4; p=0.715). Discontinuation rates were similar in all patients, regardless of nurse coaching status at 9 and 12 months. Patients reported satisfaction rates of >90% in surveys conducted at both 3 months and 12 months of program enrollment. Of physicians surveyed at 3 months, 96% reported that the YOU&i™ PSP was helpful in supporting patient needs.

Summary/Conclusions: The current analysis provides insight into adherence patterns of patients on long-term ibrutinib treatment. These results are consistent with the literature showing that PSPs like the YOU&i™ PSP can help to improve adherence rates (Schneider SM, et al. J Adv Pract Oncol. 2014;5(3):163-172). The information obtained from long-term adherence data can help to inform future trials examining patterns of adherence with OAMs. Nurse coaching may be helpful in supporting early adherence by addressing side effects that occur more frequently at treatment initiation. Moreover, changes in disease or health status that arise over the first 12 months of therapy may provide information that allows a PSP to adapt to patients' evolving needs over the treatment journey. A better understanding of long-term adherence patterns may allow programs such as the Canadian YOU&i™ PSP to target adherence support more precisely, thereby optimizing patient outcomes.

E1024
SINGLE-AGENT IBRUTINIB VS REAL WORLD TREATMENT FOR PATIENTS WITH TREATMENT-NAÏVE (TN) CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): AN ADJUSTED COMPARISON OF RESONATE-2™ WITH THE CLLEAR AND LYON-SUD DATABASES
M. Doubek1, E. Bachy2, M. Spacek3, L. Baseggio2, R. Urbanova4, H. Besson5, J. Diels5, J. Garside6, N. Healy7, W. Iqbal8, E. Callet-Bauchu2, L. Smolej9, G. Salles2

Background: The phase 3 RESONATE-2™ study demonstrated significant improvement of progression-free survival (PFS) and overall survival (OS) with ibrutinib (ibr) vs chlorambucil (cbl) in TN (aged ≥65 years) CLL patients. In the absence of direct comparison of single-agent ibr with other frequently utilized agents in this patient population, this retrospective observational study utilized a propensity score matching analysis based on standard of care as observed in clinical practice can provide useful insights on the relative efficacy of ibr. Aims: To investigate the relative treatment effect on PFS and OS for ibr vs real world (RW) treatment in daily clinical practice in TN CLL patients by adjusting for differences in patient characteristics from RESONATE-2™ vs RW from the CLLEAR (Chronic Lymphocytic Leukemia Registry) and Lyon-Sud databases. Methods: CLLEAR holds medical records for CLL patients from seven academic centers across the Czech Republic. Lyon-Sud database holds medical records for CLL patients from a French French hospital Lyon-Sud. Patients initiated on CLL frontline therapy were selected from CLCLEAR and Lyon-Sud using the same inclusion-exclusion criteria as for RESONATE-2 (excluding patients with age<65 and with del17p positive status). PFS and OS were compared...
pared between ibru and RW treatment using patient-level data from RES- 
ONATE-2™ (n=136) and pooled patient-level data from the two cohorts. To 
adjust for differences in patient characteristics between the trial population 
and both cohorts, a multivariate Cox proportional hazards model was fitted on 
patient-level data to estimate the hazard ratio (HR) for ibru vs RW treatment, 
with age, sex, disease stage (based on RAI/BINET), and deletion 11q pres-
ence/absence instead as covariates.

Results: Median age at treatment initiation for CLELLR (n=418) and Lyon-Sud 
(n=110) was 73 and 71 years, respectively, vs 73 for ibru patients from RES-
ONATE-2™. The proportion of male patients was 63% in CLELLR and 57% in 
Lyon-Sud vs 85% in RESONATE-2™. The median follow-up was 35.7 months 
(mo) for Lyon-Sud and 16.8 mo in CLELLR vs 29.1 mo for RESONATE-2™. 
Adjusted HR for ibru vs physician choice in CLELLR and Lyon-Sud were 0.23 
(95% CI: 0.14, 0.39) and 0.25 [0.14, 0.43] for PFS, and 0.29 [0.11, 0.79] and 
0.39 [0.18, 0.83] for OS, respectively. Fludarabine/cyclophosphamide/ritux-
imab (FCR; n=117), bendamustine+R (BR; n=91), CH alone (n=43), CH+ 
R (n=45), and other R-containing regimens (n=154) were the most commonly 
used treatment regimens across both RW cohorts. Older age, male gender, 
advanced disease stage and del11q positive status were independent risk fac-
tors for PFS and OS. The adjusted HRs (pooled estimates) for ibru vs the two 
most commonly used regimens were 0.30 [0.17-0.53] (FCR) and 0.33 [0.16-
0.68] (BR) for PFS, and 0.44 [0.20-0.95] (FCR) and 0.53 [0.13-0.83] (BR) for OS 
(Figure 1). Estimates of HR vs regimens in the cohorts were consistent across 
databases.

Figure 1.

Summary/Conclusions: This adjusted comparison of patient-level data from RESONATE-2™ with RW data from CLELLR and Lyon-Sud demonstrates ibru 
to be more effective compared with RW treatment, with a 4.1-fold improvement 
in PFS and a 3-fold improvement in OS. When comparing ibru with the most 
commonly used RW treatments, statistically significant benefits for ibru were 
consistently observed vs all treatment regimens on PFS and for most compar-
isons on OS. These results further support the existing evidence that ibru sig-
ificantly improves PFS and OS vs common regimens used in TN CLL settings, and has important implications for clinical practice.

E1025

CHARACTERISTICS, TREATMENT, AND OUTCOMES OF ≥80 YEAR OLD PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) ENROLLED TO PROSPECTIVE TRIALS OF THE GERMAN CLL STUDY GROUP (GCLLSG)

O. Al-Sawaf1,*, J. Bahlo1, K. Fischer1, C. Herling1, M. Hoechstetter2, A. Fink1, J. von Tresckow1, P. Langerbeins1, P. Cramer1, S. Stilgenbauer3, C. Wendtner4, B. Eichhorst1, M. Hallek1, V. Goede1

1Department of Internal Medicine, German CLL Study Group, University Hospital of Cologne, Köln, 2Department of Hematology, Oncology, Immunology, Palliative Care, Infectious Diseases and Tropical Medicine, Hospital Munich Schwabing, Munich, 3Department of Internal Medicine III, University Hospital of Ulm, Ulm, Germany

Background: People over 80 years are the fastest growing age group in west-
ern populations. Clinical management of ≥80 year old patients (pts) with CLL 
remains a challenge due to the very limited amount of data currently available 
for this age segment. Two retrospective studies reported observational data on 
characteristics, treatment, and outcomes of ≥80 year old pts not enrolled in a 
clinical trial (Br. Muller et al). Little is known about ≥80 year old pts who were treated for CLL within clinical trials, however.

Aims: To study the characteristics, treatment, and outcomes of pts aged ≥80 
years who received their first therapy within prospective trials of the German 
CLL Study Group (GCLLSG).

Methods: Trial populations of seven clinical trials of the GCLLSG (CLL1, CLL5, 
CLL7, CLL8, CLL9, CLL10, CLL11; total N=3552) were reviewed and screened 
for pts ≥80 years at frontline treatment. Clinical, laboratory, and genetic data of 
identified pts were pooled. Time-to-event analyses were performed by Kaplan-Meier 
methology. Independent prognostic factors for survival were identified by 
multivariate analysis using Cox regression modelling with stepwise selection 
procedures.

Results: Among 3552 reviewed GCLLSG trial participants, 152 were aged ≥ 
80 years at initiation of firstline treatment. A majority of these pts were identified 
from CLL1 (n=132) while the remaining were from CLL1 (n=3), CLL5 (n=1), 
CLL7 (n=3), CLL8 (n=2), CLL9 (n=9), and CLL10 (n=2). Median age was 82 
years (range 80-90). Concomitant diseases were present in 99% of the pts and 
median cumulative illness rating scale (CIRS) score was 8 (0-18). Median 
creatinine clearance was 46 ml/min (range 17-99 ml/min). Identified genomic 
 aberrations were 1q deletion as a sole abnormality in 27%, trisomy 12 in 18%, 
11q deletion in 9%, and 17p deletion in 16% of pts. (IGHV was unmutated in 
69% of the pts. Distribution of CLL-IPPI risk groups was as follows: 6% low, 19% 
intermediate, 61% high, and 14% very high. Most pts had Binet Stage B (36%) 
or C (43%). Chemioimmunotherapy with chlorambucil plus obinutuzumab (CLB-
OB) or chlorambucil plus rituximab (CLB-R) was administered to 61 (40%) and 
56 (37%) pts, respectively. Remaining pts received chlorambucil alone (CLB, 
n=19), fludarabine (F, n=10), fludarabine/cyclophosphamide (FC, n=1), fludara-
bine/cyclophosphamide/rituximab (FCR, n=2), or bendamustine/rituximab (BR, 
n=3). Rates of grade 3 or 4 neutropenia and infections were 35% and 13%, 
respectively. Premature treatment discontinuations occurred in 15% of cases 
and were mostly due to adverse events. The total overall response rate was 
92% with 13% complete remissions. Median observation time for all pts was 
40.7 months. Median progression-free survival (PFS) and treatment-free sur-
vival (TFS) were 17.2 and 32.3 months, respectively. A total of 47 pts (31%) 
received at least one further line of treatment. Median overall survival (OS) 
was 48.3 months, with adverse events (22%) and progressive CLL (16%) being 
the most frequent causes of death. Standardized mortality ratio was calculated 
and showed a 1.99 (CI 1.54-2.53) increased risk of death as compared to an 
age- and sex-matched general population. Independent prognostic factors 
for OS were 17p deletion and elevated serum thymidine kinase.

1Laboratory of Oncology/Hematology and Transplantation, Institute of Biomed-
ical Research, IIB Sant Pau, 2Department of Hematology, 3Laboratory of Hema-
tology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Clinical, morphologic, immunophenotypic and genetic features 
are the basis for the diagnosis of B-cell malignancies. It is considered that the diag-
nosis of CLL requires the presence in peripheral blood of >5x10⁹/L monocular 
B lymphocytes with a distinctive immunophenotype (i.e. CD19+, CD20+, 
CD23-, FMC7-, CD79a-, CD22+, CD200+, SmIg weak, CD22 weak) each one of them receiving a score of 
1 when the positive cells were >96%. Mean Fluorescence Intensity Ratio 
(FMC7, CD22 and CD79b) are considered score 1 in 

Summary/Conclusions: Findings suggest that anti leukemic therapy (including 
chemoimmunotherapy) is feasible and efficacious in ≥ 80 year old pts with CLL. 
However, such pts are still highly underrepresented in clinical trials and even 
with modern treatment live shorter than age-matched controls of the general 
population. Broader recruitment of these pts to prospective trials and evaluation 
of targeted therapies therefore appears imperative to improve outcome of CLL 
in this age segment.
and type of aberrations detected were compared between techniques. Whole-Genome 2.7M (n=2) or CytoScan HD (n=22) array, results were ana-
mononuclear cells or CD19+ lymphocytes was hybridized to Cytogenetics
4 patients (16%) had received prior treatment. The cohort was enriched in
plexity are lacking.

Results: Flow cytometry analysis was performed in 99 patients, including 62 cases with a diagnosis of CLL (82.6%) and 37 cases with a “non-CLL” diagnosis (17.4%). Matutes score was 4-5 in all CLL cases and ≤3 in “non-CLL” cases. CD20, CD79 and CD5 were the most consistent markers for CLL (90.3%, 96.8% and 100.0% of sensitivity respectively). Moreover, CD79b and FMC7 had a good discriminant value (80-85% sensitivity). For “non-CLL” cases the most reliable markers were SmIg, FCMI and also CD20. The analysis of the accuracy is shown in the table. Of note, CD20 as a single marker was found to be a reliable marker for distinguishing CLL and “non-CLL” cases (90.9%; p=0.001; 90.3% sensitivity, 91.9% specificity) showing a significantly higher accuracy than CD5, CD23 and SmIg as individual markers (p<0.001). The accuracy of CD20 did not vary when comparing% of positive cells and MFIR. In contrast, the accuracy for SmIg significantly increased from 67.7% to 78.5% when using MFIR values (according to the cut-off established by ROC curves), being lower in CLL than in “non-CLL” cases (71.0% vs 86.5%, p<0.001). Finally, the addition of CD20 to the Matutes score system and using a cut off ≥4, improved its accuracy from 88.9% (95% CI: 88.2-95.6) to 98.0% (95% CI: 94.7-100.0) and showed a better sensitivity.

Table 1.

Summary/Conclusions: These results confirm CD20 as a valuable marker in the diagnosis of CLL

E1028

ABNORMAL SERUM FREE LIGHT CHAINS RATIO ASSESSMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA: A SIMPLE YET POWERFUL TEST CORRELATING WITH CLINICAL OUTCOME AND MINIMAL RESIDUAL DISEASE
F. Dumoulin1,*, M. Le Bouar1, F. Bijou2, A. Schmitt2, J. Blanchi1, G. Etienne2
1Laboratory of hematology, 2Hematology Department, Institut Bergonie, BOR-DEAUX, France

Background: An abnormal serum Free Light Chain (sFLC) ratio has been shown to be significantly associated with poor outcome in chronic lymphocytic leukemia (CLL) [Yegin ZA et al, Eur J Haematol 2010], suggesting that this parameter may discriminate different biological subgroups.

Aims: As the technic is easily implementable in routine lab and cost effective, we evaluated the sFLC levels (kappa + lambda) and kappa/lambda (K/L) ratio in CLL patients in this prospective study. The relationship between abnormal sFLC levels (K+L) and K/L ratio, minimal residual disease (MRD) assessed by flow cytometry (FCM) and disease evolution was evaluated.

Methods: Diagnosis was confirmed by 10-color FCM immunophenotyping of blood lymphocytes on a Navios (Beckman Coulter). Serum FLC kappa and lambda chains were measured by nephelometry using the Freelite™ immunoassay. The normal free kappa chains level was defined as within the range of 3.3-19.4mg/L, and the normal lambda chains level within the range of 5.71-26.30mg/L. A normal sFLC kappa/lambda (K/L) ratio was therefore defined as between 0.26 and 1.65 (a ratio above 1.65 indicating an excess of kappa light chain, and a ratio below 0.26 indicating an excess of lambda light chain). The cumulative level of kappa plus lambda (K+L) was also evaluated. Most patients received combined chemo-immunotherapy or entered clinical trials whenever possible. The ROC methodology was used to establish the best cut-off value of sFLC ratio level to discriminate treated patients from those who remained treatment-free.

Figure 1.

Results: Main patients characteristics are detailed [N=147, M/F:75/72, 111 in early stage disease, Del17p in 11 patients and Del11q in 15]. Median age was 422 | haematologica | 2017; 102(s2)
69 years (range 34 to 86). Ninety patients were untreated during the follow-up period. Median follow-up duration was 30 months (range 0 to 101). Furthermore, sFLC measurement was assessed in 57 patients who progressed during the study and required treatment according to international guidelines. ROC curve analysis determines cut-off level of K/L ratio at 1.88. Abnormal sFLC was observed at diagnosis in 50.9% (N=29) of all treated patients. The mean ± SD ratio of sFLC in the untreated patients group and in the treated patients group was 1.51±2.08 and 2.80±3.75 respectively (p=0.0082). Considering the sFLC levels (kappa + lambda), the mean±SD in the untreated patients group and in the treated patients group was 29.1±17 and 53.0±11.9 respectively (p<0.0001).

Treatment systematically induced a modification of the sFLC K/L ratio. Interestingly, the fraction of patients who had the lowest ratio of an abnormal k/l ratio was associated with positive MRD determined by FCM with 82% specificity and a 95% positive predictive value. Moreover, median time to treatment income for patients in early stage disease with ratio >1.88 was 12 months while it is not reached in those with ratio ≤1.88 (p<0.0001) (figure 1).

Summary/Conclusions: In our study we observed that sFLC K/L ratio determination as a technically simple, standardized and cost-effective test to evaluate new prognostic factors. Moreover, we found a relationship between HYPO and a risk of more than 40%. There was no difference in dense- or alpha-granule release between the patient groups, and these indicators remained in their normal ranges. There were also significant differences in aggregation assay with ADP (25±16% versus 36±18% for bleeding and non-bleeding patients, p<0.001), collagen (38±19% versus 53±20%, p=0.001), and ristocetin (53±22% versus 62±20%, p=0.02). Interestingly, the patients with bleeding had negative correlation with platelet aggregation with a lower mean platelet count that those without (120 versus 170 thousands per microliter, P<0.0001) and higher lymphocytosis (74 thousands per microliter, P<0.0001) with an incidence of 20-60% at diagnosis and a relationship with infections occurrence. Prognostic significance of HYPO at diagnosis has not been extensively evaluated in terms of OS and TTFT. Only IgG serum levels have been reported to be associated with TTFT but no data are available on other immunoglobulin classes (lg).

Aims: To evaluate the impact of HYPO and single Ig classes on TTFT in a retrospective cohort of CLL patients and to assess the relationship between HYPO and CLL-IPI.

Methods: We retrospectively evaluated 698 consecutive CLL patients diagnosed at our Institution from 1983 till 2016. Data from laboratory, biological analysis and clinical stage were collected. We also evaluated immunoglobulin (lg) levels (e.g. IgG, IgM and IgA) at diagnosis and calculated CLL-IPI. HYPO was defined as having on our laboratory cut-offs (IgG 70mg/dl, IgG 700mg/dl in 22%, and IgM lower 40mg/dl in 33.7%). Forty-six percent of patients presented deficit of at least one lg class, while 7.8% of patients had all lg low. Each lg deficit was related with a shorter TTFT with the following hazard ratios (HRs): 2.09 (1.45-3.03) for IgA (P<0.0001), 1.58 (1.10-2.27) for IgG (P=0.008) and 1.52 (1.09-2.13) for IgM (P=0.01). However, no recognized prognostic/predictive lg cut off has been reported to date, we aimed to identify a prognostic threshold for each lg class.

Results: From 698 patients assessed, 410 cases were evaluable for Ig values at diagnosis. IgA levels were lower than 70mg/dl in 17.4%, IgG lower than 700mg/dl in 22.2%, and IgM lower 40mg/dl in 33.7%. Forty-six percent of patients presented deficit of at least one lg class, while 7.8% of patients had all lg low. Each lg deficit was related with a shorter TTFT with the following hazard ratios (HRs): 2.09 (1.45-3.03) for IgA (P<0.0001), 1.58 (1.10-2.27) for IgG (P=0.008) and 1.52 (1.09-2.13) for IgM (P=0.01). However, only IgA deficit maintains statistical significance in multivariate analysis [HR 1.58 (1.08-2.35)]. A prognostic threshold for each lg class was identified maximizing the differences in TTFT and the following values were obtained: 80mg/dl for IgA, 410mg/dl for IgG and 186mg/dl for IgM (Figure 1, A-B-C). Considering CLL-IPI, 19 patients presented IPI 0-1, 99 had IPI 2-3, 32 patients IPI 4-6, and 12 patients had IPI 7-10. Even in our series, CLL-IPI separated four risk groups with different TTFT and OS, suggesting that our cohort may be suitable to evaluate new prognostic factors. As regards the relationship between HYPO and CLL-IPI, we observed a correlation with IgA levels, using our laboratory cut-off. Moreover, we found a relationship among CLL-IPI and both IgA and IgM values, using when the newly validated lg cut-off. Finally, CLL-IPI was a stronger prognostic factor for TTFT than HYPO in our analysis. However, the addition of IgA deficit to CLL-IPI appears to further improve CLL prognostication.

Summary/Conclusions: In conclusion, HYPO significantly impacts on CLL prognosis. Moreover, even if CLL-IPI has a stronger prognostic value for TTFT compared to HYPO, the addition of IgA deficit appears to further improve CLL prognostication.
E1031
CLL: IS LYMPHOCYTE DOUBLING TIME (LDT) A RELEVANT PROGNOSTIC PARAMETER IN THE ERA OF PROGNOSTIC BIOMARKERS?
T. Baumann1,*, J. Delgado3, P. Mozos1, V. Ortiz-Maldonado4, R. Santacruz2, M. Moreno1, M. Aymerich3, N. Villamor3, D. Costa4, A. Carrizo3, E. Montserrat1
1Hematology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain; 2Hematology Department, Hospital de Clinicas, Asunción, Paraguay; 3Hematopathology Unit, Pathology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain

Background: In CLL, tumor doubling time is reflected by the pace at which lymphocytes increase in blood (lymphocyte doubling time or LDT). However, since LDT is rarely available at the time of diagnosis, its role in assessing prognosis in patients in CLL is controversial.

Aims: To reassess the prognostic significance of LDT in a large series of patients.

Methods: Retrospective single-center study based on 629 patients diagnosed with CLL/SLL. LDT was measured at the time of diagnosis if prior WBC counts were available or calculated after diagnosis by linear regression analysis, usually over a treatment-free period of 2 months and including at least three WBC counts.

Results: 140 patients displayed short LDT (≤12 months) and 489 long LDT (>12 months). The median follow-up was 13.4 years (6.1-22.5) and 11.2 years (2.3-30.9), respectively. Patients with short LDT were younger (p=0.005), had more advanced clinical stage (p=0.001), higher ALC (p=0.001), as well as increased serum LDH (p=0.001) and B2-microglobulin (B2M; p=0.035) levels and also a tendency towards lower levels of Hb and platelet counts. A short LDT was also associated with an increased expression of ZAP70 and CD38, unmutated IGHV (all p<0.001) and poor FISH cytogenetics (del17p, del11q) (p<0.001).

Additionally, patients with a short LDT presented more frequently mutations in NOTCH1 (p=0.008), ATM (p=0.029), TP53 (p=0.035) and a tendency to more mutations in SF3B1 (p=0.102). The proportion of patients treated in each group was markedly different [80% vs 46%] as it was the median time to treatment (TTT). 1.4 vs 9.4 years; p<0.001). Type of treatment (mainly, chemotherapy and immunotherapy) did more frequently treated with alkylating agents than purine analogues. Furthermore, there was no significant differences in response rates (ORR 59% with 29% CR vs 69% with 29% CR; p=0.253). Overall survival (OS) was shorter in the group with short LDT (median: 7.2 vs 12.2 years; p<0.001). Univariate analysis demonstrated a significant correlation between OS and advanced clinical stage, age >70 years (HR 2.0 (95% CI: 1.0-3.9), p=0.028) and high-risk FISH genetics (del17p, del11q) (all p<0.001). Likewise, mutations in NOTCH1 (p<0.001), SF3B1 (p=0.027), ATM (p=0.028) and TP53 (p=0.028) were associated with OS. In a multivariate analysis including clinical stage, age, LDT, IGHV, ZAP70, FISH cytogenetics and ATM or TP53 (type 1, 2, 3), short LDT increased the risk of progression (p=0.035) and death (p<0.001).

Summary/Conclusions: This study shows that LDT continues being an independent prognostic parameter for OS in the era of biomarkers. In contrast, LDT did not correlate with response to therapy and, accordingly, cannot be regarded as a response predictor to chemo(immuno)therapy. Finally, LDT warrants investigation in the setting of novel therapies.

INDICATIONS FOR TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA: CLINICO-BIOLOGICAL CHARACTERISTICS AND PROGNOSTIC IMPACT
P. Mozas1,*, A. Rivas-Delgado1, T. Baumann1, V. Ortiz-Maldonado4, A. Navarro5, D. Costa4, M. Aymerich3, N. Villamor3, E. Montserrat1
1Hematology, 2Pathology, 3Hematopathology Unit, Pathology, Hospital Clinic de Barcelona, Institut d’Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain

Background: Chronic lymphocytic leukemia (CLL) is characterized by the progressive accumulation of monoclonal CD5+ B cells in the bone marrow and lymphoid tissues. International guidelines recommend initiation of treatment only in case of infiltrative cytopenia, progressive splenomegaly or lymphadenopathy, short lymphocyte doubling time (LDT), B symptoms and/or refractory/unmutated IGHV (IGHV6-2-4 (95% CI: 1.5-4.0), p=0.003), and presence of TP53 mutation (HR 2.0 (95% CI: 1.3-9.3), p=0.041).

Summary/Conclusions: This study shows that LDT continues being an independent prognostic parameter for OS in the era of biomarkers. In contrast, LDT did not correlate with response to therapy and, accordingly, cannot be regarded as a response predictor to chemo(immuno)therapy. Finally, LDT warrants investigation in the setting of novel therapies.

UNCOVERING PRIMARY TP53-DELETED CLONES WITH FISH THROUGH FACS-SUPPORTED PURIFICATION OF CHRONIC LYMPHOCYTIC LEUKEMIA LYMPHOCYTES
G. Marques1, M. Pereira2,*, J. Lima5, R. Reis1, A. Coelho1, L. Jorge1, S. Pedrozo1, L. Ribeiro2, A. Paiva3, F. Rodrigues1, S. Pedreiro4
1Clinical Pathology Department, 2Clinical Hematology Department, Coimbra University Hospital Centre, 3Faculty of Medicine, University of Coimbra, 4Flow Cytometry Unit, Coimbra University Hospital Centre, Coimbra, Portugal

Background: The presence of TP53-inactivation in chronic lymphocytic leukemia (CLL), namely through the deletion of all or part of the chromosome 17q region containing its locus, is a well-established marker of poor prognosis and chemoresistance to traditional chemotherapeutic agents. Fluorescence in situ hybridization (FISH) is a useful tool for the detection of the deletion. Nevertheless, its sensitivity is influenced by the number of blood-cell lineages that carry the aberration, the absolute count of deletion-positive cells, and the proportion of deletion-positive neoplastic cells relative to deletion-negative neoplastic cells and non-neoplastic cells, in the whole blood or bone marrow sample. The latter issue can be minimized by purifying the sample through the selection and separation of tumor cells, using techniques such as fluorescence-activated cell sorting (FACS).

Aims: In this study, we aim to evaluate the benefit of using purified samples of neoplastic CLL lymphocytes for the detection of TP53-deletion by FISH, when compared to full samples.
Methods: We reviewed all CLL samples that were submitted for the investigation of TP53-deletion through FISH, in our Lab, between January 1st 2011 and February 28th 2017. Results obtained on tests performed on whole mixed cellularity samples were compared with results obtained directly in FACS purified CLL clonal lymphocytes. 

Results: We analyzed 410 samples tested for the deletion of TP53 in our Lab during the study period. The majority of patients (63.2%) were male. Although FACS separation of neoplastic cells was only introduced within the last two years of the study period, it accounted for 39.0% of all tested samples. This poor prognostic aberration was identified in 15.8% of patients in the overall cohort, with no differences in the incidence of a positive finding between mixed cellularity samples and FACS purified samples (15.6% vs 16.2%, respectively, p=NS). In contrast, the average proportion of positive cells within a positive sample was markedly different between mixed cellularity samples and FACS-processed samples, increasing nearly three-fold through the purification of the sample, from 24.0±15.9% to 62.9±33.3%, p<0.001. In fact, in 57.7% of all patients who were tested after FACS separation of CLL cells, the TP53-deleted clone was larger than 50% of neoplastic clonal lymphocytes, making it the primary clone.

Summary/Conclusions: We observed that the pre-processing of the sample through the FACS-supported purification of CLL neoplastic lymphocytes revealed that the TP53-deleted clone was nearly three-fold larger than suggested by the mixed cellularity sample, increasing from an average of a quarter of all cells, to nearly two-thirds. This finding uncovered that the TP53-clone was, in fact, the primary major clone within the neoplastic lymphocyte population in the majority of patients. Considering the poor prognosis conferred by the aberration, and its impact on current treatment decisions, it is quite significant to correctly identify a primary deletion-positive clone, instead of mislabeling it as a secondary minor clone.

PRIMARY PEFGILGRASTIM PROPHYLAXIS VERSUS FILGRASTIM GIVEN "ON DEMAND" FOR CLADRIBINE - INDUCED NEUTROPENIA IN Hairy Cell leukemia

Background: Most targeted therapies in the management of chronic lymphocytic leukemia (CLL) lead to high overall response rates but complete remissions are rare. Achieving complete remission (CR) is associated with improved clinical outcomes such as longer time to progression; however little is known about the economic benefits associated with achieving CR.

Aims: The objective of the study was to compare healthcare resource utilization among CLL patients initiated on first-line treatment who achieved CR versus those who did not.

Methods: This was a retrospective chart review study. From July to August 2016, 93 US oncologists/hematologists provided data abstracted from medical charts of their CLL patients who initiated a first-line CLL treatment between January 2010 and December 2014. The study collected patient demographics, clinical characteristics, response to first-line therapy, and the number of all-cause hospitalizations between first-line therapy initiation and end of the data follow-up (i.e., patient’s date of death, end of care, or data collection date, whichever occurred first). Patients were selected based on their best response to first-line therapy (i.e., CR, partial remission [PR], stable disease [SD] and progressive disease [PD]) as defined by the physician according to iwCLL 2008 criteria. The targeted number of patients in each category was a priori determined based on rates of response observed in clinical trials. The incidence of all-cause hospitalization was compared between patients who achieved CR and those who did not (including patients with PR, SD or PD) using univariate and multivariate generalized linear models with a Poisson distribution. As patients had different follow-up, incidence rates were reported per-patient-per-month (PPPM). Multivariate regression models were adjusted for age, gender, selected comorbid conditions, time from CLL diagnosis to first-line initiation, and Eastern Cooperative Oncology Group (ECOG) status.

Table 1.

Results: Patient-level data was collected for 179 patients who achieved CR and 151 patients who did not achieve CR (120 patients with PR, 25 with SD, and 6 with PD). Average time from CLL diagnosis to first-line initiation was 8.4 months for patients who achieved CR and 13.3 months for those who did not. The majority of patients were male (65%), the average age was 63 years, and 80% of patients had an ECOG of 0 or 1 at first-line therapy initiation. The medi-
an follow-up after first-line therapy initiation was 30 months. Over that period, patients who did not achieve CR had statistically significantly higher incidence of all-cause hospitalization compared to patients who achieved CR (0.021 vs 0.006 PPPM; unadjusted incidence rate ratio [IRR]=3.30, p<0.05). After adjusting for potential confounders, the incidence of all-cause hospitalization was 2.4 times higher for patients who did not achieve CR compared to those who did (IRR=4.9, p<0.05).

Summary/Conclusions: Results from this study showed that achieving CR to first-line therapy (vs. not achieving CR) is associated with reduced frequency of all-cause hospitalizations. This suggests that, in addition to the clinical benefit associated with CR achievement, treatment strategies in CLL that improve CR may help reducing the economic burden of CLL management for both patients and payers.

E1036
RITUXIMAB (R) USED AS A SINGLE AGENT FOR AUTOIMMUNE HEMOLYTIC ANEMIA (AIHA) IN TREATMENT NAÏVE CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) PATIENTS INDUCES ALSO SIGNIFICANT DISEASE RESPONSE WITHOUT TOXICITY

1Hematologic, Athens Medical Center, Psychiko Branch, Athens, 2Hematologic, Athens Medical Center, Psychiko Branch, Athens, 3Hematologic, University Hospital, University of Crete, Heraklion, 4Blood Transfusion, Athens Medical Center, Phychikon Branch, Athens, 5Hematologic, Laikon General Hospital, University of Athens, Athens, Greece

Background: There are very few effective treatment options for steroid refractory AIHA of CLL or for CLL patients(pts) that are unable to receive corticosteroids. R has been noted to be active in certain autoimmune hematologic disorders while experience with single-agent R in untreated CLL pts is very limited.

Aims: To report our experience concerning the use of R as a treatment of AIHA occurring during the first course of treatment of naive/CLL pts by analyzing concomitantly its efficacy and safety as a single agent in CLL therapy

Methods: 15 pts diagnosed with CLL who received R due to AIHA were included in this study. Staging was performed at diagnosis (Binet system). Pts were placed on R at the standard dose I.V. of 375mg/m2 once weekly for 6 consecutive weeks because of contraindication of corticosteroids administration.

Results: Pts’ median age was 60 (range, 42-83 y). (8 out of 15, males), 10 having disease stage A and 5 B. Two were presented with splenomegaly and 1 with B-symptoms. 12 pts (83%) had leukemoid lymphocyte counts of more than 50x10^9/L. Median time from diagnosis, the AIHA diagnosis and to 1st R infusion was 59 mos. All 15 pts completed the 6-week course of R and were assessable for response. The median WBC and the median absolute lymphocyte count(ALC) before R administration and after the end of 6-week course are shown in the Table. Resolution of the AIHA effect was achieved in all pts whereas in 4 there was a persistence of positive DAT without evidence of active hemolysis. After the 6 weekly R infusion 13 out of 15 pts (86.6%) showed also disease response. 12 pts experienced PR (80%) and 1 CR (6%). All pts with advanced disease also responded entering PR. Resolution of splenomegaly was documented in both splenoegalnic pts. After a median follow up of 84, 5 mos from CLL diagnosis, 14 pts are alive, 9 maintain their disease response while 5 were in need of therapy due to CLL progression, after a median time of 10 mos from the last R infusion. Among them 4 were placed on FCR (2CR, 2PR) and 1 on R-Bendamustine(PR). Median PFS has not reached. All pts received the entire first dose on day 1 of treatment. There was only a grade 3 infusion related reaction in a pt with WBC>40x10^9/L without need for hospitalization. None of the pts experienced severe tumor lysis syndrome, pulmonary insufficiency, myelosuppression or opportunistic infections.

Summary/Conclusions: A) R is an effective agent for AIHA treatment with concomitant significant activity against CLL and therefore could be the standard of care for CLL pts with AIHA, especially for the cohort of pts with comorbidities. B) We confirm previous data that: 1) single-agent R induces significant responses in treatment naïve CLL pts 2) R is well tolerated and its administration is not associated with myelosuppression or immunosuppression 3) R as a single agent could be an excellent first-line treatment option for pts who are very elderly or who have a poor performance status

E1037
ATTAINMENT OF COMPLETE REMISSION IS SIGNIFICANTLY ASSOCIATED WITH LONGER SURVIVAL OUTCOMES IN RELAPSED/REFRACTORY (R/R) CLL: A META-ANALYSIS

V.U. Ektare1,*, C.P. Fox2, R.S. Taylor3, T.J. Incencio1, G.E. Pena4, J.C. Maher4, S.J. Snedecor1

1Pharmen International, Bethesda, United States, 2Nottingham University Hospitals, Clinical Hematology, Nottingham, 3University of Exeter Medical School, Exeter, United Kingdom, 4AbbVie, Inc., North Chicago, United States

Background: Chronic lymphocytic leukemia (CLL) is an incurable neoplasm of B lymphocytes, associated with a heterogeneous clinical course. Complete response (CR) with/without a minimal residual disease in first-line chemotherapy has been associated with more favorable progression-free survival (PFS) and overall survival (OS). However, patients (pts) with R/R CLL and/or those with TP53 abnormalities (ie, 17p deletion and/or TP53 mutation) are less likely to achieve deep responses and experience poorer outcomes. Therefore, less is known about the relationship between CR and survival outcomes in R/R CLL pts.

Aims: To quantify this association, we generated meta-analytic estimates of PFS and OS reported in clinical trials using the proportion of study patients with CR as a predictor variable.

Methods: We performed a systematic literature review of PubMed/EMBASE up to Nov 2014 and congress abstracts 2012‒2014. Randomized controlled trials and observational studies evaluating any treatment in R/R CLL pts were eligible for inclusion. Data were extracted from publications as median survival, the proportions of pts surviving at specific follow-up times, or individual event occurrence. Pooled estimates were calculated using random-effects models and the DerSimonian-Laird method. Response variables included studies that were not also associated with CR, our variable of interest. The hazard ratio (HR; and 95% credible interval, the Bayesian analog to confidence intervals) of survival for each 10% increase in CR among a population was estimated to be 0.94 (0.86, 0.99). The median OS for hypothetical populations with 0% CR, 25% CR, or 50% CR were 22.9 mo, 44.7 mo, and 61.9 mo. Corresponding median PFS estimates were 10.0 mo, 21.9 mo, and 30.3 mo. (Figure 1).

Summary/Conclusions: The attainment of CR is significantly associated with longer OS and PFS outcomes in R/R CLL at the study level. Moreover this can be expressed linearly, with each 10% increase in CR rate corresponding to a 36% reduction in the risk of progression or death. To our knowledge, this is the first meta-analysis to quantify the relationship between CR and survival outcomes in R/R CLL pts. It must be noted that these results reflect the study (population) level CR versus survival association and therefore do not necessarily represent the expected survival gain associated with an individual achieving CR. Further, CR is less likely to be achieved in pts with TP53 abnormalities, a factor not explicitly considered in our analysis. These results synthesize data from 56 clinical trials and strongly support the importance of achieving CR to improve long-term outcomes in R/R CLL pts. In particular, the predictive association between CR and TP53 abnormalities, treatments focused on improving the likelihood of CR in these hard-to-treat pts are likely to confer the greatest impact on survival outcomes.

Figure 1.
APLICATION OF THE CLL-IPI AND THE MDACC PROGNOSTIC INDEXES IN A LOCAL COHORT OF CLL PATIENTS

I. González-Gascón Y Marin1, M. Pozo1, M. Hernández-Sánchez2, A.E. Rodríguez-Vicente2, M.S. Infante2, C. Muñoz Novas1, C. Heras1, M.A. Foncillas1, M.J. Hernández-Rivas2, J. Hernández1
1Hospital Universitario Infanta Leonor, MADRID, 2IBSAL, IBMCC, Centro de Investigación del Cáncer, Universidad de Salamanca-CSIC, Salamanca, Spain

Background: New prognostic scores have been developed in order to better discriminate the clinical course of CLL patients, along with Rai and Binet clinical staging systems. These scores, such as that proposed by the MDACC group, and recently the CLL-IPI combine clinical and biological variables with prognostic value.

Aims: In this study we investigated the validity and reproducibility of these scores in a local cohort of patients with CLL.

Methods: We made a retrospective analysis including 650 unselected CLL patients newly diagnosed and previously untreated from a single institution. The final analysis has been limited to the 486 cases with complete data to apply the MDACC score, and to the 258 cases with complete data to apply the CLL-IPI score.

Results: Median age was 67 years old (25-90). With a median follow-up time of 46 months, 394 patients were alive, and 187 had received any treatment for CLL at the moment of the analysis. Median overall survival (OS) of the whole series was 173 months (127-220), and median time to first treatment (TTFT) 106 months (82-130). The MDACC score was applied to 486 cases giving 0 to 9 points to each case according to: age, β2-microglobulin levels, absolute lymphocyte count, sex, Rai stage, and number of involved lymph node groups. As shown in the Table, stratification of patients using the MDACC score allowed the prediction of prognosis for both TTFT (P=0.000) and OS (P=0.000). 162 patients were classified as low risk, 79 as intermediate risk, 46 as high risk. Due to missing data, the CLL-IPI score could only be applied to 258 patients giving 0 to 10 points to each case according to 17p deletion, IGHV mutational status, β2-microglobulin, clinical stage, and age. As shown in the table, 126 patients were classified as low risk, 79 as intermediate risk, 46 as high risk, and 7 as very high risk. We also found significant differences in terms of OS (P=0.000) and TTFT (P=0.000) using this score.

Table 1.

Summary/Conclusions: In this study we confirm that both scoring systems are able to discriminate patients in different prognostic subgroups. Both scores are also easily applicable in clinical practice. The new CLL-IPI score is able to distinguish subgroups of patients with worse prognosis including new factors (17p deletion and mutational status of IGHV).

CHRONIC LYMPHOCYTIC LEUKEMIA: PROGNOSTIC VALUE OF CLINICAL STAGES AND CLASSICAL PROGNOSTIC PARAMETERS DEPENDING ON TREATMENT MODALITY

T. Baumann1,2, J. Delgado1, P. Mozas3, V. Ortiz-Maldonado1, R. Santacruz2, M. Rozman3, M. Aymerich1, N. Villamor3, D. Costa3, A. Carro3, E. Montserrat3,1
1Hematology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain, 2Hematology Department, Hospital de Clínicas, Asunción, Paraguay, 3Hematopathology Unit, Pathology Department, Institute of Hematology and Oncology, Hospital Clinic, IDIBAPS, University of Barcelona, Barcelona, Spain

Background: Prognostication is a key component in the management of patients with chronic lymphocytic leukemia (CLL). Prognostic factors however may change as a result of the introduction of more effective therapies.

Aims: To investigate whether the prognostic value of classical parameters has changed over time.

Methods: Retrospective single-center study of prognostic factors and outcome in patients with CLL diagnosed before (n=454) and after (n=903) 1995 when purine analogs and subsequently chemoimmunotherapy (CIT) were introduced in CLL treatment at the Hospital Clinic, Barcelona.

Results: The median follow-up was 8.3 years (0.1-33.0) for the overall series and 24.9 years (21.9-33.0) and 7.8 years (0.1-21.3) for patients diagnosed before and after 1995, respectively. Patients diagnosed before 1995 were older (p=0.001), had more advanced clinical stage (p=0.001), higher absolute lymphocyte count (ALC) (p=0.001), shorter LDT (p=0.001), and more often anemia (p=0.001) and thrombocytopenia (p=0.001) and increased serum LDH levels (p=0.019) than those diagnosed thereafter. There were no differences in β2-microglobulin (B2M) levels and ZAP70 or CD38 expression. Mutated IGHV was more frequently detected in patients diagnosed before 1995 (75% vs 55%; p=0.001). The proportion of patients receiving treatment did not differ between groups [42% (p=0.08) vs 45% (p=0.08)]. The type of therapy given to patients diagnosed before and after 1995 was: alkylating agents (91% vs 89%, p=0.1), CIT (75% vs 81%, p=0.3), and more often immunotherapy (both p=0.028). The proportion of patients achieving complete response (CR) and partial response (PR) was higher in the period after 1995 (p=0.001) and 1995 (p<0.001) for PR and CR (both p=0.001), respectively.

Secondary endpoints were time to therapeutic failure, time to progression, progression-free survival (PFS), time to relapse or death after CR or PR, quality-of-life (EQ-5D questionnaire), and frequency of adverse drug reactions (ADR). Secondary endpoints were similar in both periods.

Results: Of the 196 patients who enrolled between June 2012 and August 2015, 29 patients were included in the Safety Population, 244 in the Full Analysis Set (FAS; patients in the Safety Population who had ≥1 response evaluation). Most patients in the FAS were male (59.7%); mean age was 61.5±8.9 years. Overall, 35.6% of patients were ≥65 yr old and 80.5% had ≥1 comorbidity such as decreased renal function. The ORR was 83.2%; CR and PR rates were 59.7% and 23.5%, respectively. Generally, response rates were slightly higher than those reported in the Phase 3 pivotal trial (Knauf et al. J Clin Oncol. 2009). Eradication of minimal residual disease was achieved in 23 of the 84 evaluable
patients (27.4%). Overall, 80.3% of FAS patients did not experience therapeutic failure and 85.9% did not experience disease progression during the 2-year observation period. By the end of the study, median PFS had not been reached; 2-year PFS rate was estimated as 85.9%. Improvements from baseline were observed after 6 cycles of treatment across all EQ-SD domains. No relapses or deaths occurred in the FAS; however, 2 subjects in the Safety Population experienced fatal serious ADRs (myocardial infarction [n=1]; acute pneumonia, infections and toxic shock, and atrial fibrillation [n=1]). In concurrence with the Phase 3 trial results, hematologic disorders (19.9%; anemia, neutropenia, thrombocytopenia), most of which were Grade ≤2 in severity, were the most common ADRs (Safety Population; Table 1).

**Summary/Conclusions:** First-line therapy with bendamustine plus rituximab was well tolerated in this Russian CLL population, including elderly patients and patients with renal dysfunction or other comorbidities. Additionally, combination therapy resulted in high rates of treatment response in the CLL. These data confirm the value of bendamustine as a first-line agent for CLL in routine clinical practice in Russia.

**MUTAGENESIS OF BCR-ABL1 IS REQUIRED FOR RESISTANCE DEVELOPMENT IN DE NOVO CHRONIC MYELOID LEUKEMIA KCL-22 CELLS BUT NOT IN RELAPSED KCL-22 CELLS EXPRESSING BCR-ABL1 DEPENDENT RESISTANCE**

N. Curlik1,2, V. Polkova1,2, T. Kalina3, V. Kanderaov4, J. Linhartova1, F. Savuljud2, O. Toml1, K. Srtuv1, S. Ransdorfova1, J. Brezinova1, H. Klamova1,5, K. Machova Polakova1,5,6

1Institute of Hematology and Blood Transfusion, 2Institute of Pathological Physiology, First Medical faculty, Charles university, 3Faculty of Science, Charles University, 4Department of Paediatric Haematology and Oncology, University hospital Motol, 5Institute of Clinical and Experimental Hematology of the 1st Medical Faculty, Charles University and Institute of Hematology and Blood Transfusion, Prague, Czech Republic

**Background:** BCR-ABL1 kinase domain (KD) mutations are an important mechanism of resistance of chronic myeloid leukemia (CML) patients developing during the tyrosine kinase inhibitors (TKI) treatment. However, mechanisms underlying KD mutation acquisition in TKI-resistant CML cells are not yet well understood.

**Aims:** We studied an acquisition of mutations in the KD after an exposure of *de novo* and relapsed (grown in optimal growing medium for 24 months) KCL-22 cells to imatinib (IM). In addition, we examined kinetics of mutated sub-clones in established IM-resistant KCL-22R culture after dose-reduction of IM. We also studied changes in the expression profile of KCL-22 cultures early after exposure to IM.

**Methods:** The occurrence and kinetics of expansion of *BCR-ABL1* mutant sub-clones were studied using next-generation deep sequencing in KCL-22 cells treated with 0.4 µM IM and in established IM-resistant KCL-22R cells at 4 µM IM. In other set of experiments, KCL-22R cells were sorted according to the CD38 expression to explore whether CD38 is associated with the acquisition of *BCR-ABL1* mutations as suggested by Wang et al. (2014). A protein array was used allowing analysis of 576 proteins per sample. DNA damage pathway-RT Profiler PCR arrays were applied for gene expression analysis.

**Results:** No *BCR-ABL1* KD mutations were detected in *de novo* untreated KCL-22 cells, however T315I and E255K appeared after the exposure of the cells to 0.4 µM IM. PCR array revealed increased expression of SUMO 1 ligase and ERCC2 involved in the nucleotide excision repair pathway. Notably, we also found a significant decrease of G2/M-checkpoint protein GADD45A whose deficiency is associated with mutagenesis (Hollandcr et al., 2001). During the first culture period, T315I slowly emerged whereas E255K was not detectable. Later, E255K-bearing cells also became detectable and increased over time.

A similar time-dependent expansion of mutant-bearing sub-clones was seen in the KCL-22R cells growing at 4 µM IM. Interestingly, a mutant-clone switch from T315I to E255K in KCL-22R was accelerated after IM reduction from 4 µM to 1 or 2 µM. Moreover, the emerging of E255K sub-clones was associated by rapid decrease of CD38 expression in KCL-22R cells. Profiling of transitional KCL-22R culture, carrying both T315I and E255K sub-clones, revealed that T315I transcripts were expressed only in the CD38+ subpopulation, while E255K was detected only in CD38- cells. Unlike to *de novo* KCL-22 cells, *BCR-ABL1* mutations were repeatedly not detected in relapsed KCL-22 cells until follow-up of 60 days after the cells exposure to 0.4 µM IM. Neither *BCR-ABL1* upregulation nor gene amplification was detected in these cells. We identified considerably upregulated (D7, DTX3, ETV6, GLUL, HCLS1, HIF1α, IGF1R, MAP2K7, MYH11, TPS3) or downregulated (BAD, BID, MCL2 NOTCH3, PDKPK1) proteins early, 4 weeks after the exposure to IM. Increased expressions of HIF1α and IGF1R proteins are known to ensure proliferation, while decreased expressions of pro-apoptotic proteins BAD and BID enhance survival of CML cells in the presence of TKIs.

**Summary/Conclusions:** Our observation suggests the ability of KCL-22 cells to survive and proliferate early after the exposure to IM. *BCR-ABL1* mutations development seems to be related to a mutagenesis of imatinib in *de novo* KCL-22 cells, but not on relapsed KCL-22 cells that activated signaling pathways ensuring their survival and growing in the presence of tyrosine kinases inhibitor.

**FLOW-CYTOMETRY DETECTION OF CD26+ LEUKEMIA STEM CELLS IN PERIPHERAL BLOOD: A SIMPLE AND RAPID NEW DIAGNOSTIC TOOL FOR CHRONIC MYELOID LEUKEMIA**

D. Raspadoni1, S. Siriani1, L. Aprile1,2, E. Abruzzese2, A. Iurlo3, A. Sicuranza1, S. Galimberti4, L. Schiattone1, A. Gozzini5, P. Pregno6, G. Caocci7, G. Papini1, I. Ferrigno1, B. Mecacci1, M. Bocchia1

1Department of Paediatric Haematology and Oncology, University hospital Motol, Prague, Czech Republic

**Background:** CD26 expression in peripheral blood of patients with chronic myeloid leukemia (CML) is associated with the disease and disease status. However, the methods used for CD26 detection are not simple and rapid enough to be applied in the clinical practice.

**Aims:** We developed and validated a new technique allowing simple and rapid detection of CML stem cells in peripheral blood of CML patients.

**Methods:** We used human peripheral blood obtained from patients with CML in chronic phase (CP), accelerated phase (AP), and blast crisis (BC) and healthy controls. The cells were stained with a FITC-conjugated anti-CD26 antibody and analyzed by flow cytometry. The sensitivity and specificity of the method were determined by comparing the results with those obtained by the standard method (immunochemistry).

**Results:** The new method allowed the detection of CD26+ cells with high sensitivity and specificity. The median percentage of CD26+ cells in CP, AP, and BC was 10.5%, 12.3%, and 15.2%, respectively. The median percentage of CD26+ cells in healthy controls was 4.2%.

**Conclusion:** The new flow cytometry method is a simple and rapid tool for the detection of CML stem cells in peripheral blood, which can be easily applied in the clinical practice.
Aims: We investigated accuracy and specificity of flow cytometry PB cytometry also in PB during treatment with tyrosine kinase inhibitors.

Methods: Pts with clinical suspicion of CML entered the study after written informed consent and all were evaluated for CD26+LSCs, cytogenetics, FISH and/or BCR-ABL1 RT-PCR analysis. CD34+/CD38−/Lin− stem cell fraction and CD26 appeared a robust biomarker for identifying CML LSCs within the normal BM compartment. We recently demonstrated that CD34+/CD38+/CD26+ LSCs can be easily identified by flow-cytometry also in PB during treatment with tyrosine kinase inhibitors.

Aims: We investigated accuracy and specificity of flow cytometry PB CD34+/CD38−/Lin− LSCs identification as a new tool for the diagnosis of CML.

Results: PB samples from 107 pts with myeloproliferative features were evaluated for CD26+LSCs. Leucocytes median value was 52x10^9/L (range 5-409x10^9/L). In 83/107 (77.5%) pts we showed CD34+/CD38−/Lin− LSCs in PB and in 83/93 (100%) the diagnosis of CML was confirmed by cytogenetic, FISH and/or BCR-ABL1 RT-PCR analysis. Median value of circulating PB CD26/LuL was 14 (range 0,27-698) and a positive correlation with leukocyte count (p<0.01) was found. In 53/107 (49,5%) pts analysis was performed contextually in BM samples (range 0,27-698) and a positive correlation with leukocyte count (p<0.01) was found. Median value of circulating PB CD26/LuL was 14 (range 0,27-698) and a positive correlation with leukocyte count (p<0.01) was found. In 53/107 (49,5%) pts analysis was performed contextually in BM samples (range 0,27-698) and a positive correlation with leukocyte count (p<0.01) was found.

Summary/Conclusions: The prospective study aims to confirm the possible role of genetic predisposition and behavior of specific pro/anti-inflammatory biochemical parameters in the atherosclerotic pathogenesis during TKIs treatment. Multicentric “Prospective study of TKI induce pro-atherothrombotic status in CML, KIARO study” (Grant support: AIRC-IT) including Chronic Phase CML patients treated with any first line approved TKI in which clinical, genetic and biochemical pro-atherothrombotic profiles were evaluated at diagnosis and during treatment.

Aims: This prospective study aims to confirm the possible role of genetic predisposition and behavior of specific pro/anti-inflammatory biochemical parameters in the atherosclerotic pathogenesis during TKIs treatment.

Methods: Enrolled pts were prospectively evaluated for presence of traditional CVRFs, atherothrombotic episodes, presence of Single Nucleotide Polymorphisms (SNPs) associated to CV risk (Cardiokit) and plasma levels of several pro and anti-inflammatory cytokines. In this first interim analysis we focused on levels of LDL, oxidized-LDL (oxLDL), TNFα, IL-6 and IL-10 and the presence of SNPs of LDL-R (rs1122608), LOX-1 (rs3736235), and IL-10 (rs1800896) genes.

Results: 12 Italian Hematology Units participated to the study and up to date 95 CML patients were enrolled. We here report data from the first 43 patients on TKI treatment for at least 12 months (15 nilotinib, 14 imatinib and 14 dasatinib). No CV events were recorded to date. At diagnosis, levels of LDL (143.5±13.2), ox-LDL (237.4±99.5), TNFα (3.91±2.51), IL-6 (1.96±0.99) and IL-10 (0.34±0.15) were evaluated for the whole cohort and according to the presence/absence of the detrimental G/G allele of LDL-R (H.R. 2.26, p<0.01), IL-10 (H.R. 1.85, p<0.05) polymorphisms. During TKIs treatment we observed increased levels of LDL (p<0.05) and oxLDL (p<0.05) only in the nilotinib cohort at 3 and 12 months of treatment, regardless of the concomitant use of CV medications. No differences in TNFα and IL6 levels during the first 12 months of treatment were observed between basal levels of LDL, oxLDL and IL10 with the presence/absence of the detrimental G/G allele of LDL-R (H.R. 2.26, p<0.01), IL-10 (H.R. 1.85, p<0.05) polymorphisms. During TKIs treatment we observed increased levels of LDL (p<0.05) and oxLDL (p<0.05) only in the nilotinib cohort at 3 and 12 months of treatment, regardless of the concomitant use of CV medications. No differences in TNFα and IL6 levels during the first 12 months of treatment were observed.

Summary/Conclusions: This interim analysis, although still very preliminary, suggests that in nilotinib patients the high levels of LDL and oxLDL in combination with low levels of IL10, could induce a persistent pro-inflammatory/oxidative status potentially favoring atherothrombotic events. Additional biochemical and genetic data as well as prolonged clinical observation are needed to confirm this hypothesis. Patients enrolment and monitoring is ongoing.

**MIRNA PROFILING OF CIRCULATING EXTRACELLULAR VESICLES IN CML PATIENTS WITH MUSCULOSKELETAL PAIN ASSOCIATED WITH DISCONTINUATION OF TYROSINE KINASE INHIBITORS**

K. Ohyashiki1,2, F. Kato3,4, T. Kodama1,5, K. Koyama3,4, T. Tanaka4, K. Ohyashiki2

**Background:** Clinical trials of TKI discontinuation are still ongoing, approximately 60% of CML patients who achieved a deep molecular response for more than 2 years maintained a major molecular response after discontinuation of imatinib. However, the long-term prognosis and/or adverse events after TKI cessation remain unclear. Recent reports showed that transient musculoskeletal pain is an adverse event after TKI cessation which occurs in approximately 30% of CML patients after stopping imatinib.

**Aims:** Recent evidences suggest that extracellular vesicles (EVs) that contain genetic element such as DNA, RNA, and miRNA, are important mediators of intercellular communication. We therefore studied molecular study to ascertain the possible correlation between musculoskeletal pain and EV-miRNA expression.

**Methods:** We investigated circulating EV-miRNAs in five CML patients who did not experience musculoskeletal events and five patients with musculoskeletal pain after stopping TKIs, as well as three healthy individuals. Peripheral blood was obtained approximately 3 months after successful TKI cessation in CML patients. EVs were isolated from peripheral blood by ultracentrifugation. EV-miRNA expression profiling was performed on the EVs using NGS. The expression values of each miRNA for each sample were compared to the healthy controls. This latter T-UCR (uc.145) was associated with development of TKI resistant CML cells. This latter T-UCR (uc.145) was associated with development of TKI resistant CML cells.

**Results:** Peripheral blood samples from 45 CML patients and 15 healthy controls. This latter T-UCR (uc.145) was associated with development of TKI resistant CML cells. This latter T-UCR (uc.145) was associated with development of TKI resistant CML cells.

**Summary/Conclusions:** CML patients with increased EV-mir-140-3p achieved levels similar to those of healthy controls after re-initiation of TKI therapy, whereas CML patients who did not experience musculoskeletal pain had increased EV-mir-140-3p expression. These observations suggest that EV-mir-140-3p is a potential biomarker for the development of musculoskeletal pain during TKI discontinuation in CML patients.

**SOLUBLE AND MEMBRANE-BOUND RECEPTOR–LIGAND IMMUNE CHECKPOINTS AND CHRONIC MYELOID LEUKEMIA: CORRELATIONS WITH THE MUSCULOSKELETAL PAIN SYNDROME**

P. Rodrigues-Santos1,2,3, J.S. Almeida2,3, P. Couceiro1,2,3, V. Alves1,3, J.R. Simplicio2, L. Růžičková4, P. Freitas-Tavares4, M. Santos-Rosa1,3

**Background:** Chronic myeloid leukemia (CML) is a hematopoietic malignancy that affects the white blood cells and the bone marrow. It is caused by an abnormality in the karyotype of certain chromosomes, leading to the production of an abnormal protein called BCR-ABL. Although the disease can be treated with tyrosine kinase inhibitors (TKIs), there is a high risk of developing adverse events, including musculoskeletal pain. The musculoskeletal pain syndrome is a common adverse event in CML patients treated with TKIs, and its mechanisms are not fully understood.

**Aims:** This study aimed at the analysis of lymphocyte subsets expression and the plasma levels of immune checkpoint inhibitors during chronic myeloid leukemia (CML) therapy. We aimed to investigate the potential role of immune checkpoints in CML patients with musculoskeletal pain, and to understand the mechanisms underlying the development of this syndrome.

**Methods:** We analyzed peripheral blood samples from 45 CML patients and 15 healthy controls. We used multi-parametric flow cytometry to analyze the expression of lymphocyte subsets and the levels of immune checkpoint inhibitors. The plasma levels of the immune checkpoint inhibitors were measured using ELISA.

**Results:** We found that the expression of immune checkpoint inhibitors was significantly higher in CML patients with musculoskeletal pain compared to healthy controls. The most relevant results were the increased expression of PD-L1 and PD-L2 in CML patients with musculoskeletal pain. These findings suggest that immune checkpoint inhibitors play a role in the development of musculoskeletal pain in CML patients.

**Summary/Conclusions:** Our results indicate that the musculoskeletal pain syndrome in CML patients is associated with the activation of immune checkpoints, which are known to modulate the immune response. This suggests that targeting immune checkpoints could be a potential therapeutic strategy for the management of musculoskeletal pain in CML patients.
E1048
TYROSINE KINASE INHIBITORS SIGNIFICANTLY CHANGE THE EXPRESSION OF POLYCOMB GENES IN CHRONIC MYELOID LEUKEMIA

Background: It has been reported that, notwithstanding their clinical success, tyrosine kinase inhibitors (TKIs) are not able to eradicate the leukemic stem cell (LSC) in patients with chronic myeloid leukemia (CML). Different mechanisms have been hypothesized, especially those linked to the niche (increased osteoblastic differentiation, angiogenesis, hypoxia...). The epigenetic control seems to be relevant, and our group previously identified a correlation between the expression of some polycomb genes (PcGs) and response to TKIs, with BMI1 resulting a good predictive molecular marker (Crea, 2015).

Results: At the sixth month of treatment, 5 patients were in optimal response and one was “warning”, according to the 2013 ELN guidelines. After therapy, 55% of the tested PcGs resulted up-regulated and 23% of them in the majority of patients; whereas 3 genes (DNMT3B, SCLM2, CBX2) were down-regulated in at least half of samples. The expression of 5% of PcGs was “mixed”, up- or down-regulated in different samples. Among the up-regulated genes, some could be relevant from a biological point of view: 1) HLTF, a target for RUNX1, whose low expression in acute leukemia is correlated with poor outcome; 2) PHC2, able to silence the HOX genes, overcoming the multidrug resistance in myeloid models; 3) PCGF5, that is a marker of normal hematopoiesis; 4) MOV10, that has been reported to have an anti-viral activity, increasing levels of gamma interferon. This up-regulation is particularly interesting, because concerns all assessed samples and could explain our previous observation that Torque Teno virus replication does not occur in CML patients during TKIs therapy; 5) in the only “warning” patient, the up-regulation of SIRT2 was observed: this is in line with the observation that its up-regulation increases the oncogenic ability of K562 cells in a murine model. Among the down-regulated genes, could be relevant: 1) CBX2, that binding P16/p19 promotes the cell cycle progression; its down-expression could induce apoptosis; 2) DNMT3B, whose high levels have been reported in stem cells, and whose reduction could characterize the differentiation process; 3) ZBTB51, whose reduction could be a sign of the reduced osteoblastogenesis; one of the mechanisms responsible for the LSC preservation in the niche; 4) SMARCA1, it too correlated to the cell cycle progression. Finally, BMI1 levels seem to be relevant from a biological point of view: 1) CBX2, that binds P16/p19 promotes the cell cycle progression; its down-expression could induce apoptosis; 2) DNMT3B, whose high levels have been reported in stem cells, and whose reduction could characterize the differentiation process; 3) ZBTB51, whose reduction could be a sign of the reduced osteoblastogenesis; one of the mechanisms responsible for the LSC preservation in the niche; 4) SMARCA1, it too correlated to the cell cycle progression. Finally, BMI1 levels seem to be relevant from a biological point of view: 1) CBX2, that binds P16/p19 promotes the cell cycle progression; its down-expression could induce apoptosis; 2) DNMT3B, whose high levels have been reported in stem cells, and whose reduction could characterize the differentiation process; 3) ZBTB51, whose reduction could be a sign of the reduced osteoblastogenesis; one of the mechanisms responsible for the LSC preservation in the niche; 4) SMARCA1, it too correlated to the cell cycle progression. Finally, BMI1 levels seem to be relevant from a biological point of view: 1) CBX2, that binds P16/p19 promotes the cell cycle progression; its down-expression could induce apoptosis; 2) DNMT3B, whose high levels have been reported in stem cells, and whose reduction could characterize the differentiation process; 3) ZBTB51, whose reduction could be a sign of the reduced osteoblastogenesis; one of the mechanisms responsible for the LSC preservation in the niche; 4) SMARCA1, it too correlated to the cell cycle progression. Finally, BMI1 levels seem to be relevant from a biological point of view: 1) CBX2, that binds P16/p19 promotes the cell cycle progression; its down-expression could induce apoptosis; 2) DNMT3B, whose high levels have been reported in stem cells, and whose reduction could characterize the differentiation process; 3) ZBTB51, whose reduction could be a sign of the reduced osteoblastogenesis; one of the mechanisms responsible for the LSC preservation in the niche; 4) SMARCA1, it too correlated to the cell cycle progression. Finally, BMI1 levels seem to be relevant from a biological point of view: 1) CBX2, that binds P16/p19 promotes the cell cycle progression; its down-expression could induce apoptosis; 2) DNMT3B, whose high levels have been reported in stem cells, and whose reduction could characterize the differentiation process; 3) ZBTB51, whose reduction could be a sign of the reduced osteoblastogenesis; one of the mechanisms responsible for the LSC preservation in the niche; 4) SMARCA1, it too correlated to the cell cycle progression. Finally, BMI1 levels seem to be relevant from a biological point of view: 

Summary/Conclusions: We demonstrated that PcGs de-regulation occurs in CML patients during the treatment with TKIs, with possible pathogenetic implications. Hugger series of patients will improve the biological suggestions coming from these preliminary data.

E1049
IDENTIFICATION OF PROGNOSTIC AND SUSCEPTIBILITY MARKERS IN CHRONIC MYELOID LEUKEMIA USING NEXT GENERATION SEQUENCING

Background: Chronic Myeloid Leukemia (CML) is 20% of all leukemias diagnosed every year. Discovery of Imatinib Mesylate has brought a paradigm shift in treatment of Chronic Myeloid Leukemia, despite 15% - 20% patient showing resistance to this TKI. Therefore, it is important to identify susceptibility and prognostic markers, which can help us in predicting occurrence and prognosis of CML. We did Clinical Exome Sequencing, a panel of more than 4800 clinically important genes, in CML patients

Aims: To identify prognostic and susceptibility genetic markers in CML

Methods: Enrolled CML patients (n=15) were segregated as responders (n=10) and failures (n=8) as per ELN, 2013 guidelines. Healthy controls (n=5) were also enrolled. DNA from blood of subjects was subjected Next Generation Sequencing (NGS). Mutations present in one patient group and absent in opposite group were considered as prognostic markers, whereas rare mutations, present in more than 50% of enrolled patients and absent in healthy controls, were considered as susceptibility markers

Results: We discovered mutations in genes associated with cancer or cancer related functions in different patient groups as markers. Five of them: rs116201358, rs17882014, rs4014996, rs52897880 and rs2274329 in CBA, HLA-DRB1, UNC93B1, APOH and CA6 genes respectively, were present in responders; rs4594 in MFGE8 was present in failures. Mutations in HLA-DRA1 (rs17878951, rs11554462, c.239C>G), HLA-DRB5 (rs137863146), RPHN2 (rs193173933), CYP2F1 (rs116958558), KCNJ12 (rs76684759), FUT3 (rs151218854), BM1C (rs28370522) and PRSS1 (rs144422014) were present in half of responders.

Summary/Conclusions: We discovered potential genetic markers, which can help in predicting response to IM as frontline therapy. Susceptibility markers can be used as panel for to configure individuals prone to CML

E1050
FEATURES OF THE A2455G POLYMORPHISM OF GENE CYP 1A1 IN PATIENTS WITH CML

K. Karimov,1,2 N. Abdurahmanova1,2 K. Boboev1

1Institute of hematology and blood transfusion, tashkent, Uzbekistan

Figure 1.
Background: Chronic myeloid leukemia (CML) is the most common myelo-proliferative disorder characterized by the reciprocal translocation t(9; 22) (q34; q11), leading to the formation of chimeric oncogene BCR-ABL on the 22q-chromosome. It is known that the protein products of the genes of cytochromes ensure homeostasis at the cellular and tissue level, carrying out the metabolism of toxic compounds that can damage the genome of the cells. Previous studies have shown that there are genetic polymorphisms of these genes in a number of neoplastic diseases, including leukemia. In individuals with weakened functional genotypes of A2425G polymorphism of CYP1A1 gene expression of this enzyme and, consequently, inactivation of xenobiotics must occur very slowly, thus creating conditions for adverse action of harmful metabolites in the genome of the cells. Currently, the scientific literature discus ses the role of the negative allele A2425G polymorphism of CYP1A1 gene in the development of hematological malignancies. However, the adverse roles of genotypic variants for this gene in oncogenesis of BCR-ABL-positive patients with CML have studied not enough.

Aims: Evaluation the role of A2425G polymorphism of CYP1A1 gene in the formation the mutant clone of tumor and development of CML.

Methods: The work is performed on DNA samples isolated from the peripheral blood of the patients in the clinic of scientific research Institute of Hematology and blood transfusion in Uzbekistan. We studied 146 patients with CML. The control group was formed from 217 individuals of Uzbek nationality, without any cancer disease. The diagnosis of CML verified in accordance with the International nomenclature ISCN. Standardized PCR with detection in real-time was carried out on a thermal cycler Rotor-Gene 6000 (Corbett Research, Australia), using a set of reagents "RealTime Ready" and primers of "ligase Chain Reaction" (InterLabServis, Russia). Testing A2425 polymorphism of CYP1A1 gene was performed on a programmable thermal cycler of the company "Applied Biosystems" (USA) using test systems company "LifeTech" (Russia) according to the manufacturer’s instructions. Statistical analysis of results was carried out using the statistical software package "2009 OpenEpi, Version 2.3.1." Results: The frequencies of allele A and G are as follows: 76.7% and 12.3% in patients with CML, and 93.3% and 6.7% in the control group, respectively. The frequency distribution of genotypes A/A, A/G and G/G in patients with CML were as follows: 76.7%, 21.9% and 1.4% - in CML patients, and 86.6%, 13.4% and 0.0% - in the control group. Observed frequencies of genotypes in the studied groups was consistent with the theoretically expected and were in equilibrium with Hardy-Weinberg equilibrium (P>0.05). There was a statistically significant decrease in carriage of the adverse alleles in the population sample comparison group patients (1.4% vs 6.7%, respectively; χ2=6.8; P=0.01; OR=2.0; 95% CI 1.1-3.6) and patients without CML. At the same time, differences in the results did not reach statistical significance (P>0.05). Functions of allele A and G were as follows: 76.7% and 12.3% in CML patients, and 93.3% and 6.7% in the control group (21.9% vs 13.4%, respectively). The risk of mutant formation of the tumor clone in carriers of this genotype was 1.4 times significantly higher compared with patients not having it (χ2=4.6; P=0.03; OR=1.8; 95% CI 1.046-3.166). The homozygous genotype A/A in patients with CML, compared with the control group (21.9% vs 13.4%, respectively). The risk of mutant formation of the tumor clone in carriers of this genotype was 1.4 times significantly higher compared with patients not having it (χ2=4.6; P=0.03; OR=1.8; 95% CI 1.046-3.166). The homozygous genotype A/A of A2425G polymorphism of CYP1A1 gene has a protective character in relation to risk of CML.

Summary/Conclusions: Our results suggest that the G allele and the heterozygous genotype A/G A2425G polymorphism of CYP1A1 gene are important markers of increased risk in formation of malignant tumor cells and development of CML in Uzbekistan (P<0.05). In this case, homozygous genotype A/A of A2425G polymorphism of CYP1A1 gene has a protective character in relationship to risk of CML.

Figure 1. Evolution of hematologic toxicity grade 3-4 with time (all treatments sequences included).

Results: Demographics, risk and treatment distribution: 893 patients (533 men, 360 women) with a median age at diagnosis of 52 y (14-94y) were included with a follow up of 85±7 months (m) from diagnosis, 78±6.6 m from first treatment, and 69±6 m from first TKIs. 151 patients (16,9%) were over 70y. The risk distributions were as follows: Sokal: low (L) 48%, intermediate (I) 37% and high (H) 14%; Euro score: L 50%, I 45% and H 5%; EUTOS L: 89% and H 8%; EUTOS LT: L 70%, I 23% and H 7%. Treatment groups were the following: Group 1: IFN alpha and then imatinib or 2° GTKIs (221 patients); Group 2: imatinib only (404 patients); Group 3: imatinib and then nilotinib, dasatinib or both due to failure or intolerance (177 patients) and Group 4: 2° GTKIs in first line (93 patients). Hematologic toxicity grade III-IV. Figure 1 shows the incidence through the years (all group of treatments). From 800 patients treated with imatinib (first o second line) 67 (8,3%) had grade III-IV toxicity, and 26 had to switch treatment due to toxicity. From 166 patients treated with dasatinib (29
Poitiers, France, 4Winship Cancer Institute at Emory University, Atlanta, United States, 3Inserm CIC 1402, CHU de Poitiers, patients on IM, whether or not they had dose reductions for an AE; these rates Patients on DAS maintained higher molecular response rates than Table 1.

1Universitätsklinikum Jena, Jena, Germany, 2University of Texas MD Anderson in DAS- and imatinib (IM)-treated patients with dose reductions or interruptions that this probability is not different across different sequential treatments (imatinib 1st line or post-IFN, or switched to 2ªGTKis due to intolerance or failure) (1). This fact emphasizes the rescue potential of available TKI therapies. 2. Hematologic toxicity grade III-IV in the first two years identified a group of patients with worse survival outcome. 3. Patients over 70 years have shorter survival due to reasons different than progression. 4 Second GTKis showed better hematologic toxicity profile.

E1052
5-YEAR EFFICACY OF DASATINIB AND IMATINIB IN NEWLY DIAGNOSED PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) WITH DOSE MODIFICATIONS FROM DASISION A. Hochhausa1,1, E. Jabbrob2, H. Kantarjian2, F. Guilhot3, V. Kotas2, T. P. Hughes3, S. Shelefa3, L. Lif2, J.E. Cortesa3, 1Universitätsklinikum Jena, Jena, Germany, 2University of Texas MD Anderson Cancer Center, Houston, United States, 3Inserm CIC 1402, CHU de Poitiers, Poitiers, France, 4Winship Cancer Institute at Emory University, Atlanta, United States, 5SAHMRI, University of Adelaide, Adelaide, Australia, 6Bristol-Myers Squibb, Princeton, United States

Background: Multiple dosage strengths are approved for dasatinib (DAS), permitting dose-optimization strategies for patients who experience adverse events (AEs). In a 2-year retrospective analysis of DASISION, efficacy was maintained in DAS- and imatinib (IM)-treated patients with dose reductions or interruptions to manage AEs (Jabbour ASH 2011); cytogenetic and molecular response rates were higher for patients given DAS vs IM, even when daily doses were modified. Longer term follow-up is needed to fully understand the potential impact of dose reductions on efficacy.

Aims: To evaluate the effect of dose reduction for any AE and for pleural effusion on efficacy in DAS- or IM-treated patients from DASISION.

Methods: Treatment-naïve patients with CML-CP in DASISION (NCT00481247) were randomized to receive either DAS (100mg once/day; N=259) or IM (400mg once/day; N=260). Dose reductions for AEs (up to 2) were allowed: DAS: 80mg, then 50mg; IM: 300mg, then 200mg. Five-year molecular and cytogenetic response rates in all patients were assessed retrospectively.

Table 1.

Results: Patients on DAS maintained higher molecular response rates than patients on IM, whether or not they had dose reductions for an AE; these rates were similar in patients with and without dose reductions in each arm (table). 95 (37%) DAS- and 44 (17%) IM-treated patients had dose reductions at any time due to AEs. Median time to first DAS dose reduction was 289 days (range: 22-2123), and median time to first IM dose reduction was 160 days (range: 31-2052). For patients with reductions due to any cause, median average daily dose was DAS 83mg and IM 328mg; for DAS patients with reductions due to pleural effusion, median average daily dose was 82mg. Median duration of treat-
with high trough concentration of NIL (Figure 1). There were statistically significant correlations between median concentrations of NIL and the grades of each AE. Based on the results of the analysis using Cox proportional-hazards model, the trough concentration of NIL [hazard ratio=0.100 (1.000-2.002), P=0.004] and ABBG2 421A/A [hazard ratio=3.044 (1.155-8.027), P=0.024] were independent factors for the elevated ALT. Similarly, the trough concentration of NIL [hazard ratio=0.101 (1.000-2.002), P=0.001] and UGT1A1 *1/*1 [hazard ratio=0.475 (0.246-0.919), P=0.027] were independent factors for the elevated total bilirubin.

Summary/Conclusions: In this study, we identified the relationship between NIL trough concentration and liver dysfunction. Our finding suggests that therapeutic drug monitoring might help avoid drug interruption and discontinuation because of AEs, especially liver dysfunction.

E1054

VERY EARLY MOLECULAR RESPONSE (VEMR) WITH FRONTLINE DASATINIB TREATMENT IS A STRONG PREDICTOR OF LONG-TERM BCR-ABL1 TRANScript LEVELS IN CHRONIC MYELOID LEUKEMIA PATIENTS: PCR-DEPTH STUDY

Background: In BCR-ABL1 tyrosine kinase inhibitor (TKI) treated chronic phase chronic myeloid leukemia (CP-CML), early molecular response (EMR) at 3 months is currently identified as being one of the most important prognostic factors. Sokal risk score and dose intensity during first 3 months were strongly associated with achievement of EMR. As dasatinib is a novel, oral tyrosine kinase inhibitor with improved potency, identification of very early molecular response (VEMR) would be beneficial.

Aims: We evaluated the possibility of the VEMR at 1 month predicting long-term outcomes in newly diagnosed CP-CML patients treated with dasatinib.

Methods: In this observational, open-label study, 102 patients with CP-CML were enrolled to receive dasatinib at a dose of 100mg once daily. The primary end point was complete molecular response (CMR) by 18 months. Secondary end points including molecular response (MR) by 1, 3, 6, 12, 18, 24 months, time to and duration of MMR and CMR, and safety were tested. A receiver operating characteristic (ROC) curve from BCR-ABL1 transcript level on Day+28 was calculated to predict EMR and MMR at specific timepoints.

Results: Median age was 49 years (19-81 years) and 61 patients were male. With median follow-up duration of 28 months (0.9-33.8 months), 80 (78.4%) out of 102 patients were still on dasatinib treatment and 22 patients discontinued treatment (12 events or failure (n=2) or adverse events (n=8) or other reasons (n=9)). The BCR-ABL1 mutations, assessed in 10 patients after dasatinib discontinuation, were detected in 3 patients which were all T315I mutation. The cumulative CMR by 18 months and MMR by 24 months were 20.5% and 79.6% respectively. In safety analyses, grade 3/4 thrombocytopenia (30.3%) was most common. Pleural effusion occurred in sixteen (15.6%) patients which were mostly grade 1/2. The cut-off value of BCR-ABL1 transcript on Day+28 was 40% by ROC curve analysis. Among 95 patients who had available molecular data of both D+28 and 12 months, 50 (62.1%) patients had less than 40% of BCR-ABL1 transcript (VEMR) on Day+28. In 52 (61.2%) patients achieved MMR at 24 months. However, only 27.8% (10 out of 36 patients) of patients without VEMR achieved MMR (p=0.0001). Among 85 patients who had available molecular data of both D+28 and 24 months, fifty two (61.2%) patients achieved VEMR. In 52 VEMR patients, 46 (88.5%) patients achieved MMR at 24 months. However, only 48 (62.1%) patients achieved CMR (p=0.0001). Overall survival (OS) & progression-free survival (PFS) rates by 24 months were 98.0% and 95.1% respectively. PFS rates by 24 months for VEMR and no VEMR group were 98.4% vs 88.8% respectively (p=0.04).

Summary/Conclusions: Our study shows that VEMR at 1 month can be a strong predictor for further molecular responses as well as long-term outcome. Therefore it would be helpful to monitor BCR-ABL1 transcript level at 1 month in patients who treated with more potent TKIs.

E1055

SURVIVAL OUTCOMES IN PATIENTS WITH CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML) RECEIVING THIRD- OR SUBSEQUENT LINE (3L) TREATMENT PRIOR TO THE AVAILABILITY OF PONATINIB

D. Stellato1, L. McGarry2,*, H. Huang3, S. Hastings1, T. Delea1

1Policy Analysis Inc. (PAI), Brookline MA, 2ARIAD Pharmaceuticals, Inc., Cambridge, MA, United States

Background: PACE was a phase 2 single-arm trial of ponatinib, a 3rd-generation tyrosine kinase inhibitor (TKI), in 449 highly-refractory patients with CML or Philadelphia-chromosome positive (Ph+) acute lymphocytic leukemia (ALL) or who had the BCR-ABL T315I mutation. Overall survival (OS) for 3L CP-CML patients in PACE at 1, 2, 3 and 4 years was estimated to be 91%, 83%, 80%, and 79%, respectively. Expected survival for 3L CP-CML patients prior to the availability of ponatinib has not been documented.

Aims: To estimate OS in patients with CP-CML receiving 3L treatment prior to ponatinib via a systematic literature review.

Methods: Studies were identified from a review by Lipton et al. (2015), updated with studies identified from searches of electronic databases (MEDLINE, EMBASE, Cochrane Libraries) and abstract databases of key conferences. Landmark and median survival were extracted from study reports. Pseudo-individual patient data (IPD) for survival outcomes were derived from digitized Kaplan-Meier (KM) survival curves then pooled and analyzed using KM methods.

Results: Fifty studies (717 patients) were identified that reported median, landmark, or KM curves for survival outcomes for CP-CML patients receiving 3L treatment without ponatinib. KM curves for OS were obtained for 6 arms (3 nilotinib and/or dasatinib; 3 other TKIs). OS at 1, 2 and 3 years based on the pooled IPD is reported in the Table. To avoid confounding of OS from post-progression treatment with ponatinib, 1 study was excluded that included follow-up after the date of ponatinib’s approval.

Table 1.

Summary/Conclusions: Estimated OS in patients with CP-CML receiving 3L treatment prior to ponatinib appears to be shorter than that observed among ponatinib-treated patients in PACE: 4-year survival probability in PACE was higher than estimated 2-year survival probability prior to ponatinib. Further analyses are needed to identify and adjust for potentially confounding factors.

E1056

DETECTION AND MONITORING OF BCR-ABL1 KINASE DOMAIN MUTATIONS IN CML AND ALL PATIENTS BY NEXT GENERATION SEQUENCING AND DROPLET DIGITAL PCR, A BELGIAN PROSPECTIVE STUDY

C. De Rop1,*, H. Devos2, P. Vannuffel1, F. Nollet2

1Molecular Biology, IPG, Gosselies, 2Laboratory Medecine, AZ Sint-Jan, Bruges, Belgium

Background: Among myeloproliferative diseases, development of chronic myeloid leukaemia (CML) is associated with the emergence of the fusion oncogene BCR-ABL1 resulting from a t(9,22) chromosomal translocation (Philadelphia chromosome). This chimeric transcript is also present in all acute lymphoblastic leukaemia (ALL) patients bearing a Philadelphia chromosome (Phi+ ALL). Mutations of the BCR-ABL1 kinase domain constitute a major cause of treatment failure in CML and Phi+ALL patients receiving first or second generation tyrosine kinase inhibitor (TKI) treatment. So far, the gold standard procedure to detect BCR-ABL1 kinase domain (KD) mutations is the conventional Sanger Sequencing, endowed with an analytical sensitivity of 15-20%. Recent studies on the implementation of Next Generation Sequencing (NGS) for detection of BCR-ABL1 KD mutations showed a significant dropping down of the sensitivity level (1-5%), improving patient’s treatment management.
Aims: Both NGS and droplet digital PCR (ddPCR) were used in this prospective study. NGS screened all known mutations in the BCR-ABL1 KD and ddPCR targeted only the 3 most common mutations, T315I, E255K and Y253H, which represent approximately 75% of the ABL1 mutations. Patients eligible for the study were i) CML patients with failure or warning to all lines of TKI therapy according to the 2013 ELN-guidelines, with no suspected lack of adherence and ii) Phi+ ALL patients in diagnostic and/or molecular relapse. Monitoring was performed when clinically appropriate.

Methods: Total BCR-ABL1 RNA was transcribed into a long range cDNA covering the kinase and the regulatory and the SH2/SH3 domains of either p190 or p210 BCR-ABL1 transcripts (exons 4 to 10). For NGS, primers designed with the Ampliplex™ Designer Software were selected to generate a set of 10 amplicons. Bar-coded libraries, constructed according to the AmplicSeq™ protocol, were sequenced on the Ion Torrent PGM platform (sensitivity of 2.5%). For ddPCR, cDNA was analysed for the presence of one of the 3 main mutations (T315I, E255K and Y253H). The overall number of BCR-ABL1 mutated samples was 18 (15 CML and 3 Phi+ ALL), representing 30% of the cases. Among these samples, 27 mutations were found. 9 samples presented with one mutation: T315I (2), E255K (3), G250V (1), F359I (1), M237T (1) and E255A (1) and 9 harboured compound mutations: T315I + E255K (6) and T315I + Y253H (3). A high frequency (85%) of T315I, E255K and Y253H mutations was also observed (23/27). As far as these 3 mutations are concerned, reproducibility to determine mutational burden was found to be very high between NGS and ddPCR.

Summary/Conclusions: Advancements in sequencing technologies and further lowering sensitivity levels contribute to optimal management of CML and Ph+ ALL patients and improve treatment outcome. The earlier a mutation in the kinase domain is detected, the earlier an informed choice can be made regarding optimal subsequent TKI treatment.

CLINICAL AND IMMUNOLOGICAL EFFECTS OF NILOTINIB IN COMBINATION WITH PEGYLATED INTERFERON-A2B IN PATIENTS WITH SUBOPTIMAL MOLECULAR RESPONSE ON IMATINIB (NORDUTCHCMLC009)
1Department of Hematology, Juntendo University School of Medicine, 2Division of Hematology and Rheumatology, Department of Medicine, Nihon University School of Medicine, Tokyo, 3Department of Hematology, Saitama Medical Center, Saitama Medical University, Saitama, 4Department of Medicine, Juntendo University Nerima Hospital, Tokyo, 5Department of Hemato-Oncology, Comprehensive Cancer Center, Saitama Medical University International Medical Center, Saitama, 6Department of Hematology, Yokohama Municipal Citizen’s Hospital, Yokohama, 7Department of Hematology, Juntendo University Urayasu Hospital, Urayasu, 8Department of Hematology, Saiseikai Yokohama Nambu Hospital, Yokohama, 9Department of Hematology and Infectious Diseases, Kumamoto University Hospital, Kumamoto, Japan

Background: Chronic myeloid leukemia (CML) is a disease of hematopoietic stem cells resulting from oncogenic chromosome translocation that leads to the formation of the BCR-ABL1 fusion gene. Treatment of chronic phase (CP) CML has dramatically changed since the emergence of the first-in-class tyrosine kinase inhibitor (TKI) imatinib, and treatment based on TKI has improved the outcome in the majority of CP-CML patients. Nowadays, second generation TKIs are available and brought about faster and deeper responses, and lower disease progression rate than imatinib. On the other hand, longer treatment duration and the increased types of TKIs gave rise to various kinds of unexpected adverse events (AEs). In 2011, drug-induced peripheral arterial occlusive disease (PAOD) was first reported, followed by vascular AEs (VAEs) in 2014 (American Heart Association, 2014). Furthermore, in 2014, it was also reported that the incidence of VAEs increased with the dose and treatment duration, therefore VAEs are considered a more fatal complication of TKI treatment. However, there is no available data about the incidence of VAEs in Japanese patients.

Aims: We investigated the vascular safety issue and estimated the 1000 person-years risk of developing VAEs during TKI treatment, including imatinib, nilotinib, and dasatinib, using 3 risk assessment tools among 320 Japanese patients who were enrolled in the CML Cooperative Study Group.

Methods: A surveillance data of 320 patients enrolled in the CML Cooperative Study Group was conducted. Chronic myeloid leukemia (CML) patients diagnosed with CML-CP from April 2001 to January 2016, whose median age was 57 years old (15-80) and median time of follow up was 64.2 months. Patients in the accelerated or blastic phase (AP/BP) were excluded. The study was approved by the research ethics boards of each institutions and was conducted in accordance with the Declaration of Helsinki. All patients who developed VAEs were analyzed using 3 risk assessment tools (SCORE chart, Framingham risk score, Sultae-score) to estimate the patients’ 10-year risk of VAEs.

Results: Among the 320 newly diagnosed CML-CP patients, 16 (5.0%) cases of VAEs were reported during the study period. Seven cases were treated by imatinib, 3 cases by nilotinib, and 4 cases by dasatinib, 4 cases were a switch from imatinib to nilotinib, and 1 case was a switch from dasatinib to nilotinib. The VAEs were 9 IHD, 5 CI, and 2 PAOD cases. Results from the 3 risk assessment tools are as follows: SCORE (2 low, 9 moderate, 1 high, 4 very high risk), Framingham score (2 low, 5 moderate, 7 high risk), and Sultae-score (3 low, 1 intermediate, 4 high risk). There was a significant difference in the rate of IHD between the groups (p=0.01). The numbers of IHD, CI, and PAOD cases were 5.26 and 2.92 in the enrolled CML-CP patients, 4.65 and 2.33 in the imatinib-treated patients, 14.34 and 10.75 in the nilotinib-treated patients, 4.08 and no case in the dasatinib-treated patients, and 1.78 and 3.34 in the age-
matched general population, respectively. Among the 320 newly diagnosed CML-CP patients, 16 (5.0%) cases of VAEs were reported during the study period. Seven cases were treated by imatinib, 3 cases by nilotinib, 1 case by dasatinib, 4 cases were a switch from imatinib to nilotinib, and 1 case was a switch from dasatinib to nilotinib. The VAEs were 9 IHD, 5 CI, and 2 PAOD cases. Results from the 3 risk assessment tools are as follows: SCORE (2 low, 9 moderate, 1 high, 4 very high risk). Framingham score (3 low, 5 moderate, 7 high risk), and Suita-score (13 low, 1 intermediate, 1 high risk). The incidence rate of IHD and CI per 1000 person-years were 5.26 and 2.92 in the enrolled CML-CP patients, 4.65 and 2.33 in the imatinib-treated patients, 14.34 and 10.75 in the nilotinib-treated patients, 4.08 and no case in the dasatinib-treated patients, and 1.787 and 3.342 in the age-matched general population, respectively.

Table 1.

Summary/Conclusions: The incidence rate of IHD per 1000 person-years were higher in the nilotinib- and lower in the imatinib- and dasatinib-treated CML patients, and the patients showed almost the same rate of CI as compared with the age-matched general population, even though the incidence of VAEs were lower in Japanese compared to the European cohort. More patients were estimated to have very-high and high risk of VAEs in the SCORE and Framingham score assessment tools as compared with the Suita-score tool.

UPDATE OF CMREGISTRY: AN OBSERVATIONAL, MULTI CENTER, PROSPECTIVE FOLLOW-UP REGISTRY OF PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA WITH A HIGH PROBABILITY OF OBTAINING A DEEP MOLECULAR RESPONSE >CMR4 (IS)

J.M. Alonso-Dominguez1,*, E. Olaivarría2, M. Perez Encinas3, R. de Paz Arias4, R. Ayalá Díaz5, L.F. Casado Montero6, F. Ferrer Martín7, G. Bautista8, V. Conesa García9, C. Mba10, J.L. Steegmann11

1Hematology Department, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain, 2Hematology Department, Hammersmith Hospital, London, United Kingdom, 3Hematology Department, Hospital Clínico de Santiago, Santiago, 4Hematology Department, Hospital La Paz, 5Hematology Department, Hospital Doce de Octubre, Madrid, 6Hematology Department, Hospital Virgen de la Salud, Toledo, 7Hematology Department, Hospital Morales Meseguer, Murcia, 8Hematology Department, Hospital Puerta Hierro, Madrid, 9Hematology Department, Hospital General de Elche, Elche, 10Hematology Department, Fundación Investigación Hospital de la Princesa IIS-IIP, 11Hematology Department, Hospital de la Princesa, Madrid, Spain

Background: Since the introduction of Tyrosine Kinase Inhibitors (TKI), many patients diagnosed of Chronic Myeloid Leukemia (CML) in chronic phase achieve a deep molecular response. Around 50% of these patients are expected to manifest a high probability of obtaining a deep molecular response (>CMR4 IS) during their TKI treatment. Several clinical trials are exploring the best way to stop TKI therapy and evaluating patient and disease characteristics that could predict relapse after treatment discontinuation.

Aims: This is an update of the CMRegistry study aimed at collecting clinical data and molecular information from Spanish CML patients that have achieved a series of molecular milestones to any of the tyrosine kinase inhibitors who are likely to achieve, or have already achieved, a deep molecular response (>MR4.0 IS) are included. This likelihood of achieving >MR4 is defined, for the purposes of the study, as a bcrabl/abl ratio of: 1) ≤1% at 3 months from start of TKI therapy; 2) ≤0.1% at 6 months from start of TKI therapy; or 3) ≤0.01% any time point during treatment. Clinical data have been collected using a specific CRF. All data were registered in an anonymous manner. The BCR-ABL ratios in the IS have been provided by standardized labs in Spain.

Results: From June 2014 to February 2017, 976 patients were registered in the study. Median age was 51 years (15-88). The Sokal risk groups were as follows: 156 patients low risk, 307 intermediate risk and 129 high risk. Eutos classification yielded 714 patients in the low risk and 79 in the high risk categories. The majority of patients received first-line treatment with imatinib (626 patients), dasatinib (39 patients) or nilotinib (87 patients). Of note, 5 patients received bosutinib, 1 patient ponatinib and 74 patients were treated with Interferon previous to TKI administration. So far 14 patients have died of non-CML related conditions such as carcinoma (2 patients), ischemic heart disease, respiratory failure and sepsis. Interestingly, 2 patients developed progression of their CML to accelerated phase and blast crisis (1 patient each) with no deaths. At present, 104 patients (11%) have achieved a MR4.0, 174 patients (18%) a MR4.5 and 123 patients (13%) have obtained a complete molecular remission (undetectable bcr- abl transcripts with a sensitivity of at least 10⁻⁵).

Summary/Conclusions: Almost one thousand CML patients have been included in this spanish prospective study owing to their promising molecular response that would predict for a sustained deep molecular remission. Four hundred and one patients have already achieved a deep molecular response (>MR4 (IS)) and could be enrolled in prospective discontinuation studies.

E1060

ANALYSIS OF DASATINIB AND IMATINIB 5-YEAR EFFICACY AND SAFETY BASED ON BASELINE COMORBIDITY AND AGE IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP) IN DASISION

G. Saglio1,*, J.E. Cortes2, A. Hochhaus3, N.P. Shah4, E.L. Atallah5, M. Abaskharou6, L. LP, M.J. Mauro7

1University of Turin, Turin, Italy, 2The University of Texas MD Anderson Cancer Center, Houston, United States, 3Universitätsklinikum Jena, Jena, Germany, 4University of California San Francisco School of Medicine, San Francisco, 5Froedtert & the Medical College of Wisconsin, Milwaukee, 6Bristol-Myers Squibb, Princeton, 7Memorial Sloan Kettering Cancer Center, New York, United States

Background: Patients with CML often have comorbidities, which may influence treatment-related decisions and impact response and survival. In a retrospective analysis of 1-year data from the phase 3 DASISION study, the overall safety or response in dasatinib- or imatinib-treated patients was not substantially impacted by baseline comorbidities, although certain adverse events (AEs) trended higher in patients with ≥1 vs 0 comorbidities (Khoury ASH 2010). Further analysis is warranted to determine how comorbidities may impact long-term outcomes.

Aims: To evaluate the impact of baseline comorbidities and patient age on 5-year safety and efficacy in dasatinib- or imatinib-treated patients from DASISION.

Methods: In DASISION (NCT00481247), patients were randomized to receive dasatinib 100mg/day (N=259) or imatinib 400mg/day (N=260). For this retrospective analysis, patients were grouped as having 0 or ≥1 baseline comorbidity, by baseline disorder (diabetes mellitus, hepatobiliary disease, hyperlipidemia, cardiovascular disorder, or pulmonary condition), or by age group (<46 years, 46–65 years, >65 years). Safety (treatment-related AEs in ≥10% of patients) and efficacy (response rates by 5 years and median times to response) were assessed for each group and treatment.

Table 1.
Results: The number of patients with 0 or ≥1 comorbidity was similar in the dasatinib (66 [25%]; 193 [75%]) and imatinib (67 [26%]; 193 [74%]) arms, respectively; most (>90%) patients were <65 years old. In patients with 0 or ≥1 baseline comorbidity, the median average daily dose was comparable within arms and discontinuation rates (36%-39%) were similar within and across arms (table). The overall safety profiles were comparable in the 0 and ≥1 comorbidity groups in both arms, other than specific AEs, which had a 22 times higher frequency in patients with ≥1 vs 0 comorbidities; the majority of these were grade 1/2 AEs (table). The incidence of peripheral edema increased with patient age for both dasatinib and imatinib (<46 years: 5% each; 46–65 years: 12% and 10%; ≥65 years: 21% and 20%). In this analysis, the increased incidence of pleural effusion (PE) in dasatinib-treated patients was most highly associated with increased age: <46 years (16%) vs 46–65 years (37%) vs ≥65 years (60%). PE incidence did not appear to be related to baseline pulmonary comorbidity and was similar in dasatinib-treated smokers (33%) vs nonsmokers (27%). Within each arm, patients with 0 or ≥1 comorbidity (table) and across age groups had similar response rates and AEs, though rates were slightly higher for patients with ≥1 vs 0 comorbidities in both arms (MR4.5 on dasatinib: 46% vs 32%; MR4.5 on imatinib: 36% vs 22%). Median time to response (months) for patients with 0 or ≥1 comorbidity did not differ within each arm, but was numerically shorter for dasatinib (63 vs 36) or imatinib (MR4.5: 42 vs 47).

Summary/Conclusions: The superior efficacy of dasatinib over imatinib was shown in previous studies. Response rates and times to response were comparable in patients with 0 or ≥1 comorbidity and trended in favor of dasatinib vs imatinib. Although a few AEs (most grade 1/2) appeared to occur at a higher frequency in patients with ≥1 vs 0 comorbidities in either treatment arm, the overall rates of AEs and discontinuation rates at 5 years in patients who were treated with first-line dasatinib or imatinib did not appear to be substantially affected by baseline comorbidities.

E1062
RADOTINIB TREATMENT IN CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS WITH RESISTANCE OR INTOLERANCE TO BCR-ABL TKI: 36 MONTHS UPDATE OF RADOTINIB PHASE 2 STUDY

Background: Radotinib is an orally active, selective BCR-ABL 1 tyrosine kinase inhibitor (TKI), approved for the first-line and second-line treatment of chronic phase chronic myeloid leukemia (CP-CML) patients in Korea. Earlier 12 and 24 month results demonstrated that radotinib is effective and well tolerated in CP-CML patients with resistance and/or intolerance to BCR-ABL TKIs.

Aims: We update the long-term outcome of radotinib treatment in patients failed to BCR-ABL1 TKIs with a minimum follow-up of 36 months.

Methods: Ph+ CP-CML patients who failed prior TKI therapy were enrolled between July 2009 and November 2011. All patients were treated with radotinib 400mg twice daily. Cytogenetic and molecular assays were performed at baseline, every 3 months, and at treatment failure. Safety parameters were also analyzed. Probabilities of overall survival (OS) and progression free survival (PFS) were calculated using Kaplan-Meier method.

Results: A total of 77 CP-CML patients (18 years of age or over) were enrolled. This analysis includes data from last enrolled patient who received at least 36 months of radotinib therapy. With a median follow-up of 45.7 (range 0.9-65.7) months, 31 patients (40.3%) completed 36 months treatment, and 46 patients (59.7%) discontinued the treatment before 36 months. Main reasons of discontinuation were abnormal laboratory test (n=18), adverse events (n=4), treatment failure including disease progression and lack of response (n=18), death (n=2), and other reasons (n=4). Median duration of radotinib exposure was 19.5 (0.3-60.9) months. Cumulative incidence of complete cytogenetic response (CCyR) by 36 months was 90.0% and of patients achieving CCyR, 45.0% (18/40) achieved MMR. The drug-related safety profiles were consistent with those previously reported and new safety issues have not been observed after 12 months. Most drug-related AEs have developed within 12 months, and have shown minimal increase compared with rates at 12 months follow-up. Estimated OS and PFS at 36 months were 87.6% and 85.7%, respectively.

Figure 1. Summary/Conclusions: The 36 months data supports radotinib treatment in TKI failed CP-CML patients maintains the effective response and high rates of OS & PFS rate. Thus, radotinib demonstrated a promising alternative treatment for patients with TKIs failure.
100 YEARS OF CHRONIC MYELOID LEUKEMIA PREVALENCE IN FRANCE

M. Delord 1,2

Background: The success of imatinib and other rationally designed tyrosine kinase inhibitors (TKI) in the treatment of chronic myeloid leukemia has drastically improved the fate of CML patients. From a couple of years in median survival in the 70’s, a majority of patient now achieve a near normal life expectancy with lifelong treatment though. This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems. The success of imatinib and other rationally designed tyrosine kinase inhibitors (TKI) in the treatment of chronic myeloid leukemia has drastically improved the fate of CML patients. From a couple of years in median survival in the 70’s, a majority of patient now achieve a near normal life expectancy with lifelong treatment though. This new paradigm where CML can be regarded as a chronic disease has mechanical consequences on the disease prevalence and overall costs for health care systems.

Aims: We present here a fully detailed and comprehensive analysis of the French CML prevalence over a century from 1960 to 2060.

Methods: Prevalence of CML was estimated using a cohort component-based model from estimates of incidence rate of the disease by age and sex, population and demo-graphic projection from the National Institute of statistics and Economics Studies, and various hypotheses on the relative survival of CML patients. Prevalence of CML was estimated using a cohort component-based model from estimates of incidence rate of the disease by age and sex, population and demo-graphic projection from the National Institute of statistics and Economics Studies, and various hypotheses on the relative survival of CML patients. The number of CML patients is estimated over time and the resulting CML prevalence expressed as a number of CML patients per 100,000 inhabitants.

Results: The CML prevalence in France, expressed in cases per 100,000 inhabitants, was estimated to be around 3 before the 80’s, 6 before the 2002, 17 in 2016, 25 in 2030 where the tendency inflects, and 30 after 2040. Considering the 100% relative survival hypothesis, a target CML prevalence were defined, the level of which will be nearly reached by 2060. By simulation, we showed that given constant incidence rates and high relative survival hypotheses, the CML prevalence will be driven by population aging, and that the target prevalence, defined as the maximum CML prevalence, should be nearly reached by 2050 to levels above 30 per 100,000 inhabitants.

Figure 1. Summary/Conclusions: Due to high rates of relative survival observed after introduction of imatinib, the trajectory of the CML prevalence in France, as in other western countries, has changed. Given particular hypothesis on the CML incidence rates, this trajectory will bring the CML prevalence by the mid century to levels fully determined by population aging. For France, we have estimated this level above30 cases per 100,000 inhabitants.

The ROLE OF MICRONS IN CHRONIC MYELOID LEUKEMIA THERAPEUTIC SELECTION

R. Alves 1,2, A.C. Gonçalves 1,2, P. Couceiro 3, P. Rodrigues-Santos 3,4, P. Freitas-Tavares 1, L. Ribeiro 3, A. M. Almeida 1,2, A. B. Sarmento-Ribeiro 1,2,5,6

1 Applied Molecular Biology and University Clinic of Hematology, 2 CIMAGO, 3 Immunology and Oncology Laboratory, Center for Neurosciences and Cell Biology (CNC), 4 Immunology Institute, 5 Faculty of Medicine University of Coimbra, 6 Clinical Hematology Department, Centro Hospital e Universitário de Coimbra (CHUC), Coimbra, 7 Hematology Service, Instituto Português de Oncologia de Lisboa Francisco Gentil (IPOL), 8 CEDOC, Nova Medical School, Lisbon, Portugal

Background: Chronic myeloid leukemia (CML) is characterized by the presence of BCR-ABL fusion gene. This molecular event becomes the main therapeutic target with Imatinib as first-line treatment. In spite of the continued clinical success of Imatinib on CML treatment, the emergence of resistance to tyrosine kinase inhibitors (TKIs) has stimulated the research of the mechanisms involved. These included those related with target changing (e.g. the presence of BCR-ABL gene mutations and amplifications) and with intracellular drug concentrations (e.g. the abnormal levels of influx and efflux transporters such as OCT1/OCCT2 and PgP/BCRP, respectively). MicroRNAs (miRNAs) are important regulators of both mechanisms, and so, could influence TKIs response.

Aims: In this context, we investigated the role of miR-203, miR-21, miR-518c, miR-451 and miR-26 expression levels in TKI response in CML patients, and correlated them with TKI sensitivity, BCR-ABL levels, and disease progression, among other clinical and laboratory data.

Methods: To this end, we assessed the expression levels of miR-203, miR-21, miR-518c, miR-451, miR-26 and miR-16 (endogenous control) by TaqMan MicroRNA Assays in peripheral blood cells from 31 patients with CML at follow-up examinations. We also studied 4 CML cell lines, K562 a cell line sensitive to Imatinib, LAMA-84 a cell line with 4 copies of chromosome Philadelphia (Ph), and 2 Imatinib resistant cell lines models created in our lab (K562-RC and K562-RA). K562-RC cells, generated by continuous exposure to Imatinib, presented an IC50 8x times higher than the parental cell line (K562); in K562-RA cells (created by discontinuous exposure), the degree of resistance is 18x. Statistical analysis was performed with ANOVA and multiple comparison tests, with significance levels of 95% (p<0.05).

Results: The miR-203 and miR-518c expression was not detected in any cell line or patient sample. First, we evaluated the miRNAs expression in CML patients. Higher levels of tumor suppressor miR-451 were associated with a higher reduction of BCR-ABL levels (lower than 0.01%) in CML patients and patients with higher BCR-ABL present lower levels of expression of miR-451. This miR was also down-regulated in LAMA-84, K562-RC and K562-RA compared with sensitive cell line (K562; p<0.05). On the other hand, patients with more BCR-ABL content (between 1.0% and 0.1%) present higher expression of the oncomiRs, miR-21 and miR-26. These miRs were also up-regulated resistant cell lines. MiR-21 was more relevant for K562-RC cells (4-fold higher than K562). LAMA-84 and K562-RA cell lines showed almost 2 times more expression of miR-451. Next, we analyzed if treatment options affected miRs expression. CML patients under Imatinib treatment showed higher levels of miR-451 associated with less expression levels of miR-21 and miR-26. Imatinib had been described to be able to block the BCR-ABL negative feedback on miR-451, increasing miR function. Since miR-21 and miR-26 were also lower expressed, more PTEN is available to block PI3K-AKT-mTOR pathways, decreasing this survival signaling. Opposite profile was observed in patients that changed treatment to a second generation TKI suggesting a different effect of this TKI on microRNA expression.

Summary/Conclusions: Our preliminary results suggested the involvement of miRNAs in BCR-ABL levels regulation and in TKI response, supporting the search of a miRNAs TKI response profile that could predict the response in CML patients. This information could act as powerful tool for the stratification and selection of the best therapeutic approach (lower toxicity and cost effective), contributing to higher survival rates and better quality of life in CML patients.

IMPAKT OF ABCB1 AND ABCG2 POLYMORPHISMS ON RESPONSE TO IMATINIB AND 2G-TKIS THERAPY IN PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA

M. Tiribelli 1,*, S. Di Giusto 1, E. Toffoletti 1, D. Penna 1, D. Griguolo 1, G. Maccari 1, F. Marchi 1, M. Medoet 1, R. Fanin 1, D. Damian 1

1 Division of Hematology and BMT, Azienda Sanitaria Universitaria Integrata di Udine, Udine, Italy

Background: Overexpression of multidrug resistance proteins ABCB1 and ABCG2 confers resistance to anticancer drugs, including tyrosine kinase inhibitors (TKIs). Various ABCB1 and ABCG2 single nucleotide polymorphisms
(SNPs) affect the transporter activity, but their impact on clinical response to imatinib in chronic myeloid leukemia (CML) is discordant; even less is known on their role in patients treated with second generation (2G) TKIs dasatinib and nilotinib.

Aims: To investigate the role of the most common ABCB1 and ABCG2 genetic polymorphism in chronic phase CML patients treated with imatinib and 2G-TKIs.

Methods: We analysed four polymorphisms of ABCB1 (129T>C, 1236C>T, 2677G>T/A and 3435C>T) and two polymorphisms of ABCG2 (34G>A and 421C>A) in 196 CP-CML patients, of whom 139 treated with imatinib (114 in first line and 25 after interferon failure) and 57 treated with dasatinib or nilotinib (22 in first line and 35 after imatinib failure). We compared the rates of optimal response at 3 months (defined as BCR/ABL <10%), at 6 months (BCR/ABL<1%) and at 12 months (BCR/ABL<0.1%), progression-free survival (PFS) and time to treatment failure (TTF) according to the different protein genotypes. TTF was calculated from the start of therapy to any of the followings: progression to accelerated or blastic phase (ABP), death for any cause at any time, and treatment discontinuation for primary or secondary resistance or intolerance. PFS was calculated from the start of TKI to ABP or death.

Results: A total of 196 patients with CP-CML (median age 57 years, range 21-84) were included in the analysis. Frequency of ABCB1 and ABCG2 SNPs expression is summarized in Table 1. Considering response to therapy, either in imatinib-treated patients and in those receiving a 2G-TKI, we did not find any significant difference in terms of optimal response at the various timepoints, TTF or PFS for ABCB1 C1236T, G2677T and C3435T and of ABCG2 G34A and C412A polymorphism, even if there was a trend for a worse PFS in the few patients (n=3) with 1236 allele A treated with imatinib. Conversely, we found a lower rate of optimal response at 3 (p=0.001), 6 (P=0.005) and 12 (p=0.2) months in imatinib-treated patients with TC genotype of ABCB1 T129 SNP, though the small number of patients (7) had probably impact on statistical significance. However, TTF was shorter for ABCB1 129T>C patients, both receiving imatinib (P=0.05) and 2G-TKIs (P=0.07), and also PFS was significantly shorter in this cohort (P=0.003).

Summary/Conclusions: With the limits of the low expression rates of some SNPs, our data suggest a lower response in patients harboring 129T>C polymorphism, at least in those receiving imatinib. Other ABCB1 and ABCG2 genotypes do not seem to impact on response to TKI treatment.

E1066

THE INTRODUCTION OF SECOND-GENERATION TYROSINE KINASE INHIBITORS MAY REDUCE THE PROGNOSTIC IMPACT OF HIGH-RISK PATIENTS ON patient prognosis as determined by EUTOS score.

Background: The discovery of tyrosine kinase inhibitor (TKI) imatinib has revolutionized the conception of chronic myeloid leukemia (CML) as a mortal disease to a long-term controllable disease. The European Treatment and Outcome Study (EUTOS) score is a clinical tool that utilizes imatinib-based objectives to predict treatment response and progression free survival (PFS) in patients with CML in chronic phase (CP). However, it is currently unknown whether the introduction of second generation TKIs (2nd TKIs) affects prognostic score of patients with CML-CP, particularly among those considered high-risk according to EUTOS score.

Aims: Our study aims to highlight the critical role of the introduction of 2nd TKIs on patient prognosis as determined by EUTOS score.

Methods: Patients data was obtained retrospectively from patients enrolled in the CML Cooperative Study Group. Patients with CML-CP who were treated with any TKIs as first line therapy between April 2001 and January 2016 were selected for the study. We classified patients according to EUTOS score in the following periods: 2001-2006 (imatinib era 1G-TKI), 2007-2012 (imatinib era 2G-TKI) and 2013-2016 (next generation TKIs era 3G-TKI). We used Cox regression analysis to determine the cumulative incidence of CML-associated death (CML-ad), progression to accelerated or blastic phase (ABP), treatment discontinuation for primary or secondary resistance or intolerance (TDDR) and event-free survival (EFS). Summary/Conclusions: Among patients considered high-risk according to EUTOS score, the cumulative incidence of CML-associated death, treatment discontinuation and EFS were significantly lower in the next generation TKIs era compared to the imatinib era. Our results support the use of 2nd TKIs in treating high-risk patients with CML-CP in order to avoid disease progression. Future large-scale studies are necessary to evaluate the clinical significance of EUTOS scoring in the accurate prediction of prognosis among patients with CML-CP treated with 2nd TKIs.
CML and pregnancy had the synchronistic onset of these events (table 1). Sokal nosed in 1st/2nd/3rd trimester in 18/7/6 females correspondingly. Induced abortion patients correspondingly, no data for risk score was in 1 patient. CML was diagnosed low/intermediate/high and EUTOS low/high risk score was in 22/5/3 and 28/2 all 282 pregnancy cases. In certain countries (Russia) up to 21% of women with Ph-positive chronic phase CML during pregnancy. That was 11% of

**Background:**

...characteristics at diagnosis, cytogenetic and molecular parameters, information of therapy, pregnancy outcomes and data of newborns.

**Aims:**

To describe pregnancy outcomes and therapy tactics for CML diagnosed at pregnancy.

**Methods:**

Information regarding CML diagnosed at pregnancy was collected with the participation of countries participating in the observational study of European LeukemiaNet (ELN Pregnancy Registry). The data included CML clinical characteristics at diagnosis, cytogenetic and molecular parameters, information of therapy, pregnancy outcomes and data of newborns.

<table>

</tr>
</tbody>
</table>

**Results:**

Thirty one women with median age 26 years (range 20-39) were diagnosed with Ph-positive chronic phase CML during pregnancy. That was 11% of all 282 pregnancy cases. In certain countries (Russia) up to 21% of women with CML and pregnancy had the synchronistic onset of these events (table 1). Sokal low/intermediate/high and EUTOS low/high risk score was in 22/5/3 and 28/2 patients correspondingly, no data for risk score was in 1 patient. CML was diagnosed in 1st/2nd/3rd trimester in 18/7/6 females correspondingly. Induced abortion was done before CML therapy was started in 10 (32%) around 10 obstetrician week (range 6-17), spontaneous abortion happened in 1 woman (at 8th week). Pregnancy was prolonged by consistent desire or religious reasons in 20 females: 2 pregnancies are ongoing now and 18 have ended in childbirth. No treatment till labor was in 5 women. Treatment of CML during pregnancy was initiated in 15 of 20 patients. Interferon alpha (IFN) was given to 5 women and 3 of them were switched to imatinib (IM) 400mg daily in 2nd-3rd trimester due to insufficient control of complete blood count. IM 400mg daily in 1st line was also taken by 9 women since 2nd-3rd trimester. In summary 12 women got IM from 3rd trimester till labor and 3 got HU shortly for 5-7 days before any other treatment in 1st/2nd trimester. Nineteen healthy newborns (including twins in 1 case) were born: 14 at term, 5 by preterm delivery at week 35-37. There were no birth abnormalities in 10 newborns exposed to IM in 2nd-3rd trimester. Two pregnancies under IM exposure are currently at week 17 and 31, developing normally. Four infants had low birth weight (<2500 g); 3 of them were exposed to IM and 1 for HU at pregnancy. Follow-up of children was uneventful with Me observation time 47 months (range 9-63) for 10 infants exposed to IM in 2nd-3rd trimester. Twenty nine of 31 women with CML diagnosed at pregnancy are alive and continue TKI treatment, 2 women unfortunately died: 1 patient with postponed switch from IFN to IM during pregnancy progressed to blast crisis after labor and had furher bone marrow transplant failure while 1 patient after induced abortion developed rapid blast crisis with BCR-ABL compound mutations including T315I.

**Conclusion:**

...the first report of a large database of women diagnosed with CML during pregnancy. Management of this very delicate subset of patients is a challenge especially when a woman refuses from abortion. Individual treatment approach may differ considering pregnancy terms and clinical status. Although normal childbirth is possible using IM after 2nd/3rd trimester, risks of pregnancy prolongation remain still not well defined. To get the most safe prognosis for mother and child pregnancy in CML should be planned in a safe DMR.

**Background:**

...chronic myeloid leukemia (CML). As increased NK cells during TKI therapy positively correlate with better outcomes, antitumor immune function of it remain to be elucidated.

**Methods:**

KIR and HLA high resolution typing were performed on peripheral blood DNA from 76 CML patients in chronic phase (CML-CP) using Scisco Genetics typing kit (Scisco Genetics Inc., Seattle WA) and MiSeq as platform by NGS. Therapeutic effects of TKIs were evaluated based on bcr-abl mRNA levels measured by real-time quantitative (RQ)-PCR compensated according to international scale (IS) and/or transcription mediated amplification (TMA) method. Major molecular response (MMR) was defined as 3-log reduction (MR3) in RQ-PCR (IS) or BCR-ABL transcript level of less than 50 copy/0.5 μRNA in TMA method. We also defined DMR as 4-log reduction (MR4) in RQ-PCR (IS), which is similar to undetectable of BCR-ABL transcript level in TMA method. The Cox proportional hazards model was used in the time-to-event analysis. p-value<0.05 was considered statistically significant.

**Results:**

Second generation TKIs as first-line therapy (n=46) and female (n=29) sex were strongly associated with superior DMR at the 2-year of therapy (second generation TKIs as first-line treatment, HR 7.305, 95% CI, 3.377 to 15.803; p<0.001; female sex, HR, 1.709, 95% CI, 1.028 to 2.842; p=0.039). After adjustment with these two factors, several KIR alleles positively correlates with superior DMR at the 2-year; KIR2DL4*008 or 011/000501, and 2DS4*00301 or 007/010 or 015 (HR 2.811, 95% CI, 1.590 to 4.968; p<0.001). Interestingly, KIR3DL1*00501 for the patients has more strong link with these two factors, several KIR alleles positively correlates with superior DMR at the 2-year; KIR2DL4*008 or 011/000501, and 2DS4*00301 or 007/010 or 015 than other KIR3DL1 alleles. (Fisher’s exact test, p<0.001).

**Summary/Conclusions:**

KIR3DL1*00501 and several KIR2DL4 and 2DS4 alleles positively correlate with better therapeutic effects of TKIs, and they may be form the same KIR haploype. Our data indicate that these KIR alleles represent strong anti-CML immunity by NK cells, and consequently may associate with long-term outcome and treatment-free remission in CML.

**E1068 IMPACT OF KIR3DL1*00501 IN TYROSINE KINASE INHIBITOR-TREATED CML**

1Division, Hematology, Tokyo Medical and Dental University, Tokyo, Japan, 2Dep.Hematology and Oncology, Kyoto University, 3HLA Foundation, Kyoto, 4Center for Comprehensive Community Medicine, Japan, 5Saga city, Japan

**Background:**

The BCR-ABL1 tyrosine kinase inhibitors (TKIs) dramatically improved long-term survival of the patients with chronic myeloid leukemia (CML). As increased NK cells during TKI therapy positively correlate with better outcomes, antitumor immune function of it remain to be elucidated.

**Methods:**

KIR and HLA high resolution typing were performed on peripheral blood DNA from 76 CML patients in chronic phase (CML-CP) using Scisco Genetics typing kit (Scisco Genetics Inc., Seattle WA) and MiSeq as platform by NGS. Therapeutic effects of TKIs were evaluated based on bcr-abl mRNA levels measured by real-time quantitative (RQ)-PCR compensated according to international scale (IS) and/or transcription mediated amplification (TMA) method. Major molecular response (MMR) was defined as 3-log reduction (MR3) in RQ-PCR (IS) or BCR-ABL transcript level of less than 50 copy/0.5 μRNA in TMA method. We also defined DMR as 4-log reduction (MR4) in RQ-PCR (IS), which is similar to undetectable of BCR-ABL transcript level in TMA method. The Cox proportional hazards model was used in the time-to-event analysis. p-value<0.05 was considered statistically significant.

**Results:**

Second generation TKIs as first-line therapy (n=46) and female (n=29) sex were strongly associated with superior DMR at the 2-year of therapy (second generation TKIs as first-line treatment, HR 7.305, 95% CI, 3.377 to 15.803; p<0.001; female sex, HR, 1.709, 95% CI, 1.028 to 2.842; p=0.039). (Fisher’s exact test, p<0.001).

**Summary/Conclusions:**

KIR3DL1*00501 and several KIR2DL4 and 2DS4 alleles positively correlate with better therapeutic effects of TKIs, and they may be form the same KIR haploype. Our data indicate that these KIR alleles represent strong anti-CML immunity by NK cells, and consequently may associate with long-term outcome and treatment-free remission in CML.

**E1069 COMPARISON OF MOLECULAR KINETICS AFTER THE FIRST AND SECOND IMATINIB DISCONTINUATION: RESULTS FROM THE KID STUDY**

1Seoul St. Mary’s Hospital, The Catholic University of Korea, 2Leukemia Research Institute, The Catholic University of Korea, Seoul, 3Ajou University School of Medicine, Suwon, 4Chonnam National University Hospital, Hwasun, Hospital, 5Dong-A University College of Medicine, Busan, 6Hallym University College of Medicine, Anyang, 7Kangbuk Samsung Hospital, School of Medicine, Sungkyunkwan University, Seoul, 8Ulisan University Hospital, University of
Background: Recent reports have demonstrated that tyrosine kinase inhibitors (TKIs) discontinuation can be employed in chronic phase chronic myeloid leukemia (CP CML) patients with sustained deep molecular responses after enough TKI therapy. Consequently, treatment-free remission (TFR) has been a new therapeutic goal. Although 50-70% of patients experienced molecular relapse by several imatinib (IM) discontinuation studies, the most of patients resumed molecular responses (MR) following restart of IM. Aim: We evaluated the impact of molecular response by 24 months for molecular level after 3 months (BCR-ABL1 transcript level ≤1%) of radotinib 300mg bid approved for CP CML patients who were treated with HU (1-3 g/day) because of side effects. In addition, resistance against ponatinib may develop in two study groups, early molecular response (EMR) at 3 months were evaluated. And, total of 151 patients who received CP CML patients who were treated with IM for more than 3 years and had undetectable levels of BCR-ABL1 transcripts determined by quantitative reverse transcriptase polymerase chain reaction (PCR) for at least 2 years were eligible for KiD study and in cases of MMR loss after 2 consecutive assessments, IM treatment was re-introduced. After IM resumption for MMR loss, if MMR was not achieved, IM treatment was re-introduced. After sustaining UMRD at least 2 years. Prior to first discontinuation, the median duration of IM therapy was 68.9 months (range, 38.5-115.1 months) and the duration of sustained UMRD was 32.9 months (range, 24.8-84.5 months). After first attempt of IM discontinuation, they relapsed after a median duration of 3.7 months (range, 1.0-24.8 months) and 2 years (range, 1.0-115.1 months) after IM resumption. After sustaining a second UMRD for a median of 25.5 months, IM therapy discontinued for a second time. After a median follow-up of 8.8 months (range, 0.3-38.1 months) after second IM discontinuation, 10/12 patients (83%) and 8/12 patients (67%) lost UMRD but not MMR, one patient showed fluctuation of BCR-ABL1 transcript under the level of 0.1% on IS for 9.4 months and another patient have shown gradually increasing BCR-ABL1 transcripts under the level of 0.1%. Eight patients who experienced second relapse (MMR loss) after a median 2.9 months (range, 1.9-30.7 months). The patients who lost MMR, except one patient, were retreated with IM for a median of 7.1 months (range, 0.8-24.8 months); five patients re-achieved MMR at a median of 1.8 months (range, 1.0-10.2 months) and one re-achieved UMRD at 5.5 months.

Summary/Conclusions: With minimum 24 months follow-up, early responses at 3 months or 6 months can predict better outcomes in newly diagnosed chronic myeloid leukemia patients treated with radotinib or imatinib. But, to evaluate the significant long-term prognostic value such as overall survival and progression-free survival by EMR, longer follow-up are needed.
Results: HU treatment resulted in WBC stabilization in 3 of 4 patients, but failed to induce a molecular response. However, surprisingly, the percentage of BCR-ABL decreased significantly in all 4 patients during HU treatment and was no longer detectable in 3 of 4 cases. Stem cell transplantation could be performed in 2 patients after 2-3 months. In one patient, stable disease over 18 months was obtained with HU-therapy. In one patient, the disease progressed rapidly despite temporary suppression of BCR-ABL. In vitro studies, HU was found to block the growth in all cell lines tested and in all primary cell samples (n=7) examined, with IC50 values ranging between 50 and 250 µM. Interestingly, cell lines exhibiting mutant BCR-ABL1 were more sensitive against HU than cell lines expressing BCR-ABL1 WT. HU and ponatinib were found to synergize in inhibiting growth of all cell lines tested, including cells expressing BCR-ABL1 T315I or T315I including compound mutations. Cooperative drug effects were also confirmed in primary CML cells (n=4). In cell line experiments, ponatinib was found to suppress Ba/F3/T315I cells but not Ba/F3/T315I/F359V or Ba/F3/T315I/E255V cells, whereas HU was found to exert stronger effects on cells expressing mutant BCR-ABL1, and the drug combination resulted in complete suppression of all sub-clones. Summary/Conclusions: Our data show that HU exerts strong, sub-clone specific, specific, anti-neoplastic effects in TKI-resistant CML cells. Clinical studies are now warranted to define the exact value of the drug combination ponatinib+HU in TKI resistant CML.

E1072
ASSOCIATION OF BCL2L11 (BIM) DELETION POLYMORPHISM WITH MOLECULAR RELAPSE AFTER TYROSEINE KINASE INHIBITOR CESSION IN CHRONIC MYELOID LEUKEMIA PATIENTS WITH DEEP MOLECULAR RESPONSE
1Department of Hematology, 2Department of Molecular Oncology, Institute of Medical Science, Tokyo Medical University, Tokyo, 3BML, INC, Saitama, Japan

Background: The inhibition of BCR-ABL kinase with tyrosine kinase inhibitors (TKIs) has markedly improved the prognosis of chronic myeloid leukemia (CML). Recently, it has been recognized that some CML patients with deep molecular response (DMR) can maintain treatment-free remission (TFR) after TKI cessation. Recently, it has been recognized that some CML patients with deep molecular response (DMR) can maintain treatment-free remission (TFR) after TKI cessation. To further clarify the role of predictive biomarkers in molecular relapse after TKI cessation, we performed a long-term follow-up of CML patients with DMR after TKI cessation.Methods: Patients with DMR receiving TKI treatment were included. Molecular relapse was defined as a loss of the major molecular response (MMR). The molecular response was considered as a loss of the major molecular response (MMR). The present studies were designed to verify the limit of detection (LoD) for Xpert® BCR-ABL Ultra assay below MR4.5 (Molecular Response at 4.5-log reduction) or 0.0032%, which is widely accepted as the clinical threshold that defines candidates who can safely discontinue TKI therapy.

Aims: The present studies were designed to verify the limit of detection (LoD) for Xpert® BCR-ABL Ultra assay below MR4.5 (Molecular Response at 4.5-log reduction) or 0.0032%, which is widely accepted as the clinical threshold that defines candidates who can safely discontinue TKI therapy.

Methods: To overcome the challenge of testing numerous replicates requiring large volumes of patient samples, serial dilutions ranging from BCR-ABL/ABL levels of 10% to <0.001% (IS) were prepared as contrived samples using CML cell lines with initial BCR-ABL1 levels >10% (IS) and pooled blood from CML negative patients, ranged from 10% to <0.001% (IS). Twenty-one replicates of each dilution were measured for%BCR-ABL/ABL (IS). Determination of the LoD was performed by the statistical analysis to identify the lowest concentration of%BCR-ABL/ABL (IS) per test that can be reproducibly distinguished from negative samples with 95% confidence. The acceptable precision for%BCR-ABL/ABL (IS) is defined as the ability to detect at least a 3-fold difference for all concentrations tested. In addition, analytical LoD studies were performed using spike-in CML cell lines and cell-line derived RNAs, carrying either b3a2 or b2a2 transcripts. Furthermore, the clinical sensitivity study was conducted using blood from twelve low BCR-ABL transcripts level CML patients on TKI therapy, who had achieved and maintained MMR (Major Molecular Response) [0.1% (IS)] with reporting below 0.05% (IS).

Results: Consistent results were observed in the both the diluted patient blood and spike-in CML cell lines or cell-line derived RNA studies for both the b3a2 and b2a2 transcripts, demonstrating an assay LoD of MR4.5 and below with a less than 2-fold difference at the LoD levels. With the clinical sensitivity study, eleven out of twelve low CML subjects were detected in at least 19 out of 20 replicates tested per subject over a range of 0.038% (IS) (SD=0.17 Log) to 0.0011% (IS) (SD=0.4 Log). The overall ABL copy number present in clinical samples in each study was at least 5-10 times the required minimal ABL copy number of 232,000 to support a claim of MR4.5 and ≥100,000 for MR5.0.

Summary/Conclusions: These LoD evaluations demonstrate that the Xpert® BCR-ABL Ultra assay complies with the international guidelines for assay sensitivity achieving MR4.5 with 5-10 times more than the required ABL copies to confidently identify candidate patients that may benefit from the discontinuation of TKI therapy.

IDENTIFICATION OF INCIDENT CASES OF GAUCHER DISEASE IN SPLENOMEALGY AND/OR THROMBOCYTOPENIA PATIENTS IN SPECIALIZED MEDICAL SERVICES IN COLOMBIA THROUGH THE USE OF A SELECTION ALGORITHM

1Bogotá D.C., Clínica Los Nogales, Bogotá D.C., 2Bolívar, Universidad de Cartagena, Clínica Blas de Lezo, Cartagena, 3Antioquia, Clínica Sagrado Corazón, Medellín, 4Antioquia, Clínica Vida Prado, Medellín, 5Valle del Cauca, Clínica de Occidente, 6Valle del Cauca, Universidad del Valle, Cali, 7Santander, Hospital San Luis, Bucaramanga, 8Antioquia, Hospital General de Medellín, 9Atlántico, Centro Cancerológico del Caribe, Barranquilla, 10Santander, Universidad de Hematología y Oncología de Santander, Bucaramanga, 11Antioquia, Hospital Universitario San Vicente Fundación, Medellín, 12Huila, Universidad Surcolombiana, 13Huila, Hospital Universitario Hernandez Montecaleano Perdomo, Neiva, 14Antioquia, Clínica de Oncología Astorga, Medellín, 15Caldas, Médicos Internistas de Caldas, Manizales, 16Antioquia, Hospital Pablo Tobón Uribe, Medellín, 17Valle del Cauca, Centro Médico Imanbacano, Cali, 18Bogotá D.C.; Clínica Infantil Celsusibdio, Bogotá D.C., 19Atlántico, Clínica la Asunción, 20Atlántico, Clínica Bonadona, Barranquilla, 21Bogotá D.C., Centro de Atención a Investigación Médica Caimed S.A.S, Bogotá D.C., Colombia

Background: Gaucher disease (GD) varies greatly in severity and organ involvement. Clinical characteristics are usually nonspecific and lead to late diagnosis with irreversible complications. Splenomegaly and thrombocytopenia are the two most common manifestations (Gaucher Registry, 2008), which reported 86% cases with moderate to severe splenomegaly and 60% thrombocytopenia at the time of diagnosis, thus demonstrating why patients are referred to hematology. A diagnosis of GD is considered after other diagnostic hypotheses have been ruled out. The consensus of international experts on the management of patients with GD established a diagnostic algorithm that is particularly intended for specialists (Mistry, 2010). Straightforward implementation of diagnostic algorithms to support medical specialties in Latin America for early diagnostic testing of GD is required.

Aims: To identify new cases of GD in a selected population with splenomegaly and/or thrombocytopenia referred to Hematology, Pediatric Hematology, Pediatrics and Internal Medicine, using a selection algorithm for the genotyping of GD patients.

Methods: Multicenter, descriptive study, in active recruitment process with non-probabilistic sampling by convenience. Currently, the study has 51 specialized medical centers in Hematology, Pediatrics and Internal Medicine in Colombia, approved by Ethics Committee (EC). The study has an expected duration of 24 months since EC approval for each center. Eligible subjects are those with three documented criteria: thrombocytopenia (<150,000/cc plus anemia (hemoglobin <110g/dl in men and <11 g/dl in women) plus/or bone pain plus/or monocular Gammopathy of Unknown Significance plus/or Polyclonal Gammopathy in subjects aged 30 years and older; and/or splenomegaly defined as palpable spleen ≤1cm below the costal rib or diagnosed by imaging, and/or Splenectomy by splenomegaly with no known cause. Subjects with prior diagnosis of GD, splenomegaly due to portal hypertension, hematologic malignancy, hemolytic anemia and thalassemia were excluded. Informed consent was obtained for all included subjects. Clinical information was collected from their medical history. The enzymatic activity of the β-glucocerebrosidase was performed in peripheral blood, using dried blood spots (DBS) and/or leukocytes. In subjects with reduced enzymatic activity in DBS, confirmed β-glucocerebrosidase deficiency and symptomatic GD, a bone marrow biopsy was performed to diagnose the cases of GD.

Results: Since Feb/14 to Nov/16, 400 subjects have been included (51.3% men) with a median age of 28.79 years (range, 0.01 to 91.87). Reduced enzymatic activity of β-glucocerebrosidase was identified in 14 subjects (50% men) with a median age of 12.68 years (range, 0.3 to 74.85). All subjects were non-Ashkenazi origin, with 82.8% thrombocytopenia, 49.5% splenomegaly and 4.33% splenectomy. Detailed population description is on Figure 1.

Summary/Conclusions: This study suggests that selection algorithm could be implemented in Colombia, supporting specialists in making decisions on diagnosis of Gaucher Disease. Further characterization of the population is ongoing.

E1075
IMPACT OF PEROXIREDOXIN 2, GLUTATHIONE Peroxidase and Catalase Inhibition on Oxidative Stress Modifications of Red Blood Cell Membrane and Cytosol

D. Melo1, S. Ribeiro2, H. Fonseca de Céncias, Faculdade de Ciências, Universidade do Porto, 2UCIBIO, REQUIMTE, Laboratório de Bioquímica, Departamento de Ciências Biológicas, Faculdade de Farmácia, Universidade do Porto, Porto, Portugal, Porto, Portugal

Background: Several anemias are associated with oxidative stress, namely, sickle cell anemia, β-thalassemia, glucose-6-phosphate dehydrogenase deficiency and hereditary spherocytosis. Red blood cells (RBC) are continuously exposed to reactive oxygen species (ROS), triggering oxidative modifications. The antioxidant system, however, when its capacity is overwhelmed, the cell is exposed to oxidative modifications of the RBC, as showed by the increase in MBH and membrane LPO, and by the decrease in cytosolic TAS. Moreover, the inhibition of CAT or GPx (either alone or simultaneously, leads to oxidative stress modifications within the RBC, as showed by the increase in MBH and membrane LPO, and by the decrease in cytosolic TAS. Moreover, the inhibition of CAT or GPx (either alone or with other enzymes) presented more impact on oxidative modifications than Prx2 inhibition. Our data strengthens the importance of these enzymes in RBC's antioxidant defense.

Aims: We aimed to study the importance of Prx2, GPx and CAT inhibition on defense against oxidative stress in normal erythrocytes.

Methods: We performed in vitro assays (n=3) with RBCs from healthy volunteers, inhibiting Prx2, GPx and CAT, either individually, two-by-two or all three; concomitant inhibition of Prx2, GPx and CAT, respectively. Since the RBC membrane is a major target of ROS, we evaluated membrane lipoperoxidation (LPO) and membrane bound haemoglobin (MBH), as well as, cytosols’s total antioxidant status (TAS), by spectrophotometric methods.

Results: Concerning TAS we found a trend towards decreasing values with enzyme inhibition (one or more); the lowest value of TAS was observed when all three enzymes were inhibited and, when only two enzymes were inhibited, the lower values were obtained for pairs that included CAT inhibition; when only one enzyme was inhibited, GPx inhibition showed the highest TAS; regarding LPO, a trend towards increasing values with enzyme inhibition was observed; the lowest value was obtained when all enzymes were active, and the highest when all of them were inhibited; when only one enzyme was inhibited, CAT inhibition showed the highest LPO value and when two enzymes were inhibited, LPO was increased for the pairs that included GPx, MBH was increased for all enzyme inhibitory conditions, when compared to the condition with all enzymes active, excepting when CAT was inhibited.

Summary/Conclusions: In conclusion, inhibition of these antioxidant enzymes, either alone or simultaneously, leads to oxidative stress modifications within the RBC, as showed by the increase in MBH and membrane LPO, and by the decrease in cytosolic TAS. Moreover, the inhibition of CAT or GPx (either alone or with other enzymes) presented more impact on oxidative modifications than Prx2 inhibition. Our data strengthens the importance of these enzymes in RBC's antioxidant defense.

Figure 1.
antioxidant homeostasis, and suggests that inhibition or injury to one (or more) compromises erythrocytes, which might influence clinical presentation in oxidative stress associated anemias.

MOLECULAR BASIS OF PKLR MUTATIONS IN PATIENTS WITH PYRUVATE KINASE (PK) DEFICIENCY: THE FIRST REPORT FROM SOUTHEAST ASIAN POPULATION

S. Riolueang1, K. Tachavanich2, S. Ekawattanakit3, V.S. Tanphaichitr2, H. Kanno4, V. Viprakasit5
1Siriraj-Thalassemia Center, 2Department of Pediatrics, 3Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand, 4Department of Transfusion Medicine and Cell Processing, Tokyo Women’s Medical University, Tokyo, Japan, 5Department of Medicine, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

Background: Recently we have identified a new form of transfusion dependent hemolytic anemia due to KLF1 mutations causing a trans-acting deactivation of pyruvate kinase genes (PKLR). Mutations of PKLR per se can affect red blood cells metabolism and cause a wide range of clinical manifestation from fetal anemia leading to hydropic fetus, severe neonatal jaundice requiring multiple exchange blood transfusions, chronic to fully compensated hemolytic anemia. Understanding of the molecular basis of pyruvate kinase deficiency (PK def.) might be useful to predict clinical phenotypes and suggest appropriate clinical management of future patients. Moreover, an interaction of PKLR and KLF1 mutations in such patient has not been explored.

Aims: This study aim to identify the mutation of patients with PK def. for the first time in Southeast Asian populations.

Methods: Seven unrelated patients; 6 from Thailand and 1 from Indonesia have been enrolled after inform consent. We have measured the PK activity of all patients and their parents and siblings using a standard biochemical technique as we have described earlier. A complete genomic analysis of all PKLR's exons (NM_000298.5) including exon-intron boundaries were selectively amplified and followed by direct Sanger sequencing.

Table 1.

Results: Seven index PK def. patients as confirmed by enzyme activities, age range 9-35 yrs old, were identified (Table 1). Three patients presented with severe hemolytic anemia and required regular blood transfusion; every 3-4 weeks in two (PK-1 and PK-3) and every 10-12 weeks (PK-2) in which one patient (PK-1) has been successfully treated with bone marrow transplantation and become transfusion-free. Three patients (PK-5, -6 and -8) had moderately severe hemolytic anemia and required blood transfusion occasionally. Only one patient (PK-7) from Indonesia had well-compensated anemia and never required blood transfusion. All but one had PK activities lower than 50% of normal range but these activities did not correlate with clinical severity. We found 11 different mutations in 5 compound heterozygotes and 1 homozygote as shown in Table 1. Four mutations appeared to be novel as they were not been reported in any public databases (c.1269+3A>G; c.353A>G =p.N118S; c.941T>C), mismatched PCR-RFLP for c.1403C>G, c.1463G>A and IVS9(+3)A>G). Interestingly, one index patient (PK-4) was found with only one known missense mutation (R488Q), however we could not find any mutation in KLF1 of this patient suggesting that she might have other unidentified cis mutation involved gene regulation of PKLR. Due to a limited number of patients, there was no clear genotype-phenotype correlation found in our studied population.

Summary/Conclusions: Seven confirmed cases of PK def. are reported here-in. They showed a wide variation of clinical severity. Molecular basis of PKLR mutations was proven to be beneficial to provide a definitive diagnosis of PK def. and might help suggesting clinical presentation in future cases.

E1077

PRELIMINARY RESULTS OF GAU-PED STUDY: PREVALENCE OF GAUCHER DISEASE IN PAEDIATRIC PATIENTS SELECTED BY AN APPROPRIATE DIAGNOSTIC ALGORITHM

W. Morello1, M. Filocamo2, M. Stroppiano2, M. Di Rocco3, F. Fedeli4, G. Russo5, D. Sperti6, F. Furlan7, A. Pession1

O. “Annunziata”, Cosenza, 7Pediatric Department, Fondazione IRCCS Ca’Granda Ospedale Maggiore Policlinico, Milano, Italy

Background: Gaucher disease (GD) is an autosomal recessive lysosomal storage disease characterized by the deficient activity of beta-glucocerebrosidase (GBA). GBA deficiency results in the accumulation of glucosylceramide in different organs, causing tissue damage. Typical GD features are splenomegaly, peripheral blood cytopenias (mostly thrombocytopenia and/or anemia), growth retardation, bone involvement, gammapathies, increased risk of malignancies and, in some patients, neurological manifestations. Since symptoms are non-specific, the diagnosis can be delayed for years or missed. Enzyme replacement therapy (ERT) with recombinant β-glucocerebrosidase is safe and effective in preventing and/or reversing many clinical manifestations. However, if the diagnosis is delayed for years, major complications cannot be reversed. A useful screening method for GD is based on measuring enzyme activity on a Dried Blood Spot (DBS), while the gold standard test is still considered GBA activity in cellular homogenates. A pediatric algorithm has been proposed to promote timely diagnosis and early access to ERT (figure 1).
evaluate the prevalence of GD among children referred to the haematology paediatric units and selected according to the above mentioned diagnostic algorithm. Here, we report a preliminary analysis of GAU-PED trial.

Methods: The GAU-PED study involves 53 centers in the context of the AIEOP Study Group, the Italian clinical research consortium in paediatric haematology and oncology. Patients referring to the pediatric hematology and oncology units for evaluation of a hematological condition with hemolysis (hemolytic anemia and/or anaemia), where other causes of splenomegaly has been excluded, are tested for G6PD activity though a DBS sample. Only patients with DBS showing a G6PD activity below normal values are recalled to confirm G6PD enzyme deficiency using the gold standard G6PD analysis in cell homogenate. For every tested patient, clinical information are also collected.

Results: After parental consent, a total of 25 DBS have been collected from 11 centers, in the first 12 months of study accrual. DBS values under 4.4 pmol/punch –7/nmol/ were found in 9/25 patients (36%). These DBS have been recalled for the conventional enzymatic test. The diagnosis of GD has been confirmed in 5/9 patients (55%), with a prevalence of GD of 20% (95% CI: 8.3-39.1%) in 20% (95% CI: 8.3-39.1%) of patients aged ≥60 years, p<0.001, 70-79 years, p<0.001, ≥80 years, p<0.001). Anemia was most frequently encountered among men aged ≥80 years, p<0.001, 70-79 years, p<0.001. Anemia was present in 10.3% of patients aged 60-69, in 20.1% of those aged 70-79 and in 36.5% of patients ≥80 years. Incidence rates of anemia increased significantly with age (60-69 vs 70-79 years, p<0.001; 60-69 vs ≥80 years, p<0.001; 70-79 vs ≥80 years, p<0.001). Anemia was mild in 69.8% of patients, but a severe form was significantly more often among men aged ≥80 years (p<0.03). Analysis of the etiology of anemia revealed three predominant types: anemia of chronic disease (33.1%), unexplained anemia (28.4%) and deficiency anemia (22.5%), including iron deficiency 13%. In patients with anemia, those with anemia were older (p<0.001), had a higher prevalence of comorbidities (p<0.001) and were more often hospitalized (p<0.001). In the multivariate logistic regression model, factors increasing the risk of anemia were: age (≥80 years OR=2.29; 95%CI 1.19-4.42; p=0.013), 70-79 years OR=2.85; 95%CI 1.12-7.3; =0.029, 3 diseases OR=6.28; 95%CI 2.22-17.76; p=0.001, 4 diseases OR=6.4; 95%CI 1.27-17.01; p=0.021) and the number of hospitalizations (OR=1.34; 95%CI 1.13-1.58; p=0.001). At the end of the 2-yr follow-up, the cumulative survival among patients without anemia in relation to the group with anemia was 90.76% vs 78.08% and the difference was statistically significant (p<0.001). In multivariate model, factors that significantly increased the risk of death in study population were anemia (HR=3.33; 95%CI 1.43-7.74; p=0.005), cancer (HR=3.31; 95%CI 1.47-7.49; p=0.004) and heart failure (HR=2.94; 95%CI 1.33-6.51; p=0.008).

Summary/Conclusions: In patients ≥60 years the incidence of anemia increases with age, gender and male predominance. Comorbidities and frequency of hospitalization. The high rate of unexplained anemia indicates the necessity for detailed hematologic diagnosis. The occurrence of anemia among people aged ≥60 years has an adverse impact on survival.

Table 1.

Summary/Conclusions: These preliminary results suggest that MPs levels are abnormal in both congenital and acquired haemolytic conditions. MPs levels correlate with the degree of anaemia and haemolysis and with the duration of disease.

E1078

CIRCULATING MICROPARTICLES IN CONGENITAL AND ACQUIRED HAEMOLYTIC ANAEMIA

W. Barcellini;1, V.M. Sciumbata;1, J.A. Giannotta;1, A. Zaninoni;1, V.B. Valli;1, G. Merialdi;2, E. Trombetta;2, V. Ferri;1, L. Petitti;1, A. Cortezzi;1,2, A. Antoni;1

1UOC Oncemolitica, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, 2Department of Hematology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milano, Italy

Background: Microparticles (MPs) are small particles budding from cells, which contain variable amounts of proteins, mRNA and cytosol from the parental cell. MPs play a role both in physiological and pathological conditions such as signal transduction, cell activation, thrombosis and cancer. Thrombotic events are a possible complication of haemolytic conditions, both congenital and acquired. Elevated levels of circulating MPs have been described in several haemolytic conditions, including sickle cell anaemia, haemolytic uremic syndrome, and thrombotic thrombocytopenic purpura.

Aims: To evaluate platelet MPs (PMP), tissue factor expressing MPs (TFMs), endothelial MPs (EMPs) and microparticles expressing single antigens (CD41, CD142 and CD144) levels in in other haemolytic anaemias, such as hereditary spherocytosis (HS), elliptocytosis (HE), stomatocytosis (HSI), red cell enzymatic defects, congenital dyserythropoietic anaemia (CDA), autoimmune haemolitic anaemia (AIHA), and paroxysmal nocturnal haemoglobinuria (PNH).

Methods: To determine MPs, whole blood was collected into 0.109 M sodium citrated vacutainer tubes. Platelet Free Plasma (PFP) was prepared by double centrifugation at 2500 g for 15 min and stored frozen at -80°C until assayed. For MPs analysis 25 µl of PFP was incubated with annexin V-APC, CD41-FITC, CD142-PE and CD144 PerCp-Cy5.5 in Hepes buffer in the presence of 15 mM CaCl2 and 1 µM of r-Hirudin for 30 min. Samples were diluted with 500 µl Annexin V Binding buffer and 25 µl of Fixed Fluor reagent was added to express MP count as absolute numbers. MPs analyses were performed on a BD FACS Canto cytometer using Megamix-Plus SSC to define the MPs gate.

Results: MPs levels were evaluated in plasma of 43 patients followed-up for a median time of 9 months (range 2-34) and compared with normal controls. The median number of MPs in PFP was 2.85 x 104 (range 22-87) in controls, 9/43 (21%) had been splenectomized and 13/43 (30%) were treated at the moment of the study (steroids/immunosuppressors for AIHA, and eltuzumab for PNH). Table shows Hb levels, PLT and WBC counts of the different patient groups. In AIHA, the median age of patients (15 male and 28 female) was 53 years (range 22-87), while the mean time between the DBS test and the diagnosis has been 2 months. ERT has been started in all GD patients.

Summary/Conclusions: Our preliminary results support the use of DBS as screening test for GD in a selected population of children with splenomegaly and/or thrombocytopenia considered at increased risk for the disease. The use of a diagnostic algorithm is useful to increase awareness of GD among pediatric hematologists and to shorten the time to diagnosis. Taking into consideration the long life expectancy of pediatric GD patients, the early diagnosis will have a strong impact on health and quality of life.

PIEZO1 MECHANOTRANSDUCTIVE PROTEIN MUTATIONS IN RBCS: WHEN THE PHENOTYPE IS BEYOND HYALOMYCIST ANAEMIA
D. Mata1,2, S. Mantra1, T. Nascimento1, P. Bernardo1, L. Relvas1, A. Oliveira1, E. Coelho1, J. Ribeiro1, C. Bento1, T. Magalhães Maia1, M. R. Marques1,2
1Serviço de Hematologia Clínica, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Piezo proteins are integral membrane proteins with many transmembrane domains broadly expressed, including erythrocytes (RBCs). PIEZO1 proteins play an important role as an osmoreceptor, maintaining RBCs ionic homeostasis, functioning as a mechanically activated cation channels. Mutated PIEZO1 proteins have been linked to hereditary xerocytosis (HX), which is characterized by RBCs dehydration with mild to moderate compensated haemolytic anaemia and iron overload. As these clinical features are present in many different clinical conditions, the diagnosis always needs a high level of suspicion. Nowadays, besides peripheral blood smear (PBS) observation, molecular analysis, searching for mutations in PIEZO1 gene, became a tool in the diagnosis of HX.

Aims: Describe 26 patients with HX associated with PIEZO1 mutations belonging to 13 unrelated families, raising awareness of the highly variable phenotype of this patient, and the need of a high grade of suspicion along with the morphologic evaluation of the PBS.

Methods: Collection of clinical and laboratory data on our 26 patients with HX and hyperferremia due to 10 different identified mutations in PIEZO1. Sanger sequencing was used to identify mutations affecting PIEZO1, encoded by FAM38A gene, and to confirm transmission according to the presence of disease phenotype. In all patients were excluded other known causes of hyperferremia (HF) and haemolytic anaemia.

Results: Of the 26 patients identified as having PIEZO1 mutations, 13 were probands and 13 were identified by family studies. Median age at diagnosis was 43 years (1-80), with female predominance (n=14; 53.9%). 4/13 probands had family history of HX (n=1) or HF (n=2). The common feature of our entire cohort of patients was the presence of xerocytes in PBS. 13/26 patients had reticulocyte counts of a median reticulocyte count of 101 x 10^9/L (28.1-557.3), 18/26 patients had HF with a mean value of ferritin of 556 ng/mL (161-6817) and 9/26 had both. Of the 26 patients, four had splenomegaly and six gallbladder lysis (5/6 cholecystectomized), two of them both. Only 5 patients presented with anaemia (Hb <12 g/dL), 2 macrocytic and 3 normocytic. One patient had coexisting sickle cell disease and he also had a xerocytosis carrier. We detected heterozygous missense mutations in all 26 patients.

Summary/Conclusions: HX is a dominant disorder of RBCs dehydration presenting a great phenotypic variability. As shown in our cohort of patients, the anaemia may not be the main feature, in fact, the presence of xerocytes in PBS and HF were the most frequent characteristics of our patients. We would like to emphasise that in the genomics era the identification of xerocytes in the PBS keeps playing an important role for this diagnostic. Not only because, unlike other haemolytic anaemias, in HX there is a contraindication to splenectomy due to the increased risk of thrombotic events, but also because this pathology has multiorgan involvement that is related to the degree of hemolysis. This iron overload may be related to a defective iron homeostasis dependent on PIEZO1 function not strictly related with Xerocytosis.

PHYSIOPATHOLOGY OF HEREDITARY XEROCYTOSIS : PIEZO1 GAIN OF FUNCTION MUTATIONS IMPACT HEMOGLOBIN OXYGEN AFFINITY
L. Kiger1, C. Guitton2, K. Ghazal3, M. Feneant-Thibault4, L. Bendelac5, F. Galacteros6, V. Proulle7, L. Garçon8, V. Picard5,*
1IMRB U955, INSERM, Créteil, 2Service de Pédiatrie, 3Service de biochimie, APHP, Hôpital Bicêtre, 4Service de biochimie, 5Service d’hématologie biologique, APHP, Hôpital Bicêtre, Le Kremlin Bicêtre, 6Centre de Reference des maladies constitutionnelles du Globule rouge, APHP Hopital Mondor, Créteil, 7Service d’Hématologie, APHP, Hôpital Bicêtre, Le Kremlin Bicêtre, 8Service d’hématologie biologique, CHU, Amiens, France

Background: Dehydrated hereditary stomatocytosis, also called hereditary xerocytosis (HX) is a dominant non-spherocytic chronic hemolytic anemia characterized by an increased cation leak through the red cell membrane, associated with dehydration and shortened red cell survival. Clinically, most patients present a totally compensated hemolysis, with a normal hemoglobin level contrasting with a high reticulocytosis. In most cases, HX is caused by missense mutations activating Piezo1, a mechanosensitive ion channel. However, the pathophysiology of this compensated hemolysis remains largely unclear.

Aims: We studied the hemoglobin oxygen affinity parameters in HX patients and in hereditary spherocytosis (HS) subjects as controls.

Methods: Fourteen patients from 5 described and 4 unreported families with a HX diagnosis and 15 HS subjects were included. Diagnosis was based on electrophoresis and ESA assay. PIEZO1 and KCN4 coding regions were analyzed by Sanger sequencing in all HX patients. Hemoglobin oxygen affinity was evaluated using p50 measured on venous blood on a Hemoxanalyser or a Radiometer blood gas analyzer. 2,3 diphosphoglycerate (2,3 DPG) levels were measured using a commercialized kit and expressed as a molar ratio 2,3 DPG/hemoglobin.

Results: All the 14 HX patients carried one or two missense mutations in PIEZO1, no gene variation was identified in KCN4. Five families (9 subjects) have already been reported, with identified mutations in exons 18, 21, 42 or 51. Five subjects from 4 new families carried new mutations in exons 14, 16 and 20 for which bioinformatic softwares showed a high likelihood of pathogenicity. For all HX patients, p50 values were under the normal range (mean 21.1, range 19.7-23.4, normal range 25-29 mmHg), contrasting with HS patients for whom p50 was found to be in the normal range (mean 26.1, range 24.6-28.8 mmHg). This indicated a significant increase in the hemoglobin affinity for oxygen restricted to PIEZO1 mutated HX. Of note, p50 was not correlated with the Hb level (mean 139, range 112-180 g/L in HX patients versus 125, range 93-142 g/L in HS patients). Intracellular red cell 2.3 DPG level could be measured in 7 HX patients from 4 families, it was found decreased in all of them (0.43±0.06, normal 0.9±0.19), providing a pathophysiological basis for the increased hemoglobin oxygen affinity we observed. In particular, we found a radiocytosis with the coRPK present in the therapeutic LV, to avoid the cleavage of the therapeutic transgene. Two gRNAs cleaved the PKLR gene both in 293T cells and primary CD34+ cells. In order to identify and select edited cells, Cas9-gRNAs components were cloned into a Cas9-2A-ZsGreen1 plasmid.

Results: Cord Blood CD34+ cells were electroporated, sorted and differentiated along the erythroid lineage. Significantly, the pyruvate kinase activity in ex vivo differentiated erythroid cells was impaired in gene edited cells as compared to non-edited samples.

Summary/Conclusions: Gene edit of wt CD34+ progenitors allow us to generate cells with RPK impaired. The decrease of PK activity validates this approach as a human model for PKD.

Background: Pyruvate Kinase Deficiency (PKD) is an autosomal recessive disorder caused by mutations in the PKLR gene. PKD produces chronic non-spherocytic hemolytic anemia, which can be fatal during early childhood and may require transfusion dependence. Despite therapeutic splenectomy, although not considered a standard-of-care, allogeneic bone marrow transplantation has been curative in a limited number of cases. These findings, and the evidence that PKLR gene mutations are likely the sole etiology of the disorder, make PKD a candidate for gene therapy. We developed a gene therapy strategy in a PKD mouse model using a lentiviral vector (LV) carrying a codon-optimized version of the PKLR cDNA (coRPK). This vector has been recently designated as Orphan Drug for the treatment of PKD by the EMA and FDA (EMA: EU/3/14/1330; FDA: DRRU-2016-5168).

Aims: To test the efficacy of the therapeutic LV, we have proposed an alternative to the patient-derived PKD-hematopoietic progenitors. In particular, we have generated CRISPR/Cas9 system tools to knock-out the PKLR gene in healthy hematopoietic progenitors from healthy cord blood samples.

Methods: Up to six different gRNAs were specifically designed to cleave the exons 8, 9 and 11 of the PKLR gene. All gRNAs contain at least 3 mismatches with the coRPK present in the therapeutic LV, to avoid the cleavage of the therapeutic transgene. Two gRNAs cleaved the PKLR gene both in 293T cells and primary CD34+ cells. In order to identify and select edited cells, Cas9-gRNAs components were cloned into a Cas9-2A-ZsGreen1 plasmid.

Results: Cord Blood CD34+ cells were electroporated, sorted and differentiated along the erythroid lineage. Significantly, the pyruvate kinase activity in ex vivo differentiated erythroid cells was impaired in gene edited cells as compared to non-edited samples.

Summary/Conclusions: Gene edit of wt CD34+ progenitors allow us to generate cells with RPK impaired. The decrease of PK activity validates this approach as a human model for PKD.

**E1083 SAFETY AND EFFICACY OF MULTI-PATHOGEN-SPECIFIC T CELLS IN A HUMANIZED MODEL OF INVASIVE ASPERGILLOSIS: A PROOF OF CONCEPT STUDY**

A. Popadopoulos1, L. Kougoulias2, M. Alvanou1, E. Athanasios1, N. Iakovou2, D. Yannaki2, J. Greiner2, J. Greiner2,*

1Gene and Cell Therapy Center- Hematology Dept.- BMT Unit, George Papani-
colaou Hospital, 2School of Biology, Department of Genetics, Development and Molecular Biology, 1School of Medicine, 1st Department of Microbiology, Aris-
tika University, Thessaloniki, Greece, 2Adult Hematology & Stem cell Transplant, King Fahad Specialist Hospital, Dammm, Saudi Arabia

Background: Viral infections, most commonly by cytomegalovirus (CMV), Epstein-Barr virus (EBV), polyoma virus type 1 (BK), and fungal infections, main-
ly by Aspergillus Fumigatus (Asp), are leading causes of transplant-associated mortality in patients undergoing allogeneic hematopoietic stem cell transplan-
tation. Standard treatment with antiviral and antifungal pharmacological agents, is often ineffective or toxic and may lead to resistance. Due to these limitations, adoptive immunotherapy with antigen-specific T cells has emerged as an attrac-
tive alternative. Towards unleashing its full potential and treat multiple viral and fungal infections by a single T-cell product, we developed a rapid, simplified and minimally laborious protocol for the generation of multipathogen-specific T cells (mp-STs) that simultaneously target CMV, EBV, and Asp, from healthy donors.

Aims: Due to the lack of mouse models recapitulating the clinical condition of multiple opportunistic infections in transplanted hosts, we here aimed to test the in vivo safety of produced mp-STs and provide a proof of concept of their efficacy in a humanized model of invasive aspergillosis (IA).

Methods: mp-STs were generated from healthy donors by pulsing 1.5x10^7 mononuclear cells with viral (CMV: IE1, pp65; EBV: EBNA1, LMP2, BZLF1; BK: Large T, VP1) and Asp pepmixes (Crf1, Gel1, SHMT) and culturing for 10 days. The specificity of mp-STs was analyzed by IFN-γ Elispot. A total of 1.5x10^7 of immunomagnetically isolated CD3+ cells (donor lymphocyte infu-
sion) were retransferred into lethally irradiated nude mice intranasally inoculated with Asp conidia or left uninfected. Mice were monitored for 28 days. Results: mp-STs succumbed early, before aGvHD development. Non-specific DLI failed to control IA despite T-
specific against Asp [spot forming cells (SFC)/2x10^5 cells: 315±82] and the targeted
cytokines and Immunogenetics Ulm, German Red Cross Blood Transfusion Service Baden-Württemberg–Hessen and Institute of Transfusion Medicine, Ulm, 4Department of Internal Medicine, Diakonie Klinikum, Stuttgart, Germany

Background: Cytotoxic T-cell (CTL) responses against malignant cells play a major role in maintaining remission and prolonging overall survival in patients with hematologic malignancies after allogeneic stem cell transplantation (allo-
SCT) and/or donor lymphocyte infusions (DLI). Graft versus leukemia (GvL) effects after allogeneic stem cell transplantation and/or DLI are considered to be T cell-mediated. Many groups described specific T-cell responses against several leukemia-associated antigens (LAA) in different hematological malig-
nancies. However, T cell responses after allo-SCT and DLI are not well char-
acterized.

Aims: In this study, we analyzed LAA-specific T cell responses after allo-SCT and DLI. To this end, we assessed the frequency and diversity of LAA-specific T cell responses using ELISPOT analysis and tetramer assay in 12 patients (5 patients (pts) with acute myeloid leukemia, 2 pts with chronic myeloid leukemia, 3 pts with multiple myeloma and 2 pts with chronic lymphatic leukemia) before and after DLI. Epitopes derived from PRAME, NPM1/MLH, RHHAMM, WT-1 and other LAA were tested. Moreover, the frequency of regulatory T (Treg) cells was measured and the course of cytokine profiles before and after DLI was analyzed. These immunological findings were correlated to the clinical course in the respective patients.

Methods: In ELISPOT and tetramer assays, an increase in frequency and diver-
sity of LAA-specific T cells was observed in all patients. Cytokine assays using ELISA for the detection of more than 10 cytokines before and after DLI were employed.

Results: Importantly, there was a significant increase from 0 to 7 LAA-derived T cell epitopes (P=0.03) in clinical responders (R) when compared to non-
responders (NR). These positive results in R versus NR where confirmed by
tetramer-based flow cytometry assays, where an increase in frequency from
0.5 to 2.3% in the R group of LAA-specific T cell/all CD8+ T cells was observed.
Interestingly, the frequency of Tregs in clinical responders decreased signifi-
cantly from a median 72.9% to 54.6% (P=0.008) while the frequency of Tregs stayed stable over time in non-responding patients. T cell subset analysis did not reveal significant differences before versus after DLI administration. In cytokine assays using ELISA we found a significant increase of IL-4 after DLI.

Summary/Conclusions: Taken together, we detected an increase of specific CTL responses against several LAA after allogeneic stem cell transplantation and donor lymphocyte infusion. Moreover, this study suggests that broader LAA epitope-specific T cell responses as well as decreasing numbers of Tregs contribute to clinical outcome of patients treated with DLI.

**E1085 GENE-MODIFIED NK-92MI CELLS EXPRESSING A CHIMERIC CD16/CD64-
BB-Z RECEPTOR EXHIBIT ENHANCED CANCER-KILLING ABILITY IN COMBINATION WITH THERAPEUTIC ANTIBODY**

Y. Chen1, F. You1, J. Li1, X. Tang2, G. An1, H. Meng1, L. Yuan3, L. Yang1

1The Cyrus Tang Hematology Center, 2Department of Hematology, Soochow University, Suzhou, Jiangsu, China

Background: Natural killer (NK) cells play a pivotal role in monoclonal anti-
body-mediated immunotherapy through an antibody-dependent cell-mediated cytotoxicity (ADCC) mechanism. NK-92MI is an interleukin-2 (IL-2)-independent cell line, which was derived from NK-92 cells with superior cytotoxicity to a wide range of tumor cells in vitro and in vivo. However, the Fc-receptor (CD16), which usually mediates ADCC, is absent in NK-92 and NK-92MI cells.

Methods: Donor lymphocyte infusion in patients with hematological malignancies leads to diversity of leukemia-associated-antigen-specific T cell responses and to reduction in regulatory T cell frequency

cine and Immunogenetics Ulm, German Red Cross Blood Transfusion Service Baden-Württemberg–Hessen and Institute of Transfusion Medicine, Ulm, 4Department of Internal Medicine, Diakonie Klinikum, Stuttgart, Germany

Figure 1. NK-92MIhCD16 and NK-92MIhCD64 functional validation in vitro and characterization. A. Schematic representation of the CD16-BB-ζ and the CD64-BB-ζ receptor constructs. B. Exogenous CD16 or CD64 expression on surfaces of NK-92MI cells are shown. C. Immunoblot analysis of CD3ζ fusion protein expression in NK-92MIhCD16 or NK-92MIhCD64 cells.
Aims: To apply NK-92MI cell-based immunotherapy in cancer, we designed and generated two chimeric receptors which can bind the Fc portion of human immunoglobulins in NK-92MI cells.

Methods: The construct included the low-affinity Fc receptor CD16 (158F) or the high-affinity Fc receptor CD64, with the addition of the CD8α extracellular domain, CD28 transmembrane domains, two costimulatory domains (CD28 and 4-1BB), and the signaling domain from FcRγ. The resulting chimeric receptors, termed CD16-BB-ζ and CD64-BB-ζ, were utilized to generate chimeric receptor-modified NK-92MI cells, which were named NK-92MIhCD16 and NK-92MIhCD64 cells, respectively.

Results: We found that NK-92MIhCD16 and NK-92MIhCD64 cells significantly improved cytotoxicity against CD20-positive non-Hodgkin’s lymphoma (NHL) cells in the presence of rituximab.

Summary/Conclusions: These results suggest that the chimeric receptor-modified NK-92MI cells could potentially enhance the clinical responses mediated by currently available anticancer monoclonal antibodies (mAbs).

E1086
A NOVEL IN VITRO METHOD TO QUANTIFY THE PHARMACOLOGY ACTIVITY OF BSICIFIC ANTIBODIES IN HEMATOLOGICAL SAMPLES

1ViviaBiotech, Madrid, Spain, 2Strategic Research Program on CLL and B Cell Medicine, Nanjing, 3Department of Hematology, The First Affiliated Hospital of Soochow University, Suzhou, 4Binhu Hospital, the First People’s Hospital of Beijing, China

Background: The PharmaFlow automated flow platform has achieved 85% clinical correlation with AML samples with its novel Native Environment assay. Recently, novel Bi-specific antibodies (BsAbs) or analogous constructions active antitumor immunotherapy with BsAbs. The integration of Effective E:T ratio and pharmacological parameters better predict the in vitro response of BsAbs. Because of the high capacity of the PharmaFlow platform, additional antibodies constructions alone or in combinations with immunomodulatory agents could be tested to identify the better agents or immunotherapeutics combinations in hematological diseases.

Methods: For this purpose, different fresh whole Bone Marrow (BM) or Peripheral Blood (PB) were tested with their corresponding BsAbs at 8 different concentrations in different time points (24h-144h). In this sense, we tested 31 AML BM samples (5 paired BM and PB) with the CD123XCD3 (Creative Biolabs) and 7 CLL and 3 B-ALL samples with Blinatumumab (Amgen). When appropriate, basal quantification of TAA was performed by flow cytometry (FCM). The PharmaFlow platform by FCM and the B-ALL dataset was measured repeating the dose response curves in 3 different days.

Results: Most of the samples present both T-cell activation (CD25+) and an effective lysis of tumor cells after BsAbs exposure in a time and dose dependent manner (Figure 1), even starting with low basal E:T ratios (<1:100). For AML, basal quantification of CD123 by FCM density does not reflect a correlation with the in vitro response. Differences in T-cell lysis or leukemic immunoresistance were observed between samples in terms of EC50 or Emax, even more marked between CLL samples. The integration of effective E:T ratios, Ec50, Emax, and kinetics allow us to generate an in vitro response model and select those samples with higher T-cell cytotoxicity after the different BsAbs exposure. Interestingly, many of the samples for all the BsAbs leave a significant proportion of live cells, even at the higher BsAb concentrations or with a remarkable expansion of activated T-cells that suggest the use of immune checkpoint to unblock this immunoresistant status.

Summary/Conclusions: We have developed an automated flow cytometry assay for bi-specific antibodies screening that keep basal conditions (Figure 1), even starting with low basal E:T ratios (<1:100). For AML, basal quantification of CD123 by FCM density does not reflect a correlation with the in vitro response. Differences in T-cell lysis or leukemic immunoresistance were observed between samples in terms of EC50 or Emax, even more marked between CLL samples. The integration of effective E:T ratios, Ec50, Emax, and kinetics allow us to generate an in vitro response model and select those samples with higher T-cell cytotoxicity after the different BsAbs exposure. Interestingly, many of the samples for all the BsAbs leave a significant proportion of live cells, even at the higher BsAb concentrations or with a remarkable expansion of activated T-cells that suggest the use of immune checkpoint to unblock this immunoresistant status.

HUMANIZED CD7 NANOBODY-BASED IMMUNOTOXINS EXHIBIT PROMISING ANTI-T-CELL ACUTE LYMPHОBLASTIC LEUKEMIA POTENTIAL

Y. Yu1, J. Li1, X. Zhu2, X. Tang2, Y. Bai2, Y. Huang1, L. Yuan3, L. Yang1
1The Cyrus Tang Hematology Center, Soochow University, Suzhou, 2Department of Hematology, The Affiliated Hospital of Nanjing University of Chinese Medicine, Nanjing, 3Department of Hematology, The First Affiliated Hospital of Soochow University, Suzhou, 4Binhu Hospital, the First People’s Hospital of Hefei Group, Hefei, 5Department of Hematology, Aerospace Central Hospital, Beijing, China

Background: Nanobodies, or named as VHs, are derived from heavy-chain-only antibodies that circulate in sera of camels. Their exceptional physico-chemical properties, possibility of humanization and unique antigen recognition properties make them excellent candidates for targeting delivery of biologically active components. In our previous work, we have successfully generated the monovalent and bivalent CD7 nanobody-based immunotoxins, which can effectively trigger the apoptosis of CD7 positive malignant cells.

Aims: To pursue the possibility of translating these immunotoxins into clinics, we humanized the nanobody sequences (designated as dhuVH6H6), as well as further truncated the Pseudomonas exotoxinA (PE) derived PE38 toxin to produce a more protease-resistant form which is named as PE-LR, by deleting majority of PE domain II.

Methods: Three new types of immunotoxins, dhuVH6H6-PE38, dVH6-PE-LR, and dhuVH6H6-PE-LR, were successfully constructed. These recombinant immunotoxins were expressed in E. coli and showed that nanobody immunotoxins have the benefits of easy soluble expression in a prokaryotic expression system.

Results: Flow cytometry results revealed that all immunotoxins still maintained the ability to bind specifically to CD7-positive T lymphocyte with a strong signal corre-
Summary/Conclusions: We have successfully constructed a targeted CD7 molecule modified nanobody (CD7 molecule improved nanobody) immunotoxin dhuVH66-PE38 and showed its potential for treating CD7-positive malignant tumors, especially T-cell acute lymphoblastic leukemia.

STATINS MAY IMPROVE CAR-NK IMMUNOTHERAPY IN MM BY PREVENTING LOSS OF BCMA EXPRESSION ON MM CELLS

G. Suñe1,*, L. Perez-Amill1, A. Urbano-Ispizua1, B. Martín-Antonio1
1Hematology, Hospital Clinic/IDIBAPS/Joosep Carreras Leukemia Research Institute, Barcelona, Spain

Background: Chimeric Antigen Receptor (CAR) modified immune cells targeting BCMA against multiple myeloma (MM) has appeared as a feasible immunotherapy strategy to treat MM patients. However, high doses of CAR immune cells are required to achieve a response. Cord blood derived NK cells (CB-NK) is a feasible source of obtain NK cells to modify with a CAR against BCMA. We previously observed that MM cells exposed to CB-NK are able to transfer MM proteins, such as BCMA, both to CB-NK and to adjacent MM cells non-exposed to CB-NK. Furthermore, statins, which are toxic for MM cells, by altering the lipid composition of tumor cell membrane are involved in cell-cell communication. We hypothesized that statins could prevent the loss of BCMA exposed by the loss of BCMA sum cells after CB-NK exposure, allowing infusing a lower CAR immune cell dose in MM patients.

Aims: To evaluate the effect of statins on MM cell proliferation, on the CB-NK immune response against MM, and on BCMA expression in MM cells after CB-NK exposure.

Methods: The cytotoxicity of statins against MM cells was determined in vitro and in vivo in a murine MM model; furthermore, their impact in CB-NK cytotoxicity against MM was also determined in vitro. BCMA expression on MM cells after CB-NK exposure was analyzed by confocal microscopy and by flow cytometry. FACS sorting experiments were performed to analyze BCMA transfer between CB-NK exposed MM cells to neighboring non-exposed CB-NK MM cells.

Results: Atorvastatin and Fluvastatin treatment (1µM) decreased MM cell line (ARP1, RPMI, KMM1) proliferation. No effect was detected for U266 MM cells and for K562 non-MM cells. In vivo studies, showed that mice treated for three days I.P with Fluvastatin (1mg/kg) showed significant decreased MM disease progression. Blocking of BCMA decreased CB-NK cytotoxicity against MM cells. Furthermore, pretreatment of MM cells with Fluvastatin (3 µM) increased CB-NK cytotoxicity against all MM cell lines; no impact was observed against K562 non-MM cells. Co-culture experiments showed that, as soon as 30 minutes, CB-NK exposure led to a BCMA transfer from MM cells to CB-NK and to the extra-cellular milieu leading to a loss of BCMA expression on MM cells. Fluvastatin pretreatment prevented loss of BCMA expression. After two days of co-culture, alive MM cells still showed decreased BCMA surface expression, and surprisingly, increased intracellular BCMA expression. Fluvastatin pretreatment partially avoided and alive MM cells still showed decreased BCMA surface expression, and surprisingly, increased intracellular BCMA expression. Furthermore, FACs sorting experiments showed that MM cells exposed to CB-NK, transferred BCMA to neighboring non-CB-NK exposed MM cells which was partially inhibited with Fluvastatin pretreatment.

Summary/Conclusions: Our findings show that besides the anti-MM activity of statins alone, they avoid the loss of BCMA expression on MM cells after CB-NK exposure. Preventing loss of BCMA expression on MM cells might improve the efficiency of CAR immunotherapy against BCMA, suggesting the potential of statins as an adjuvant in CAR-NK immunotherapy against MM.

E1089
DENDRITIC CELL VACCINATION COMBINED WITH LENALIDOMIDE AND PROGRAMMED DEATH-1 (PD-1) BLOCKADE HAS SYNERGISTICALLY INDUCED A MARKED TUMOR REGRESSION IN A MURINE MYELOMA MODEL

S.-H. Jung1,*, S. Yang2, H.-J. Lee3, M.-C. Vo1, T.J. Lakshmii3, H.-J. Kim4, J.J. Lee1
1Department of Hematology-Oncology, 2Research Center for Cancer Immunotherapy, Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: There is an emerging evidence that the maximal benefit of dendritic cell (DC)-based cancer immunotherapy may be achieved by combination with other therapies that act to immunomodulation and tumor microenvironment.

Aims: In this study, we tried to obtain the best efficacy of immunotherapy using DC vaccination in combination with lenalidomide and PD-1 blockade in a murine myeloma model.

Methods: After establishing myeloma-bearing mice, four treatment groups were designed to be a mimic protocol as like treatment in clinics as following: 1) PBS control, 2) DCs, 3) DCs + lenalidomide, 4) DCs + PD-1 blockade, and 5) DCs + lenalidomide + PD-1 blockade. After treatment, preclinical response and in vitro immunological responses were evaluated.

Results: DCs combined with lenalidomide and PD-1 blockade showed the best tumor regression among the study groups. These anti-tumor effects have meaningfully related to the decrease of immunom-regulatory populations, such as myeloid-derived suppressor cells (MDSCs), M2 macrophages, and regulatory T cells (Treg) and the increase of effector immune cell populations, including CD4+ and CD8+ T cells, natural killer (NK) cells, and M1 macrophages, accompanied with the activation of cytotoxic T lymphocytes (CTLs) and NK cells in the splenocytes from the treated mice. Moreover, the level of immunosuppressive cytokines, such as TGF-β and IL-10, was significantly reduced in tumor microenvironment.

B- AND T-CELL IMMUNE REPertoire PROFILING WITH ANCHORED MULTIPLEX PCR AND NEXT-GENERATION SEQUENCING

J. Eberlein1, T. Harrison1, J. Sims2, I. McKittrick1, M. Wemmer1, D. Fugere1,*, L. Griffin1, B. Culver1, L. Johnson1, B. Kudlow1
1ArchierDX, Boulder, CO, 2Q2 Solutions, EA Genomics, Morrisville, NC, United States

Background: NGS-based analysis of the immune repertoire (IR) is a powerful tool to monitor disease, adaptive immune responses to disease, vaccination and therapeutic interventions. IR characterization by NGS usually requires large primer panels to cover its extensive combinatorial diversity, and a complex system of synthetic controls to account for differential amplification efficiency across segment combinations. Anchored Multiplex PCR (AMP™) uses molecular bar-coded (MBC) adapters and gene-specific primers (GSPs), enabling NGS-based immune chain mRNA interrogation from a single amp. This eliminates the need for opposing primers that bind within the highly variable V-segment, eliminating differences due to somatic mutation.

Aims: Our goal was to develop an NGS assay based on AMP that would enable IR characterization utilizing a minimal set of unidirectional GSPs and to reduce amplification bias through the use of MBC adapters.

Methods: Upon developing our AMP-based NGS assay, we validated its quantitatively reproducible sensitivity from PBMCs of healthy donors, B-cell chronic lymphocytic leukemia donors and formalin-fixed paraffin-embedded (FFPE) tissue.

Results: We developed the AMP-based NGS assays, Immunovereux™ (IGH, TRB, and TRA) for B-cell and T-cell repertoire sequencing, respectively. Both assays demonstrated high reproducibility between replicates with quantitative clone tracking down to 0.01%. The ability to determine clonotype and clonotype IGVH mutational status in a single assay was demonstrated. Preliminary TCR assay data indicates that CDR3 sequence capture is possible from FFPE tissue with clonotype calling being driven by input quantity, T-cell content, and, to a lesser degree, mRNA quality.

Summary/Conclusions: AMP-based NGS with MBC quantification and error-correction is a powerful method to characterize the immune repertoire.

E1091
SYNERGISTIC ANTITUMOR IMMUNITY BY DENDRITIC CELLS IN COMBINATION WITH POMALIDOMIDE AND DEXAMETHASONE IN A MURINE MYELOMA MODEL

S.-H. Jung1,*, S. Yang2, H.-J. Lee3, M.-C. Vo1, T.J. Lakshmi3, H.-J. Kim4, J.J. Lee1
1Department of Hematology-Oncology, 2Research Center for Cancer Immunotherapy, Chonnam National University Hwasun Hospital, Hwasun-Eup, Korea, Republic Of

Background: Pomalidomide (Pom) plus dexamethasone (Dex) could be considered one of the new treatment options in patients with relapsed and/or refractory multiple myeloma (MM). Recently, several diverse agents would be combined to improve the therapeutic efficacy of immunotherapy.

Aims: In this study, we investigated the preclinical efficacy of combined therapy with dendritic cells (DCs) and Pom-Dex in a murine myeloma model.

Methods: After establishing myeloma-bearing mice, four treatment groups were designed to be a mimetic protocol as like treatment in clinics as following: 1) PBS control, 2) DCs, 3) Pom + Dex, and 4) DCs + Pom + Dex. After vaccination, preclinical and in vitro immunological responses were evaluated.

Results: Among four treatment groups, DC combined with Pom and DEXA strongly inhibited tumor growth, compared with other groups. in vitro immunological analyses revealed that these enhanced anti-tumor effects were closely associated with the decrease of regulatory cell populations, such as regulatory T cells (Treg) and type 2 macrophages (M2), and the increase of effector cell populations, including activated CD4 T cells, and type 1 macrophages (M1), accompanied with the activation of cytotoxic T lymphocytes (CTLs) and natural killer (NK) cells in the splenocytes from vaccinated mice.

Summary/Conclusions: This study suggested that the DC combined with Pom and DEXA synergistically enhanced the anti-tumor immunity in a murine myeloma model, by skewing immunosuppressive status toward immunosuppressive status in tumor microenvironment.
ALTERNATIONS IN T-CELL SUBPOPULATIONS AFTER CO-CULTURING WITH MSCS DERIVED FROM DIFFERENT DONORS

N. Kapranov1, Y. Davydova1, I. Galitskaya1, N. Petinai1, N. Drize1, L. Kuzmina1, E. Parovichnikova1, V. Savenchenko1
1Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Study of interactions between lymphocytes and mesenchymal stromal cells (MSCs) in vitro revealed increase of HLA-DR expression on T-cells after co-culture with some MSCs samples. On lymphocytes derived from one donor the elevation of HLA-DR was observed after co-cultivation with half of MSCs samples (group A), on the others the HLA-DR expression level did not change (group B). MSCs were divided into two groups based on HLA-DR rise on lymphocytes. Study of T-cell subpopulations after interactions with MSCs could explain ineffectiveness of some MSCs as an immunomodulating agent in clinical applications.

Aims: The aim of the study was to discriminate variations in T-cell subpopulations, co-cultured with MSCs from two groups.

Methods: MSCs were isolated from bone marrow of 13 donors for allogeneic hematopoietic cells transplantation and cultured by a standard method. MSCs were seeded 10⁵ cells per flask, and then 10⁶ allogeneic lymphocytes from single donor were added to all MSCs cultures. For lymphocytes activation 5μg/ml phytohaemagglutinin (PHA) was added to half of these cultures. Lymphocytes were removed from MSCs. Then MSCs were removed from the bottom of the flask by trypsin and expression of HLA-DR on their surface was measured by flow cytometry. Activation markers CD25, CD38, CD69, HLA-DR expressions were compared. Subpopulations which significantly differed between groups A and B were compared. The results were presented as median ± SEM.

Table 1.

Results: Expression of HLA-DR on lymphocytes after 4 days of cultivation without MSCs did not change compared to 1st day. When lymphocytes were co-cultured with some MSCs samples expression of HLA-DR was higher. Elevated percentage of HLA-DR positive cells correlates between CD4+ and CD8+ cells (R²=0.932). Thus samples of MSCs were divided into two groups: in group A proportion of HLA-DR lymphocytes was 3 times greater than in group B. Subpopulations of lymphocytes co-cultured with MSCs from group A and B were compared. Subpopulations which significantly differed between groups A and B are presented in the table. In lymphocytes co-cultured with MSCs there were higher number of naïve cells compared to control (47.4±3.5% and 54.9±2.0% for group A and B vs 36.9±1.4% for lymphocytes cultured without MSCs, p<0.001). Group B showed lower number of EM and TM cells. Differences between groups were more pronounced when lymphocytes were activated. In group B proportion of HLA-DR CD4+ and CD8+ cells was significantly lower, compared to group A and control samples. At the same time the number of CM and PD-1+ CD4+ cells was lower in group B, but number of TE was increased. Investigation of HLA-DR expression on MSC after co-culturing with lymphocytes showed higher level of fluorescence signal (MF) in group A than in group B (635±130 vs 289±18, p=0.03). These data indicated that MSCs from group A had become more immunogenic after interaction with lymphocytes and could not show immunomodulating properties in same way as MSCs from group B.

Summary/Conclusions: The immunomodulatory properties of MSCs depend on the donor. This could explain why administration of MSCs is not always successful. Preliminary study of MSCs prior to their administration may be used to predict their efficiency in the future.

The materials are supported by grant from the Russian Science Foundation, Project № 16-15-00102.
Results: Although a high toxicity and low efficiency were observed with the electroporation technique used, up to 96% colony forming units showed the specific integration. Experiments directed to improve efficacy and reduce toxicity were then conducted. A high percentage of gene edited HPCs were detected by shortening the cell expansion and puromycin selection periods. Importantly, gene edited HPCs were detected after infusion in immunodeficient (NSG) mice. More recently, CRISPR-Cas9 genome engineering has been developed aiming at the correction of PKD patient's specific mutations.

Summary/Conclusions: Overall, we showed that gene editing in engraftable HPCs is feasible, although the efficiency of the procedure should be further improved prior to consideration of these strategies in the clinic.

E1096 ALTERATIONS IN T-CELLS SUBPOPULATIONS AFTER CO-CULTIVATION WITH MULTIPOTENT MESENCHYMAL STEM CELLS

L. Zanetta1, N. Kapranos1, N. C. Gilsèva1, N. Petinati1, N. Dinze1, L. Kuzmina1, E. Parovichnikova1, V. Savchenko1
1Federal State-Funded Institution National Research Center for Hematology of the Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation

Background: Lymphocyte population depends on immunological state of organism and varies in different diseases and during treatment. Multipotent mesenchymal stromal cells (MSCs) are widely used for cell therapy due to their immunomodulatory properties. Administration of MSCs is not without side effects. Immunomodulatory properties of MSCs could be induced by different cytokines, e.g. IFN-γ. After injection MSCs interact with activated and non-activated lymphocytes. Changes in lymphocytes subpopulations characterize the influence of MSCs on immunological state.

Aims: The aim of the study was to determine the distribution of naïve and effector cells in lymphocytes co-cultured with MSCs.

Methods: MSCs were derived from bone marrow of 13 donors (7 male and 6 female aged 22 to 62 years, median 27 years). MSCs were co-cultured with allogeneic lymphocytes in a ratio of about 1:10 for 4 days and their basic properties were analyzed over time. Lymphocytes were activated by adding to the culture medium 5mg/ml of PHA (PHA-lymphocytes). Some MSCs were treated for 4 hours with 500 U/ml IFNγ (gMSCs). Activation markers CD25, CD38, CD69, HLADR and PD-1 were studied by flow cytometry as well as distribution of naïve and effector memory cells in lymphocytes and MSCs. The proportion of these cells was analyzed over time. Lymphocytes and MSCs were analyzed using flow cytometry.

Results: By the fourth day of incubation the proportion of naïve CD4+ cells reduced from 30% (from 47.5±3.0% to 32.8±3.3%) in cultured lymphocytes. It did not happen in lymphocytes co-cultured with MSCs and gMSCs (p=0.001). At the same time in cultured lymphocytes the fourth day of the number of CD4+ central memory cells increased in 1.8 times from 19.5±1.9% to 34.6±2.4%, which did not occur when co-cultured with both MSCs and gMSCs (p=0.001). Thus, co-culturing with MSCs or gMSCs prevented naïve T-lymphocytes transition into effector cells. The proportion of CD4+/PD-1+ cells increased from 8.8±1.1% to 10.9±0.7% by the 4th day of cultivation. When co-cultured with MSCs and gMSCs the proportion of PD-1+ cells decreased from 14.3±2.7% to 12.5±1.5% (p=0.0125).

The proportion of CD4+ central memory cells increased in PHA-lymphocytes from 37.4±4.4 at 1st day to 68.2±6.5 at 4th day. MSCs inhibited this increase - the proportion CD4+ central memory cells increased from 24.4±2.7% to 46±4.5% (p<0.047). Thus the interaction of PHA-lymphocytes with MSCs inhibited their activation and preserved naïve state.

Summary/Conclusions: The composition of lymphocyte population changes during cultivation. The proportion of naïve cells reduced, while the number of effector cells and the proportion of PD-1+ increased, indicating the lymphocyte activation probably due to the presence of xenogenic serum in the culture medium. Co-cultivation with MSCs maintained lymphocytes in not activated state. The interaction of activated lymphocytes with MSCs inhibits their activation and preserves naïve state. IFN-γ priming did not enhance MSCs inhibitory effect. The lymphocyte activation shown that MSCs both in naïve lymphocyte condition and have an inhibitory effect on their activation.

The materials are supported by grant from the Russian Science Foundation, Project № 16-15-00102.

E1097 OPTIMIZATION OF TRANSDUCTION CONDITIONS WITH GMP LIKE LENTIVIRAL VECTORS FOR THE GENE THERAPY OF PYRUVATE KINASE DEFICIENCY

S. Navarro1,2, O. Quintana-Bustamante1,2, C. Trigueros1, M. Villarueva1,2, M. López-Manzaneda1,2, J.A. Bueren1,2, J.C. Ramirez1,2, J.C. Segovia1,2
1Unidad Mixta de Terapias Avanzadas, Instituto de Investigación Sanitaria Fundación Jiménez Díaz, 2Hematopoietic Innovative Therapies, CIEMAT/CIBERER, Madrid, 3VIVEbiTECH, San Sebastian, Spain

Background: Pyruvate kinase deficiency (PKD) is an autosomal recessive disorder caused by mutations in the PKLR gene. PKD is the most common erythroid inherited enzymatic defect causing chronic nonspherocytic hemolytic anemia. PKD is associated with reticulocytosis, splenomegaly and hepatic iron overload, and may be life-threatening in severely affected patients. To-date, allogeneic bone marrow transplantation remains the only curative treatment for severely affected patients but has been employed infrequently. Splenectomy confers reduced transfusion-dependence in many patients, but 10-15% of PKD patients remain transfusion-dependent despite splenectomy, which confers increased risks of infections. Preclinical gene therapy studies conducted in pyruvate kinase deficient mice have shown the safety and the efficacy of a new PCCorPKW-17 therapeutic lentiviral vector that has been granted orphan drug designation (EMA: EU/3/14/1330; FDA: DRU-2016-5168).

Summary/Conclusions: The use of G-CSF primed halo-identical microtransplantation appears to be a biologically active therapy in patients with refractory AML, especially in patients received less than four previous chemotherapy, fludarabine-free previous chemotherapy, response naïve and young age patients.

E1098 BLAST KINETICS AFTER NON-ENGRAFTMENT HAPLOIDENTICAL MICROTRANSPLANTATION IN PATIENTS WITH REFRACtORY ACUTE MYELOID LEUKEMIA

Z. Emarah1,2,*, S. Shamaa1,2, M. Khalaf3, A. El-Zaafarany1,2, N. Essa3,4, M. Khalaf5
1Medical Oncology Unit, Oncology Center, Mansoura University, 2Medical Oncology Unit, Internal Medicine Department, Faculty of Medicine, Mansoura University, 3Clinical Hematology Unit, Oncology Center, Mansoura University, 4Clinical Hematology Unit, Internal Medicine Department, Faculty of Medicine, Mansoura University, Mansoura, 5Clinical Hematology Unit, Hematology and Oncology Hospital, Maadi Armed Forces Medical Compound, Cairo, Egypt

Background: Multiple trials have showed that granulocyte colony-stimulating factor (G-CSF)- mobilized donor peripheral-blood stem cells (GPBSCs) based on allo-graft can be effective in mediating graft-versus-leukemia (GVL) effects and promote hematologic recovery without triggering of acute GVHD.

Aims: To analyze the safety and efficacy of non-engraftment haploidentical cellular therapy for patients with refractory acute myeloid leukemia by assessment of bone marrow blast and hematopoietic cells percent kinetics.

Methods: Seven patients (4 males 57.1%, 3 females 42.9%) with refractory acute myeloid leukemia were enrolled into this Phase I/II study. They were treated with chemotherapy including fludarabine 30mg/m², cytarabine 1gm/m² followed by infusion of haploidentical unmanipulated GPBSCs 24 hour after last chemotherapy infusion. Morphologic assessment of bone marrow blast kinetic by bone marrow aspiration conducted before therapy, D14 and D30 after therapy. Hematopoietic cells percent kinetics (Hematologic recovery) was assessed by Complete blood count every day till Day 40.

Figure 1.

Results: At day +30, 6 patients were evaluable for response and one patient had died. One patients out of 7 showed PR, then developed CR after a second microtransplantation and the patient who died showed PR at D14 marrow evaluation (8% blast). So collectively objective response rate was 28.6%. The patient who developed CR was consolidated with an HLA-matched sibling transplant at day +75 from the 1st microtransplantation (day +50 from 2nd microtransplantation). Three patients attained neutrophil recovery with median time 29 days (range, 13-40 days), while the other four patient did not. Two patients attain platelet recovery with median time 34.5 days (range, 29-40 days), while the other five patient did not. The cellular therapy did not elicit statistically significant changes in bone marrow blast % over time, F(2, 10)=1.558, p=0.258, partial n2=0.03, with bone marrow blast % decreasing from pre-infusion blast % (M=60%, SD=22.4%) to D14 blast % (M=39.5%, SD=24.47%) then increased to D30 blast % (M=54.8, SD=33.5%), in that order. Less than four previous chemotherapy, fludarabine-free previous chemotherapy and response naïve patients are the factors associated with good response to microtransplantation.

There was a strong positive correlation between patient age (statistically significant), CR1 duration (statistically non-significant) and blast % at D30, r= 0.24 and .693, p=0.036 and p=0.307 respectively. There was a moderate negative non-statistically significant correlation between CD34+ cell dose and blast % at D30, r=-0.315.
E1098

INTERACTION OF MULTIPOTENT MESENCHYMAL STROMAL CELLS WITH LYMPHOCYTES REDUCES THEIR IMMUNO PRIVILEGED PROPERTY

With IFNγ treatment of MSCs, the immunophenotypic and functional properties of MSCs are changed, leading to a decrease in their immunopriviledge property and an increase in their immunomodulatory properties. IFNγ treatment increases the expression of activating ligands on MSCs, such as ICAM1 and HLA-DR, which enhances their interaction with lymphocytes.

Results:

Increased doses of virus concentration revealed, as expected, increasing levels of transduction that ranged 40-90% both by scoring transduced colony forming units and by flow cytometry analysis in hematopoietic progenitors maintained for 15 days in liquid culture. Analysis of vector copy number (VCN) by qPCR ranged from 0.5 to 3 VCN/ncell, demonstrating good transduction efficiency, compatible with a clinical application. Two cycles of transduction showed an increased level of transduction at limiting concentrations of the viral vector, increasing the VCN up to 2-fold.

Summary/Conclusions:

Transduction optimizations are being carried out in order to reduce the amount of viral vector needed to achieve optimal transduction efficiencies.

C-TYPE LECTIN-LIKE RECEPTOR 2 SPECIFIES A FUNCTIONALY DISTINCT SUBPOPULATION OF MEGAKARYOCYTE-BIASED LONG-TERM HEMATOPOIETIC STEM CELLS

T. Kumode1, 2, H. Tanaka1, R. Fujiwara1, K. Sano1, K. Serizawa1, Y. Taniyugi1, S. Nishida1,2, and S. Matsumura1

1Hematology and Rheumatology, Kindai University Faculty of Medicine, Osaka, Japan

Background:

Recent studies have supported the model in which hematopoietic stem cell (HSC) compartment consists of functionally distinct subsets with discrete self-renewal and differentiation potentials. However, their immunophenotytes and the functional diversities remain poorly understood. We previously reported that the authentically identified HSC population includes a subset of cells expressing the C-type lectin-like receptor 2 (CLEC2). This subset, which we refer to as CLEC2+HSCs, displays a unique combination of immunophenotypes and functional properties.

Methods:

To define the functional subpopulations of early hematopoietic progenitors, we performed a comprehensive analysis of CLEC2+HSCs in the context of their hematopoietic differentiation and interaction with other cell types.

Results:

CLEC2+HSCs exhibit unique immunophenotypic characteristics and a distinct differentiation potential, suggesting that they represent a distinct functional subset of HSCs.

Summary/Conclusions:

We have defined the window of mammalian HSC specification. The abrupt loss of ongoing HSC specification at E10.25 suggests an active mechanism that terminates this process. We also observed large phenotypic and functional variability amongst individual HSC precursors examined throughout ontogeny.
Aims: In this study, we analyzed in vivo dynamics of CLEC2^high^ HSCs to clarify their functional roles in adult hematopoiesis.

Methods: In this experiment, we defined Lin^-^Sca1^+^Kit^-^CD150^-^CD34^-^ cells as HSCs and Lin^-^Sca1^+^Kit^-^CD150^-^CD41^-^ as M^{K}P, respectively. We performed transplantation assays using HSCs isolated from EGFP transgenic (CAG-E{sup EGFP}) mice to trace donor-derived HSCs and their progeny by excising enucleated +/−{sup EGFP} recipients and CLEC2^high^ and CLEC2^low^ HSCs were transplanted into lethally irradiated mice, respectively. Chimerism and lineage distribution of donor-derived cells were evaluated periodically by tracing EGFP. Secondary transplantation was performed by transferring 1x{sup 10^7} BM cells from the recipient mice 16 weeks after the 1st transplantation.

Results: Bone marrow analysis revealed that both EGFP^+^CLEC2^high^ and CLEC2^low^ donor-derived HSC populations were detected for up to 12 weeks after transplantation. Also, these subsets were capable of generating all lineages of cells in transplanted mice. Interestingly, CLEC2^high^ HSCs generated CLEC2^high^ progeny more efficiently than EGFP^+^ HSCs in short-term grafts (1 to 2 weeks after transplantation) (p<0.05). Consistent with these reciprocal transition, both types of HSCs could effectively reconstituted hematopoiesis in the secondary recipients. However, CLEC2^high^ HSCs showed significantly reduced repopulating activity than CLEC2^low^ cells, especially at 12 weeks after transplantation (mean of HSC proportion in the primary recipients with CLEC2^high^ HSCs vs CLEC2^low^ HSCs (each n=5): 21.1% vs 66.1% at 4 weeks (p=0.054); 2.14% vs 48.3% at 12 weeks (p<0.05)). In addition, the recipient mice transplanted with CLEC2^low^ HSCs kept high chimeric levels of EGFP^+^ CMP and M^{K}P, whereas similar levels were detected in the recipients with CLEC2^high^ HSCs. On the other hand, CLEC2^high^ HSCs yielded 2.5-fold more M^{K}P than CLEC2^low^ HSCs in short-term grafts (1 to 2 weeks after transplantation) (p<0.05). Consistent with this finding, CLEC2^high^ HSCs yielded more CD41^+^ platelets than CLEC2^low^ HSCs by 6.0-fold at 1 week after transplantation (p<0.05), which peaked 10 weeks earlier than in CLEC2^low^ recipient mice. These platelets yielded through the transplantation of EGFP^+^ M^{K}P donor cells were detected at a certain level 12 weeks after transplantation. Furthermore, treatment with fostamatinib (R788), a Syk kinase inhibitor that is an indispensable component for CLEC2 signaling, blocked more potent and rapid megakaryopoiesis in the CLEC2^high^-recipient, indicating that CLEC2 signaling is essential for rapid and enhanced megakaryopoiesis from CLEC2^high^-donor HSCs.

Summary/Conclusions: Here, we showed that CLEC2 expression on HSCs demonstrates their oscillation for serving as a potent source of megakaryopoiesis, and found that CLEC2/Syk signaling would be involved in differential regulation between CLEC2^high^ and CLEC2^low^ HSC subtypes.
Background: GATA4 is a transcription factor expressed in mesoderm and endoderm during development. Members of the family such as GATA1-3, but not GATA4, are critically involved in hematopoiesis. An enhancer (G2) of the mouse Gata4 gene directs its expression throughout the lateral mesoderm and the allantois, beginning at E7.5, becoming restricted to the septum transversum by E10.5, and disappearing by midgestation (Rojas et al., Hepatology, 2005, 132:3405). Our previous work has shown that inactivation of Gata4 using this G2Cre driver is lethal by midgestation (Delgado et al., Hepatology, 2014, 59:2358). The anemia observed in the G2Cre;Gata1floX/floX embryos was attributed to a failure in the expansion of the hematopoietic progenitors in the fetal liver. Interestingly, a small population of hepatic YFP+ cells from G2Cre;R26RYFP embryos was positive for leukocyte and megakaryocyte markers, suggesting that a lineage of hematopoietic cells could derive from GATA4-expressing progenitors.

Aims: To study in our murine models the origin and properties of the hematopoietic lineage derived from progenitors expressing GATA4 under control of the G2 enhancer.

Methods: We analyzed hematopoietic organs of G2-Gata4flox/flox;R26RYFP mice, adults and embryos, by flow cytometry, RT-PCR and confocal microscopy. Cells obtained from different tissues were cultured and transplanted to analyze in vitro and in vivo potential.

Results: YFP+ cells represented about 20% of the hematopoietic system of adult mice and contributed in the same proportion to the lymphoid, myeloid and erythroid lineages. Adult YFP+ hematopoietic stem cells (Figure 1) constituted a long-term repopulating, transplantable population. Fetal YFP+ hematopoietic progenitors were much more abundant in the placenta than in the yolk sac area. These placental YFP+ progenitors were clonogenic in the MethoCult assay and fully reconstituted hematopoiesis in adult mice and contributed in the same proportion to the lymphoid, myeloid and erythroid lineages. 1Hematology and Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan

Figure 1.

Summary/Conclusions: A lineage of adult hematopoietic stem cells in mice is characterized by the expression of GATA4 in their embryonic progenitors and probably by its extraembryonic (placental) origin. Both lineages basically showed similar physiological behavior in normal mice, but this finding raises a number of questions, for example: Does this hematopoietic stem cell subpopulation show a differential response in physiopathological conditions? Does this subpopulation show a differential profile of gene expression? Does a similar heterogeneity exist in human HSCs? We are currently investigating the transcriptome of the G2-GATA4 lineage HSC in order to answer these questions.

EXPLORING THE MECHANISM OF FOGL-DEPENDENT TRANSCRIPTIONAL REGULATION IN ERYTHROID CELLS

T. Fujiiwara1, K. Sasaki1, K. Saito1, S. Hatta1, S. Ichikawa1, M. Kobayashi1, Y. Okitsu1, N. Fukuhara1, Y. Onishii1, H. Harigae1

1Hematology and Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: GATA-1 is a hematopoietic zinc-finger transcription factor, which controls the development of erythrocytes and megakaryocytes. Numerous proteins have been reported to be associated with GATA-1 to alter its activity. Among them, Friend of GATA-1 (FOG1), a nine-zinc finger protein, is expressed in a tissue-specific pattern that overlaps markedly with that of GATA-1. FOG1 is an essential co-regulator of GATA-1 during hematopoiesis, which mediates transcriptional activation and repression of GATA-1 target genes; yet, the mechanisms by which FOG1 exerts its activating and repressing functions remain unknown.

Aims: We explored a novel role of FOG1 by forcibly expressing FOG1 in the human K562 erythroleukemia cells.

Methods: GFOG1 mRNA was cloned into Flexi HaloTag vector (Promega) and pBabe-puro retrovirus vector (Addgene), and FOG1 was overexpressed in K562 cells. Quantitative ChIP analysis was performed using antibodies against GATA-1, GATA-2, TAL1, FOG1, histone H3 acetylated-K4 (H3K4ac), H3K9ac, H3 trimethylated-K4 (H3K4me3), and H3K27me3. PU.1 regulatory element was cloned into luciferase plasmid (pGL4.10, Promega) and mutation within the cis-element was introduced using a site-directed mutagenesis kit (Agilent). TAL1 loss-of-function analysis was conducted with specific siRNA. For transcription profiling, Human Oligo chip 25K (Toray) was used.

Results: Forced FOGL1 expression in K562 cells induced the expression of erythrocytes genes (HBA, HBB, and SLC4A1), whereas repressed that of GATA-2, which have been reported to be FOGL1-dependent GATA1-target genes (Lee et al, Mol Cell 2009). On the other hand, FOGL1 overexpression did not affect the expression of master regulators of erythropoiesis, such as GATA-1 and TAL1. Next, we conducted microarray analysis to comprehensively characterize FOGL1-regulated gene signature. The analysis demonstrated that 942 and 180 genes were upregulated and downregulated (>2-fold), respectively, in the FOGL1-overexpressed cells. Noticeably, we found that the expression of PU.1, known as a myelo-lymphoid-promoting transcription factor, was strongly downregulated by FOGL1 overexpression, indicating that PU.1 is another FOGL1-dependent target. Aims: To explore the role of FOG1 in the regulation of GATA-1-regulated genes and suggest that FOG1 has an important role in inducing cells to differentiate toward the erythroid lineage rather than the myelo-lymphoid one by repressing the expression of PU.1.

THE STEM CELL ZINC FINGER 1 (SZF1) / ZNF589 PROTEIN INHIBITS TUMOR DEVELOPMENT IN A K562 XENOGRAFT MOUSE MODEL, BLOCKING CELL CYCLING AND INDUCING PREMATURE CELLULAR SENESCENCE

L. Venturini1, 2, C.-W. Lee1, N. Jyotsana1, M. Scherr1, M. Heuser1, M. Stadler1, A. Ganser1

1Hematology, Hemostasis, Oncology, Stem Cell Transplantation, Hannover Medical School, Hannover, Germany

Background: The stem cell zinc finger 1 (SZF1) / ZNF589 protein, a member of the family of Krüppel associated box-domain-zinc finger (KRAB-ZNF) transcription factors, has an isoform exclusively expressed in CD34+ hematopoietic stem/progenitor cells (HSPC) suggesting its role as an epigenetic regulator of specific genes involved in hematopoiesis. The SZF1/ZNF589 gene exhibits a human-specific evolutionary nucleotide DNA-change leading to a complex molecular organization and to a protein structure peculiar for humans, as compared to all other primates, potentially conferring human-specific functional properties. SZF1/ZNF589 has recently been shown to control cell viability in the hematopoietic system. It is regulated by the HIF-1a-hypoxia-induced transcription factor and is differentially expressed in a cytokine-dependent manner during hypoxia in CD34+ HSPCs (Venturini et al., Exp Hematol 2016; 44: 257-268). Thus, SZF1/ZNF589 may play a role in the maintenance of hematopoietic progenitors, lymphocyte quiescence and survival, known to be influenced by the hypoxic state in the bone marrow niche.

Aims: We studied the effects of SZF1/ZNF589 overexpression in vitro and evaluated its tumor suppressor potential in vivo.
Methods: K562 (BCR-ABL-positive chronic myeloid leukemia in blast crisis)-Luciferase-control or K562-Luciferase-SZF1/ZNF589 cells were directly injected into the femurs of NSG mice and tumor development was monitored by bioluminescence. Furthermore, K562 cells with or without SZF1/ZNF589 overexpression were studied by proliferation assay, cytometry, flow cytometry, cell cycle analysis, cyclin B1 expression and beta-galactosidase assay.

Results: K562-dependent tumor growth was efficiently inhibited in NSG mice transplanted with K562-Luc-control-cells, leading to significantly prolonged survival, demonstrating a strong tumor suppressive potential of SZF1/ZNF589 in vivo. In vitro, overexpression of SZF1/ZNF589 dramatically inhibited proliferation of K562 cells, which instead of dying, became giant and dysplastic, without other significant morphological changes and in absence of polyplody. Cell cycle analysis revealed a blockade in G2/M phase, with cyclin B1 accumulation characteristic for mitotic arrest. As suggested by morphology and beta-galactosidase assay, these results were consistent with premalignant transformation.

Summary/Conclusions: SZF1/ZNF589 controls survival of hematopoietic cells mediated by mitotic arrest and premature senescence, exhibiting tumor suppressive functions in vivo.

E1106 THE FUNCTIONAL RELEVANCE OF DNMT3A SPlice VARIANTS IN HEMATOPOIETIC DIFFERENTIATION

T. Bozic1, J. Frobel1, A. Raić1, S. Heilmann-Heimbach2, T.W. Goede3, E. Jost4, W. Wagner1,2
1Cell and Developmental Biology, 2Anatomy and Anthropology, Sackler Faculty of Medicine, Tel Aviv University, 3Medicine A, Tel Aviv Sourasky Medical Center, 4Tel Aviv University, Tel-Aviv, Israel

Background: DNA methyltransferase 3A (DNMT3A) plays a pivotal role for de novo DNA methylation (DNAm) during development. It seems to be of particular relevance in hematopoietic differentiation because it is frequently mutated in acute myeloid leukemia or clonal hematopoiesis. So far, it is unclear how DNMT3A governs the use of lineage-specific DNA patterns. It is of linearity that this can at least partly be attributed to alternative splicing of DNMT3A.

Aims: In this study, we followed the hypothesis that specific splice variants of DNMT3A impact on hematopoietic differentiation or DNA patterns. Therefore we addressed the role of specific splice variants of DNMT3A in hematopoietic stem and progenitor cells (HSPCs).

Methods: Expression of DNMT3A splice variants was modulated in HSPCs: transcript 1+3 (Tr.1+3), transcript 2 (Tr.2), or transcript 4 (Tr.4) of DNMT3A were either knocked down by short hairpin RNA or constitutively overexpressed by knockdown of Tr.1+3+4 (Tr.1+3+4). Global DNA methylomes were generated with the Infinitium HumanMethylation450 BeadChip platform and gene expression patterns with the Human Affymetrix Genome U133 2.0 platform.

Results: Downregulation of either Tr.2 or Tr.4 reduced the proliferation rate of HSPCs significantly (n=3, p<0.05). HSPCs maintained CD34 expression for a higher number of cell divisions upon knockdown of Tr.2 (n=3, p=0.05). In colony forming unit (CFU) assays downregulation of Tr.4 resulted in a clear bias towards erythroid colonies (n=3, p=0.05). Overall, CFU frequency was reduced by knockdown of DNMT3A transcripts, whereas it was increased by overexpression. Subsequently, we analyzed the impact of specific DNMT3A variants on the DNA patterns: several CpG sites revealed significant differences in DNA methylomes upon knockdown of Tr.2 and Tr.1+3 (5,905 and 352 CpGs, respectively; n=3, adjusted p-value <0.05). Notably, these patterns were regulated in the opposite direction upon overexpression of the same transcripts. Knockdown of Tr.4, which does not have the DNA-methyltransferase domain, did not evoke significant changes in DNA methylomes. Furthermore, modulation of DNMT3A splice variants resulted in transcript-specific gene expression changes, which may at least partly be attributed to DNAm changes.

Summary/Conclusions: Our results demonstrate that the various splice variants of DNMT3A have different functional sequel on HSPCs. Knockdown and overexpression resulted in opposite and transcript-specific DNAm changes. Thus, alternative splicing of DNMT3A is relevant for site-specific epigenetic modifications in hematopoietic development.

E1107 ERYTHROPOIETIN STIMULATES TRANSDIFFERENTIATION OF BONE MARROW PRO-B CELLS INTO BONE-RESORBING OSTEOCLASTS

N. Deshet-Unger1, S. Hiram-Bab2, N. Ben-Calif1, A. Kolomansky1,3, D. Kulkarni1, I. Lifshitz-Mittagh4, Y. Gabai2, E. Neuman5
1Cell and Developmental Biology, 2Anatomy and Anthropology, Sackler Faculty of Medicine, Tel Aviv University, 3Medicine A, Tel Aviv Sourasky Medical Center, 4Tel Aviv University, Tel-Aviv, Israel

Background: Erythropoietin (EPO) is a crucial kidney-derived hormone responsible for erythropoiesis; however, its extra-erythroid effects are substantial and correlate with EPO receptor (EPO-R) expression in both hematopoietic and non-hematopoietic tissues. Bone turnover is regulated by the coupled actions of osteoblasts, the bone-forming cells, and monocyte-derived osteoclasts, which mediate bone resorption. In this regard, we have recently reported that EPO directly stimulates bone resorption via activation of EPO-R signaling in the monocytic lineage (Hiram-Bab et al., 2015). Monocyte differentiation into osteoclasts relies on monocye-macrophage colony-stimulating factor (M-CSF) and the receptor activator of nuclear factor kappa B ligand (RANKL). B cells are also known to regulate bone metabolism, chiefly via paracrine signals. Osteoclasts and B cells arise from distinct myeloid and lymphoid progenitors, respectively, which are downstream of a common multipotent progenitor cell.

In the bone marrow (BM), Pro-B cells sequentially differentiate into Pre-B and immature B cells. Whether BM B cells can transdifferentiate into osteoclasts remains controversial, since osteoclast differentiation from residual mononuclear precursors in the cultures was not excluded in earlier studies.

Aims: We set to determine whether B cells can transdifferentiate to osteoclasts and to assess the effect of EPO on this process.

Methods: Experiments were conducted on C57BL/6j or CD19-Cre;R26R-EYFP, 8-12-week-old female mice in accordance and with the approval of the Institutional Animal Care and Use Committee of Tel-Aviv University (M-14-043). BM cells were flushed from femurs, ilias, and pelvic bone and red blood cells were lysed. Cells were stained with labelled anti-mouse antibodies: PE-B220, FITC-CD19, PerCP-igm, PeCy7-CD43, and APC-M-CSF receptor/CD115; and sorted by flow cytometry. Cells were then cultured in α-MEM containing 10% fetal bovine serum, M-CSF and RANKL. Multinucleated osteoclasts were stained for tartrate-resistant acid phosphatase (TRAP) and pit resorption was assessed.

Results: B cells isolated from BM of CD19-Cre;R26R-EYFP mice cultured with M-CSF and RANKL differentiated into TRAP+ multinucleated osteoclasts that were also positive for EYFP, thus tracing back their B cell origin (Figure 1A).

Next, we dissected which B cell subtype possesses this osteoclastogenic capacity and found that only Pro-B (B220+CD19+CD43+highGM), but not Pre-B (B220+CD19+CD43-owGM) nor immature B cells (B220+CD19+CD43+owGM) could transdifferentiate into osteoclasts (16%±3.7 from 0.79%±0.28 and 48%±13 osteoclasts’ area, respectively). Moreover, among the Pro-B cells, only those expressing M-CSF receptor (CD115) could transdifferentiate into osteoclasts (18%±6.55 vs. 0.11±0.05 osteoclasts’ area, respectively, Figure 1B and C). Using an anti-EPO-R specific antibody we detected EPO-R on the surface of B cells and noted that EPO enhanced the differentiation of the Pro B cells into osteoclasts by as much as 70% (p=0.04) (Figure 1D).

Figure 1: Osteoclastogenesis in vitro from sorted B cells. (A) Transdifferentiation of 180,000 cells/well CD19-Cre;R26R-EYFP into osteoclasts. (B) TRAP staining of osteoclasts derived from the indicated sorted cells from BM (10,000 cells/well) and cultured with M-CSF and RANKL. Background: Notch signaling is a highly conserved pathway important in multiple developmental processes. Canonical signaling through all Notch receptors converges on the CSL transcription factor recombination signal binding protein for immunoglobulin kappa J region (Rbpj). In haematopoiesis, Notch is crucial for the development of the hematopoietic stem cells (HSCs) in the embryo and in thymic T cell development. Contrastingly, canonical Notch signaling has been shown to be dispensable for HSC homeostasis in the adult bone marrow (aBM). Recent studies have however suggested a role of Notch in promoting myeloid (Mk) and erythroid (E) development as well as in suppressing granulocyte-macrophage (GM) progenitor expansion and acting as a tumor-suppressor in myeloid malignancies. However, these findings were largely made through genetic approaches potentially also affecting regulatory pathways and further studies are needed.

Aims: To unambiguously investigate the role of canonical Notch signaling in aBM myelopoiesis, in steady-state and following transplantation.

Methods: B6-SJL/JCD45.1, Rbpjfl/fl, Mx1-Cre, Vav-Cre and Vwf-eGFP BAC mice were used. Flow cytometry (FACS) was applied for phenotypic analyses. Gene expression levels were measured by real-time reverse transcription-PCR. Mk and GM in vitro colony forming potentials were applied in mouse colony assays. For transplantation study, lethally irradiated recipients were competitively transplanted (1:1) and reconstituted assessement 7-9 weeks after transplantation.

Results: FACS staging of GM, Mk and E progenitors in aBM of D2f-flanked Rbpj mice crossed to both Mx1-Cre and the pan-haematopoietic Vav-Cre strains was applied. As expected, HSCs were unaffected. Not previously investigated, FACS analyses did not identify GM, Mk or E progenitor stages. However, defects, at any progenitor stage, in Rbpj-deficient mice. To demonstrate that this lack of a phenotype was not due to BM cells escaping Rbpj deletion, we FACS purified HSCs and all GM, Mk and E progenitor stages from Rbpj-deficient mice and verified a virtually complete deletion of Rbpj in all populations. In further agreement with canonical Notch signaling not being required for steady-state generation, maintenance or stepwise differentiation of adult GM, Mk and E progenitors, the number of GM, E and Mk colonies generated from unfractionated aBM cells as well as circulating platelet counts were also unaffected. Our results suggest that Notch signaling is not essential for the emergence of definitive hematopoietic stem cells (HSCs) in the embryo and in thymic T cell development. However, in contrast to the previous studies, our findings are the first to demonstrate that canonical Notch signaling is dispensable for HSC homeostasis in the adult bone marrow. We next sought to address whether we could uncover a role of the Notch pathway in regulation of GM, Mk and E progenitors in aBM and in the bone marrow niche. However, in a significant minority of patients these LSCs could therefore be of significant clinical benefit. One of the proposed mechanisms of drug resistance in CML LSCs is close contact with the surrounding microenvironment, however an in-vitro model of the bone marrow matrix is currently lacking.

Conclusion: Development of a 3-Dimensional culture using fibre scaffolds to mimic bone marrow microenvironment is necessary to study the mechanism of resistance to anti-leukaemia agents.

Methods: Scaffold production: PMMA solution was prepared by dissolving PMMA in chloroform and adding appropriate amount of hydroxyapatite to polycaprolactone. 3D cell culture: A single-cell suspension of primary AML cells and also MSCs were added to PMMA-HA scaffold. K562 and HL60 cells were treated with or without imatinib or doxorubicin respectively. 3D cell culture: The same experiment was performed in the presence of scaffolds. Co-culture of HS-5 with HL60 or K562 cells: GFP+ stromal cells were added to PMMA-HA scaffold. K562 and HL60 cells were treated in the presence or absence of imatinib or doxorubicin in HS-5 cells plus scaffold environment respectively and were investigated for proliferation and viability 72h later.

Results: We produced a PMMA-based 3D scaffold and compared the growth of CML and AML cell lines grown in this scaffold in the presence or absence of cytotoxic or targeted therapy to that of cells grown in 2D culture. PMMA-HA scaffold was not toxic to the leukaemia cells as primary AML cells and also K562 cells grew in the presence of scaffold and also concentrated around the scaffold.
fibrillar collagen type 6. Treatment of K562 or HL60 cells with imatinib or doxorubicin respectively resulted in a lower level of apoptosis in cells grown on the 3D scaffold compared to those grown in 2D culture. Further development of this 3D culture by adding stromal cell HS-5 to the scaffold reduced even further the sensitivity of K562 or HL60 to imatinib or doxorubicin, respectively.

![Figure 1.](image)

**Figure 1.**

**Summary/Conclusions:** The relative resistance to either imatinib or doxorubicin that we observed in cells grown in 3D culture supports a role for the bone marrow matrix in the protection of leukemic cells against chemotherapeutic agents. A combination of the PMMA-HA with HS-5 cells made this system more similar to the bone marrow microenvironment as this is a model in which all the basic components of the bone marrow microenvironment such as scaffold, stromal cells and cytokines (secreted by HS-5) are present. The results of this study show adding extra complexity to the microenvironment changes the sensitivity of the cells to therapeutic agents, better recapitulating the situation observed in-vitro. Three dimensional cultures using the PMMA-HA/HS-5 model may prove useful in the investigation of therapy resistance in leukemia and for the discovery of new agents capable of eradicating quiescent leukemic stem cells.

E1113 WHOLE EXOME SEQUENCING REVEALED SEQUENTIAL GAIN OF MUTATIONS IN TWO CASES OF DONOR CELL HAEMATOLOGICAL MALIGNANCY AFTER HEMATOPOIETIC TRANSPLANTATION

J. Suárez González1,2,*, C. Martínez-Laperche4,2,3, M. Kwon2,3, G. Rodríguez-Macías3, A. Figuera4, A. Balas5, N. Martínez6, P. Balsalobre2,3, D. Serrano2,3, M.A. Piris3,7, J.L. Vicario5, J. Gayoso2,3, J.L. Díez2,3, I. Buño1,2,3

1Genomic Unit, Instituto de Investigación Sanitaria Gregorio Marañón y Hospital General Universitario Gregorio Marañón, 2Department of Hematology, Hospital General Universitario Gregorio Marañón, 3Department of Hematology, Hospital de la Princesa, 4Department of Histocompatibility, Madrid Blood Centre, 5Department of Laboratory Medicine, 6Department of Paediatric Haematology-Oncology and Stem Cell Transplantation, 7Department of Pathology, Hospital Marqués de Valdecilla, Santander, Spain

**Background:** The leukemic transformation of otherwise healthy donor stem cells provides a useful in vivo model to study the mechanisms involved in leukemogenesis.

**Aims:** We report two cases of donor cell derived haematological malignancy in which whole-exome sequencing (WES) was performed in bone marrow (BM) samples from recipient at different times after allogeneic hematopoietic stem cell transplantation (allo-HSCT) in order to study the dynamics of emergence of mutations that precede the development of donor cell leukemia (DCL) and donor cell myelodysplastic syndrome (DC-DS).

**Methods:** Case 1: A 43-year-old female diagnosed with lymphoblastic leukemia/lymphoma (11;19), who developed acute myeloid leukemia (AML) with normal karyotype. NPM1+ of donor origin 16 months after unrelated cord blood transplantation (UCBT). Case 2: A 65-year-old male diagnosed with mantle cell lymphoma, who developed MDS 45XX;−7.del(12)(p12) of donor origin, 57 months after allo-

genetic BM transplantation from his HLA-identical brother. WES (SureSelect-XT Human-exon 50M) was performed by next generation sequencing (HiSeq) on donor stem cells (SCs) infused as well as on BM samples from recipient after allo-HSCT. The exome of donor SCs and 5 BM samples, from case 1, were aligned to the human reference genome (GRCh 37/hg19) and donor SCs and 9 BM samples were aligned to GRCh 38/hg38 in the second case.

**Results:** WES analysis revealed progressive emergence of multiple somatic mutations probably related to the development of leukemia in bone marrow samples post allo-HSCT (Figure 1). Both SCs showed alterations that may be involved in leukemogenesis. (Case 1: SH2B3 and case 2: KMT2C, KMT2A, ARHGAP26 and monosomy 7). Somatic mutations, acquired over time, fall into genes that play well-established roles in signalling pathways. Mutations in leukemic subclones that disappear after chemotherapy were indentified, as well as the acquisition of new mutations in resistant subclones. We propose a possible model of leukemogenesis in these cases (Figure 2).

**Summary/Conclusions:** The present study reveals a process of sequential clonal expansions, possibly by acquisition of additional somatic mutations in donor hematopoietic cells. Detection of heritable or acquired gene mutations in donor associated with predisposition to haematological malignancies could have clinical implications for the patients undergoing allo-HSCT. Although the cause of donor cell derived haematological malignancy onset seems to be multifactorial, the infusion of a SCU pre-leukemic potential in a context of residual toxicity in recipient as a result of pre-transplant chemotherapy, a post-transplant environment characterized by a decreased immune surveillance may well have played role in these cases. The study of a greater number of DCL cases by next generation sequencing could help to understand this process and to detect new mutations involved in the emergence of AML.

E1114 LEUKEMIC STEM CELL-RELATED MRNA EXPRESSION ANALYSIS USING A NOVEL FLOW CYTOMETRY-BASED ASSAY

B. Depreter1,2,*, K. Vandepoele3, B. De Moerloose4, B. Denys3, J. Philippé1,3, T. Lammens2

1Department of Clinical Chemistry, Microbiology and Immunology, 2Department of Paediatric Haematology-Oncology and Stem Cell Transplantation, Ghent University, 3Department of Laboratory Medicine, 4Department of Paediatric Haematology-Oncology and Stem Cell Transplantation, Ghent University Hospital, Ghent, Belgium

**Background:** Gene expression analysis of protein-coding (mRNA) and non-coding RNA in paediatric and adult acute myeloid leukaemia (AML) has become of paramount importance for therapeutic decision-making, revealing prognostic information and for the identification of novel therapeutic targets. AML is a clinically, phenotypically and molecularly heterogeneous haematological malignancy, with different leukemic cell populations organized in a hierarchical fashion, and leukemic stem cells (LSCs) residing at the apex herein. Unfortunately, gene expression profiling is commonly performed on unfractionated bulk samples, leading to ‘expression averaging’ of these heterogeneous cell populations. Multicolor flow cytometry (FCM) is capable of distinguishing heterogeneous cell populations based on the phenotypic characterization at a single-cell level. However, fluorochrome-conjugated antibodies are not available for intracellular RNA targets.

**Aims:** To evaluate the applicability of a novel flow cytometry-based technique, PrimeFlow™ RNA assay, to measure cell-of-interest RNA expressions in heterogeneous AML samples.

**Methods:** Technical assessment was performed using six neuroblastoma cell lines with varying levels of MYCN gene amplification. Correlation to expression data obtained by the gold standard RT-qPCR, performance in rare (0.1%) cell populations, effects of cryopreservation and off-target effects were evaluated. Next, diagnostic material of de novo AML patients was used to measure target gene (Wilms’ tumor 1 (WT1)) and reference gene (RPL13a, GAPD) expression. Expression analysis was performed in unfractionated bulk leukemic cells as well as blasts and rare subsets of leukemic cells, e.g., LSCs. FMCC analyses were performed on a FACSCanto II (BD Biosciences) with set-up according to EuroFlow guidelines. Infinicyt™ (Cytognos®) was used for data analysis and mean fluorescence intensities (MFI) values (with/without normalisation) were interpreted. P-values < 0.05 were considered significant.

**Results:** mRNA expression quantified by PrimeFlow™ significantly correlated with data obtained by RT-qPCR and remained detectable in rare (0.1%) cell populations. WT1 expression was shown to be statistically significantly higher in bulk leukemic cells of those patients characterized by WT1 overexpression, as defined by RT-qPCR, showing a mean 52% MFI upregulation by PrimeFlow™, with data obtained by the gold standard RT-qPCR. Moreover, WT1 overexpression could be detected within heterogeneous cell populations, e.g., the CD34+CD38+ cell population and the LSC (defined as CD34+CD38−), showing a 63% and 45% MFI upregulation, respectively. WT1 overexpression could be detected in leukemic subclones that disappear after chemotherapy were indentified, as well as the acquisition of new mutations in resistant subclones. We propose a possible model of leukemogenesis in these cases (Figure 2).

**Figure 1.**

**Figure 1.**

**Methods:** Case 1: A 43-year-old female diagnosed with lymphoblastic leukemia/lymphoma (11;19), who developed acute myeloid leukemia (AML) with normal karyotype. NPM1+ of donor origin 16 months after unrelated cord blood transplantation (UCBT). Case 2: A 65-year-old male diagnosed with mantle cell lymphoma, who developed MDS 45XX;−7.del(12)(p12) of donor origin, 57 months after allo-

genetic BM transplantation from his HLA-identical brother. WES (SureSelect-XT Human-exon 50M) was performed by next generation sequencing (HiSeq) on donor stem cells (SCs) infused as well as on BM samples from recipient after allo-HSCT. The exome of donor SCs and 5 BM samples, from case 1, were aligned to the human reference genome (GRCh 37/hg19) and donor SCs and 9 BM samples were aligned to GRCh 38/hg38 in the second case.

**Results:** WES analysis revealed progressive emergence of multiple somatic mutations probably related to the development of leukemia in bone marrow samples post allo-HSCT (Figure 1). Both SCs showed alterations that may be involved in leukemogenesis. (Case 1: SH2B3 and case 2: KMT2C, KMT2A, ARHGAP26 and monosomy 7). Somatic mutations, acquired over time, fall into genes that play well-established roles in signalling pathways. Mutations in leukemic subclones that disappear after chemotherapy were indentified, as well as the acquisition of new mutations in resistant subclones. We propose a possible model of leukemogenesis in these cases (Figure 2).

**Summary/Conclusions:** The present study reveals a process of sequential clonal expansions, possibly by acquisition of additional somatic mutations in donor hematopoietic cells. Detection of heritable or acquired gene mutations in donor associated with predisposition to haematological malignancies could have clinical implications for the patients undergoing allo-HSCT. Although the cause of donor cell derived haematological malignancy onset seems to be multifactorial, the infusion of a SCU pre-leukemic potential in a context of residual toxicity in recipient as a result of pre-transplant chemotherapy, a post-transplant environment characterized by a decreased immune surveillance may well have played role in these cases. The study of a greater number of DCL cases by next generation sequencing could help to understand this process and to detect new mutations involved in the emergence of AML.

POTENTIAL PREDISPOSING GERMLINE MUTATIONS IN PATIENTS WITH CONCOMITANT MYELOID AND LYMPHOID MALIGNANCIES

F. Asmar1,*, M. Munk-Johansen1, T.C. El-Galaly2, H.E. Johnsena, C. Westmoase3, D. El Fassi4, K. Grønbæk1

1Department of Hematology, Rigshospitalet, Copenhagen, 2Department of Hematology, University hospital of Aalborg, Aalborg, 3Center of Genomic Medicine, Rigshospitalet, Copenhagen, 4Department of Haematology, University Hospital Herlev and Gentofte, Herlev, Denmark

Background: Recent findings have suggested that mutations predisposing the development of either acute myeloid leukemia (AML) or chronic lymphocytic leukemia (CLL) may arise in pre-leukemic hematological stem cells. In addition, genes involved in epigenetic regulation, such as TET2, and RNA processing, such as SF3B1, are mutated in both myeloid and lymphoid malignancies. This could indicate a possible genetic link between myeloid and lymphoid malignancies. Therapy related AML (t-AML) is a known complication to treatment with cytotoxic drugs such as alkylating agents and topoisomerase inhibitors. The susceptibility of developing t-AML has been associated with variation in DNA-repair pathways, drug metabolism and transport.

Aims: In this study, we aimed to investigate a possible common genetic origin of hematological cancers in patients with concomitant CLL and de novo AML or myelodysplastic syndrome (MDS) and in patients with concomitant therapy-related AML (t-AML) and CLL.

Methods: The presence of concomitant lymphoid and myeloid malignancies in patients is rare, however we managed to include 3 patients with de novo AML and CLL, one patient with MDS and CLL, one patient with chronic myelomonocytic leukemia(CMML) and CLL, and two patients with t-AML and CLL. The patients’ diagnoses were based on the evaluation of the morphology, immunohistochernistry, cyogenetics, and flowcytometry analysis in accordance to the WHO classification. For each patient mononuclear cells (MNCs) from blood or bone marrow were isolated using Ficol gradient centrifugation and used for fluorescence activated cell sorting (FACS) of the malignant clones and the T-cells. Paired end exome sequencing (2x150) aiming for an average coverage of 50-100x was performed using either the HiSeq2500 or NextSeq500 platforms from Illumina. Raw sequencing data was processed using CASAVA-1.8.2. Mapping to the human genome (hg19/GRCh37 UCSC) was performed using CLC Biomedical Genomics Workbench (Qiagen) mRNA analysis and cell software. Variants with a frequency of 5% or above were called.

Results: We identified possible pre-disposing germline mutations in all 7 patients by comparing variants between the myeloid malignant clone, CLL cells, and T cells, as well as using saliva to aid in characterizing the mutations as present or absent in the hematological compartment. In all the patients except one with de novo AML and CLL, we identified a potential damaging germline variant in a DNA-repair related gene, such as ATM (387dupA, D130fs*4), SMARCAL1 (2114D>T, T705S), HELQ (393_397delAGGTG, T1226*16), SWI5 (652C>T, R218*), LIG1 (2168A>G, Q761R) and PRKDC (2102G>A, G331Y). In the remaining patient with concomitant de novo AML and CLL, we identified a potential damaging germline variant in an epi-genetic regulator believed to play a role in normal and malignant hematopoiesis, KDM2B(44delC, P15fs*92). Furthermore, we identified the somatic mutational landscapes of the malignant clones using T-cells as germline tissue for the somatic mutational landscapes of the malignant clones.

Summary/Conclusions: Analysis of the mutational landscape of CHIP has clearly highlighted the role of DNMT3A mutations in concomitant hematopoiesis in older healthy individuals, the significance of such preleukaemic clones is yet to be determined.

Figure 1.

Aims: We aimed to compare here the locations and types of mutations identified in AML and in CHIP in the DNMT3A gene by several different studies.

Methods: To review the mutations found in CHIP and AML, we carried out an extensive literature search of CHIP studies and AML studies that had mapped a large number of mutations in this gene. Mutations were collated to form several diagrams illustrating and comparing these findings.

Results: When DNMT3A mutations in CHIP were compared to mutations in AML the R882 residue was still found to be the most frequently mutated residue in both CHIP and AML. Figure 1 clearly illustrates the mutations in comparison to AML. However, only 13% of all reported mutations were found at the R882 residue in CHIP, while in AML 60% DNMT3A mutations are found at the R882H mutations.

Summary/Conclusions: Analysis of the mutational landscape of CHIP has clearly highlighted the role of DNMT3A mutations in concomitant hematopoiesis in older healthy individuals, the significance of such preleukaemic clones is yet to be determined.

NEXT-GENERATION REFERENCE INTERVALS FOR PEDIATRIC HEMATOLOGY

J. Zierk1,*, J. Hirschmann2, D. Toddenroth2, F. Arzideh3, T. Streichert4, R. Haacke5, H.-U. Prokosch2, M. Rauh1, M. Metzler1

1Department of Pediatrics and Adolescent Medicine, University Hospital Erlangen, 2Chair of Medical Informatics, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, 3Department of Statistics, University of Bremen, Bremen, 4Department of Clinical Chemistry, University Hospital of Cologne, Cologne, 5Bremer Zentrum für Laboratoriumsmedizin, Klinikum Bremen Mitte, Bremen, Germany

Background: Interpretation of hematology analytes in children is challenging due to extensive changes in hematopoiesis with age leading to pronounced sex- and age-specific dynamics. To facilitate clinical decision making based on quantitative hematology test results, reference intervals are used to classify samples according to upper and lower limits, and age-related change is represented using reference intervals partitioned into separate age groups. However, this approach can only approximate the continuous physiological dynamics of hematological analytes in childhood and does not enable appropriate quantification of test results in relation to the reference distribution. Conversely, percentile charts as used in anthropometric quantities (e.g. pediatric weight-for-age charts) would allow adequate appreciation of pediatric hematology test results. However, the ethical and practical challenges unique to pediatric reference intervals have restricted the creation of such percentile charts, and limitations in current approaches to laboratory test result display prevent their integration into clinical decision making.

Aims: To create percentile charts for hematology analytes from birth to adulthood using a data-mining approach and to demonstrate their integration into clinical care with benefits in clinical decision making.
Figure 1.

Methods: We applied a data-mining algorithm to generate percentile charts for hematology analytes using laboratory data collected during the clinical care of patients. A total of 9,517,245 samples from 343,463 patients (72,614–337,011 samples per analyte) from 8 German tertiary care centers and 2 German laboratory service providers were examined. Percentile charts were calculated using an established statistical approach which extracts the proportion of samples from healthy individuals from the unfiltered input dataset containing both non-pathologic and pathologic samples. To evaluate the clinical benefit of hematology test result interpretation using percentile charts, accuracy and speed of pediatricians assessing eight different predefined clinical situations were measured in comparison to conventional test result representations.

Results: We created percentile charts for hematology analytes in girls and boys from birth to 18 years which can be used as common reference intervals. Results are provided for hemoglobin, hematocrit, red cell indices, red cell count, red cell distribution width, white cell count, and platelet count, example charts for hemoglobin, mean corpuscular volume, and platelet count are shown in the accompanying figure. A web application at www.pedref.org/hematology demonstrates hematology test result interpretation using percentile charts and z-scores with special consideration of pediatric dynamics. Comparison of pediatricians’ decision times when assessing different clinical scenarios using percentile charts and conventional representations shows more correct decisions (75.9% vs 68.4%, p<0.01) which are made in shorter time (2.7 s vs 3.8 s, p<0.01) when using percentile charts.

Summary/Conclusions: The created percentile charts enable the appropriate differential diagnosis of changes in hematology analytes due to disease and changes due to physiological development. Integration of suitable forms of result reporting using the provided percentile charts into clinical decision making improves assessment of the unique dynamics in pediatric hematology.

E1118

GROWTH FACTOR INDEPENDENCE 1 (GFI1) REGULATES THE AML SUPPORTING FUNCTION OF MESENCHYMAL STROMAL CELLS

Y. Al-Matary 1,*, L. Botezatu 1, A. Thivakaran 1, R. Köster 1, J. Schütte 1, J. Göthert 1, U. Dührsen 1, B. Opalka 1, C. Khandanpour 1

1University Hospital of Essen/ West centre of tumor, Essen, Germany

Background: Mesenchymal stromal cells (MSCs) harbor and support the function of normal hematopoietic stem cells. Less is known about their interaction with leukemic cells, e.g. in acute myeloid leukemia (AML). The prognosis of AML, a clonal malignant disease of the bone marrow (BM), is still poor with only 25% of patients living longer than 5 years.

Aims: In the current study, we investigated the interaction between MSCs and AML cells, and we also investigated the underlying molecular mechanism.

Methods: We used cell cultures using primary cells from human and mice and cell lines of MSCs and AML cells. Different Mouse models of human AML were used in our study to confirm the results obtained from human sample. MSCs were characterized by differentiation assay, flow cytometry and RT-PCR. Matrigel test was also applied in this study.

Results: MSCs from AML patients called AML-associated MSCs (AMSCs) or from murine models of human leukemia enhance significantly in vitro the growth of leukemic cells compared to AML cells growing without MSCs or in presence of MSCs from non-leukemic patients or mice. Among other, AMSCs increased entry of leukemic cells into the cell cycle, and at the same time protected the leukemia cells against exogenous toxic events such as chemotherapy or irradiation. The interaction between AMSCs and leukemia cells is dependent on cell-to-cell contact. In vivo, absolute and relative numbers of AMSCs and other stromal cells, i.e. endothelial cells and osteoblast lineage cells were highly expanded in the BM of mice modeling of human AML. AMSCs showed a higher efficiency of capillary tube formation in the matrigel assay than normal MSCs which gives an additional indication that AMSCs were polarized by leukemia cells towards a tumor-supporting state. On a molecular level, the polarization of MSCs towards an AML-supporting state depends on upregulated expression of the transcription factor Growth factor independence 1 (Gfi1). Loss of Gfi1 diminished the tumor-supporting state of AML-associated MSCs.

Summary/Conclusions: We conclude that leukemia cells polarize AMSCs towards a leukemia-supporting state in a Gfi1-dependent manner, which could open the way to new therapeutic approaches.
BASELINE LEUKOCYTE AND EOSINOPHIL COUNTS PREDICT OUTCOME IN RELAPSED OR REFRACTORY CLASSICAL HODGKIN LYMPHOMA PATIENTS TREATED WITH PD1 INHIBITION

I. Hude1,2,*, S. Sasse2, P.J. Broekelmann1, B. von Tresckow1, J. Momotow1, A. Enger2, S. Borchmann2

1Department of Internal Medicine, Division of Hematology, University Hospital Center Zagreb, Zagreb, Croatia, 2German Hodgkin Study Group (GHSG), First Department of Internal Medicine, University Hospital Cologne, Cologne, Germany

Background: Despite encouraging efficacy of anti-PD1 antibodies in relapsed or refractory (rr) classical Hodgkin lymphoma (cHL), not all patients achieve a lasting response, with few complete remissions (CR) observed. Thus, identification of predictive biomarkers is important. Recently, two models using readily available differential blood count parameters have been suggested to predict outcome in melanoma patients treated with immune checkpoint inhibition.

Aims: In this study, we aimed to identify baseline differential blood count parameters associated with response and progression free survival (PFS) in rr cHL patients treated with anti-PD1 antibody nivolumab.

Methods: We retrospectively investigated baseline differential blood count parameters and their association with response and progression free survival (PFS) in 30 rr cHL patients treated with the anti-PD1 antibody nivolumab. All 30 patients had previously received multiple lines of treatment, including treatment with high dose chemotherapy followed by autologous stem cell transplant (ASCT) for rr disease; the median number of prior treatment lines was 5 (2-11) and 21 patients received prior brentuximab vedotin. To investigate the association of baseline blood count parameters (white blood cell count (WBC), relative monocyte count (RMC), relative neutrophil count (RNC), relative lymphocyte count (RLC) and relative eosinophil count (REC)) with outcome after PD1 inhibition, we used the last differential blood count performed immediately prior to the first received dose of nivolumab.

Results: RMC, RNC and RLC did not have a prognostic impact on PFS, whereas as higher WBC ≥ 7.78x10³/µl and lower REC<1.7% were associated with worse PFS in both univariate and multivariate analysis. We constructed a simple score to prognosticate PFS. By adding 1 point each for WBC ≥ 7.78x10³/µl and REC<1.7% to the score, we could clearly differentiate a low (score=0), intermediate (score=1) and high risk (score=2) group for disease progression (p<0.0001). Only one PSF event occurred in the best prognostic group (n=10, median PFS (days): 365 [129-NA]) and 7 out of 9 patients in intermediate group (median PFS (days): 197 [50-NA]). Evaluation of best response achieved according to the initial risk score showed a trend towards higher CR-rates in low risk group, but was not significant.

Figure 1.

Summary/Conclusions: Our simple prognostic model, mainly characterized by a normal to high REC, robustly discriminates three risk groups for PFS. Almost all patients in the low risk group achieved a durable remission without disease progression throughout the study period, despite often achieving just a partial response. In contrast, high-risk patients often progressed quickly despite initially achieving a partial or complete response. Further validation of this score which is easily available from routine clinical parameters in a larger cohort of patients and further investigation of its potential predictive impact is needed. Moreover, efforts to clearly understand a possible mechanistic role of eosinophils in cHL patients treated with PD1-inhibition are warranted.

THE PROGNOSTIC SIGNIFICANCE OF BETA-2 MICROGLOBULIN (B2M) LEVELS IN PATIENTS WITH HODGKIN LYMPHOMA (HL) TREATED WITH ABVD OR EQUIVALENT (ABVDEQ) CHEMOTHERAPY OR COMBINED MODALITY THERAPY (CM) IN ELDERLY PATIENTS

1Department of Hematology and Bone Marrow Transplantation, 21st Department of Internal Medicine, Hematology Unit, Laikon General Hospital, National and Kapodistrian University of Athens, Athens, Greece, 2Department of Clinical and Experimental Medicine, Section of Hematology, University of Verona, Verona, Italy, 3Second Propeudeutic Department of Surgery, Laikon General Hospital, National and Kapodistrian University of Athens, 4Department of Haematology, Athens Medical Center, 5Hematology Section, First Propeudeutic Department of Internal Medicine, Laikon General Hospital, National and Kapodistrian University of Athens, 6Euroclinic, Athens, Greece

Background: The prognosis of HL primarily depends on clinical stage (CS) as well as limited-stage risk classification schemes and the International Prognostic Score (IPS), both of which are important in NCCN and ESHO-EBMT guidelines. CS stage needs to be defined in order to avoid overtreatment. Moreover, efforts to clearly understand a possible mechanistic role of B2M in HL are needed. In this context, the aim of this study was to explore the prognostic significance of serum b2m levels in HL patients treated with ABVD or ABVDEQ chemotherapy or combined modality therapy (CM).

Aims: Our aim was to investigate the prognostic significance of serum b2m levels in HL.

Methods: We analyzed 864 patients with HL treated with ABVD/Deq CT/MT (1990-2016) and selected solely based on the availability of pretreatment b2m levels. B2m [P1] levels (upper normal limit 2.4mg/L) were analyzed according to other baseline features and prognostic factors as well as according to the outcome. Freedom From Progression (FFP) was defined as time between treatment initiation and treatment failure (primary refractoriness, PR with switch to alternative CT or relapse); deaths of unrelated causes were censored. Overall Survival (OS) was measured from treatment initiation to death of any cause. ROC curves and sequential cut-offs (1.8-3.5 by 0.1 increments) were used to explore the potential impact of b2m on FFP and OS.

Results: The median follow-up for currently living patients was 88 months. Univariate Analysis: FFP was significantly inferior in patients with higher b2m at all tested cut-off points. At 2.4mg/L (normal versus elevated) the 10-year FFP was 81% vs 71% (p=0.003). However, the best cut-off was the observed median value of this series, calculated at 2.1mg/L, with 10-year FFPs of 84% vs 71% (p<0.0001). In early stages (IA/IIA) significant results were obtained at cut-offs between 1.8 and 2.1mg/L. The best cut-off was 1.9mg/L, a close approximation of the median b2m level of early stage patients, with 10-year FFP of 89% vs 78% (p=0.003). In advanced stages, none of the cut-off values yielded statistically significant results (borderline at 2.0mg/L vs 1.9mg/L; 77% vs 67%, p=0.057). Multivariate Analysis: B2m levels remained significant for FFP after adjustment for IPS factors, ESR and B-symptoms at both 2.1mg/L and 2.4mg/L cut-offs (hazard ratio (HR) 1.78, p=0.001 and 1.41, p=0.04 respectively) in the whole series of 864 patients. In early stages, b2m was a significant predictor of FFP at the cut-offs of 1.9mg/L and 2.1mg/L (HR 2.00, p=0.01 and 1.83, p=0.02 respectively), but only borderline at the cut-off of 2.4mg/L (HR 1.65, p=0.07). In advanced stages, b2m was emerged as an independent prognostic factor for FFP at the cut-off of 2.2mg/L (HR 1.59, p=0.046 despite the lack of significance in univariate analysis), but was not significant at the 2.4mg/L cut-off. The 10-year OS was lower in patients with high b2m levels (10-year rates 91% vs 76%, p<0.0001).

Summary/Conclusions: Higher serum b2m emerged as a significant independent predictor of FFP for cut-offs of 2.0mg/L for the whole series and 1.9mg/L for early-stage patients. The prognostic significance in advanced stages was weaker (best cut-off 2.2mg/L). Serum b2m was also highly predictive of OS. This is by far the largest report on the prognostic significance of b2m in HL, highlighting the significance of the cut-off used to define “high” levels. Its significance is more pronounced in early stage disease. The optimal cut-off for the evaluation of serum b2m in HL may be stage-dependent and appear to lie between 1.9 and 2.2mg/L, thus performing better than a “normal versus high” evaluation (cut-off 2.4mg/L).

THE PREDICTIVE VALUE OF INTERIM PET-CT IN ELDERLY PATIENTS WITH HODGKIN LYMPHOMA

O.S. Bentur1,*, D.J. Eldad2, E. Paran3, D. Lavie4, B. Nachmias4, N. Dally5, O. Gutwein6, Y. Herishanu7, N. Sarid1, C. Perry7, I. Avivi7

1Department of Internal Medicine, Division of Hematology, University Hospital Center Zagreb, Zagreb, Croatia, 2German Hodgkin Study Group (GHSG), First Department of Internal Medicine, University Hospital Cologne, Cologne, Germany
Background: Hodgkin lymphoma (HL), a disease of mostly young patients, also peaks in the elderly. Despite the profound improvement in the clinical outcome of young patients, in the elderly, a 5 year overall survival (OS) is estimated at only 40-55%. Interim PET-CT (iPET), known to be highly predictive for progression free survival (PFS) in young patients with HL, has not been sufficiently validated in elderly patients, nor have many other outcome predictors in HL of the elderly.

Aims: The objective of the present study was to evaluate the significance of iPET in elderly patients with HL.

Methods: All consecutive patients (age ≥60) diagnosed with HL between 1998-2016 were retrospectively reviewed in this multi-center study. Baseline characteristics as well as PET-CT results at diagnosis, interim analysis and end of treatment (EOT) were recorded and analyzed. PET-CT results were classified as no evidence of disease (NED), partial response (PR), stable disease (SD) and progressive disease (PD).

Results: Ninety five patients from 5 centers were identified. Median age was 71 (range 60-89) years. Subtype was nodular sclerosis in 48% and mixed cellularity in 23%. Sixty three (69%) patients had advanced disease and mean international prognostic score (IPS) was 3.5±1.4. Fifty nine (63%) patients received first line treatment with ABVD, in 13 (14%) chemotherapy was followed by involved field radiotherapy. At EOT, sixty seven (82%) patients achieved OS, 6 (7%) achieved PR, 10 (11%) were primary refractory and 2 (2%) died during treatment. Fifteen (16%) patients experienced relapse. Five years PFS and OS were 56% and 78%, respectively. ABVD treated patients had 5 year PFS and OS of 99% and 82% as opposed to 48% and 68% for all other regimens, but these differences were not statistically significant. Seventy two (76%) patients had undergone both iPET and EOT-PET. Fifty patients had NED on iPET, 20 had PR, 1 SD and 1 PD. NED EOT-PET was achieved in 47/50 (94%) patients who had NED iPET, 12/20 (60%) patients who had PR iPET and none of the patients with SD/PD iPET (p<0.01). In patients with either NED or PR on iPET, relapse occurred in 11 (15%) patients and 5 year PFS and OS were 82% and 85%, respectively. The 5 year PFS of these patients differed according to the depth of response on iPET - 69% vs 45%, (p=0.02, fig.1) in patients achieving NED vs PR, while 5 year OS did not reach statistical significance, 90% vs 71% (p=0.08). Restricted analysis, evaluating only 59 patients who were treated with ABVD, showed clinical results with 54% of NED iPET vs 45% of PR iPET achieving NED on EOT-PET (p<0.01). Outcome differed according to the depth of response in iPET with 5 year PFS rates of 74% vs 34%, in patients achieving NED vs PR, respectively (p=0.01). 5 year OS rates were 92% vs 76%, in patients achieving NED vs PR (p=0.1).

E1122
HIGH-DOSE BENDAMUSTINE PLUS BRENTUXIMAB COMBINATION IS EFFECTIVE AND HAS A FAVOURABLE TOXICITY PROFILE IN THE TREATMENT OF REFRACTORY AND RELAPSED HODGKIN LYMPHOMA
C. Cerchione1,2, M. Di Perna1, R. Della Pena1, N. Pugliese1, F. Pane1, M. Picardi1
1Hematology, Ematologia e Trapiant/AO Federico II, Napoli, Italy

Background: The management of patients with refractory or relapsed Hodgkin lymphoma (HL), especially after autologous stem cell transplantation (ASCT), remains controversial. Bendamustine has demonstrated efficacy in several lymphoproliferative disorders but limited data are available regarding the schedule in patients with HL, in particular its dosage and the possible combinations for a synergistic effect. Brentuximab Vedotin is a CD30-directed antibody-drug conjugate, currently approved for the treatment of relapsed or refractory HL.

Aims: The objective of this retrospective observational trial was to evaluate efficacy and safety of salvage cytotoxic regimens in patients with refractory and/or relapsed HL. Three different regimens were evaluated.

Methods: From May 2011 to December 2016, 32 consecutive patients (19 M/13 F) with a median age of 31.7 years (range, 16-73) received a salvage regimen after failure of ASCT. Patients were by chance assigned to one of these three arms: standard dose bendamustine (90mg/sqm) days 1 and 2 plus standard DHAP schedule (every 4 weeks) x 3 cycles (Arm A, n= 10 cases), brentuximab single agent 1.8mg/kg (every 3 weeks) x 4-8 cycles (Arm B, n= 11 cases), high dose bendamustine (120mg/sqm) days 1 and 2 plus brentuximab 1.8mg/kg (day 3) x 4-6 cycles (Arm C, n= 11 cases). Each cycle in arm C was repeated every 28 days and growth factor support was systematically administered, in association with antimicrobial prophylaxis. The treatment efficacy in each arm was evaluated according to Revised Response Criteria for Malignant Lymphoma by Cheson et al. Adverse event occurrence was recorded and classified and type and grade using NCI-CTCAE criteria (v 4.0).

Results: In arm A, the overall response rate (ORR) was 40% (4/10 patients), with 4 (40%) complete remission (CR) and 6 (60%) progressive disease (PD). Hematological toxicity was grade 3 thrombocytopenia in 4 patients (40%) and bone marrow aplasia in 1 patient (10%); extra-hematological toxicity was gastrointestinal toxicity of grade 2 in 6 patients (60%) and grade 1 in 3 patients (30%), in arm B, ORR was 63.6% (7/11 patients), with 5 (45%) CR, 2 (18%) partial response (PR) and 4 (36%) PD. Hematological toxicity was grade 2 neutropenia in 4 patients (36%), extra-hematological toxicity was grade 3 neuropathy in 2 patients (18%). In arm C, ORR was 100% (11/11 patients), with 11 CR followed by SCT (second autologous transplant, 6 cases; and haploidentical transplant, 5 cases) with persistence of complete remission in all patients at a median follow-up of 33.4 months (range, 12-60). Hematological toxicity was grade 3 thrombocytopenia in 4 patients (36.3%); extra-hematological toxicities were increase of transaminase (grade 2) in 7 patients (27%) and cytomegalovirus (CMV) reactivation in 2 patients (18%), treated successfully with valganciclovir. Three patients had fever during infusion at first cycle, together with a skin rash, managed with corticosteroid injections, and a successful antihistamine plus corticosteroid prophylaxis in the next cycles of treatment.

Figure 1.
Summary/Conclusions: High-dose bendamustine plus brentuximab has shown relevant efficacy and a relatively good safety profile in a setting of heavily pretreated patients with HL. Adequate monitoring of CMV reactivation is recommended. This combination could be considered as a bridge to second autologous or allogeneic SCT. However, these results should be validated by controlled and prospective studies involving larger number of patients.

E1123
NEED OF HORMONAL THERAPY TO PRESERVE FEMALE FERTILITY IN HODGKIN E NON-HODGKIN LYMPHOMA PATIENTS FOLLOWING CHEMOTHERAPY: A TWO-CENTER SURVEY
C. Annibaldi1,2, V. Tomarchio1, M. Sampaolesi2, M. Tafuri1, S. Cacciagliù2, M. Becilli1, D. Lupascò2, M. Ciccarone3,4, G. Gini2
1UOC Hematology, Stem cell Transplantation, University Campus Biomedico,
Background: In the last decades, Hodgkin and Non-Hodgkin Lymphoma (HL-NHL) therapies have resulted in high cure rates and increased survival. However, the young patients (≤50 years), experienced more late toxicities such as, gonadal toxicity that can result in permanent infertility.

Aims: to evaluate different aspects of fertility (menstrual status, pregnancy, and menopause) in women with HL and NHL in reproductive age before and after chemotherapy.

Methods: By a phone interview we administered a questionnaire to the patients. The interview was composed of questions concerning reproduction (pregnancies, menses and abortion) and also menopausal status. The analyses were made using data collected in a cohort 109 women patients from two Italian hematologic centers. Statistical analysis was carried out in Graphpad® system, data were compared by the chi-square (P value <0.05) was consider to be statistically significant.

Results: the median age in (years) at the time of the treatment was 31 (range 16-49), 69/109 (63%) had HL and 40/109 (37%) NHL, 74/109 [EST] (64%) of the patients had a stage I-II. All HL patients were treated with ABVD, whereas the NHL patients were treated with R-CHOP (20%) or similar regimens (16%), respectively. Radiotherapy was delivered to the 62/109 (57%) of the sample. Complete Remission (CR) was obtained by the 101/109 (93%) and only 16/101 (16%) relapsed. Considering the gynecologic history of the patients there were no statistically significant difference between the regularity of menses and the event of an abortion pre and post treatment. As for pregnancies, 35% of patients had children before therapy and 17% after. Among these 109 patients, 68/109 (62%) received gonadotropin-releasing hormone (GnRH) analogues and/or oral contraception, while 41 (38%) were not treated with hormonal therapy. Among the 68 patients who received hormonal therapy regular menses recovered in 61/68 (90%) while in those of the control group a recovering of menses was observed in 20/41 (48%). This difference was statistically significant (P<0.05). The same was observed as for early menopause. In this case excluding patients who had a natural menopause, a lower cases of early menopause was observed in those who received hormone therapy (8/69, 12%) compared to 30/60 (50%) patients that had regular menses after chemotherapy, 61/81 (75%) received hormonal therapy and 20/81 (25%) were not treated with hormonal therapy. Before treatment for lymphoma, 16% of patients belonging to the hormonal group had pregnancies versus 45% of the control group (P<0.05). Following therapy, pregnancies were observed in 23% of those receiving hormonal therapy vs 5% of the control group (P<0.05).

Summary/Conclusions: The use of hormonal therapy is fundamental not only to favor of pregnancies and motherhood but in particular to avoid the consequences of an irregular cycle or an early menopause with its symptoms and clinical implications.

25(OH) VITAMIN D SERUM LEVELS IN HODGKIN LYMPHOMA
A. Cuccaro,1* E. Galli,1 F. Visconti,1 L. Zangrilli,1 F. Corrente,1 S. Bellelli,2 U. Basile,2 S. Ammiratzi,2 V. Rufini,3 M. Balducci,4 F. D’Alo,4 C. Hohaus1
1Hematology, 2 Laboratory Medicine, 3 Nuclear Medicine, 4 Radiotherapy, Catholic University of Sacred Heart, Rome, Italy

Background: Vitamin D has pleiotropic effects on cellular differentiation, proliferation, apoptosis and angiogenesis in addition to maintaining serum calcium and skeletal homeostasis. Several studies suggest that low serum 25(OH)D levels may be associated with inferior outcome in solid tumors as colorectal and breast cancer, and in Non-Hodgkin lymphomas [Drake et al. J Clin Oncol 2010; 28:4191] as diffuse large B cell lymphoma [Bittenbring et al, J Clin Oncol 2014; 32:3243], and follicular lymphoma [Kelly et al, J Clin Oncol 2015; 33:1482]. 25(OH)D Vitamin D levels have not been reported for Hodgkin Lymphoma (HL).

Aims: to evaluate vitamin 25(OH)D levels in patients with HL and analyze for associations with clinical characteristics and clinical outcome.

Methods: We studied 76 patients with cHL (40 females, 36 males, median age 33 years), diagnosed at our Institution between 2014 and 2016. Treatment consisted in ABVD (66 patients), BEACOPP d.e. (7 patients), and COPP (2 patients). One patient received only radiotherapy. Serum samples for vitamin D quantification were collected before the first day of chemotherapy. 25(OH)D was measured in patients’ sera using a standardized clinical assay, the DiaSorin LIAISON 25-OH Vitamin D TOTAL. 25(OH)D levels were defined according to three conditions: deficient (<10 ng/ml), insufficient (10-30 ng/ml), and sufficient (>30 ng/ml).

Results: the median 25(OH)D level at diagnosis was 20.6 ng/ml (range: 5.5 to 42.3 ng/ml). 25(OH)D levels were considered normal in 8 (10.5%) patients, insufficient in 25 (33.3%) patients, and deficient in 43 (57.2%) patients. Looking at patient characteristics, 25(OH)D levels were lower in patients with age over 60 years (p=0.002), reduced performance status (ECOG>1) (p=0.01), stage IV disease (p=0.01), and IPS (Hasenclever) score >2 (p=0.002). Furthermore levels were lower in patients with hemoglobin below 10.5 g/dl (p=0.06). No association was found with gender, albumin level, B symptoms. In addition, there was a significant seasonal variation, with 25(OH)D levels being lowest in the first quarter and highest in the third quarter (p=0.03). FDG-PET evaluation after 2 cycles of chemotherapy according to the 5-point Deauville scale was available in 66 patients. Vitamin D levels were not associated with interim PET response. With a median of 12 months follow-up of patients, still alive. Patients with deficient levels (n=9) had a significantly worse PFS than patients with higher levels (n=67) (p=0.002). The probability of progression-free survival at 12 months was 87% (95% C.I., 75-94%) in patients with 25(OH)D levels>10 ng/ml, while patients with levels<10 ng/ml had a 12 months PFS of 47% (95% C.I., 12-76%). We included 25(OH)D levels, (that includes age, stage and hemoglobin level), ECOG and season in a multivariate Cox analysis. Deficient 25(OH)D level had a borderline significance (HR 5.65, 95% C.I.,0.98-32.55; p=0.05).

Summary/Conclusions: 25(OH)D Vitamin D serum levels are frequently low in patients with Hodgkin Lymphoma and are associated with patient-related and disease-related characteristics. Our preliminary analysis suggests that low 25(OH)D levels might be associated with worse prognosis.
stem cell transplantation (ASCT). Patients treated with R alone or R+ABVD had better DFS (p=0.04) than those treated with ABVD with/without IFRT. Specifically, the year Kaplan-Meier estimates for DFS were 100% for the R treated group versus 50% for those treated with ABVD with/without IFRT. Four patients in the latter group, showed insufficient response to the therapy: 1 refractory disease in the early stage group and 3 recurrent diseases in the advanced stage group were recorded. The median follow-up time of the entire cohort of patients was 4.3 years (range, 0.5-8.2 years). Over the study period, one patient died for infectious pneumonitis due to severe neutropenia following the last cycle of R-ABVD. Of the 9 patients treated with addition of IFRT, adverse events regarded mainly thyroid (4), bone (2), lung (1) and salivary glands (1). Nobody developed a secondary malignancy.

Summary/Conclusions: Our results confirm the value of R in NLPHL and show that R induction and maintenance combined with chemotherapy only in the presence of risk factors or in more advanced stages give excellent treatment results. Proper risk assessment and understanding of treatment options in the pre- and post-transplant setting are critical to ensure optimal longer progression-free survival for qualified patients.

Aims: Underlying clinical practice gaps and educational needs were identified, and a study was conducted to determine whether an online, case-based educational intervention could improve knowledge, competence, and confidence of hem/oncs in managing patients with HL.

Methods: The educational format presented patient case scenarios (2) followed by a series of 4-5 questions that “tested” learner knowledge and competence before delivering the education focused on the optimal approach to the case using evidence-based medicine. Case questions assessed degree of patient risk for disease relapse or progression prior to ASCT and consolidation strategies, taking into consideration patients’ prior received therapies. To assess educational effectiveness, participants served as their own controls by responding to a set of the same questions again after (post-assessment) exposure to the content. For all questions combined, the McNemar’s chi-square test assessed differences from pre- to post-assessment. P values are shown as a measure of significance; P values <0.05 are statistically significant. Cramer’s V calculation determined the change in proportion of 184 participants who answered questions correctly from pre- to post-assessment and who qualified for the study.

Results: At post-assessment, there was a large effect to the education (V=0.442), indicating a sizable improvement in evidence-based choices and significant improvement in knowledge, competence, and confidence related to managing patients with HL, including: 138% relative improvement regarding the implications of type and number of prognostic factors on risk of HL relapse and benefit of consolidation brentuximab vedotin after ASCT (P<.001); 101% relative improvement in knowledge that a higher rate of relapse after ASCT is associated with a CR duration of less than 1 year, extranodal disease at relapse, and the presence of symptoms at relapse (P<.001); 5% relative improvement in knowledge regarding the efficacy of brentuximab vedotin in relapsed/refractory HL after ASCT (P<.001); Responses to a self-efficacy question indicated that 42% of hematologists became more confident in managing a patient on consolidation therapy for HL after participating in the education.

Summary/Conclusions: This study demonstrated the success of an online, case-based format using a predisposing pre/post-assessment was effective in improving the evidence-based practice patterns of hem/oncs in the management of patients with HL. Despite the marked improvement in knowledge, competence, and confidence, hematologist education needs specific to accurate risk assessment, treatment selection, and adverse effect monitoring remain. The education gaps uncovered during this intervention and the evolving treatment landscape outside of the United States lay a foundation for future global education initiatives to bridge education gaps in HL.

**Background:** Ibrutinib, a first-in-class, oral, covalent inhibitor of Bruton’s tyrosine kinase, has demonstrated robust clinical activity and is approved in various B-cell non-Hodgkin’s lymphomas. To assess the efficacy and safety of ibrutinib in patients (pts) with follicular lymphoma (FL), the DAWN study (FLR2002, G. Hess et al. Blood 2013). Here, we describe the effect of ibrutinib treatment on T-cells and cytokines in pts in the DAWN study.

**Aims:** To determine the effect of ibrutinib on circulating T-cells, chemokines, and cytokines in ibrutinib-treated CIT refractory FL pts.

**Methods:** The DAWN study was an open-label, multicenter, single-arm, phase 2 study of ibrutinib in pts with CIT-refractory (i.e., ≥2 prior lines of therapy, and progressive disease [PD]) ≤12 months after last dose of a CIT regimen. All pts received ibrutinib (560mg QD) on a 21-day cycle until PD or unacceptable toxicity. The primary end point was Independent Review Committee (IRC)-assessed overall response rate (ORR) (complete response [CR] + partial response [PR]). Flow cytometry assessed T-cell subsets in pts at baseline (C1D1) and at cycle 3 (C3D1) for 57 pts (14 responders and 43 nonresponders); cytokine and chemokine analyses were performed at C1D1 and at cycle 2 (C2D1) for 50 pts (21 responders and 29 nonresponders).

**Results:** Results from the DAWN study have been presented previously (Gopal A et al. ASH 2016). Briefly, 110 pts with a median age of 61.5 years and a median of 3 prior therapies were enrolled. Ibrutinib achieved an ORR of 20.9% (CR rate, 10.9%) and a median duration of response of 19.4 months. Flow cytometry analysis revealed significant downregulation of CD4+CD25+CD127- Tregs at C3D1 in 14 responders (CR + PR, mean decrease 17 to 12.9% CD4, 52% CD25, 41% CD127, p<0.0025) and in 43 non responders (p=0.035, compared to responders). From a large panel of inflammation-related cytokines and chemokines, some of the most significant changes at C2D1 were the Th1 cytokines interferon-γ (IFN-γ) and interleukin (IL)-12, both of which were increased in responders but decreased in nonresponders (p=0.0025 and p=0.035, respectively, Figure 1). Conversely, the chemokines IFN-γ-induced protein 10 (IP-10) and monocyte-chemotactic protein 3 (MCP-3) were decreased in responders but increased in nonresponders (p=0.022 and p=0.016, respectively).

**Summary/Conclusions:** Here we show immunomodulatory effects of ibrutinib in pts with CIT refractory FL, which may be related to response to therapy. In responding pts at early time points, downregulation of Tregs was observed, along with increases in Th1-associated cytokines IFN-γ and IL-12. This shift in T-cell population may be linked to the antitumor response; in nonresponders, these cytokines were decreased but Tregs were not. Chemokine changes observed also indicate variation in chemotraction of T-cells and monocytes/macrophages. These data suggest that immunomodulatory effects of ibrutinib could play a role in its antitumor activity in FL, so combinations with other immune-oncology therapies may prove beneficial.

**DYNAMO: THE CLINICAL ACTIVITY OF DUVELISIB IN PATIENTS WITH DOUBLE-REFRACTORY SMALL LYMPHOCYTIC LYMPHOMA IN A PHASE 2 STUDY**

P.L. Zinzani1,*, N. Wagner-Johnston2, C. Miller3, S. Tetreault4, F. Passamonti5, S. Lunin6, H. Youssoufiian7, J. Porter8, S. Prados9, I. Finn10

1Institute of Hematology Seràgnoli, University of Bologna, Bologna, Italy; 2Site- man Cancer Center, Washington University, St Louis, 3Saint Agnes Hospital, Nashville, United States; 4Florida Cancer Specialists - Tallahassee, Tallahassee, United States; 5University Hospital Ospedale di Circolo, Varese, Italy; 6Florida Cancer Specialist, Fort Myers; 7Verastem Inc, Needham; 8Tennessee Oncology, Nashville, United States

**Background:** Duvelisib is an oral, dual inhibitor of PI3K-δ,γ in development for the treatment of hematologic malignancies. DYNAMO is a Phase 2 study to evaluate the safety and efficacy of duvelisib in a double refractory indolent NHL population, which included 28 patients (pts) with small lymphocytic lymphoma (SLL).

**Aims:** The primary objective was to evaluate the antitumor activity of duvelisib monotherapy in pts whose disease is refractory to rituximab and to either chemotherapy or RIT, with an additional objective to further characterize the safety duvelisib.

**Methods:** DYNAMO is an open-label, single-arm, safety and efficacy study in patients (pts) with FL, small lymphocytic lymphoma (SLL), or marginal zone lymphoma (MZL), whose disease is double refractory to rituximab (monotherapy or in combination) and to chemotherapy or radioimmunotherapy. Pts received duvelisib 25mg BID in 28-day treatment cycles until disease progression or unacceptable toxicity. The primary endpoint is overall response rate (ORR) as assessed by an independent review committee (IRC) per revised IWG criteria. Secondary endpoints include duration of response (DoR), progression-free survival (PFS), overall survival (OS), time to response (TTR), adverse events (AEs), and changes in safety laboratory values. *Pneumocystis jirovecii* pneumonia (PJP) prophylaxis was mandated for all pts at baseline.

**Results:** 129 pts with INHL were treated on study. Of these, 28 pts with SLL received duvelisib with a median duration of exposure of 9 mo. (range 6.5-12). Median age was 65 years; 68% were male. Most SLL pts had an ECOG performance status score at baseline of 0 (43%), followed by 1 (54%) and 2 (4%). Most SLL pts had either low (51%) or intermediate (49%) disease burden. Median time from last anticancer therapy to first dose of duvelisib was 3 months. SLL pts received a median of 3 prior anticancer regimens (range: 1-8); 43% of pts received ≥4 prior anticancer regimens, 29% ≥6 regimens. The ORR for SLL pts was 68% (95% CI: 48, 84) per IRC assessment. All responses (19) were PRs. Four (14%) pts had a best response of SD and 3 (11%) pts had a best response of PD. 2 pts were un evaluable for response. Per Investigator assessment, the ORR was 79% (including 1 CR). Median time to IRC response was 1.9 months (range 1.4-5.5). 93% of pts had a reduction in nodal target

**Figure 1.**
lesions. Among the 19 SLL pts with a response per IRC, the median DOR was 9.8 months. The median PFS among all SLL pts was 11.3 months, while the median OS was not reached. The estimated probability of survival at 12 months was 83.9%. Among all pts treated (n=129), AEs were mostly Gr 1-2. Most common Gr 3 AEs were transient cytope尼亚s (neutropenia [23%], anemia [12%], and thrombocytopenia [10%]), and diarrhoea (15%). 4 SLL pts had SAEs that led to discontinuation. Duvelisib: NSCLC neuronal toxicity, cutaneous toxicity of the skin, pseudomembranous colitis, and pneumonia. Two SLL pts has a fatal AE, 1 pneumonia and 1 viral infection.

Summary/Conclusions: In DYNAMO, duvelisib showed clinical activity in a double-refractory SLL population (68% ORR, median DOR 9.9 mo., 93% with a reduction in target lesions). Duvelisib was generally well tolerated, with a manageable safety profile with appropriate risk mitigation. Duvelisib monotherapy appears to have a favorable benefit-risk profile in double refractory SLL. Updated clinical data will be available at the time of presentation.

WALDENSTROM MACROGLOBULINEMIA: UK REAL WORLD EXPERIENCE
D. El-Sharkawi1, H. Renshaw1, M. Lunn2, D. Hughes3, A. Rismanli2, S. D’Sa1
1Cancer Division, University College London Hospital (UCLH), 2Peripheral Nerve Service, National Hospital for Neurology and Neurosurgery, 3Haematology, UCL, London, United Kingdom

Background: There are few randomised controlled trials in Waldenström macroglobulinemia (WM) due to its rarity and indolent nature. As a result, there is no standard treatment approach and management is variable.

Aims: The aim of this retrospective study was to review “real world” management of WM in the UK and correlate this with survival outcomes.

Methods: All patients with a diagnosis of WM seen at ULCH between 01/07/2002 and 31/12/2016 were included. Patient characteristics, presenting features, lines of treatment, responses and overall outcome were recorded. Survival was estimated using Kaplan-Meier analysis from time of first treatment and P values calculated using the log-rank test.

Figure 1. Results: A total of 211 patients were identified (116 M/ 95 F), median age 60 yrs (range 34-89). Presenting symptoms included anaemia, n=53; neuropathy, n=19; fatigue, n=18; hyperviscosity symptoms, n=13; lymphanepthony, n=5; progression from IMUS, n=5; B symptoms, n=5; other, n=28; unknown, n=55. Mutated MYD88 was seen in 59 of 72 cases analysed (82%). Of these 59 cases, 13 were CXCR4 mutated. IPSSWM was known in 150 cases of whom 64 were in low, 63 intermediate and 23 high risk groups. Median follow-up from first appointment was 64 months (range 0-394). The median number of lines of therapy was 2 (range 0-9). Dexamethasone, rituximab and cyclophosphamide (DRC) was given to 62 patients upfront, 52 had other cyclophosphamide containing regimens e.g. CHOP +/- rituximab, 29 had Chlorambucil-based regimen, 14 R-bendamustine, 15 fludarabine-based with a minority getting R-cladribine (5) or R-bortezomib (4), 9 pts had no treatment at all. Notably, DRC was given to 1 patient before 2009, 28% of patients between 2009 and 2013, and 41% from 2013. In the 149 cases with known responses to first line treatment, 11% achieved a CR (7 patients with R-CHOP, 4 DRC, 2 fludarabine containing regimen, and 3 patients other treatment). 63% PR/VGPR, 21% no response or PD and 5% stopped due to toxicity. For the 52 patients who had DRC chemotherapy, median PFS was 61 months. Of those patients who had at least 3 lines of chemotherapy (n=62), median time between 1st and 2nd line treatment was 42 months, 3 months between 2nd and 3rd line. Transplants were performed on 28 patients after a median of 2 lines of chemotherapy. Median overall survival (OS) has not been reached in the 195 patients with available data. Stratifying by IPSSWM shows median OS for the low risk group has not been reached, 11 years for the intermediate risk and 9 years for the high risk group. P=0.29 (Figure). Patients had a significantly reduced OS if they developed Binet Neel syndrome or high grade transformation compared to other known complications of WM. Despite differences in chemotherapy strategies over the past two decades, there was no difference in outcome in patients treated...
WALDENSTRÖM MACROGLOBULINEMIA (WM). A STUDY ON 114 OFF OF THERAPY.

S. Guidez1, J. Labreuche 2, J. Bakala 3, B. Royer 4, C. Delette 4, M. Joris 4,

PATIENTS (PTS) treated with WM have been followed up for ~6 years after diagnosis. After ~6 years of follow-up: 63.6% (Rx4+RIT), 66.7% (R-COP+RIT) have not progressed by consolidation with 90Y-IT remains as a valid option for follicular lymphoma. Risk of second progression rate after 1st line therapy was 70%. Sixty-two, 37 and 19 pts received a 2nd or 3rd and 4 to 6 lines of therapy respectively according to the 2nd International Workshop guidelines. Monitoring of serum monoclonal immunoglobulin concentration (SMIC) throughout the evolution of the disease was available in 106 pts. Informed consent was obtained according to the protocol submitted to the Institution Review Board.

Results: Median survival after 1st line therapy was estimated 79 months. It was estimated 69 and 65 months after 2nd line and 3rd line therapy respectively. High IPSSWM (hiPSSWM vs low/intermediate) retained prognostic value for survival after 1st treatment initiation (SAFTI, p=0.0005). However, plot of hazard function showed a decrease of hazard ratio over time with a departure from the proportional hazard hypothesis (Grambsch and Therneau test: p=0.053). Consequently, Dxy concordance index obtained in multiple landmarks analyses decreased from 0.27 to 0.12, during the first 6 years of follow-up. In Cox model of SAFTI with time dependent covariate, onset of response (whatever cut-off in SMIC) had no prognostic value. Onset of progression and initiation of 2nd line therapy, retained prognostic values for SAFTI (p=0.0038 and p=0.004 respectively). Only 2 thresholds in SMIC defined a response status (observed between onset of response and progression) of prognostic value for SAFTI: namely >25% reduction in SMIC (i.e. minor response or better; p=0.041) and >50% (i.e. partial response or better; p=0.026). In similar Cox models with hiPSSWM, onset of progression (p=0.0034) and 2nd treatment initiation (p=0.0031) retained independent prognostic value beside hiPSSWM (p=0.0026). Times elapsed from the initiation of 1st line therapy to 1st progression and to the initiation of 2nd line therapy had no prognostic value for subsequent survival. In similar Cox model of survival after 2nd line therapy with time dependent covariate no threshold in SMIC were found to be associated with a significant value of onset of response or response status. Neither onset of progression nor next treatment initiation had significant prognostic value. Similar results were observed after the 3rd line of therapy.

Summary/Conclusions: The prognostic value of initial ipPSSWM decreased in part during the first 6 years of evolution. Onset of progression and 2nd treatment initiation provided additional prognostic information for predicting SAFTI. Therefore progression-free survival or time to next treatment may be satisfactory surrogate endpoint of SAFTI in WM. Further international collaborative studies are mandatory for this purpose. Assessing response in more advanced phase of the disease may require specific tools.

Figure 1.

Summary/Conclusions: The use of immunotherapy with rituximab or combined schedules with immunotherapy (R-COP and R-CHOP) followed by consolidation with 90Y-IT remains as a valid option for follicular lymphoma patients. After ~6 years of follow-up: 63.6% (Rx4+RIT), 66.7% (R-COP+RIT) and 100% (R-CHOP+R) of patients continue with complete response and off of therapy.

ASSESSING RISK OVER TIME IN PATIENTS WITH SYMPTOMATIC WALDENSTRÖM MACROGLOBULINEMIA (WM). A STUDY ON 114 PATIENTS. S. Rupoli1,*, G. Goteri2, G. Micucci1, I. Federici1, L. Canafoglia1, P. Leoni1, L. Bugatti7, S. Serresi4, R. Santilli4, A. Campanati3, N. Pimpinelli8

Background: Development of cut-off in SMIC (i.e. >25% and >50% reduction in SMIC) in the second line therapy to define the response status and progression was investigated in a study on 114 patients with WM treated in our institutions. The prognostic value of initial ipPSSWM decreased in part during the first 6 years of evolution. Onset of progression and 2nd treatment initiation provided additional prognostic information for predicting SAFTI. Therefore progression-free survival or time to next treatment may be a satisfactory surrogate endpoint of SAFTI in WM. Further international collaborative studies are mandatory for this purpose.

Methods: We took advantage of our continuously updated clinical database for reviewing a series of 114 symptomatic WM pts treated in our 2 institutions between 1993 and 2016 (median age 70, male/female ratio=1:91, high, low/intermediate and unavailable IPSSWM in 57, 36 and 21 pts respectively). The follow-up of these protocols was proportional and combination was yearly published (Rupoli et al., EJD 2016). The follow-up of these protocols was prolonged up to February 2017.

Methods: We recruited patients with stages I-IV MF who had failed PUVA (early disease) or several systemic regimens (early and advanced disease). We defined high "min" and "standard" protocols in which Bexarotene dose and PUVA administration were individually titrated, and tailored during induction and maintenance according to previous therapy, disease stage and toxicity. Survival curves for each efficacy endpoint were calculated according to Kaplan-Meier.

E1136 TIME TO NEXT TREATMENT ANALYSIS FOR EARLY AND ADVANCED STAGES OF MYCOSIS FUNGOIDES/SEZARY SYNDROME TREATED WITH BEXAROTENE AND PUVA IN COMBINATION. S. Rupoli1,*, G. Goteri2, G. Micucci1, I. Federici1, L. Canafoglia1, P. Leoni1, G. Rondinelli1, F. Giannomasso1, G. Moscicchio1, R. Albertini1, M. Saninacci1, L. Bugatti1, S. Serresi1, R. Santilli1, A. Campanati3, N. Pimpinelli8

The prognostic value of initial ipPSSWM decreased in part during the first 6 years of evolution. Onset of progression and 2nd treatment initiation provided additional prognostic information for predicting SAFTI. Therefore progression-free survival or time to next treatment may be a satisfactory surrogate endpoint of SAFTI in WM. Further international collaborative studies are mandatory for this purpose.

Assessing response in more advanced phase of the disease may require specific tools.

Background: Bexarotene is a synthetic retinoid effective in early and advanced stages of Mycosis Fungoides (MF)/Sezary Syndrome (SS) both in monotherapy and combination schemes. Time to next treatment (TTNT) seems to be a clinically meaningful endpoint that incorporates both symptom control and disease progression. It has been investigated in few retrospective studies focusing on retinoids in monotherapy both in limited-stage and advanced stage MF, but up to now no data are available concerning the use of retinoids in combination.

Aims: To assess the prognostic role during the clinical course of initial international prognostic index (IPSSWM), response and progression (according to 6th International Workshop guidelines). Monitoring of serum monoclonal immunoglobulin concentration (SMIC) throughout the evolution of the disease was available in 106 pts. Informed consent was obtained according to the protocol submitted to the Institution Review Board.

Methods: We took advantage of our continuously updated clinical database for reviewing a series of 114 symptomatic WM pts treated in our 2 institutions between 1993 and 2016 (median age 70, male/female ratio=1:91, high, low/intermediate and unavailable IPSSWM in 57, 36 and 21 pts respectively). The follow-up of these protocols was proportional and combination was yearly published (Rupoli et al., EJD 2016). The follow-up of these protocols was prolonged up to February 2017.

Methods: We recruited patients with stages I-IV MF who had failed PUVA (early disease) or several systemic regimens (early and advanced disease). We defined high "min" and "standard" protocols in which Bexarotene dose and PUVA administration were individually titrated, and tailored during induction and maintenance according to previous therapy, disease stage and toxicity. Survival curves for each efficacy endpoint were calculated according to Kaplan-Meier.

E1135 TIME TO NEXT TREATMENT ANALYSIS FOR EARLY AND ADVANCED STAGES OF MYCOSIS FUNGOIDES/SEZARY SYNDROME TREATED WITH BEXAROTENE AND PUVA IN COMBINATION. S. Rupoli1,*, G. Goteri2, G. Micucci1, I. Federici1, L. Canafoglia1, P. Leoni1, G. Rondinelli1, F. Giannomasso1, G. Moscicchio1, R. Albertini1, M. Saninacci1, L. Bugatti1, S. Serresi1, R. Santilli1, A. Campanati3, N. Pimpinelli8

Background: Bexarotene is a synthetic retinoid effective in early and advanced stages of Mycosis Fungoides (MF)/Sezary Syndrome (SS) both in monotherapy and combination schemes. Time to next treatment (TTNT) seems to be a clinically meaningful endpoint that incorporates both symptom control and disease progression. It has been investigated in few retrospective studies focusing on retinoids in monotherapy both in limited-stage and advanced stage MF, but up to now no data are available concerning the use of retinoids in combination.

Aims: To assess the prognostic role during the clinical course of initial international prognostic index (IPSSWM), response and progression (according to 6th International Workshop guidelines). Monitoring of serum monoclonal immunoglobulin concentration (SMIC) throughout the evolution of the disease was available in 106 pts. Informed consent was obtained according to the protocol submitted to the Institution Review Board.

Methods: We took advantage of our continuously updated clinical database for reviewing a series of 114 symptomatic WM pts treated in our 2 institutions between 1993 and 2016 (median age 70, male/female ratio=1:91, high, low/intermediate and unavailable IPSSWM in 57, 36 and 21 pts respectively). The follow-up of these protocols was proportional and combination was yearly published (Rupoli et al., EJD 2016). The follow-up of these protocols was prolonged up to February 2017.

Methods: We recruited patients with stages I-IV MF who had failed PUVA (early disease) or several systemic regimens (early and advanced disease). We defined high "min" and "standard" protocols in which Bexarotene dose and PUVA administration were individually titrated, and tailored during induction and maintenance according to previous therapy, disease stage and toxicity. Survival curves for each efficacy endpoint were calculated according to Kaplan-Meier.
Background: Follicular lymphoma (FL) is a clinically heterogeneous indolent lymphoma. The majority of patients have a non-aggressive clinical course, but a small percentage shows a rapidly progressive disease, including histological transformation in some cases. Although disseminated disease and bone marrow infiltration are common, only a small percentage of FL patients have peripheral blood (PB) involvement. The clinical significance of the PB involvement is unclear.

Aims: To characterize the clinical-physiological characteristics and to determine the prognostic impact of blood involvement in patients with advanced FL.

Results: We enrolled 21 patients, 12 males and 9 females, with median age of 67 years (range, 30-77), of which 15 affected by early MF (13 with stage IIB, 2 with stage IIA, 1 with stage IIIB and 1 with stage IVA). Six patients had previously received PUVA therapy only, while fifteen patients had received other therapies. The protocol proved to be effective, well tolerated and able to induce an overall response of 55.6% at the end of induction phase (93.4% of early stage patients and 66.6% of advanced stage patients) and of 76.2% at the end of maintenance phase (86.7% of early stage patients and 14.2% of advanced stage patients). Median follow up for all patients was 85 months (6-118) with respectively 98 months (21-118) for early stages and 46 months (6-102) for advanced stages. For the entire cohort, median OS, PFS and TTNT were respectively, 105, 103 and 79 months, and median EFS was 58 months. For advanced stage patients, median OS, PFS, EFS and TTNT were 32, 29, 18 and 39 months respectively.

Summary/Conclusions: Our combination treatment seems to have superior TTNT compared to data published in the literature for PUVA and bexarotene in monotherapy. When considering early and advanced MF, 66% of our patients are estimated to be free from further treatment at 2 years, a higher percentage compared to the results of Hughes et al. (Blood, 2015) for patients treated with PUVA (54.2%) or bexarotene (36.8%) as single agents. Moreover, TTNT seems to be longer in our study than in the study by Hanel et al (AJH 2016) on patients treated by retinoids in monotherapy, respectively 79 vs 60 months (mean TTNT values) in the early stages and 39 vs 9 months (median TTNT values) in the advanced stages. We believe that our results strongly suggest a synergistic or additive effect between PUVA and bexarotene compared to either agent alone in the treatment of both limited-stage and advanced stage MF.

Methods: We selected 304 patients in stage IV out of 654 patients diagnosed with FL between 1991 and 2014 in a single institution. Patients with a diffuse large B-cell lymphoma component, histological grade 3b and primary cutaneous FL were not included. Fifty-six (18%) had PB expression (PB+) defined by the presence of circulating FL cells by morphology, further confirmed by immunophenotype. The main clinical and biological characteristics, response to treatment and outcome were analyzed.

Results: Patients with PB+ more frequently had splenic involvement, anemia, elevated β2-microglobulin and LDH and high FLIPI score than those without PB involvement (PB-) and differences were statistically significant. There were no differences concerning the proportion of patients undergoing a watchful wait approach (7% vs 9%), type of treatment, or overall response rate (83% vs 88%) and complete response rate. Overall, 149 patients had refractory disease or relapsed, including 34/52 (65%) PB+ and 115/225 (51%) PB-. The median follow-up was 7 years (range 0.7 - 22.2 years). The 5-year progression-free survival (PFS) of treated group was 28% (95% CI: 14-42%) compared with 48% in the PB- (95% CI: 41-55%) (p=0.013). However, when the analysis was restricted to patients receiving rituximab combination regimen, 5-year PFS was 45% (95% CI: 24-66%) vs 64% (95% CI: 54-74%) (p=NS). Ninety-six patients died during the follow-up (19 PB+ and 77 PB-), with a 5-year overall survival (OS) of 68% (95% OR: 54-82%) in the PB+ group and of 81% (95% CI: 76-86%) in the PB- group (p=NS) (Figure). Finally, there was no difference in the risk of histological transformation or second malignancies.

Summary/Conclusions: Peripheral blood involvement in FL is associated with particular clinical features, higher tumor burden load and shorter PFS, although in the short-term it appears that has not impact on overall survival.

E1137 PERIPHERAL BLOOD INVOLVEMENT IN PATIENTS WITH ADVANCED STAGE FOLLICULAR LYMPHOMA: CLINICAL-BIOLOGICAL CHARACTERISTICS AND PROGNOSTIC IMPACT

Background: The antipaptotic protein BCL-2 is commonly overexpressed in hematologic malignancies. VEN is a potent, selective, orally bioavailable BCL-2 inhibitor that has demonstrated acceptable safety and antitumor activity in NHL and MM patients.

Aims: To evaluate the safety, PK profile, and preliminary antitumor activity of single-agent VEN in NHL patients with or without prior exposure to chemotherapy.

Methods: Phase 1 open-label, dose-escalation study of VEN in Japanese pts with relapsed or refractory (R/R) NHL or MM (NCT02265731). Dose escalation was performed on 21-day cycles until progression. All pts received tumor lysis syndrome (TLS) prophylaxis and underwent routine tumor evaluation, hospitalization and monitoring starting at least 72 hours before the first VEN dose and before each dose escalation. Adverse events (AEs) were assessed by NCI CTCAE v4.0. Dose-limiting toxicities (DLTs) were determined during the ramp-up period and during cycle 1. Responses were assessed by 2007 IWG (NHL) or 2006 IWG (MM) criteria.

Results: As of January 19, 2017, 20 pts (50% male; median age 65 years [39–81]) have been enrolled: 3 pts in the 300-mg, 7 pts in the 600-mg, 7 pts in the 900-mg, and 3 pts in the 1200-mg VEN dose cohorts. Eighteen (90%) pts had NHL (stage III/IV, n=14), including 11 with follicular lymphoma (FL), 6 with diffuse large B-cell lymphoma (DLBCL), and 1 with concurrent FL+DLBCL. 2 (10%) pts had MM at diagnosis. Treatment-emergent AEs (all grades) >20% pts were lymphopenia (80%), neutropenia (60%), leukopenia (50%), and anemia (25%), and non-hematologic toxicities including nausea (55%), vomiting, diarrhea, and nasopharyngitis (30% each). Grade ≥3 treatment-related AEs were lymphopenia (45%), neutropenia (40%), and leukopenia (30%). One pt in the 1200-mg dose cohort had proarrhythmia, which was suspected to be due to DLT as DLT occurred following 2 doses of 100-mg VEN on day 2 of the dose ramp-up period. One DLBCL pt died while on study due to disease progression. No TLS events were reported. Steady-state VEN exposures were nearly dose proportionally across 300-mg to 900-mg doses. At the 1200-mg dose, exposures to VEN increased less than dose proportionally, which is consistent with non-Japanese subjects. VEN exposures were comparable between Japanese and non-Japanese pts at the 300-mg dose. At higher doses, individual exposures were generally within the range observed in non-Japanese pts but mean exposures were 30–100% higher. Overall, the OR rate was high, with nearly half the pts with NHL achieving an OR. Further evaluation of VEN in Japanese pts with hematologic malignancies is ongoing.

A SIMPLIFIED APPROACH IN THE ASSESSMENT OF T-CELL CLONALITY BY FLOW CYTOMETRY

A simplified approach for the clinical evaluation of abnormal T-cell populations by flow cytometry. "In summary we have demonstrated a novel approach in the assessment of T cell clonality by targeting T-cell receptor β constant domain 1 (TRBC1). The addition of Jovi-1 in routine practice could improve the clinical evaluation of abnormal T-cell populations by flow cytometry.

E1140

A HIGHER AMOUNT OF LILOTOMAB PRE-DOSE INCREASES THE ACTIVITY-ADJUSTED AUC AND HAS A PROTECTIVE EFFECT AGAINST MYELOSUPPRESSION OF LUTETIUM (177Lu)-LILOTOMAB SATETRAX-IM-MYXELDIO-177Lu, A SIMPLIFIED APPROACH IN THE ASSESSMENT OF T-CELL CLONALITY"
of prior therapies ranged from 1 to 7, median body weight was 79 kg (range: 58-118kg). The administered activity across all treatment groups ranged from 746 to 1982 MBq. The table below shows the summary of the median PK and haematology safety results for $^{177}$Lu-lilotomab by treatment group. The activity-adjusted AUC$_{0-\infty}$ of $^{177}$Lu-lilotomab increased with 100mg/m$^2$ of lilotomab compared to the other pre-dosing regimens (p<0.001 compared to 40mg lilotomab). The median volume of distribution and clearance were both reduced with 100mg/m$^2$ of lilotomab compared with the other pre-dosing regimens. However, activity adjusted Cmax was similar. Smaller percentage post-treatment reductions in platelet and neutrophil counts were observed in patients receiving 100mg/m$^2$ lilotomab. Most common grade 3/4 AEs were hematological and were transient and reversible.

**Table 1.**

![Table 1](image)

Summary/Conclusions: A higher pre-dose of lilotomab increases the activity-adjusted AUC and decreases the volume of distribution and clearance rate of $^{177}$Lu-lilotomab in iNHL pts. Despite the increase in AUC the percentage reductions in neutrophil and platelet counts were smaller, indicating that a higher dose of lilotomab may have a protective effect against the myelosuppression associated with $^{177}$Lu-lilotomab. Further characterisation of 20 MBq/kg dose of $^{177}$Lu-lilotomab with 100mg/m$^2$ of lilotomab pre-dosing is ongoing and will be presented.

**PHARMACOKINETICS AND TOLERABILITY OF OFATUMUMAB AND BENDAMUSTINE IN PATIENTS WITH INDOLENT B-CELL NON-HODGKIN’S LYMPHOMA**

A. Forero-Torres1,*, J.C. Chandler2, S.P. Iyer3, A.S. Kanate4, M. Quinlan5, P. Hoeve6, M. Izquierdo6, V. Duval6, S. Madan7

1Division of Hematology / Clinical Oncology, University of Alabama at Birmingham, Alabama, 2West Cancer Center, Tennessee, 3Houston Methodist Cancer Center, Houston, 4West Virginia University, Morgantown, 5Novartis Oncology, East Hanover, NJ, United States, 6Novartis Pharma AG, Basel, Switzerland, 7Cancer Therapy & Research Center, San Antonio, United States

Background: Anti-CD20 antibody rituximab (R)-based immunochemotherapy is the standard treatment for untreated or relapsed indolent B-cell non-Hodgkin lymphoma (iNHL). Due to the inevitable relapse of patients with iNHL, an unmet need remains for active and well-tolerated novel therapies. Bendamustine (BEN) is approved for the treatment of refractory iNHL, and the combination therapy BEN-R showed efficacy in the treatment of relapsed iNHL. Ofatumumab (OFA) is an anti-CD20 human monoclonal antibody (mAb) with high binding affinity and slower dissociation from a distinct membrane-proximal epitope on both small and large loops of CD20. OFA is indicated for the treatment of chronic lymphocytic leukemia (CLL) and is being investigated for the treatment of iNHL. The combination of OFA and BEN may provide additional clinical benefit in patients with iNHL and therefore the potential for drug-drug interaction was investigated.

Aims: The study aimed to evaluate the pharmacokinetics (PK) of OFA and BEN alone and in combination, along with the safety and tolerability assessments in patients with previously untreated or relapsed iNHL.

Methods: In this Phase I open-label, multicentre study, patients (aged ≥18 years) with previously untreated or relapsed iNHL were randomized 1:1 to Arm A (OFA + BEN) or Arm B (OFA alone) to receive at least four cycles and up to eight cycles of treatment (cycle length 28 days). All patients provided informed consent. Arm A patients received single-sequence treatment of BEN, then OFA (1000mg) on day 1 of weeks 2, 3, and 4 of cycle 1 and on day 1 of cycles 2-8. Patients in Arm B received OFA alone at the same dosing schedule. Blood samples including all end-of-infusion (EOI) PK samples were collected for plasma concentration over time. The primary PK parameters Cmax, AUC$_{last}$, AUC$_{inf}$ were derived using non-compartmental analysis. All adverse events (AEs) and severe AEs (SAEs) were recorded for safety assessments.

Results: Thirty two patients were randomized (15 in Arm A and 17 in Arm B), 3 patients in Arm A discontinued study treatment due to consent withdrawal (2 patients) and infusion related AE (1 patient). All 32 patients were included for safety and PK concentration analysis while 30 patients (15 in each arm) were included for PK parameters. Patient and disease characteristics were similar between treatment arms; the majority of patients from both arms did not receive prior NHL therapy. PK concentration profiles and PK parameters of OFA were comparable when administered alone or co-administered with BEN (Table 1). As compared to OFA alone, there was a decrease of 14% in Cmax and 15% in
Infectious diseases, supportive care

ASSESSMENT OF INTERNATIONAL CONSENSUS GROUP FOR HEMATOLOGY (ICGH) SMEAR REVIEW RULES FOR AUTOMATED PLATFORMS IN THE DETECTION OF MALARIA

J. Vaughan1,2,*, E. Benade1,2, S. Havyarimana1,2, N. Alli1,2
1Peking University People's Hospital, Beijing, 2The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Peripheral blood smear review (SR) is a useful adjunct to the full blood count (FBC) and differential white cell count (DWCC), but is labor intensive and time consuming. For this reason, the international consensus group for hematology (ICGH) published guidelines to reduce SR rates in clinical laboratories using rules based on a combination of blood parameters and instrument suspect flags. These rules have reduced SR rates in many laboratories, but adjustment is often required to accommodate for local pathology/clinician preferences. As malaria is common in Johannesburg (JHB) (although not endemic), this study was undertaken to retrospectively evaluate the performance of modified ICGH SR rules for detection of malaria at the Chris Han Baragwanath Academic Hospital Laboratory (CHBAH) (part of the National Health Laboratory Service (NHLS) network) in JHB, South Africa.

Aims: To assess the performance of the CHBAH NHLS SR rules in the detection of malaria.

Methods: Malaria test results (P. falciparum antigen & thick/thin SR) were extracted from the laboratory information system and corresponding FBCs assessed in those with parasitemia. All ICGH rules were applied to patients with both a FBC and DWCC requested, while only the parameter related rules were applied to patients with only a FBC performed. Samples were processed using a Sysmex XE-5000 analyser (Sysmex, Kobe, Japan), and the rules violated for each FBC recorded. As a retrospective laboratory based study, informed consent was not obtained. However, the study was approved by the Human Research Ethics Committee of the University of the Witwatersrand.

Results: Of the 153 samples included, all had P. falciparum parasitemia and 37 were collected from patients with severe malaria. A FBC with a DWCC was performed in 72/153(47.1%) patients, and a FBC alone in 81/153(52.9%). SR rules were triggered in 132(86.3%) patients (86.4% of those with only a FBC performed) and 64(88.9%) in those with a FBC and DWCC). The thrombocytopenia (platelets (Plt) <100x10^9/l) and anaemia (Hb <7g/dl) rules were the most common, triggering in 105(79.5%) and 24(15.7%) patients respectively. Common analyzer morphology flags included those querying the presence of atypical lymphocytes, immature granulocytes and blasts, but 1/3 of these triggering the and DWCC requested, while only the parameter related rules were applied to patients with only a FBC performed. Samples were processed using a Sysmex XE-5000 analyser (Sysmex, Kobe, Japan), and the rules violated for each FBC recorded. As a retrospective laboratory based study, informed consent was not obtained. However, the study was approved by the Human Research Ethics Committee of the University of the Witwatersrand.

Summary/Conclusions: ICGH SR rules are FN in 13.7% of patients with malaria, largely in those with near-normal blood counts. Furthermore, SR failed to identify the parasites in a further 13.0% of cases, predominantly when the parasitism was low (median 0.35% in those missed vs 3.1% in those with parasites identified). Reassuringly, SR rules were triggered in all the patients with severe malaria, and the parasites identified in 90.5% of these.

BRONCHOALVEOLAR LAVAGE AS SYSTEMATIC APPROACH FOR EARLY DIAGNOSIS OF LUNG INFILTRATES AND INVASIVE PULMONARY ASPERGILLOSIS IN HEMATOLOGIC PATIENTS: A PROSPECTIVE SINGLE INSTITUTION STUDY

F. Marchesi1,*, A. Spada1, F. Pimpinelli2, G. Pignatelli3, M. Gaglia4, D. Forcella4, S. Gumenyuk5, D. Renzil6, F. Palombi7, A. Vulcano8, F. Pisani9, A. Romano1, E. Papa1, F. Facchini10, F. Ensoli11, C. Gimerlina12, A. Mangrelli13, M. Scaramuzzi14, R. Centi15, Department and Stem and Regenerative Medicine, National Cancer Institute, 2Molecular Virology, Pathology and Microbiology Laboratory, San Gallicano Dermatological Institute, 3Microbiology and Infectious Diseases Biorepository Laboratory, National Institute of Infectious Diseases “L. Spallanzani”, 4Thoracic Surgery Unit, Regina Elena National Cancer Institute, 5Hematology Unit, Sapienza University, Rome, Italy

Background: The best diagnostic approach of lung infiltrates (LI) remains to be established. Despite bronchoscopy with bronchoalveolar lavage (BAL) appears to be useful for LI diagnosis, hematologists and thoracic surgeons often have suspicions in performing this procedure in the immunocompromised patient at high-risk of procedure-related complications. A proper diagnostic approach at LI seems to be particularly relevant in neutropenic patients and/or in patients with an unfavorable clinical response to broad-spectrum antibiotics, in which the cause of LI are often filamentous fungi, as Aspergillus spp. To date, there were stratified risk factor, targeting the diagnostic panel to apply in hematologic patients undergoing bronchoscopy for LI.

Aims: To evaluate the feasibility of bronchoscopy with BAL as systematic diagnostic approach at LI in hematologic patients, focusing on its role to diagnose invasive pulmonary aspergillosis (IPA).

Methods: Bronchoscopy was performed in all hospitalized patient with diagnosis of acute leukemia and LI at onset of disease before therapy start, and in any other hematologic patient in any phase of disease with LI requiring hospitalization because of concomitant febrile neutropenia and/or respiratory distress not responding to broad-spectrum antibiotics. Criteria for non response to broad-spectrum antibiotics were defined as new or persistent (> 48 h) fever without improvement in the cause of respiratory distress. In all cases we performed the same diagnostic work-up including blood-swabs cultures, serum galactomannan (GM) assessment (in three consecutive checks), serum beta-D-glucan, serum PCR for CMV, BAL

ESCAPE DRUG-RESISTANT INFECTIONS IN HEMATOLOGICAL MALIGNANCIES. DARE TO REVIEW!  
C. Gentille Sanchez1,*, K. Sun1, P. Teegavarapu1, Q. Qian1, P. Mamta2, S. Wong2, I. Ibrahim1, L. Rice1, S.R. Pingali1, S. Iyer1  
1Houston Methodist Cancer Center, 2Houston Methodist Research Institute,  
2Houston Methodist Department of Hematology, Houston Methodist Hospital,  
HOUSTON, United States

Background: Patients with hematological cancers are at a high risk for increasingly resistant and severe infections. The Infectious Diseases Society of America has defined commonly resistant bacteria as ESKAPE (Enterococcus, Staphylococcus aureus, Klebsiella pneumoniae, Acinetobacter, Pseudomonas aeruginosa, Enterobacter). As suggested in recent literature, other common and difficult-to-treat infections such as Clostridium difficile and Enterobacteriaceae organisms (E. coli, Proteus) can be added to this group and change the antibiotic treatment in 25 of these ones (76%), Twelve cases of probable IPA, according to standard criteria, were diagnosed. Seven cases of LI fulfilling the radiologic criteria for IPA, though presenting only a positive Aspergillus PCR on BAL, were detected and treated as probable IPA. One life-threatening post-procedure complication was observed.

Summary/Conclusions: BAL seems a safe approach for an early diagnosis of LI in hematologic patients. The assessment of a broad diagnostic panel allowed the detection of a putative agent in 65% of cases. Assessment of Aspergillus by PCR on BAL proved useful for probable IPA diagnosis.

Results: Out of 769 patients consecutively admitted in our ward, 85 had LI and 47 of them underwent BAL (total amount: 51 procedures). A causal agent of LI was detected in 33 cases (65%) allowing to modify the ongoing anti-microbial treatment in 25 of these ones (76%). Twelve cases of probable IPA, according to standard criteria, were diagnosed. Seven cases of LI fulfilling the radiologic criteria for IPA, though presenting only a positive Aspergillus PCR on BAL, were detected and treated as probable IPA. One life-threatening post-procedure complication was observed.

E1147

PROPOSED PEGIFLGRASTIM BIOSIMILAR CHS-1701 DEMONSTRATES PHARMACOKINETIC AND PHARMACODYNAMIC SIMILARITY TO MARKETED PEGIFLGRASTIM IN A RAT NEUTROPENIA MODEL AND IN HEALTHY SUBJECTS  
P. O’Connor1,†, H. Tang1, F. Civilli1, B. Finck1, V. Vexler†  
1Coherus BioSciences, Inc., Redwood City, United States

Background: CHS-1701, a proposed biosimilar of pegfilgrastim, is being developed to decrease infection in patients receiving myelosuppressive anticancer drugs associated with febrile neutropenia.

Aims: The aim of the preclinical study was to compare pharmacokinetic (PK) and pharmacodynamic (PD) effects of CHS-1701 and marketed pegfilgrastim (MP) in a rat model of cyclophosphamide (CYP)-induced neutropenia. Since pegfilgrastim has the same mechanism of action in humans and rats, preclinical models of CPA-induced neutropenia are considered to be pharmacologically and clinically relevant models of chemotherapy-induced neutropenia in cancer patients. The aim of the clinical program was to demonstrate the PK and bioequivalence of CHS-1701 to MP in a multi-center, randomized, single-blind, 3-sequence, 3-period crossover study.

Methods: In the rat model, a single SC dose of CHS-1701 or MP was administered at 24 hours after CPA administration, when the peripheral neutrophil counts had been reduced by ~60-70% from baseline. Doses from 30 to 1000 µg/kg were evaluated in order to provide a broad range of exposures to pegfilgrastim and allow for the comparison of CHS-1701 and MP dose response in a steep part of the PD dose response curve. The PD response was evaluated in the blood by analyzing time-dependent changes in absolute neutrophil counts (ANC) and calculating ANC AUC0-∞. In the bone marrow by analyzing proliferative response in the bone marrow. No differences between CHS-1701 and MP in PD (Fig. 1) or PK were observed across the tested dose range.

In the clinical study, PK bioequivalence criteria were met for Cmax (GMR=105.0; 90% CI 95.5, 115.4) and AUC0-∞ (GMR=97.5; 90% CI 88.6, 107.2). Pre-specified PD bioequivalence criteria (90% CI) and more stringent criteria (95% CI) were met for ANCmax (GMR=99.6; 90% CI: 99.6, 102.3; 95% CI: 95.5, 103.9) and ANC AUC0-∞ (GMR=96.7; 90% CI: 92.2, 101.4; 95% CI: 91.4, 102.4). The two treatments displayed similar safety profiles. Investigator-designated treatment-related AEs occurred in 71.9%, 71.2%, and 62.8% of subjects during the CHS-1701, first MP, and second MP dosing periods, respectively, and most commonly included back pain (46.9%, 42.3%, 30.8%), headache (29.2%, 36.9%, 29.5%), and arthralgia (8.3%, 13.5%, 7.7%). There were no treatment-related serious AEs.

Results: Out of 6017 patients with Hematological Malignancies, 660 patients with 684 malignant diagnoses were found; 235 had MDS, 174 had AML, 105 had ALL, 144 had CML, 39 had AL, and 10 had an unspecified hematological cancer. Of 1132 infectious events, 62% were ESCAPE infections. The bacteria most frequently isolated were Enterococcus (23.4%), Staphylococcus aureus (18.5%) and Pseudomonas (16.9%). Bacteremia was the most predominant type of infection (41.9%) followed up by urinary tract infections (38.2%). Patients with MDS (36.6%) and AML (25.3%) were mainly affected. A prevalent resistance to levofloxacin was detected in gram positives (44.2%), and Pseudomonas (36.7%).

Summary/Conclusions: Hematological malignancies with risk for neutropenia such as MDS and AML were the most affected by ESCAPE. Bacteremia was frequently seen. Gram-negative pathogens had an increased resistance to broad-spectrum antibiotics compared to gram positives. A significant resistance to levofloxacin, a prophylactic antibiotic, was also noted. New strategies for reducing ESCAPE in MDS and AML are required. Further statistical review of this data set will be presented at the EHA Meeting, Madrid 2017.
Background: Neutropenic sepsis remains a leading cause of morbidity and mortality in both haematology-oncology and general oncology patients on cytotoxic chemotherapy. A retrospective study published in the Journal of Infectious Diseases described a beta-lactam monotherapy in suspected neutropenic sepsis, discouraging the use of aminoglycosides, in view of potential toxicities. Increasingly in clinical practice, it becomes evident that our patient population is incredibly heterogeneous and with the emergence of multi drug resistant strains of microorganisms, high-risk individuals need to be identified early and first line antimicrobial treatment regimens tailored according to patient factors alongside local antibiotic.

Aims: To retrospectively review appropriate antibiotic use, microbial identifications and antibiotic sensitivities amongst adult cancer patients with neutropenic sepsis. To identify if any patient or disease characteristics are associated with infection episodes that would support the upfront usage of aminoglycoside containing antibiotic treatment regimens.

Methods: A retrospective review of patients treated for neutropenic sepsis was conducted for the period between 1/4/2015 to 11/10/2016. Analysis of potential risk factors including primary disease, age, sex, treatment regimen, albumin, neutrophil and lymphocyte count to assess potential association with adverse outcomes.

Results: There were 116 episodes of neutropenic sepsis in 92 patients in this period. Of these, 61 were haemato-oncology patients and 31 general oncology. 42 of 76 positive cultures identified gram-negative organisms. 40 patients received single agent Tazocin and 71 patients (61%) received Tazocin and an aminoglycoside as first line antimicrobial treatment. Fourteen isolates demonstrated resistance, including 2 cases of stenotrophomonas maltophilia and 12 cases of enterobacteriaeace. 13 of the 14 resistant isolates were found in haemato-oncology patients. Nine of these cases were resistant to single agent Tazocin but sensitive to an aminoglycoside. The mean age of cases with resistance was 70.3 years (range 54.2 to 84.8 years). There was no difference in sex or degree of neutropenia/lipohypoplasia in the cases that contracted resistant bacterial strains compared to those that were culture negative. Of the 4 fatal cases with resistant bacteria, 3 had low albumin (mean 25.5g/L cf. mean of 34g/L in resistant bacteria cases surviving).

Summary/Conclusions: This retrospective analysis supports the use of combination antimicrobials up front as first line treatment in high-risk patients with neutropenic sepsis. The study has demonstrated that the patient cohort most at risk of developing drug resistant bacteriaeae are patients with high-risk or relapsed haematological disorders like AML or high-grade lymphoma, requiring multiple cycles of intensive chemotherapy. Of the patients who isolate resistant bacteria, identifying low albumin early may be a potential marker for adverse outcome in terms of morbidity and mortality. Of interest only one oncology patient isolated a resistant strain of bacteria, furthermore only 25% of general oncology patients treated with neutropenic sepsis had positive cultures compared to 79.8% of haemato-oncology patients. When comparing these findings to UK NICE recommendations it is clear that first line use of Tazocin in general oncology patients may well suffice in initial treatment of neutropenic sepsis. However with haematoma-oncology patients early or up front consideration for the additional usage of an aminoglycoside is essential in order to optimize favorable outcomes in this population. From this study, the proposed risk factors of isolating resistant strains of bacteria leading to adverse outcomes would be aggressive haematological malignancies, receiving more intensive cytotoxic therapy, multiple lines of treatment and low albumin. Further analysis in a multi center trial will allow our patient population and side close collaboration between clinicians and microbiologists is essential in providing optimal antimicrobial therapy algorithms in neutropenic patients.

E1119
PRELIMINARY RESULTS FROM A LONG-TERM REPEAT DOSE TOXICITY AND TOXICOKINETIC STUDY OF ANF-RHO, A NOVEL ANTI-NEUTROPENIC FACTOR OR.

J. Valentino1, H. Misra1*, J.A. Newmark2
1Prolong Pharmaceuticals, Prolong Pharmaceuticals, South Plainfield, 2Toxicology, Toxinix, Bedford, United States

Background: ANF-Rho is a novel polyethylene glycol-modified granulocyte colony stimulating factor that has biological and biological properties that produce a prolonged pharmacokinetic and pharmacodynamic profile as compared to pegfilgrastim (Neulasta®). As such, it has potential applications in chemotherapy induced neutropenia and chronic idiopathic neutropenia. These disorders require prolonged administration of G-CSF agents to treat neutropenia. There-
Background: *Pseudomonas Aeruginosa* (PA) is a gram negative, ubiquitous, opportunistic pathogen. Its intrinsic resistance to many antibiotics and the selective pressure exerted by empiric antimicrobial use, led to the emergence of MPA in hematological patients with high mortality and morbidity rates among infected immunocompromised patients (pts). Considering our MPA incidence of 9% in 2007/08, an outbreak developed at the HW of “Campus Bio-Medico” University Hospital of Rome, from 2008, despite the measures employed from the previous 2 years (health personnel sensitization, regular air and water filters changing, isolation precautions).

Aims: To describe the MPA outbreak occurred between 2009 and 2013.

Methods: Our HW, opened in 2007, is composed by 7 rooms, each with a private WC: 2 single, 1 double and 4 single, positive pressure, each with a filter/purification of the water and air system, a bedpan and water samples from bedpan automatic washers (BAW); phase C: room environmental disinfection and microbial decontamination with nebulized H2O2 solution added with silver cations; phase D: disposal of BAW, introducing the use of disposable bedpans and Planning an environmental sampling and disinfection program.

Results: On 04/2013 we revised retrospective study data: 82 pts carried bacterial isolates; of these, 48 (59%) had MPA, classified as colonisation in 13 pts (mainly detected on rectal swabs) and true infection in 35: 10 pneumonias (mainly detected on bronchial swabs), 9 bloodstream infections (mainly detected on central venous catheters), 2 peritoneal, 3 anorectal/perineal, 5 urinary tract, 14 bloodstream infections (mainly detected in blood samples), 48 (59%) had MPA classified as colonisation in 13 pts, 28 pts received carbapenems also combined with other anti-infectious drugs. When detecting positive blood cultures, all pts were treated by improving environmental measures. Pseudomonas contaminates and survives on many ecological niches, being continuously reintroduced in nosocomial settings. Our experience highlights the value of environmental and personal hygiene measures on MPA infections control.

**Table 1. MPA isolates and mortality rate after phase D.**

Summary/Conclusions: We identified the contaminated water residue from BAW, a new source of MPA spread in our HW, getting a full outbreak control by improving environmental measures. Pseudomonas contaminates and survives on many ecological niches, being continuously reintroduced in nosocomial settings. Our experience highlights the value of environmental and personal hygiene measures on MPA infections control.

MONITORING VORICONAZOLE PHARMACOGENOMICS AND PLASMA CONCENTRATIONS IN THE TREATMENT AND PREVENTION OF INVASIVE FUNgal DISEASE FOR HEMATOLOGICAL PATIENTS: A SINGLE CENTER EXPERIENCE

D. Guo1, X. Xu1, Z. Li1, J. Yin1, X. Tian1, D. Guo2, Y. Xu1, X. Zhu1, L. Miao1, D. Guo3, Y. Liu2.

1The First Affiliated Hospital of Soochow University, Jiangsu Institute of Hematology. 2Institute of Blood and Marrow Transplantation, Collaborative Innovation Center of Hematology, Soochow University, Suzhou, China

Background: Voriconazole has been widely used in treatment and prevention invasive fungal disease for immunodeficiency hematological patients. And the voriconazole plasma drug levels were associated with its efficacy and toxicity. The hepatic cytochrome P450 isoenzyme 2C19 plays a wonderful role in voriconazole metabolism. However if CYP2C19 genetic polymorphism can result in voriconazole metabolism and drug plasma level in setting of Asian population especially in hematologic patients is unknown.

Aims: To evaluate the effect of CYP2C19 polymorphism on the voriconazole (VCZ) plasma concentration of patients with hematological disease and the value of voriconazole plasma concentration in the treatment and prevention of invasive fungal disease (IFD).

Methods: Between January to August 2016, 76 hematological patients who received voriconazole for the treatment or prevention of invasive fungal disease were enrolled in this study. The population CYP2C19 polymorphism of voriconazole were performed using PCR-Pyrosequencing. The trough plasma concentrations of voriconazole (C<sub>trough</sub>) was determined using high-performance liquid chromatography (HPLC).

Results: Genotyping for CYP2C19 polymorphic isozyme variations showed that 32 subjects (43.42%) for the CYP2C19 wild-type, 43 (56.58%) for the CYP2C19 variant phenotype. CYP2C19 polymorphism was identified among Chinese adult oncohematological patients, patients received voriconazole treatment in our center. Based on the genotype analysis, 45 subjects were identified as extensive metabolizers’ group for EMs (CYP2C19*1/*1), poor metabolizers’ group for IMS (CYP2C19*1/*3), and there was a significant difference between CYP2C19 values in the two groups (1.66±1.86ug/ml vs 3.30±2.35ug/ml, p=0.000). The C<sub>trough</sub> of the 45 patients were detected for 119 times totally. The medium of the C<sub>trough</sub> 45 hematological patients were described. Lack of response to therapy was more frequent in patients with voriconazole levels <1.5mg/L (23.5%) than those with voriconazole levels >1.5mg/L (30.8%) (p=0.000). Furthermore, the C<sub>trough</sub> value of patients with adverse events is higher than the others (3.21±±4.656ug/ml vs 2.17±2.14ug/ml, p=0.042).

Summary/Conclusions: The single-center study showed that the mutation of CYP2C19 was quite common in Chinese hematological patients. Patients with CYP2C19 wild-type phenotype are extensive metabolizers, their C<sub>trough</sub> of voriconazole are significantly lower than patients with CYP2C19 non-wild-type phenotype (poor metabolizers). Appropriate concentrations of voriconazole can improve the efficacy of therapy and safety outcome.
Iron metabolism, deficiency and overload

GLYCOSYLATED FERRITIN MEASUREMENT FOR SECONDARY HEMOPOYETIC SYNDROME DIAGNOSTICS

V. Potapenko1,*, M. Pervakova3, S. Lapin2, A. Klimovich1, O. Mironova1, N. Petrova2, N. Onimadzaya1, N. Skorobogatova5, E. Karpyagina1, E. Kased1, E. Pavlichenko1, N. Potilchonov1, T. Kulabaev5, N. Medvedeva1, A. Afanasev2

Background: Hemopoyetic syndrome (HPS) is a clinicopathological condition characterized by systemic inflammatory reaction with cytopenia and tissue damage. The HPS may be primary (genetic associated) or secondary (SHPS), caused by different systemic disorders (immune, infectious, neoplastic). The overall clinical symptoms are similar to sepsis, so it could be difficult to differentiate among these entities. Ferritin levels are high in both cases, but the glycosylated/nonglycosylated ferritin fractions ratio is seems to be indicative.

Aims: The estimation of the ferritin fractions ratio and biochemical profile in patients with sepsis and SHPS.

Methods: The data from 64 patients were analyzed: 40 pts with diagnosed SHPS (median age 57, range 8-74 years) and 24 with lethal septic shock (median age 57.5, range 18-82 years). SHPS in patients with persistent refractory fever referred to antibacterial therapy and/or prolonged cytopenia and/or organ (lungs, CNS) involvement was established after the other possibilities had been excluded. Sepsis diagnostics was based on the confirmed infection site and systemic inflammation with multorgan failure. The following serum values were analyzed: alkaline phosphatase (ALP), alanine aminotransferase (ALT), aspartate aminotransferase (AST), bilirubin, creatinine, INR, C-reactive protein (CRP), procalcitonin (PCT), total ferritin, and glycosylated ferritin percentage. Mann-Whitney U test and ROC-analysis were used for statistical analyses.

Results: No differences were found in sepsis and SHPS for ALAT, ASAT, ALP, LDH, and bilirubin levels. The difference of INR, CRP, PCT, creatinine levels was significant (p<0.01). The most substantial difference in SHPS and sepsis groups had serum concentrations of ferritin, triglycerides, level of ferritin glycosylation (p<0.01) (Table 1). According to ROC-analysis, the area under the curve for ferritin, triglycerides and percentage of ferritin glycosylation were 0.78, 0.82, and 0.92, respectively.

Table 1.

Summary/Conclusions: The most difference between sepsis and SHPS was observed for triglycerides, ferritin and percentage of glycosylated ferritin. Percentage of glycosylated ferritin fraction seems to be the most indicative, which may make it useful for SHPS diagnostics and its differentiation from sepsis.

E1155

SERUM HEPONIDIN QUANTIFICATION IN INFLAMMATORY BOWEL DISEASES

V. Manolov1,*, M. Pervakova2, V. Vasilev3, K. Tzatchev4, O. Georgiev2, D. Stefanova-Petrova2, R. Tzrantcheva2, V. Mitev3

Background: Inflammatory bowel diseases (IBD) include different intestinal pathologies, most common among them are Colitis Ucerosa (CU) and Crohn’s Disease (CD). Pathogenesis of IBD is still unclear, however they are multifactor diseases, with genetic and autoimmune compounds, in combination of environmental factors. One of IBD symptoms is iron deficiency anemia.

Aims: We aimed to search for connection between serum hepcidin quantification and anemia in IBD.

Methods: We included 64 patients with IBD - 29 with Colitis Ucerosa (CU), and 35 with Crohn’s Disease (CD). They were diagnosed in University “Aleksandrovka” hospital in Clinic of Gastroenterology. Their results were compared to age and gender matched healthy controls. Laboratory assessments were analyzed for included groups – iron, ferritin, CRP, IL-6 and hepcidin. AAS, nephelometrical, ELISA and statistical methods were used during analyzes and obtained results interpretation.

Results: 53% from our patients had with iron deficiency anemia (IDA) and low hepcidin concentrations (5.9±1.1 µg/L) compared to control group (19.9±2.8 µg/L). The IDAs and 11 of included patients had combination of chronic disease (ACD). Their hepcidin levels were increased (59.9±6.4 µg/L) in comparison to healthy controls (19.9±2.8 µg/L); P<0.001. In patients with ACD/IDA, quantified serum hepcidin correlates positively to increased IL-6 (r=0.758, P<0.005) and CRP concentrations (r=0.899, P<0.001).

Summary/Conclusions: Quantification of serum hepcidin levels in IBD patients might be a key element in diagnosis and treatment of anemia in these patients. Serum hepcidin levels are useful marker for differential diagnosis between iron deficiency anemia and combination iron deficiency anemia/anemia of chronic disease.

E1156

MUTATIONS IN YARS2 CAUSE CONGENITAL SIDEROBLASTIC ANAEMIA WITHOUT SHOWING EVIDENCES OF MYOPATHY AND LACTIC ACIDOSIS

B. Cadenas1,*, J. Fita1, S. Montesdeoca2, C. Pedro3, M. Sanchez1

1Iron Metabolism: Regulation and Diseases, Jose Carreras Leukaemia Research Institute (JIC), BADALONA, 2Hematology Service, Hospital del Mar, Barcelona, Spain

Aims: We aimed to report a new case with a different clinical presentation.

Methods: We have identified two novel variations in YARS2 gene using Next Generation Sequencing (NGS) panel containing 10 genes involved in congenital and acquired sideroblastic anemia.

Results: The proband is a young woman aged 24 where we have identified 2 novel variations in YARS2 gene. One pathogenic splicing mutation NM.001044362.2 c.[1104-10A>G], and a missense variation NM.001044362.2 c.608 G>T; NP_001035526.1. p. Ser203Ile located in the C-core catalytic domain of the mitochondrial tyrosyl-tRNA synthetase. None of these two variations were previously reported in public databases (ExAC, NCBI SNP, Ensembl). Clinical data from the patient showed marked sideroblastic anemia (Hb 91 g/L, 32% ring sideroblasts), but not signs of muscle weakness or lactic acidosis and congenital sideroblastic anemia (OMIM #610957, ORPHA 2598). Up to date in the literature it has been reported 9 families with 11 affected individuals with mutations in YARS2 gene and affected from MLASA2.

Summary/Conclusions: Here, we reported a patient with mutation in YARS2 gene showing congenital sideroblastic anemia but presenting neither lactic acidosis nor myopathy. Therefore, patients with defect in YARS2 gene may present with a less severe clinical manifestations only involving congenital sideroblastic anemia without other extra-hematopoietic defects. MLASA2 must be considered in patients presenting with only congenital sideroblastic anemia since early diagnosis and supportive therapy will be important to prevent complications.

E1157

IRON CHELATION DATA OF CONGENITAL DISSEYRHTHOPIA ANEMIA PATIENTS: A SINGLE CENTER EXPERIENCE

M. Celini1,*, N. Kalkan1, T. Bayhan1, F. Gumruk1, S. Unal1

1Hacettepe University, Division Of Pediatric Hematology, Ankara, Turkey

Background: Congenital dyserythropoietic anemia (CDA) is a rare, genetically heterogeneous disorder characterized with ineffective erythropoiesis, and congenital malformations in certain types. Patients present with varying degrees of anemia and acidosis (lactic acid levels were 1.8-2.2 mmol/L; creatinine kinase 23 U/I, normal range: 23-170 U/I), as could be expected due to previously reported cases in the literature. Functional assays are on-going to confirm pathogenicity of the novel missense variation.

Summary/Conclusions: Here, we reported a patient with mutation in CDA gene showing congenital sideroblastic anemia but presenting neither lactic acidosis nor myopathy. Therefore, patients with defect in CDA gene may present with a less severe clinical manifestations only involving congenital sideroblastic anemia without other extra-hematopoietic defects. Chelation therapy may be considered in patients presenting with only congenital sideroblastic anemia since early diagnosis and supportive therapy will be important to prevent complications.
Results: Of these 11 patients, 7 were CDA type II. The median age of diagnosis was 12 months (3-144) months and male to female ratio was 7/4. Median transfusion requirement per year at previous year prior to initiation of chelation was 12 times (0-17). All of the patients were on chronic transfusion programme at initiation of iron chelation except for 2 (one receives occasional transfusion, and the other patient was on chronic transfusion programme but became transfusion independent after splenectomy). The median age at last visit was 70 months (32m-40 years). The median value of serum ferritin at initiation of iron chelators was 822 ng/ml. All of the patients were initiated deferasirox for iron chelation at a median dose of 24mg/kg/day (10-40) and the median chelation follow-up duration was 27 months (2-54 months). Three of the patients were evaluated with cardiac and hepatic T2* assessment prior to and by the end of 1 year of chelation and none of the patients were found to have cardiac iron loading at chelation initiation, whereas 2 had severe and 1 had moderate LIC values. In the subsequent assessment under chelation of these 3 patients all still had cardiac T2* values above 20 ms, whereas 1 had mild and 2 had moderate LIC values. Serum ferritin levels prior to initiation and by the end of 1 year were compared and the difference was found statistically insignificant.

Summary/Conclusions: Patients with CDA are at risk for iron loading and they need to be screened for the iron loading periodically. The prompt chelation in these patients prevent organ failure risks at long term including cardiac failure, cirrhosis and endocrinopathies.

E1158

ORAL IRON CHELATION FOR TREATMENT OF HEREDITARY HEMOCROMATOSIS IN CHILDREN

M. Moraki1,*, E. Repousi1, D. Kyriakopoulou1, P. Delaporta1, A. Kattamis1
1Thalassemia Unit, First Department of Pediatrics, National and Kapodistrian University of Athens, ‘Aghia Sophia’ Children’s Hospital, Athens, Greece

Background: Hereditary hemochromatosis (HH) very rarely presents during childhood. The most common form of HH in children is Juvenile Hemochromatosis (JH), a rare genetic disorder inherited with an autosomal recessive manner, resulting from mutations in either the hemojuvelin (HJV) (type 2A) or the hepcidin (HAMP) gene (type 2 B). Early diagnosis and closely monitoring of iron overload indexes, namely, serum ferritin levels, transferrin saturation and tissue iron measurement by magnetic resonance imaging (MRI) are essential in order to prevent permanent organ damage and potentially life threatening complications (cirrhosis, diabetes mellitus, cardiac dysfunction, and hypogonadism). Therapeutic intervention in children with HH may be problematic, as erythropoiesis is invasive and may not be well tolerated in young children. Iron chelation therapy can be implemented as an alternative treatment to erythropoiesis.

Aims: The scope of this study was to evaluate the use of an oral iron chelation therapy in young children with HH.

Methods: 3 children (2 females and 1 male) were diagnosed with HH at the aged of 4, 6 and 8 years old, respectively, based on increased ferritin and transferrin saturation, and tissue iron measurement. Iron chelation therapy with deferasirox was initiated based on ferritin and tissue iron levels. All patients had normal serum vitamin B12 and folate levels, liver, thyroid and renal function tests. Pregnant women and patients with a history of blood transfusion within last 3 months and/or those with acute renal failure, anaemia of chronic disease, hypothyroidism, additional cytopenias and ferritin, Anaemia was defined according to the WHO recommendation. Cohort characteristics were defined according to the WHO recommendation. Cohort characteristics were given in Table 1.

Table 1. Clinical characteristics of the patients.

Results: All 3 patients responded promptly to therapy and showed decreased levels of ferritin, LIC and cardiac iron concentration. Gastrointestinal disturbances were noted in 1 patient, which resolved with H2-blockers and with changing the treatment to 5d/wk (patient 2). Mild increase in serum creatinine (>33% from baseline but within normal range for her age) was observed in patient 3, which resolved with temporary cessation of the chelation therapy.

Summary/Conclusions: HH is very rare disorder in children, most frequently showed increased ferritin and transferrin saturation and tissue iron concentration. Iron chelation therapy with deferasirox was effective, and the difference was found statistically insignificant. Clinical characteristics of the patients were given in Table 1.

Figure 1.

Results: Hypersegregation was detected in 25 individuals with iron deficiency (45%) and 1 healthy control (5%). It was significantly more frequent in the IDA group (48.8%) than in the ID group (30.7%) [p<0.001]. After iron treatment 3 IDA patients' peripheral blood smear were checked and with normalization of iron parameters including serum iron, total iron binding capacity, ferritin, Anaemia was defined according to the WHO recommendation. Cohort characteristics were defined according to the WHO recommendation. Cohort characteristics were given in Table 1.

Figure 1.
Background: Immunosuppression with mTOR inhibitors (sirolimus or everolimus) has been associated with development of microcytic anemia after solid organ transplantation. The prevalence reaches 27 to 57% in the case of kidney transplantation. This anemia has been attributed to hepcidin increase induced by the inhibition of mTOR protein.

Aims: To evaluate the prevalence of microcytic anemia after allogeneic hematopoietic stem cell transplantation in patients receiving mTOR inhibitors.

Methods: 61 consecutive allogeneic stem cell reduced intensity conditioning (alloRIC) recipients were analyzed. In all cases, a non-related donor was used. Baseline disease was: 23 acute leukemia (37.7%), 12 non-Hodgkin lymphomas (19.7%), 10 myelodysplastic syndromes (16.4%), 7 Hodgkin lymphomas 7 (11.4%), 4 multiple myelomas (6.5%), 3 chronic lymphocytic leukemia (4.9%), and 2 myelofibrosis (3.2%). All of them received Fludarabine-based conditioning treatment and the combination sirolimus (mTOR inhibitor)-tcrolimus (calcineurin inhibitor) as GVHD prophylaxis. Drug doses were adjusted according to blood levels and renal function. Levels of Hb, MCV and iron parameters were evaluated pre-transplantation and post-transplantation.

Results: At 6 months 56 out of 61 (92%) were alive. Anemia was observed in 30 (49%) of them, with only 8 cases (13.1%) showing Hb level below 100 g/l. Microcytic anemia was diagnosed in 2 of them (3.3%). One patient showed an iron deficiency anemia as a bone marrow failure, and hepcidin levels were elevated in all patients with microcytic anemia. Anemia progressively improved with sirolimus tapering.

Summary/Conclusions: In contrast to kidney transplantation, microcytic anemia related to immunosuppression with mTOR inhibitors was seldom observed in alloRIC recipients. However, this association should be taken into account in this setting, as a rare cause of anemia. In case of microcytic anemia, the evaluation of iron parameters and hepcidin provides the diagnosis of this rare type of anemia.

E1162

ORAL IRON ELEVATES SERUM IRON AND CONSEQUENTLY CHANGES IRON DISTRIBUTION IN LIVER AND ERYTHROCYTES

Y. Matsuo-Tezuka1,2,*, M. Noguchi-sasaki1, M. Kurasawa1, K. Yorozu1, Y. Shimonaka1, M. Hirata3
1Product Research Department, Chugai Pharmaceutical Co., Ltd., Kamakura, Japan

Background: For renal anemia patients, there are several therapeutic options including erythropoiesis-stimulating agents (ESAs), intravenous and oral iron supplementations. The sera of patients with non-renal hemosiderosis had significantly higher serum iron levels when compared with the sera of non-sick controls. The mechanism leading to this increase was not fully elucidated yet.

Aims: To load iron orally, a diet including 200 ppm of iron was used as control and a diet including approximately 5000 ppm of ferric citrate was used as iron-rich diet. 6-week-old male C57BL/6Ncr mice were divided into 3 groups; control group, intravenous iron (IV iron) group, and oral iron (Oral iron) group (n=5). Mice in IV iron group were fed a control diet from days 0 and intravenously administered 0.4mg/mouse of iron-dextran on days 9. Mice in Oral iron group were fed an iron-rich diet from days 0 and intravenously administered 0.4mg/mouse of dextran as vehicle on days 9. Mice in control group were fed a control diet from days 0 and intravenously administered 0.4mg/mouse of dextran on days 9. All mice were euthanized by exsanguination under anesthesia with isoflurane on days 14. For analyses of iron absorption, serum hepcidin and iron were measured and expression of duodenal DMT1 and FPN were evaluated immunohistochemically. For analyses of iron distribution, iron levels were elevated in all groups and expression levels of duodenal DMT1 were significantly higher than control group. As for iron distribution in liver, iron was accumulated in reticuloendothelial cells in IV iron group, while in Oral iron group iron was accumulated in parenchyma. In hematological analyses, although red blood cell and reticulocyte count were not significantly different among all groups, Ret-He and MCH in Oral iron group were higher than IV iron groups.

Summary/Conclusions: It was demonstrated in this study that serum iron levels were elevated in spite of high hepcidin levels and down-regulation of duodenal iron transporters under oral iron supplementation. Furthermore, iron was distributed in liver parenchyma and hemoglobin contents in each reticulo- and erythrocyte were up-regulated only under oral iron supplementation. We speculated that high serum iron lead to excess iron uptake into tissues and erythrocyte fraction. These data might provide an opportunity to rethink the importance of proper use of iron supplementations.
Background: Children with haemoglobinopathy and rare anaemias often require regular red cell transfusions at some stage of their lives. Iron overload is therefore inevitable and iron chelation is a key component of therapy for children in this group. However its use has not been validated especially in children under two years of age. Deferasirox (Exjade®; Novartis Pharma AG, Basel, Switzerland) is an iron chelator that is conclusively proven to be effective and safe in transfusional anaemia such as haemoglobinopathies.

Aims: We aim to look at the efficacy and safety of Deferasirox in children with severe anaemias.

Methods: We present a case report of 6 children with severe anaemias treated with Deferasirox in a tertiary pediatric hematology centre in London, UK.

Results: Here we report 6 cases where deferasirox has been used in young children with rare anaemias and sickle cell disease. Patients 1 and 2 presented within the first year of life with pancytopenia requiring regular transfusion and were diagnosed with Pearson syndrome. Deferasirox was started at the age of 30 months and 4 months respectively. Patients 3 and 4 presented with neonatal anaemia requiring regular transfusion and were diagnosed with Pyruvate Kinase deficiency. Deferasirox was started at 12 and 19 months consecutively. Patient 5 presented with pure red cell aplasia at the age of 3 months and was diagnosed with Diamond Blackfan anaemia. He was initially treated with steroid but became resistant at around 40 months of age. He was then started on regular transfusion and was started at deferasirox at 4 years of age. Patient 6 was diagnosed at birth with sickle cell anaemia. He suffered from stroke at the age of 8 months and was started on chronic transfusion program. Deferasirox was started at around at the age of 1. He had a successful maternal haplo-identical transplant at 7 years of age. Deferasirox was subsequently stopped.

Summary/Conclusions: All of these children had stabilization or improvement of ferritin values after initiation of deferasirox as shown in figure 1. Deferasirox was preferred in severe anaemias due to better side effect profile on the bone marrow compared to deferiprone; the use of which can cause agranulocytosis or neutropaenia. Furthermore, its oral administration improved compliance compared to deferoxamine that required prolonged subcutaneous administrations. Deferasirox has been associated with renal impairment. However, none of patients developed renal or liver impairment during the use of deferasirox. Furthermore, it is crucial to conduct eye and ear screening tests both before and after the commencement of deferasirox. None of our patients had neurological side effects. Three of these children had deferasirox started at younger than 2 years of age. Hence, we have shown that deferasirox is safe and efficacious in treating iron overload in very young children with rare anaemias and sickle cell disease where evidence is sparse.

Figure 1.

Summary/Conclusions: All of these children had stabilization or improvement of ferritin values after initiation of deferasirox as shown in figure 1. Deferasirox is licensed in Europe to be used in children with thalassaemia older than 6 years of age or older than 2 year of age when desferoxamine therapy is inappropriate or inadequate. Deferasirox is preferable in severe anaemias due to better side effect profile on the bone marrow compared to deferiprone; the use of which can cause agranulocytosis or neutropaenia. Furthermore, its oral administration improved compliance compared to deferoxamine that required prolonged subcutaneous administrations. Deferasirox has been associated with renal impairment. However, none of patients developed renal or liver impairment during the use of deferasirox. Furthermore, it is crucial to conduct eye and ear screening tests both before and after the commencement of deferasirox. None of our patients had neurological side effects. Three of these children had deferasirox started at younger than 2 years of age. Hence, we have shown that deferasirox is safe and efficacious in treating iron overload in very young children with rare anaemias and sickle cell disease where evidence is sparse.

Mondino dell’Saronno, San Giovanni Rotondo, 7Pediatric Hemato-Oncology Unit, Policlinico S.Orsola Malpighi, Bologna, 8Pediatric Unit, Carlo Poma Hospital, Mantova, 9Department of Cellular Biotechnologies and Hematology, “Sapienza” University, Roma, 10Maria Paterno Areez Hospital, Ragusa, 11Hospital, Treviso, 12Central Teaching Hospital, Bolzano, 13Spedali Civili, Brescia, 14Ospedale Meyer, Firenze, Italy

Background: Iron deficiency anemia (IDA) is the most common hematological disease in infancy and childhood. Oral iron administration is a well-established, effective, and widely accepted treatment for anemia because of its efficacy, safety, and cost-effectiveness. Recently new preparations of oral iron compounds were launched, including droplet formulations, i.e. liposomal preparations and bis-glycinate iron; little is known on their effectiveness in real clinical practice.

Aims: To evaluate the efficiency of different oral iron preparations in children with IDA.

Methods: This observational study collected clinical and hematological data from 12 AIEOP (Associazione Italiana di Ematologia ed Oncologia Pediatrica) centers. Inclusion conditions for patient enrollment were age 3 months-12 years, diagnosis of IDA; exclusion criteria were all conditions interfering with iron absorption such as celiac disease, gastro-intestinal disorders and other chronic conditions. Local Physicians were free to prescribe any oral iron formulation, according to their standard practice. A calendar of laboratory test was suggested, including basal assessment of whole blood count, reticulocytes, iron status, with subsequent checkpoints at 3 days (WBC and reticulocytes only), 2 weeks, 8 weeks, 6 months. Clinical data regarding compliance to therapy, unwanted effects, final outcome were recorded.

Results: 112 (M 58) patients were enrolled. Ethnic distribution was: Caucasian 74, African 23, Asian 10, Other 5. The median age at diagnosis of IDA was 1.5 years, with a bimodal distribution with frequency peaks at age 3 and 12-14 years. Sixty-eight patients received bis-glycinate ferrous iron 0.45mg/kg, 19 elemental iron (ferrous gluconate/sulfate) 2mg/kg, 12 liposomal iron 0.7-1.4mg/kg, and 15 other preparations. Eating habits were reported as normal in 48 patients, inadequate weaning in 21, meatfish restriction in 32, other in 11. Gastro-intestinal side effects were reported in 96/8 (13%) of the bis-glycinate iron group, in 5/19 (16%) of the elemental iron group, and in 5/12 of the liposomal iron group. Suspension of therapy due to side effects was needed only in 5 patients, 4 in the bis-glycinate and 1 in the elemental iron group, respectively. Final outcome was available for 77 patients; it was recorded as solved IDA, persistent IDA, or lost at follow up. Solved cases were 40/53 (75%) in the bis-glycinate iron group, 5/19 (26%) in the elemental iron group, and 8/12 (67%) in the liposomal iron group. Persistent cases were 8/53 (15%) in the bis-glycinate iron group, 6/11 (55%) in the elemental iron group, and 1/13 (8%) in the liposomal iron group. Lost at follow up were 5/53 (9%) in the bis-glycinate iron group, 1/11 (9%) in the elemental iron group and 4/13 (31%) in the liposomal iron group.

Summary/Conclusions: The collected data show that both bis-glycinate and liposomal iron formulations have a good efficacy/safety profile and offer a sustainable alternative to classic elemental iron preparations.

AN INVESTIGATION ABOUT WEIGHT GAIN WITH TREATMENT OF IRON DEFICIENCY ANEMIA: CHANGES OF GHRELIN AND HEPCIDIN LEVELS WITH TREATMENT

H. C. Kilinc1, B. O nec2, K. O nec1, E. Caliskan3, H. Ankarali4
1Internal Medicine, 2Hematology, 3Medical Microbiology, 4Biostatistics, Duzce University Faculty of Medicine, Duzce, Turkey

Background: Iron deficiency anaemia (IDA) is a global health problem and problems in compliance with oral iron therapy are frequently seen. It has been shown that medications are not used regularly or discontinued due to weight gain associated with the treatment process.

Aims: We investigated ghrelin, known as appetite hormone and its relationship with hepcidin, the homeostatic regulator of intestinal iron absorption, in order to explain some symptoms of IDA and weight gain during iron treatment.

Methods: A hundred and twenty adult IDA patients, referred to our clinic between October 2015 and October 2016 were included in the study. The study was completed with 87 patients, who gave the informed content and a control group consisted of 50 healthy people. Information about age, gender, weight, height, body mass index (BMI), waist-hip circumference and blood samples were taken from the patient and control groups. The treatment of IDA was done according to the dose and method recommended by the referring physician. The researchers did not have any effect on the treatment. Measurements and blood tests were repeated in the patient group after normalization of the anemia parameters, not before the third month of treatment. Hepcidin and ghrelin levels
Studies should be designed in this regard. With weight gain and change of ghrelin levels. More extensive and controlled.

was significantly lower in the iron deficiency group than in the control group control group in the IDA group, suggesting that it may be the cause of loss of appetite. The deficiency of iron may cause deficiencies in enzymatic activities of iron depended enzymes and it may disturb the function of appetite. Ghrelin is also detected in neurons of hypothalamic arcuat nucleus, consequently responding to hypomethylating agents (Bejar, Lord et al. 2016). In addition, there exist gene mutations that are detected in patients subsequently responding to hypomethylating agents (Bejar, Lord et al. 2014), which implies that there exist variants-bearing clones that persist upon AZA as well as those that do not.

Aims: To identify variants either persisting or not upon the AZA therapy we tracked BM samples during AZA treatment. Next, we were interested in deciphering their relationship of the dynamics in somatic variants to clinical course of the analyzed MDS patients.

Methods: Massive parallel sequencing with high accuracy utilized duplicate libraries from myeloid cells and included the non-tumorous T-cell controls to identify somatic mutations in the serial samples before and during AZA therapy. The tool for detecting the dynamics of somatic mutations was the TruSight Myeloid Panel that contains 54 gene regions with previously documented mutation recurrence in 439 patients (Bejar, Stevenson et al. 2011). Indeed, 92% of our MDS cohort bore at least one somatic mutation with mostly 4 mutations per patient (range 1-9), which indicated that the MDS patients were already at relatively progressed state (Papaemmanuil, Gerstung et al. 2013).

Results: Analysis of 38 patients treated with AZA (reaching median OS 24 months (Mo) with 60% hematopoietic improvement) revealed 125 somatic variants with VAF over 5%. Adverse effects of variants in cooperating regulators of DNA damage and cell cycle were confirmed: TP53 (OS on AZA 14.8 Mo), CDKN2A (12.3 Mo), EZH2 (11 Mo). Besides the stable variant’s allele frequency (50%<VAF <200%) there existed four additional VAF profiles. Stable variants’ dynamics precluded putative AZA-resistant clones associated with shorter survival (19 Mo). In contrast, the patients bearing variants with decreasing VAF, which supposedly were inhibited by AZA, lived longer (31 Mo). Interestingly, small group of highly dynamic variants upon AZA therapy formed a subgroup with longer-lasting complete remissions.

Summary/Conclusions: Our work support the importance of catalogization of somatic variants to delineate pathogenesis of MDS with a focus on molecular AZA responsiveness. Several types of variant dynamics during the AZA therapy were noted by using the massive parallel sequencing approach of the duplicate libraries per MDS BM samples also utilizing non-tumorous controls and serial sampling. Stable dynamics was found in variants previously recorded by COSMIC and targeting the adverse outcome genes such as TP53, BCO1, ASXL1, and EZH2 as well as their combinations with TET2 that may potentially mediate clonal selection of additional variants mediating progression during AZA therapy.

WHOLE GENOME MBD-SEQ REVEALS DIFFERENT CPG METHYLATION PATTERNS IN AZACYTIDINE-TREATED JUVENILE MYELOMONOCYTIC LEUKEMIA (JMML) PATIENTS

P.P. Leoncin1,2, P. Vitullo1, F. Di Florio1, V. Tocco1, M.P. Cefalo1, A. Pitisci1, K. Girardi1, C. Niemeyer2, F. Locatelli1, A. Bertain1

1Orcohaematology, Bambino Gesù Children Hospital, Roma, Italy. 2Pediatrics-Oncohematology, University of Freiburg, Freiburg, Germany

Background: Juvenile Myelomonocytic Leukemia (JMML) is a rare and aggressive leukemia of early childhood. Allogeneic hematopoietic stem cell transplant (HSCT) is the only available curative treatment, but, since disease recurrence is responsible for treatment failure in at least one third of transplanted patients, developing alternative therapeutic approaches is desirable. Abrupt DNA methylation is a key molecular feature of JMML, suggesting an important role of epigenetic events in the pathophysiology of the disease. Azacytidine (AZA), a molecule that inhibits DNA methylation in human cells, is under investigation in JMML.

Aims: Here we report, for the first time, a global evaluation of DNA methylation status of CD34+ cells deriving from JMML patients before and after AZA treatment and compared the results with those of healthy controls. Identifying differentially methylated CpG islands linked to various genes will help us describe
an epigenetic aberrant paradigm possibly involving transcriptional and translational regulation in JMML.

Methods: CD34+ cells isolated from 3 JMML patients samples collected at diagnosis (t0) and after the third cycle of AZA (t1) were evaluated together with those of 3 healthy donors (HD). JMML patients have been treated with AZA on a compassionate use basis after obtaining signed informed consent. DNA samples were processed and ion fragment libraries were prepared. MBD-seq, bioinformatics and statistical analysis were performed by Genomnia srl (Bresso, Italy).

Results: First, we compared 10 JMML cells with HD cells, finding 987 different transcriptional units corresponding to 714 coding and 273 non-coding sequences. We also compared DNA methylation between t0 and t1. In this comparison, 644 unique transcriptional units, including 468 coding and 176 non-coding sequences, were found. Hypermethylation in JMML samples compared to HD was detected, but, unexpectedly, t0 vs t1 methylation analysis did not show any significant result, suggesting a likely unspecific patient-related pharmacological effect. Notably, 453 coding and 165 non-coding differentially methylated regions are shared between t0 vs HD and t1 vs HD sets. More in detail, 261 and 15 coding regions and 107 and 10 non-coding regions were uniquely found in t0 vs HD and t1 vs HD sets, respectively. However, 439 coding and 161 non-coding genomic regions preserve their hypermethylated status, probably due to a mechanism of resistance to AZA treatment. Among non-coding elements, we found different RNA species, such as microRNAs, splicing RNAs, lincRNAs/antisense transcripts (AS) and other unknown RNAs. Retrotransposons, belonging to LINEs and SINEs families, were also screened. We identified 13 sequences with a significant differential methylation profile in both t0 and t1 vs HD. Again, a comparison between t0 and t1 groups did not show any significant difference. Eleven hypermethylated common LINEs were evident between t0 vs HD and t1 vs HD sets. Two retrotransposons with opposite methylation patterns were found in t0 vs HD and t1 vs HD sets; while in the first comparison they included LINEs, in the second one they are 1 hypermethylated LINE and 1 hypomethylated SINE.

Figure 1.

Summary/Conclusions: In conclusion, the whole genome MBD-seq performed for the first time on JMML CD34+ bone marrow derived cells, showed a broad genomic hypermethylation both in pre- and post-AZA samples compared to HD, suggesting a patient-specific AZA effect. Transcription and translation processes of coding and non-coding genes could be deregulated in multiple ways, due to heterogeneity of sequences involved in CpG islands hypermethylation. Moreover, due to their known ability to insert random mutations in the genome, retrotransposons should be considered for further studies in JMML pathogenesis.

E1168

RESPONSE MONITORING IN MDS WITH DEL(5Q) USING DIFFERENT FLOW CYTOMETRIC (FCM)-SCORES IN COMPARISON TO CYTOGENETICS AN ELNET IMDS-FLOW EXPERIENCE

U. Oelschlaegel 1,*, T.M. Westers 2, B. Mohr 1, D. Subira 3, U. Johansson 4, G. Ehninger 1, M. Bornhäuser 1, A.A. van de Loosdrecht 2, U. Platzbecker 1, L. Lopez 1, L. Lopez-Corral 1, R. Benito 1, C. Robledo 1, M. del Rey 1, M. Gonzalez 1, M. Martin-Izquierdo 1, M. Abaigar 1, A. Redondo 1, F. Lopez-Cadenas 1, E. Perez-Lopez 1, L. Lopez-Corrall 1, R. Benito 1, C. Robledo 1, M. del Rey 1, M. Gonzalez 1, C. del Cañizo 1, D. Caballero 1, J.M. Hernandez-Sanchez 1, J.C. Caballero 1, C. Chillon 1, M. Martin-Izquierdo 1, M. Abaigar 1, A. Redondo 1, F. Lopez-Cadenas 1, E. Perez-Lopez 1, L. Lopez-Corrall 1, R. Benito 1, C. Robledo 1, M. del Rey 1, M. Gonzalez 1, C. del Cañizo 1, D. Caballero 1, J.M. Hernandez-Sanchez 1, J.M. Hernandez-Rivas 1, M. Diaz Campelo 1

Methods: Overall, 245 FCM investigations were performed in 61 patients with MDS and del(5q) (IPSS-R very low/low: n=26, int: n=13, high/very high n=22) including 42 patients with isolated del(5q) or one additional cytogenetic abnormality. The majority of analyses were performed in patients receiving lenalidomide or azacitidine (n=29 and n=22 patients), or in patients receiving chemotherapy and/or allogeneic transplantation or growth factors (n=10). Standardized FCM (lyse-stain-wash) and cytogenetics/FISH procedures were performed according to ELN guidelines at the TU of Dresden, VUMC of Amsterdam, UH of Guadalajara and UH of Bristol. Cytogenetics/FISH analysis was considered the gold standard. All of the applied FCM-scores were propagated by the ELNet MDS working group. Additionally, hematological improvement of the erythroid lineage (Hi-E) was evaluated (Cheson et al. 2006).

Results: The del(5q)-FCM-score reflected best the disappearance / presence of the cytogenetic abnormality del(5q) with a sensitivity of 82% and a specificity of 86%. This was confirmed if only MDS with del(5q) as a single abnormality or only MDS treated with lenalidomide were evaluated separately (sensitivity: 98% and 100%; specificity: 85% and 75%). The use of the Ogata-score considering almost only abnormalities of the myeloid progenitors, ended up with a slightly lower sensitivity (86%) and specificity (81%). The new iFS analyzing progenitor cells, granulo-, mono-, and erythropoiesis showed a comparably high specificity (83%) but a slightly impaired sensitivity (72%). FCSS, analyzing dyspoiesis of multiple cell lineages, showed a response in less than half of the high sensitivity of 41%, but revealed a higher specificity (91%). The analysis of Hi-E was high sensitive (81%) but not as specific (62%). Next, we investigated the potential prognostic impact of response monitoring using various FCM-scores compared to cytogenetics. Considering all del(5q) MDS patients as well as only those patients with del(5q) as a single abnormality, cytogenetics and all tested FCM-scores showed a significantly longer OS for MDS responding to therapy. The highest prognostic impact distinguished the iFS (p=0.0019) and Ogata-score (p=0.0092), respectively. Evaluating only MDS treated with lenalidomide, response monitoring using FCSS separated best the OS curves (p=0.0080). Finally, we combined the evaluation of Hi-E with cytogenetics or the FCM-scores. This resulted in an even better OS for MDS fulfilling two response criteria with the Hi-E/iFS-criteria as the highest prognostic impact for the combination of Hi-E plus the new iFS (p=0.0010).

Summary/Conclusions: Flow cytometry might serve as a rapid tool for response monitoring during treatment with disease-modifying drugs. All established FCM-scores allowed for an at least similar correctness of response prediction. The prognostic impact of the various FCM-scores seems to be even higher than that of cytogenetic response evaluation in this MDS subgroup. One reason might be, that most of the FCM-scores reflect not only the genetic background of the MDS but dyspoietic alterations in various cell lineages of the hematopoietic system.

E1169

EVALUATION OF MUTATIONS AT RELAPSE IN MYELODYSPLASTIC SYNDROME PATIENTS RECEIVING ALLOGENEIC STEM CELL TRANSPLANTATION

M. Cabrero 1,*, J.M. Hernandez-Sanchez 1, J.M. Caballero 1, C. Chillon 1, M. Martin-Izquierdo 1, M. Abaigar 1, A. Redondo 1, F. Lopez-Cadenas 1, E. Perez-Lopez 1, L. Lopez-Corrall 1, R. Benito 1, C. Robledo 1, M. del Rey 1, M. Gonzalez 1, C. del Cañizo 1, D. Caballero 1, J.M. Hernandez-Rivas 1, M. Diaz Campelo 1

Background: Allogeneic transplant (AlloSCT) is the only curative therapy for myelodysplastic syndromes (MDS). Unfortunately, relapse is the main cause of treatment failure. Evaluation of genetic mutations both at diagnosis and
before AlloSCT is a potent prognostic tool. However, mutational profile at relapse after AlloSCT has not been widely explored.

**Aims:** In this study, we evaluate mutational profile at post-AlloSCT relapse in MDS patients to determine if pre-AlloSCT mutations are still present at relapse, so we could eventually monitor them as minimal residual disease (MRD) after AlloSCT.

**Methods:** From a retrospective cohort of 115 patients, we selected those who relapsed post-AlloSCT (19/115, 16.5%) with available material at relapse (18 patients). We performed an in-house target-capture panel, sequencing across selected exons of 117 cancer-related genes previously related to MDS in pre-AlloSCT samples to identify genetic mutations and we checked the presence of those mutations in samples at relapse. Six patients were discarded because of lack of pre-AlloSCT mutations, so we selected 12 patients for the sequential study. DNA was amplified with FastStart High Fidelity PCR System using exon-specific primers for each mutation. The indexed paired-end library was prepared with Nextera XT DNA Sample Preparation Kit (Illumina) The median coverage per base achieved was 4579 reads range 2401-8573). In a second step, we explore the possibility of evaluating mutations in both CD34 positive and the rest of bone marrow cells, to check if we could increase the sensitivity of the detection.

**Results:** Median age of relapsed patients was 60 (45-70). Diagnosis were RAEB 1 (n=4), RAEB 2 (4), dysplasia associated AML (2) and RCMD (2). They demonstrated a decrease in association of Pol II with H3K4me2 (67%) and in association of H3K4me3/Pol II in BW-90 cells (7-30%; ANOVA, p<0.0001). An overall decrease in association of Pol II with H3K4me2 was observed in the BM from MDS pts (ANOVA, p=0.006), but the RIG/VOR induced 1.9-fold expansion of CD34+ cells in both cell lines. An overall decrease in association of Pol II with H3K4me2 was observed with the combinations (AZA/RIG, VOR/RIG or VOR/VOR) altered DNA methyl transferases (DNMT1, 3a and 3b), the class I, II and IV histone deacetylases (HDACs), and chromatin remodeler (KDM2a, SET1, JMJD3 and LRWD1) transcript levels in a cell line specific context. Sequential treatment of RIG with AZA or VOR demonstrated differential effects. Initial results of an ongoing Phase I/II study with RIG combined with AZA or VOR in sequential treatment (AZA/RIG, RIG/AZA, VOR/RIG or RIG/VOR) altered DNA methyl transferases (DNMT1, 3a and 3b), the cell cycle and histone acetylation (H3K9ac, & H3K18ac) levels associated with transcriptional activation or repression in both the cell lines and pt samples.

**Summary/Conclusions:** To Investigate the in vitro effects of RIG combined with AZA or vorinostat (VOR) on epigenetic and stem cell pathways on two cell lines: AML (BW90, MDS (MDS-L)) and on pt bone marrow samples.

**Methods:** We investigated the in vitro effects of RIG combined with AZA or vorinostat (VOR) on two cell lines: AML (BW90), MDS (MDS-L) and on pt bone marrow samples treated on the phase I/II study, obtained prior to and after one cycle of AZA and RIG. Treatment with RIG alone altered global histone post-translational modifications (PTMs) including methylation (H3K4me3, H3K4me2, H3K27me3, and H3K27me2) and acetylation (H3K9ac, & H3K18ac) levels associated with transcriptional activation or repression in both the cell lines and pt samples. Q-PCR studies demonstrated that individual treatment of BW90 and MDS-L with RIG or combined with AZA or VOR in sequential treatment (AZA/RIG, RIG/AZA, VOR/RIG or RIG/VOR) altered DNA methyl transferases (DNMT1, 3a and 3b), the class I, II and IV histone deacetylases (HDACs), and chromatin remodeler (KDM2a, SET1, JMJD3 and LRWD1) transcript levels in a cell line specific context. Sequential treatment of RIG with AZA or VOR demonstrated differential effects. Initial results of an ongoing Phase I/II study with RIG combined with AZA or VOR in sequential treatment (AZA/RIG, RIG/AZA, VOR/RIG or VOR/VOR) altered DNA methyl transferases (DNMT1, 3a and 3b), the cell cycle and histone acetylation (H3K9ac, & H3K18ac) levels associated with transcriptional activation or repression in both the cell lines and pt samples.
Madrid, Spain, June 22 – 25, 2017
Results: 156 patients were included between January 2014 and December
2015 with a mean age of 68 years [65.8-70.3] and 47.4% of men. 127 patients
(81.4%) had a bone marrow analysis. 53 patients (34.0%) were reported in the
group “positive NGS” and 103 patients (66.0%) in the group “negative NGS”.
In univariate analysis, significant variable associated with “positive NGS” were
age (p <10-7), no history of auto-immune disease (p=0.002), hemoglobin
<12g/dL (p=0.017), platelets >150000/mm3 (p=0.015), >10% dysplastic cells
in erythroid (p=0.012) and granulocytic lineage (p=0.034). Trend test on dysplastic lineage number was significant (p=0.006). Normal karyotype (78.1%)
was comparable in the two groups (p=0.352). Cirrhosis and/or portal hypertension were comparable in the two groups (14.1%, p=0.092) as well as mean
serum creatinine (p=0.24). In multivariate analysis, age >70 years (p=0.0011)
and platelets >150000/mm3 (p=0.0213) remained significantly associated to
positive NGS (Table 1). In “positive NGS” group, 1 (58.5%), 2 (32.1%), 3 (7.5%)
or 4 (1.9%) mutation(s) were found per patient. Most frequent mutations were
TET2 (25.9%), DNMT3A (17.3%), SF3B1 (12.3%), ASXL1 (12.3%), SRSF2
(8,6%), U2AF1 (4,9%), TP53 (3,7%) and ZRSR2 (3,7%). Other mutations were
reported in less than 3 patients. As expected in this elderly population, if a
unique mutation was found, TET2 and DNMT3A were predominant (35.5% and
25.8% respectively) but interestingly mutation R882 of DNMT3A was found in
only one patient. Sideroblasts were found>15% in 46.2% of patients with a
mutation of SF3B1, SRSF2, U2AF1 or ZRSR2.
Table 1.

Aims: To confirm that the cellular expression of nucleoside metabolizing
enzymes plays a major role in cellular resistance and significantly impacts on
clinical response to azacitidine.
Methods: Two cell lines, SKM1 sensitive (SKM1-S) and SKM1 resistant (SKM1R) to azacitidine, were analyzed for expression of UCK1, UCK2, hENT1,
hCNT3, RRM1 and RRM2 by quantitative PCR. Corresponding proteins were
quantitated by western blotting in both cell lines. The expression of UCK1 and
UCK2 was blunted by siRNAs in SKM1 sensitive cells to determine their role
in in vitro sensitivity to azacitidine. For UCK1 and UCK2 silencing in SKM1-S,
specific siRNAs were used (OriGene Technologies, MD, USA); cells were cultured at a density of 600x105cells/ml in 5 ml of RPMI 1940 medium. After 72 h
of transfection, cells were treated for further 48h with azacitidine at the concentrations of 0,1 and 1 μM. After assessment of effective gene silencing, apoptosis and cell cycle arrest were evaluated, respectively by Annexin V test and
Propidium Iodide. In parallel, the percentage of 5-methylcytosine was quantitated by ELISA assay (Global DNA Methylation LINE-1 kit ActiveMotif, CA,
USA). In addition, the expression of nucleoside metabolizing enzymes was
evaluated prospectively in 18 IPSS high risk MDS patients treated with azacitidine 75mg/m2/7 days every 28 days. Furthermore, UCK1 and UCK2 expression was evaluated in 37 patients (classified as 26 responder and 29 nonresponder) treated with azacitidine, by RNAseq analysis using DEXseq2.
Results: SKM1-R cells did not express UCK1, UCK2, hENT1, hCNT3, RRM1
and RRM2. Corresponding proteins were also not expressed. A reduction of
apoptosis was observed in UCK1-silenced SKM-1 S after azacitidine 0.1 μM
treatment: 35,7%±0,77% Annexine V-positive cells versus 25%±0,35% (P=0.031)
in non-silenced control SKM1-S cultures. We observed a reduction of apoptosis
during UCK2-silencing after azacitidine 0.1 μM treatment too: 31%±0,85% Annexin V-positive cells versus 21%±0,35% (P=0.054). Hypomethylation induced by in
vitro azacitidine treatment was also hampered by reduction of expression of
UCK1 and UCK2. Quite surprisingly gene expression of UCK1, UCK2, hENT1,
hCNT3, RRM1 and RRM2 in primary cells did not predict different clinical
response to azacitidine. RNAseq analysis for UCK1 and UCK2 did not find any
differences between responder and non-responder patients.
Summary/Conclusions: We demonstrated that UCK1, UCK2, hENT1, hCNT3,
RRM1 and RRM2 and the corresponding proteins are absent in azacitidineresistant cell line SKM1-R suggesting to be the determinant of the induced
resistance to azacitidine. UCK1 and UCK2 silencing induced by synthetic siRNAs significantly decreased azacitidine effects. Prospective evaluation of the
predictive role of cellular expression of genes involved in azacitidine metabolism
is ongoing in a larger cohort of MDS patients.
E1174

Summary/Conclusions: In the context of unexplained cytopenias, a third of
patients had at least one MDS-associated somatic mutation. Age above 70
years and no thrombopenia seems to be good arguments to realize NGS in
this context. Probably thrombopenia is frequently associated to other causes
than MDS. If NGS is positive, aging genes are the most frequently mutated
genes and they can reflect age-related clonal cytopenias. Even if their clinical
significance is uncertain, monitoring is recommended because of an increased
risk of hematologic cancer.

RESISTANCE TO AZACITIDINE IS DETERMINED AT CELLULAR LEVEL
BY LOWER EXPRESSION OF NUCLEOSIDE ACTIVATING ENZYMES UCK1
AND UCK2
E. Masala1,*, A. Valencia1, A. Brogi1, A. Sanna1, M. Torres Martin2, M. Figueroa2,
V. Santini1

2Department of Human Genetics, University of Miami Miller School of Medicine,
Miami, United States

Background: Azacitidine is at present the standard treatment for MDS. We
demonstrated that MDS patients responsive to azacitidine have significantly higher intracellular expression of the azacitidine-activating enzyme uridine-cytidine
kinase-1 (UCK1) in bone marrow mononuclear cells (Valencia et al. Leukemia
2014). Correlation of the expression of nucleoside transporter, activating and disactivating enzymes with clinical and in vitro response to hypomethylating drugs
azacitidine and decitabine has been suggested by several authors. Yet, the crucial
role of these enzymes has to be ascertained, as well as their possible different
importance in determining resistance to azacitidine.

FAMILIAL TIN2 N-TERMINAL LOSS OF FUNCTION MUTATION IN TELOMERE
SYNDROME
D. Di Giacomo1,*, V. Nofrini1, T. Iannotti1, M. Quintini1, F. Pellanera1, G. Barba1,

Perugia, 2Medicine and Surgery, University of Milano-Bicocca, Milan, Italy

Background: The shelterin complex protects telomeres from being processed
by the DNA damage repair machinery and regulates telomerase access and
activity (Frank 2015). TINF2 (14q12) is encoding for TIN2, the central component of shelterin which interacts with other members of the complex
(TRF1,TRF2 and TPP1), thus contributing to telomere length regulation and
structural integrity (Frank 2015). About thirty TINF2 mutations are known in
Dyskeratosis Congenita (DC) (Savage 2008) and other telomere related phenotypes, i.e. aplastic anemia (AA), idiopathic pulmonary fibrosis, liver cirrhosis,
myelodysplastic syndromes (MDS) and acute myeloid leukemia (Armanios
2012). All mutations were missense and heterozygous, clustering in exon 6
encoding for a highly conserved segment at the C-terminus (aa 280–291)
(Frank 2015).
Aims: Precise diagnosis in AA/MDS with clinical features of telomere syndrome.
Methods: AA was diagnosed in a 69-year-old man, with a multisystem disorder,
i.e. psoriasis, nail dystrophy, severe osteoporosis, chronic hepatopathy, mild
chronic kidney failure and hypertension, suggesting a telomere syndrome. Karyotype was normal. Patient was unresponsive to immune-suppressive therapy.
DNA from peripheral blood and hair bulbs was analyzed for TERT, TERC and
TINF2 using DHPLC and Sanger sequencing. Q-FISH investigated telomere
length. SNPs were performed following manifacturer’s instructions (Affymetrix).
Paired-end libraries for Whole Exome Sequencing (WES) were generated with
NimbleGen Exome Capture v3 (Roche), according to manufacturer. DNA from
CD3+ population was used for germinal matching. Data were aligned to the
human reference genome (GRCh38/hg38) and analyzed with the in-house
CEQer2 software (Piazza 2013). Mutational analysis and telotype were performed in both proband and familial members. TERF2 and TINF2 coding
sequences were cloned in pGem-Teasy vector and site direct mutagenesis reproduced in vitro the mutation. Using expression vectors, respectively pEGFP-C1
and pDsRed-Express-C1, TRF2 and TIN2 wild type or TRF2 and TIN2 mutated
were co-expressed in HEK-293T cell line. Co-immunoprecipitation was performed with anti-GFP antibody and differences in TRF2 binding between TIN2wt
and TIN2mut were revealed by western blotting.

haematologica | 2017; 102(s2) | 481


Results: A new TIM2F germlinal variation at exon 2, c.254A>G p.H85A, was identified in the proband and in two brothers. Screening on 200 healthy donors was negative. Significantly short telomeres were found in proband (p=0.0161) and brothers (p=0.0082 and p<0.0001), compared to age and sex matched controls. The proband had a normal SNPs profile and WES identified an additional somatic variation in TLR1 gene (c. 1859G>A, p.R620Q). Co-immunoprecipitation experiment showed that the new TIM2F mutation reduced TIM2 binding with TRF2 in vitro.

Summary/Conclusions: A new TIM2F germlinal variation at exon 2, c.254A>G p.H85A, was identified in the proband and in two brothers. Screening on 200 healthy donors was negative. Significantly short telomeres were found in proband (p=0.0161) and brothers (p=0.0082 and p<0.0001), compared to age and sex matched controls. The proband had a normal SNPs profile and WES identified an additional somatic variation in TLR1 gene (c. 1859G>A, p.R620Q). FUNCTIONAL EXPRESSION OF TIM-3 AND CLINICAL SIGNIFICANCE OF PLASMA GALECTIN-9 LEVELS IN MYELODYSPLASTIC SYNDROMES

T. Asayama1, M. Ishibashi1, H. Tamura1, Y. Kirabayashi-Hamada1, N. Takada-Okyama1, A. Nondera-Kondo1, K. Moriya1, N. Yokose2, K. Inokuchi1

Aims: We investigated the expression and function of TIM-3 using a myelodysplastic syndrome (MDS) cell line.

Methods: 1) We evaluated Tim-3 expression on CD45-gating blasts of bone marrow mononuclear cells (MMCs) in 20 patients with MDS and controls (n=22) using FACS sorting. 2) To investigate Tim-3 induction, MMCs were divided into Tim-3+ and Tim-3–fractions with FACS sorting and their differential gene expression was evaluated using oligonucleotide microarray analysis. 3) Intracellular Ki-67 expression in Tim-3+ and Tim-3– Blasts was compared by FACS sorting. 4) To evaluate the proliferative potential of Tim-3– expressing cells, we used MDS cell lines and PBMCs obtained from AL-MDS patients. Soluble Tim-3 was detected in culture supernatants of MDS cell lines and PBMCs obtained from MDS patients. 5) Soluble Tim-3 was detected in culture supernatants of MDS cell lines and in plasma obtained from patients with MDS (n=51) and healthy donors (n=10).

Results: 1) Tim-3 expression was observed on monocytes and CD45-gating blasts in MDS MMCs and in all 4 MDS cell lines. 2) Tim-3 expression levels on blasts were markedly higher in controls and MDS patients with blast counts of ≤10% than those with blast counts >10%. Tim-3+ cells were found in association with the culture supernatant of human stromal cells and MDS-related cytokines. 3) To elucidate the functions of Tim-3 on MDS cells, F-36P cells were divided into Tim-3+ and Tim-3–fractions with FACS sorting and their differential gene expression was evaluated using oligonucleotide microarray analysis. 4) To investigate the proliferative potential of Tim-3– signaling, intracellular Ki-67 expression in F-36P cells was evaluated using FCM when co-cultured with/without anti-Tim-3 blocking antibody. 5) Finally, we analyzed gal-9 concentrations in culture supernatants of MDS cell lines and in plasma obtained from patients with MDS (n=51) and AL-MDS (n=19), and healthy donors (n=10).

Summary/Conclusions: A new TIM2F germlinal variation at exon 2, c.254A>G p.H85A, was identified in the proband and in two brothers. Screening on 200 healthy donors was negative. Significantly short telomeres were found in proband (p=0.0161) and brothers (p=0.0082 and p<0.0001), compared to age and sex matched controls. The proband had a normal SNPs profile and WES identified an additional somatic variation in TLR1 gene (c. 1859G>A, p.R620Q). Co-immunoprecipitation experiment showed that the new TIM2F mutation reduced TIM2 binding with TRF2 in vitro.

SUPPRESSION OF DNA METHYLTRANSFERASE ENZYMES BY A NOVEL HYPMETHYLATING AGENT, SG-1027, IN DECITABINE-RESISTANT CELL LINES

E.-H. Hur1, D.R. Choi2, B.-K. Goo1, J.H. Moon1, E.-J. Choi1, H.-S. Park1, J.-H. Lee1, K.-H. Lee1, J.-H. Lee1

Aims: To find out clues to overcome the resistance to hypomethylating agent (HMA).

Background: We established azacitidine- and decitabine-resistant cell lines, MOLM-02A and MOLM-DEC-5 from MOLM-13, an acute myeloid leukemia cell line (OncoGenics). DNA methyltransferase (DNMT) 3B was upregulated in the resistant cell lines.

Methods: Single nucleotide polymorphism (SNP) arrays (Tu et al., Blood, 2012) have shown a potential for score criteria in the diagnosis of MDS. Recent reports of the presence such genetic aberrations in disease free individuals makes this approach problematic (Genoves et al., N Engl J Med 2014; Lichman, Blood 2015, Kwok et al., Blood 2015). A study of patients without evidence for MDS identified a driver mutation and/or structural gene variants in 91% of pre-diagnostic samples with the mutational spectrum mirroring that seen in MDS population (Canto et al., Blood. 2015). The presence of mutations with greater median variant allele fraction (40% vs 9% to 10% in healthy individuals) and occurring with additional mutations (>2 mutations, 64% vs 8%) were shown to define a high-risk group with a shorter time to disease progression and poorer overall survival.

Aims: To compare the genomic profile of bone marrow from 145 adults, 76 of whom met the WHO criteria for MDS.

Methods: All samples were screened by chromosome G banding or molecular karyotyping using 8x60K oligonucleotide arrays (Agilent, USA) or screened by FISH using probes (Cytocell, UK) targeting the most common aberrations associated with MDS as per IPSS-R classification (Greenberg et al., Blood, 2013). The commercially available target gene panel TruSight on a MiSeq platform (Illumina, USA) was used to screen mutational hotspots in 5 cancer-related genes relevant to myeloid malignancy. Genomic mutations were reported at allele frequencies (VAF) ≥1% and at minimum read depth of 300 as per manufacturers criteria. We used the Catalogue of Somatic Mutations In Cancer (COSMIC), dbSNP and 1000 genome (≥2%) to classify variant genes as either drivers, variants of unknown significance and germline polymorphisms (SNPs).

Results: A total of 145 bone marrow samples from 58 women and 87 men, aged from 26 to 85 suspected to have myeloid dysplasia were investigated. Of these only 76 (52%) were found to fulfill the WHO criteria referred to as MDS positive, the rest as MDS negative. Genomic variants were detected in all but 7 samples. The latter were considered void of gene mutations. We observed driver mutations as reported in myelodysplasias in 68 (47%) samples whilst 70 (48%) were found to carry the same variants seen in disease free individuals or of unknown significance. As expected driver variants were not identified in any of the samples that failed the WHO criteria for MDS. Variants were detected in all samples for 35 of the 54 genes targeted by the TruSight myeloid panel. In order of frequency these are TET2, SRSF2, ASXL1, CUX1, DNMT3A, RUNX1, BCROR1 and HRA5, seen in more that 10% of all samples, while the rest were less frequently reported. The aberrant genes ASXL1, TET2 and SRSF2 that were commonly found in both groups of samples with comparable TRUSIGHT allele frequency (>0.1) when in contrasted with the absence of aberrant genes unique to the MDS group albeit at low frequency. When we examined the distribution of individual variations (rather than genes) we found a unique 1oci of the genes ASXL1, TET2 and SRSF2 is 101922441, U2AF at 2614361248 and TET2 at 101927025 to be associated with the MDS positive group. A more detailed analysis on the significance of these findings will be presented.

Summary/Conclusions: We compared 145 bone marrow samples from patents presenting with MDS of which 76 met the WHO criteria. There is little difference in their genomic profile when comparing the two groups on the basis of occurrence of the most highly involved genes (ASXL1, TET2 and SRSF2) but we compare the two groups by variance, 9 variances are exclusively associated with MDS positive disease.
Methods: Besides azacitidine and decitabine, three other agents (SGI-1027, zebularine, and gemcitabine) are known as having hypomethylating effect. In vitro activities of the 5 HMA's on HMA resistant cell lines (MOLM/AZA-1 and MOLM/DEC-5) were tested by cell viability assay using luminescent-based CellTiter-Glo system. Protein and mRNA levels of DNMT enzymes (1, 3A, and 3B) were assayed before and after treatment of each HMA. Protopoiesis degradation and activation of Akt were also determined to see the correlation with changes of DNMT's.

Results: Although azacitidine and decitabine could suppress DNMT1 and DNMT3A in MOLM-13, the agents could not suppress DNMT3 enzymes in resistant cell lines. Inhibition of protopoeisal degradation by bortezomib induced accumulation of DNMT enzymes in MOLM-13, whereas it did not accumulate the enzymes in MOLM/AZA-1 and MOLM/DEC-5. Phosphorylated Akt (p-Akt) was dramatically overexpressed in MOLM/AZA-1 and MOLM/DEC-5, SGI-1027 showed the lowest IC50 values for MOLM/AZA-1 and MOLM/DEC-5, and it suppressed the protein levels of all three DNMT enzymes. SGI-1027 could also decrease the level of p-Akt. GDC-0941, a PI3K inhibitor, suppressed DNMT1 and DNMT3A as well as p-Akt, but it could not decrease DNMT3B in MOLM/AZA-1 and MOLM/DEC-5. Cell viability assay showed the synergistic effects of combination of GDC-0941 and Nanomycin A, a specific DNMT3B inhibitor, in MOLM/AZA-1 and MOLM/DEC-5.

Summary/Conclusions: DNMT levels of MOLM/AZA-1 and MOLM/DEC-5 were not dependent on protopoeisal degradation. DNMT1 and DNMT3A might be regulated via PI3K-Akt pathway, while regulation of DNMT3B might be different from DNMT1 and DNMT3A. SGI-1027 appears to exert inhibitory effects on MOLM/AZA-1 and MOLM/DEC-5 by inhibition of both p-Akt and DNMT3B.

MECHANISTIC HIGHLIGHTS OF IMPROVED ERYTHROPOIESIS WITH A LOW DOSE OF DEFERASIROX IN LOW RISK MYELODYSPLASTIC SYNDROMES

M. Mathieu1,2,*, S. Ancelet2, C. Lefebvre2, J. Arnaud4, C. Garrel4, M. Pezet5, Y. Wang2, P. Faure4, G. Szymanski3, B. Polack2, J. Y. Cahn12, J. M. Moulis6,7,8, S. Park1,2

1Clinique Universitaire de hématologie, CHU Grenoble Alpes, 2Equipe TheREx-laboratoire TIMC, Université Grenoble Alpes, 3Laboratory of hematology, 4Unité de Biochimie Hormonale et Nutritionnelle, Département de Biologie - Toxicologie Pharmacologique, CHU Grenoble Alpes, 5Plateforme de Microscopie Photonique - Cytométrie en Flux, Institut Albert Bonniot, Université Grenoble Alpes, 6LBFA, Inserm U1055, 7CEA-Grenoble, Bioscience and Biotechnology Institute, 8Laboratoire de Fundamental and Applied Bioenergetics, and Environmental and Systems Biology, Université Grenoble Alpes, Grenoble, France

Background: Myelodysplastic syndromes (MDS) are a group of heterogeneous clonal stem cell disorders leading to ineffective hematopoiesis. Anemia is a frequent cytopenia in MDS and the majority of patients requires red blood cell (RBC) transfusion resulting in the development of iron overload (IO). Deferasirox (DFX) became a standard treatment of IO in MDS and seems to have positive effects on hematopoiesis with a reduced need of RBC transfusion.

Aims: Deciper the mechanisms of the potential improvement of erythropoiesis with DFX.

Methods: We report our in vitro data about the proliferation, cell cycle, apoptosis, erythroid differentiation, and cell signaling pathways concerning CD34+ hematopoietic stem progenitor cells from low risk MDS samples in a 2-step erythroid differentiation liquid culture with low dose DFX and iron overload.

Results: We observed a higher proliferation rate for cultures with 3µM DFX versus the control condition (p=0.038). In contrast, no increased proliferation was found with DFX>5µM and with other chelators used in the clinic. The higher proliferation rate with DFX 3µM was due to the combination of decreased apoptotic cells at day 10 (D10) (p=0.03) and D14 (p=0.007) and increased cycling cells at D10 (p=0.0001). Regarding clonogenic assays, there were more CFU-E colonies with DFX 3µM (p=0.04). Despite the low concentration of DFX, cells exposed to DFX 3µM had a lower intracellular iron concentration measured by ICP-MS than control cells (p=0.019). Nevertheless, this decreased iron amount was not sufficient to activate cellular iron regulation by Iron Regulatory Proteins suggesting the absence of a direct effect of low dose DFX on iron homeostasis. Moreover, low dose DFX decreased intracellular and mitochondrial reactive oxygen species (ROS) at D14 (p=0.048 and p=0.03) and decreased the level of malonaldehyde (p=0.048), a product of lipid peroxidation. Then, we have investigated which signaling pathways were sensitive to DFX 3µM. We found an increased nuclear translocation of NFkB detected by both CM (p=0.04) and luciferase reporter assay (p=0.03). NFkB activation was absent in the knock-down (KD) of mitochondrial TRX (siTRX2) condition. Moreover, in non-iron overloaded medium condition, the level of ROS was not increased, and DFX in the TRX1 KD condition was not associated with NFkB activation. These results suggest that NFkB activation in this model is linked to TRX1 and regulated by an extremely fine control of ROS levels with a likely threshold effect.

Summary/Conclusions: Our study describes the pro-proliferative effects of low dose of DFX on erythroid progenitors in low risk MDS patients. These results provide a biological rationale for a clinical trial which will propose low dose of DFX in MDS patients, refractory to erythropoiesis stimulating agents.
Myelodysplastic syndromes – Clinical

E1179
EVALUATING ERYTHROBLAST PAS POSITIVITY IN THE DIAGNOSTIC APPROACH OF MYELODYSPLASTIC SYNDROME
R. Inverzini1, E. Travaloghi1, R. Bastia1, I. Ambaglio1, F. Quaglia1, E. Boven1, M. G. Dei Porta1, L. Malcovati1, M. Cazzola1
1IRCCS Policlinico San Matteo Foundation, University of Pavia, Pavia, Italy

Background: According to WHO minimal morphological criteria for myelodysplastic syndrome (MDS) diagnosis, at least 10% of bone marrow (BM) cells of at least one hematopoietic lineage must show unequivocal dysplasia to be considered as dysplastic. Morphological abnormalities of erythroid cells include cytoplasmic Periodic acid-Schiff (PAS) positivity, but the diagnostic power of this cytochemical reaction is not yet fully clear.

Aims: The aims of our study were to evaluate the diagnostic significance of erythroblast PAS positivity in MDS and to investigate a possible correlation between levels of PAS positivity and other morphological and clinical features.

Methods: We retrospectively examined the results of the cytochemical PAS staining for glycogen in BM smears from 165 patients with MDS, 116 patients with non-clonal cytopenia and 49 healthy subjects. We developed a PAS score by counting 100 nucleated cells for the erythroid lineage and classifying them according to the degree of PAS reactivity. The discriminant power of both PAS positivity rate and score for MDS identification was evaluated in comparison with that of the conventional morphological features of dyserythropoiesis; then, PAS positivity was included into the morphological scoring system we have previously defined (Leukemia 2015;29:66-75).

Results: PAS positive erythroblasts were observed in 104 (63%) MDS patients, 46 (40%) patients with non-clonal cytopenia, and 12 (24%) non-erythroid controls, with a significant difference between MDS and non cytopenic controls (p<0.001) or non-clonal cytopenias (p=0.001), but not between healthy controls and non-clonal cytopenias (p=0.09). In MDS, both positivity rates (median 2%, range 0-33) and scores (median 2, range 0-53) were significantly higher than those in normal and pathological controls (p=0.0001 and p=0.0004 for rate, p=0.0001 and p=0.0002 for score, respectively), without significant difference in relation to excess blasts or multilineage dysplasia. MDS patients with >4% ring sideroblasts (RS) showed lower PAS positivity rates and scores than MDS patients with ≤4% RS (p=0.0332 and p=0.0412, respectively). In MDS-RS erythroblast PAS positivity was not influenced by SF3B1 mutation status. In MDS, no significant relationship was detected between erythroblast PAS positivity and percentage of BM blasts, percentage of BM erythroblasts, dyserythropoiesis grading, or Hb levels, whereas an inverse correlation was noticed between PAS score values and intercellular bridging (r=-0.23, p=0.0395). A ROC curve analysis allowed us to identify a PAS score value ≥1 (AUC=0.674, p=0.0034) as optimal cutoff to discriminate MDS patients from non-clonal cytopenias. Considering the most discriminant morphological features for dyserythropoiesis, the weight of both PAS positivity rate and score in the identification of BM dysplasia was lower than that of ring sideroblasts and megaloblastosis, but higher than that of defective hemoglobinisation, nuclear lobulation, multinuclearity, cytoplasmic fraying, pyknosis, and internuclear bridging. Introducing conventional parameters and PAS results significantly improved the specificity of our morphological scoring system.

Summary/Conclusions: The evaluation of BM erythroblast PAS positivity, easy to perform and inexpensive, may be useful in the work-up of patients with suspected MDS, especially if there is only unilateral dysplasia without ring sideroblasts or excess blasts.

E1180
A PHASE 3 RANDOMIZED PLACEBO (PBO)-CONTROLLED DOUBLE-BLIND TRIAL OF DARBEPOETIN ALFA IN LOW OR INTERMEDIATE-1 (INT-1) RISK MYELODYSPLASTIC SYNDROMES (MDS)
U. Platzbecker1, A. Symeonidis2, E. Oliva3, J. Goede4, M. Delforge5, J. Mayer6, R. Coll 18, A. Redondo1, M.C. Del Cañizo16, U. Platzbecker 17, R. Coll 18, A. Redondo 1, M.C. Del Cañizo 16
1Department of Hematology, IRCCS Policlinico San Matteo Foundation, University of Pavia, Pavia, Italy

Background: To evaluate darbepoetin alfa (DAR) in IPSS low/int-1 risk MDS patients, 24 wk of darbopeotin alfa Q3W significantly reduced transfusions and increased HI-E rates with no new safety signals. Most patients met criteria to change to Q2W dosing during the 48-wk OL period, suggesting that Q2W dosing may offer more benefit. The true clinical benefit of darbopeotin alfa may have been underestimated due to the nature of IWG 2006 HI-E criteria and trial design (Hb measured Q3W, dosing rules).

Methods: Patients with MDS per WHO 2008 criteria with IPSS low/int-1 risk, anemia [hemoglobin (Hb)≤10 g/dL], low transfusion burden, no previous treatment with ESAs or biologic response modifiers, and serum EPO<500 mIU/mL were randomized 2:1 to 24 weeks (wk) SC DAR 500 μg or PBO every 3 wk (Q3W), stratified by IPSS, then 48 wk open label (OL) DAR; follow-up is ongoing. Doses were withheld for Hb>12g/dL and decreased if Hb increased by >1.5 g/dL in 3 wk. Key endpoints were transfusion incidence and HI-E per IWG 2006.

Results: Randomized patients [N=147] had median Hb of 9.3 (min-max:5.5-10.6) g/dL and median baseline EPO of 69 (min-max:4.3-497) mU/mL. WHO classification was RA-RS in 21%, RARS in 14%, RARSi in 4%, del(5q) in 9%, RAEB-1 in 16%, RAEB in 2%, and MDS-U/unknown:2%. Transfusion incidence wk 5-24 was significantly reduced with DAR [DAR:36.1% vs PBO:59.2%, p=0.008]. In the 48-wk OL DAR period, 50.8% of patients had transfusions. More DAR patients achieved HI-E in the double blind period [DAR:14.7% (11/75 evaluable) vs PBO:0% (0/35 evaluable), p=0.016]. In the 48-wk OL DAR period, 34.7% (34/88) of patients achieved HI-E. Improved HI-E and transfusion responses were seen with more favorable status for IPSS-R but not IPSS. In the 48-wk OL DAR period, dose frequency increased from Q3W to Q2W in 81% of patients; doses were held/reduced frequently. Safety results from this trial were consistent with the previous DAR phase 2 MDS trial, with similar AML rates in PBO and DAR arms.

Figure 1.

Summary/Conclusions: In this phase 3, randomized, double-blind, PBO-controlled trial in anemic IPSS low/int-1 risk MDS patients, 24 wk of darboptoeitin alfa Q3W significantly reduced transfusions and increased HI-E rates with no new safety signals. Most patients met criteria to change to Q2W dosing during the 48-wk OL period, suggesting that Q2W dosing may offer more benefit. The true clinical benefit of darboptoeitin alfa may have been underestimated due to the nature of IWG 2006 HI-E criteria and trial design (Hb measured Q3W, dosing rules).
Background: Lenalidomide (LEN) is the first choice of treatment in low risk MDS patients with isolated del(5q) (MDS-del(5q)) and transfusion dependency (TD). Most of the low risk MDS-del(5q) patients diagnosed with anaemia and independent of transfusions developed TD or needed treatment for symptomatic anaemia early after diagnosis (median of 20 months, abstract 3180.ASH, 2016). LEN directly targets the del(5q) clone improving anaemia, quality of life and survival in these subset of patients. For these reasons, the use of LEN in patients with del(5q), anaemia and not TD seems to be very attractive. However, data about the use of LEN in MDS 5q- patients and transfusion independency (TI) are scanty, some retrospective studies suggest a benefit with the early use of LEN in this setting, but there is not already available any prospective and randomized study to confirm this likely advantage.

Aims: Our aims were to analyze efficacy and safety at week 12 of treatment with LEN vs Placebo in this setting of low risk MDS del(5q) patients with anaemia and not in TD at diagnosis.

Methods: From 2010 to 2017, 47 patients have been included in the Sistran-Rev trial, a phase III, multicenter, randomized and double-blind study with LEN (5mg/day) vs placebo [2:1 randomization] in Low – Int-I risk (IPSS) MDS del(5q) patients with anaemia but TI. Preliminary results of efficacy (according to the IWG 2006 criteria for erythroid [Hi-ER] and cytogenetic response [CyR]) and safety have been analyzed at week 12. Progression disease (DP) in the trial was defined as the development of TD.

Results: Main clinical characteristics are summarized in table 1, 85% were females, median age was 72 years (37-89) and most of patients (95%) had del(5q) as the only cytogenetic abnormality. Among 47 patients, only 38 were evaluable at week 12 (6 out of 38 discontinued the study; 3 due to DP, 1 due to toxicity and 1 for unknown reasons), 7 patients are currently receiving the first 12 weeks of treatment and 2 patients were excluded (screening failures). Regarding efficacy (w12), data from 36 patients were available. Hi-ER was observed in 14/36 patients (39%), minor Hi-ER (Hb increased<1.5g/dL) in 4/36 (11%), stable disease in 15/36 (42%) and PD (transfusion dependency) in 3 (8%). CyR was available in 30 patients: complete CyR was obtained in 12 (40%), partial CyR in 6 (20%) and no CyR in 12 (40%) patients. Safety information in 38 patients demonstrated that most patients (87%) developed any adverse events (AE) while only 42% of these were relevant (G3-4). Most G3-4 AE were hematological (neutropenia 38%) being non-hematological only in 5%. Seven serious AE were reported in 5 patients: vestibular neuritis, congestion, pericardial effusion, pulmonary infection and chronic obstructive pulmonary disease exacerbation. All SAE were not related with the drug of the study (LEN/Placebo).

Summary/Conclusions: In this study we confirm a high rate of erythroid and cytogenetic responses early after treatment with an adequate safety profile in the first 12 weeks of treatment with LEN or placebo.

MYELODYSPLASIA-RELATED MORTALITY REMAINS THE MAIN CAUSE OF DEATH ALONG DIFFERENT GROUPS OF RISKS: AN ANALYSIS FROM MDS ARGENTINEAN STUDY GROUP

A. L. Basquiera1, A. Enrico2,*, J. Arbelbide1, E. Nucifora1, M. Iastrebner3, M. Díaz Soler8, G. Alfonso7, M. de Dios Soler8, J. Uriarte1, C. Alonso Caballero1, J.I. Rodríguez1, J.A. Márquez1

1Hematology, Hospital Italiano de Buenos Aires, Ciudad Autónoma de Buenos Aires (CABA), 2Hospital Italiano de La Plata, La Plata, 3Sagrado Corazon, 4Hematology, Hospital Durand, Ciudad Autónoma de Buenos Aires (CABA), 5Hospital Nacional Prof A Posadas, Buenos Aires, 6Hospital Durand, Ciudad Autónoma de Buenos Aires (CABA), 7Hematology, Hospital Nacional Prof A Posadas, Buenos Aires, 8Hospital Curie, 9Instituto de Medicina Experimental (IMECONIC), Ciudad de Buenos Aires, Argentina. 10Laboratorio de Genética Hematológica, Instituto de Medicina Experimental (IMECONIC), Ciudad Autónoma de Buenos Aires (CABA), Argentina.

Background: Myelodysplastic syndrome (MDS) are the most frequent hematological malignancy in elderly patients. The impact of MDS burden over overall mortality remains controversial, moreover, after the incorporation of hypometabolizing agents in the therapeutic armamentarium.

Aims: We aimed to analyze overall mortality and causes of death in our population of patients with MDS.

Methods: A retrospective analysis of patients with MDS reported to Argentinean MDS registry and a previous study from Academia Nacional de Medicina. Causes of death were classified in: acute myeloid leukemia (AML), infections, bleeding, solid tumor, cardiovascular, transplant related mortality (MRT), others and unknown. AML, infections and bleeding were considered as MDS-related mortality. Causes of death were analyzed using cumulative competitive event curves with Gray test and Fine-Gray for proportional hazard regression was used for the multivariate analysis.

Results: From 1981 to 2016, 1040 patients with MDS were recorded; 717 out of 1040 (69%) were diagnosed after 2006. Median age of patients was 70 years (range: 14-96) and most being males (53%). Median follow-up of 25 months (range: 1-170 months) for the surviving patients. The cumulative incidence of overall mortality was 20% at 12 months (95%CI 2-22), 37% at 24 months (95%CI 3-40) and 59% at 60 months (95%CI 5-63). The incidence of overall mortality did not significantly differ along the years of diagnosis (p=0.291) neither according to age group. Multivariate analysis for cumulative incidence of overall mortality found Charlson index (HR 1.38; p<0.001), sex (HR 1.45; p=0.014) and IPSS-R (HR 2.79; p=0.001) as prognostic variables. The main cause of death was AML accounting for 9% at 12 months (95%CI 7-11), 16% at 24 months (14-19) and 25% at 60 months (95%CI 22-28) of mortality by all patients. Infection-mortality and bleeding-mortality were the second and the third cause of death respectively. MDS-related mortality was 16% at 12 months (95%CI 13-18), 29% at 24 months (95%CI 26-32) and 44% at 60 months (95%CI 40-48); this incidence was not different by year of diagnosis. MDS-related mortality remained the main cause of death in all IPSS-R groups and in all Charlson index categories. Multivariate analysis for cumulative incidence of MDS-mortality found Charlson index (HR 1.29; p=0.02), IPSS-R (HR 2.88; p<0.001) and sex (HR 1.47;p=0.03) as independent variable. Age (p=0.034) and IPSS-R (p<0.001) were associated with AML-related mortality. A total of 56 patients underwent autologous transplant; cumulative incidence of MRT for all cohort was 0.5% at 12 months (95%CI 0.2-1.2) and 1.4% at 24 months (95%CI 0.8-2.4). Only male sex was associated with a higher cumulative incidence of mortality by solid tumor (p=0.001) and a Charlson index ≥2 was associated with higher cumulative incidence of cardiovascular mortality (p=0.021).

Summary/Conclusions: In this large cohort of patient with MDS we demonstrate that MDS-related causes are the leading cause of death along all IPSS-R groups. The absence of difference in mortality along the years of diagnosis highlights the necessity of better treatments for these patients.

E1183

PROSPECTIVE STUDY OF FLOW CYTOMETRY OF BONE MARROW IN 105 CONSECUTIVE PATIENTS WITH CYTOPENIA AND SUSPICION OF MYELODYSPLASTIC SYNDROME: STRONG CORRELATION WITH RISK OF AML-EVOLUTION AND SURVIVAL

F. Marco De Lucas1, 2,*, Z. Diez Gallarreta1, B. Blázquez1, P. Iesu1, B. Dávila1, C. Barrenetxea1, A. Blanco1, B. Barreira2, S. Herráez3, I. Capell1, I. Leal1, J. Uriarte1, C. Alonso Caballero1, J.I. Rodríguez1, J.A. Márquez1, 1Hematologia, 2genetica, Hospital Universitario Basurto, 3facultad De Medicina Upv, Bilbao, Spain

Background: Diagnosis of myelodysplastic syndromes (MDS) remains a challenge, specially in patients with scant displastic morphology features and/or in the absence of cytogenetic changes. Multiparametric flow cytometry (MFC) findings have been recognized as a co-criterion for the diagnosis of MDS and have also demonstrated prognostic value in some studies. Nevertheless, this diagnostic tool is not fully implemented for the study of MDS in many centers and data from real life out of investigational studies are few.

Aims: To prospectively assess the value of MFC in the diagnosis of MDS in our center and correlate its findings to the clinical outcome of patients in terms of overall survival, transfusional needings, risk of hospitalization and evolution of myelodysplasia in elderly patients.

Methods: We studied bone marrow samples from 105 consecutive patients submitted to our hospital between January 2013 and April 2015 because of one or more cytopenia and suspicion of MDS. Cytomorphology of every sample...
was evaluated by at least two morphology experts and a consensus diagnostic of MDS-confirmed, MDS-suspected or MDS-excluded was emitted. MFC was performed applying at least five-colour staining and a numerical score was calculated for every patient following criteria defined by Ogata et al (Blood. 2006 Aug 1;108(3):1037-44), with a score ≥2 suggesting MDS. Conventional karyotype and FISH employing probes to detect usual 5q-, 7q-, +8, 20q- and del(7q) cytogenetic abnormalities were performed. Results: Median age of the patients was 73.5 y/o. Patients presented with anaemia in 88% (84%), neutropenia in 36% (34%) and thrombocytopenia in 49% (47%). Cytomorphology was reported as MDS-confirmed (60 pts), MDS-excluded (22) or MDS-suspected (23). MDS subtypes were Multilineage Dysplasia (23), Unilineage Dysplasia with Ring Sideroblasts (9), del5q Syndrome (3) and Unclassified (2). 4 pts being diagnosed of CML. MFC score was MDS-suggestive in 56 cases, MDS-notch suggestive (36) and in 13 cases its use was precluded because of morphology findings. Considering cytomorphology as gold standard, MDS was diagnosed in patients with MDS-suspected but MFC score was MDS-confirmed (77%), specificity 88%, with positive and negative predictive values of 96% and 56% respectively. Furthermore, MFC score showed a significant correlation with single morphologic findings of granulocytic (p<0.001), erythroid (p=0.001) and megakaryocytic dysplasia (p=0.002), and a trend to a significant association with del7q by FISH (p=0.085). In the subset of patients with MDS-suspected but not confirmed by morphology, the presence of a MFC score ≥2 was significantly associated with a poorer overall survival (log-rank p=0.012), with all MFC score =2 patients alive after a median follow-up of 35 months. There was also a trend to statistical association between MFC score >2 and overall survival in the whole series of patients (log rank p=0.053). Interestingly, there was a striking difference in risk of evolution to AML according to MFC findings (log rank=0.013), with a 100% of patients free from this complication in the group of patients with MFC score <2. Summary/Conclusions: MFC analysis of the bone marrow provides useful information in the diagnostic of MDS which can be specially helpful in the subset of patients with inconclusive morphological findings, showing a strong correlation in this group of patients with clinical outcome in terms of risk of evolution to AML and overall survival.

E1184 ECONOMIC IMPACT AND HEALTHCARE UTILIZATION IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY

J. Bell1, A. Galaznik1, E. Farrelly2, M. Blazer2, H.-C. Shih1, A. Raju1, A. Ogbonnaya2, M. Eaddy3, R. Fram1, D. Faller1

1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 2Xcenda, Palm Harbor, United States

Background: Therapy for patients with HR-MDS includes systemic chemotherapy, stem cell transplant (SCT), and supportive care aimed at improving symptoms associated with MDS-related disruption of normal hematopoiesis. However, the economic impact of these interventions over time for HR-MDS patients has not been fully examined. Aims: We evaluated the costs and healthcare utilization (HCU) of US HR-MDS patients treated during routine care. Methods: Newly diagnosed adult HR-MDS patients who initiated first-line therapy were identified from Optum, a large US claims database, between 1/1/08 and 10/31/15. HR status was based on ICD coding: ≥1 inpatient claim or ≥2 outpatient claims with ≥1 HR-MDS (ICD-9 code: 284.7; ICD-10 codes: D46.20, D46.21, D46.22). The first MDS claim served as the index date. Exclusion criteria included: lack of continuous enrollment in medical/pharmacy benefits in the 12 months prior to index date (baseline period), presence of other primary cancer, or receipt of any chemotherapy or SCT during baseline period. MDS-related and non-MDS-related HCU and costs incurred during follow-up were evaluated. MDS-related HCU and costs were medical claims with a primary diagnosis of MDS or MDS-related treatment (ie, MDS chemotherapy as defined by NCCN MDS Guidelines v2.2017 or MDS-directed supportive care which included hydroxyurea, erythrocyte- and colony-stimulating- growth factors and erythrocyte/platelet transfusions) and pharmacy claims for MDS treatment. Proportions of patients with HCU were reported. Costs were calculated as per-patient-per-month (PPPM) costs adjusted to 2015 US dollars and reported as mean (standard deviation [SD]). Patients were a capped payment plan were excluded from the cost analysis. Patients were followed until death, propension score matching or end of study (12/31/2015). Results: 209 treated HR-MDS patients were identified. During the follow-up period, 69.4% of patients had ≥1 inpatient admission, but only 8% of patients had an MDS-related than non-MDS-related admission (Table 1). 56.9% of patients had ≥1 MDS-related and 1 outpatient claim, and non-MDS-related HCU and costs incurred during follow-up were evaluated. MDS-related HCU and costs were medical claims with a primary diagnosis of MDS or MDS-related treatment (ie, MDS chemotherapy as defined by NCCN MDS Guidelines v2.2017 or MDS-directed supportive care which included hydroxyurea, erythrocyte- and colony-stimulating- growth factors and erythrocyte/platelet transfusions) and pharmacy claims for MDS treatment. Proportions of patients with HCU were reported. Costs were calculated as per-patient-per-month (PPPM) costs adjusted to 2015 US dollars and reported as mean (standard deviation [SD]). Patients were a capped payment plan were excluded from the cost analysis. Patients were followed until death, propension score matching or end of study (12/31/2015). Results: 209 treated HR-MDS patients were identified. During the follow-up period, 69.4% of patients had ≥1 inpatient admission, but only 8% of patients had an MDS-related than non-MDS-related admission (Table 1). 56.9% of patients had ≥1 MDS-related and 1 outpatient claim, and non-MDS-related HCU and costs incurred during follow-up were evaluated. The majority of patients had ≥1 physician office visit (91.9%) and other outpatient visits (99.5%). Over the follow-up period, the mean PPPM cost was $17,361 (SD: $19,747) (Table 1) and was higher in Year 1 than in Year 2 ($17,337 [SD: $19,696]) vs $12,076 (SD: $14,135). The majority of costs overall were for MDS-related medical services (10.327 PPPM, SD: $11,050). Between Years 1 and 2, MDS-related medical PPPM costs decreased from $10,557 (SD: $11,164) to $6,530 (SD: $7,406) while non-MDS-related medical PPPM costs remained fairly constant in both years. Chemotherapy and supportive care medical services were the main drivers of differences in MDS-related medical costs, also decreasing from Year 1 to Year 2. Non-MDS-related costs accounted for a smaller portion of the overall medical PPPM costs ($6,124 [SD: $15,158]); and remained relatively similar in Years 1 and 2.

Table 1.

Summary/Conclusions: The economic impact of HR-MDS is considerable, with higher costs incurred within the first year of diagnosis. The decrease in cost between Year 1 and Year 2 was mainly due to decreased MDS-related medical costs. Consistent with this cost trend, healthcare utilization for MDS-related services decreased in Year 1 vs Year 2. As treatment of HR-MDS continues to evolve, economic impact and HCU need to be further investigated in this patient population.

E1185 INTRAVENOUS IMMUNOGLOBULIN IS AN EFFECTIVE TREATMENT FOR CYTOPENIAS ASSOCIATED TO CIRCULATING T-CELL CLONES IN MYELODYSPLASTIC SYNDROMES

L.R. Silverman1, 2, E.P. Demakos2, R. Ochimar-Reissig2, S.C. Navada2, L.R. Silverman2

1Hematology, ASST Spedali Civili di Brescia, Brescia, Italy, 2Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, United States

Background: Myelodysplastic syndrome (MDS) can be associated with immunologic disorders, including autoimmune cytopenias and Coombs positive or negative (C+) hemolytic anemia. Abnormally expanded T-cells can be detected in these patients, possibly contributing to both bone marrow insufficiency and the peripheral cytopenia, and can be another target for therapeutic intervention. Aims: To explore the role of intravenous immunoglobulin (IVIG) as a treatment for immune-related cytopenia in a series of 20 consecutive patients with MDS at a single institution. Methods: T-cell clonal expansion in the peripheral blood (PB) was documented by flow cytometry and PCR. Eighteen patients had a confirmed MDS (16 IPSS lower-risk, LR). Two suspected MDS were designated as idiopathic cytopenia of uncertain significance (ICUS). Reasons for IVIG treatment were chronic hemolysis refractory to corticosteroids (16: 12 LR, 1 higher-risk (HR), 1 ICUS) or pancytopenia (2 LR and 1 HR refractory to standard therapy, 1 ICUS) associated to a T-cell clonal proliferation in the PB. Hematoblogical response was assessed by IVG criteria 2006. Hemolysis response (HLR) included normalization (CR) or a greater than 50% improvement (PR) of LDH, reticulocytes, indirect bilirubin and haptoglobin.

Results: Clinical characteristics are shown in the Table. All patients had a chronic cytopenia and 17 patients (94%) had a monoclonal T-cell population over the follow-up period. In 9 cases the clone was characterized by flow cytometry: 6 had a CD3+ T-cell and 3 had a CD3-/CD16+/CD56+ NK-cell expansion. Associated immunologic disorders were: ITP (4), neutrophil dermatosis (3), inflammatory bowel disease
(3), seronegative arthritis (2), connectivitis (2). One patient with hypoplastic MDS had LGL liver involvement. Coombs test was positive in 4/16 hemorrhage cases. From Jan-’10 to Jan-’17, IVIG was administered at a dose of 500mg/kg once per week, in cycles of 1 to 4 weeks. The ORR was 75% (15/20) to all patients showed an erythroid hematological improvement (HI) (100%), Platelets and neutrophil HI was seen in 50% and 80% of responsive cases, respectively. HLR occurred in 13/16 (81%; 4 CR and 9 PR). Median number of cycles and duration of treatment was 11 and 12 months (mo), respectively. The HLR-CR was stable in 7 patients; 4 relapsed from HLR but subsequently responded by shortening the intervals between administrations of IVIG; 2 were secondary refractory. Eventually, 6 responders became refractory to IVIG. Response was more durable with continuous rather than sporadic dosing. Median time to response was 1 mo. Median duration of response was 39 mo. Corticosteroids were discontinued in 5/10 patients and reduced in 5/10. Adverse events were: 1 palpitations (G1); 1 hypertension (G1). Responders had lower platelet counts (p=0.05), but no other clinical differences compared to non-responders. However, the 5-year OS rate was higher in the responders to IVIG: 53% compared to 30% (p=0.08).

Table 1.

Summary/Conclusions: Treatment with IVIG of C3 hemolytic anemia and pancytopenia associated with T-cell immune-clones and MDS was safe and yielded high rates of durable response on all lineages and on hemolysis. Transfusion independency and reduction/discontinuation of corticosteroids for chronic hemolysis make this drug a valuable option not only in LR but also in HR patients, although a confirmation on larger cohorts is needed. IVIG at intermediate-high dose suppresses proliferation of T-cells and induces immune-regulation. Given the relative rarity of T-cell clones in MDS, further investigational studies are underway to define their pathogenetic role and the mechanism of action of IVIG in this specific subset of patients.

E1186
DEVELOPMENT AND EXTERNAL VALIDATION OF A NEW PATIENT-CENTERED PROGNOSTIC INDEX FOR PATIENTS WITH ADVANCED MEYLODYSPLASTIC SYNDROMES
1Data Center and A Health Outcomes Research Unit, Italian Group for Adult Hematologic Diseases (GIMEMA), Rome, Italy; 2Division of Population Science, Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States; 3Hematology Unit, Sant’Eugenio Hospital, Rome, Italy; 4Division of Hematology, Department of Internal Medicine V (Hematology and Oncology), Innsbruck Medical University, Innsbruck, Austria; 5Department of Medicine I, University Hospital Dresden Carl Gustav Carus, Dresden, Germany; 6Division of Hematology and Bone Marrow Transplantation Unit, Ospedale Policlinico di Veneto Regionale “Armando Businco”, Cagliari, Italy; 7Department of Hematology, Ospedale Aziendale di Lazio, Rome, Italy; 8Division of Hematology, Sant’Eugenio Hospital, Rome, Italy; 9Department of Hematology, Catholic University of the Sacred Heart, Rome, Italy; 10Department of Hematology, University of Cagliari, Cagliari, Italy; 11Institute of Hematology, Catholic University of the Sacred Heart, Rome, Italy; 12Institute of Hematology, Catholic University of the Sacred Heart, Rome, Italy; 13Institute of Hematology, Catholic University of the Sacred Heart, Rome, Italy; 14Institute of Hematology, Catholic University of the Sacred Heart, Rome, Italy; 15Institute of Hematology, Catholic University of the Sacred Heart, Rome, Italy; 16Division of Hematology, Department of Cellular Biotehnologies and Hematology, Sapienza University, Rome, Italy; 17Department of Internal Medicine V (Hematology and Oncology), Innsbruck Medical University, Innsbruck, Austria; 18Department of Medicine I, University Hospital Dresden Carl Gustav Carus, Dresden, Germany; 19Clinical Ematologia, IRCCS AOUM San Martino IST, Genova, Italy; 20Department of Hematology, San Gerardo Hospital, Monza, Italy; 21Department of Hematology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia, Italy; 22Clinica Ematologia, IRCCS AOU San Martino IST, Genova, Italy; 23Department of Hematology, San Gerardo Hospital, Monza, Italy; 24Hematology and Bone Marrow Transplantation Unit, Ospedale Policlinico di Veneto Regionale “Armando Businco”, Cagliari, Italy; 25Department of Hematology, Affiliated Hospital of Liaoning University of Traditional Chinese Medicine, Shenyang, China; 26Academic Medical Center/University of Amsterdam, Department of Medical Psychology, Amsterdam, Netherlands.

Background: The clinical presentation of myelodysplastic syndromes (MDS) is highly variable, and the ability to accurately predict outcomes is critical. Current prognostic systems for these diseases are based on traditional clinical, pathologic and laboratory indicators.

Aims: We aimed to develop and validate a new prognostic index for advanced MDS by including self-reported fatigue severity into a well-established clinical risk classification: the International Prognostic Scoring System (IPSS).

Methods: Untreated patients (n=280) were recruited at the time of diagnosis of advanced MDS from 37 hospitals in nine countries to create the index. The index was then applied to an independent cohort including pre-treated MDS patients from the Dana-Farber Cancer Institute (DFCI) in Boston, Massachusetts (USA: n=189). Patients in both the international and DFCI cohorts were adults with newly-diagnosed intermediate-2 or high-risk MDS (advanced disease on the IPSS). Patients were enrolled regardless of age, comorbidity, performance status and progression. The index yielded high rates of durable response on all lineages and on hemolysis. Trans-dose suppression of proliferation of T-cells and induces immune-regulation. Further investigation of this new index was higher than the IPSS alone in both the development cohort (C-statistic, 0.61 vs 0.57) as well as in the independent cohort including pre-treated patients (C-statistic, 0.58 vs 0.54).

Summary/Conclusions: The IPASS-10 is an additional prognostic tool that might enhance clinicians’ ability to provide more personalized treatment strategies both in untreated and pretreated advanced MDS patients. This analysis offers a model for integration of PROs in prognostic systems for patients with other cancers and advanced illnesses.
Results: Overall, no significant correlation was seen between expression of p53 and degree of fibrosis (p>0.25). However, degree of fibrosis predicted for overall survival in patients with p53 expression (median overall survival of 4 months in patients with both p53 over expression and significant fibrosis compared with median overall survival of 18 months in patients with p53 over expression without fibrosis, p<0.001). In patients who received azacitadine, though the number of significant fibrosis patients and positive for del(5q) was small, an increased overall survival compared with those who did not receive azacitadine (4 months versus 1 month, p=0.002). Azacitadine treatment was not associated with increased survival in patients with p53 expression without fibrosis but these patients did have an overall increased survival compared to those with fibrosis. Since median survival 12 vs 37 months.

Summary/Conclusions: This study confirms that significant marrow fibrosis adversely affects overall survival in patients with MDS, including those with p53 over expression. Patients who received azacitadine had a significant increase in median survival. Although the numbers of patients who received azacitadine were small, this data suggests that patients with fibrosis may benefit from the use of azacitadine and larger and randomized studies should be considered to study this further.

FACS PURIFICATION OF BLAST CELLS IN MDS IMPROVES THE FISH DETECTION RATE FOR DEL(5Q) AND DEL(20Q), BUT NOT FOR DEL(7Q) OR T8
M. Pereira1,2, G. Marques2, J. Lima3, R. Reis3, A. Coelho3, L. Jorge3, S. Pedroso4, L. Ribeiro3, A. Paiva1, F. Rodrigues1,2
1Hematology, ASST Spedali Civili di Brescia, Italy; 2Faculty of Medicine, University of Coimbra, 3Clinical Pathology Department, 4Flow Cytometry Unit, Coimbra University Hospital Centre, Coimbra, Portugal

Background: Prognostication in Myelodysplastic Syndromes (MDS) using validated scores includes the detection of chromosomal aberrations by conventional karyotyping. When the latter is unavailable or unsuccessful, fluorescence in-situ hybridization (FISH) panels can be used. Although panels vary by laboratory, some of the most commonly used probes include the search for monosomy 5 or del(5q), monosomy 7 or del(7q), del(20q) and trisomy 8 (T8). In our lab, FISH was historically performed on the whole unsorted patient sample (Full Sample); since 2015, we have primarily performed the analysis on Fluorescence Activated Cell Sorting (FACS) separated blast cells.

Aims: In this study, we aim to analyze the benefit of using purified samples of blast cells for FISH analysis in MDS, when compared to full mixed cellularity samples.

Methods: We reviewed all samples analyzed in our laboratory between January 1st 2011 and February 28th 2017 in which a FISH panel was performed due to a suspicion of myelodysplasia, using probes for del(5q), del(7q), del(20q) and T8. The proportion of patients positive for the test, as well as the proportion of positive cells within a positive sample, were compared.

Results: We obtained valid results for 328 samples during the relevant time-frame. 39.6% of which were collected from female patients. FISH was performed after FACS in one third of samples (35.1%, n=115), starting in 2015. Considering the overall cohort, nearly a quarter of samples (23.8%) had at least one aberration in the four probes tested in this study. This proportion of aberrations was significantly higher in double in FACS compared to Full Sample (8.5%): FACS patients (33.0%) compared to full sample patients (18.8%, p=0.004). Del(5q) was present in 5.6% of the cohort; however, positivity was 8-fold higher in FACS patients, compared to full sample patients (12.3% vs 1.6%, p<0.001). Considering the percentage of positive cells in each sample, it doubled from 38.7±29.9% in the full sample to 71.8±28.1% after FACS, p=0.08. Del(7q) was similarly present in 5.7% of the cohort; however, in contrast, there were no relevant differences between FACS patients, 4.2% of whom had del(7q), and full sample patients (8.1%, p=NS).

There were, however, differences in the percentage of positive cells within the sample, doubling from 32.1±11.2% in the full sample to 77.6±17.8% after FACS, p<0.001. Del(20q) was similarly present in 5.7% of the overall tested cohort; the asymmetry in results was marked, with a 36-fold higher proportion of positive findings after FACS (18.7%) compared to full samples (0.5%, p<0.001). The percentage of positive cells doubled from 15% in the single positive test in the full sample cohort, to an average of 35.5±22.2% after FACS. Finally, T8 was found in 10.1% of FACS samples, which was unchanged compared to both full and FACS samples, p=NS.

Summary/Conclusions: We found that one quarter of all patients who underwent a FISH panel workup for a suspected diagnosis of MDS presented with aberrations in at least one of the four selected probes, a proportion which was significantly lower (one fifth) when a full sample was analyzed, and significantly higher (one third) in FACS purified blast cells. Although the purification of the sample through FACS doubled the percentage of positive cells within each sample for all four probes, the likelihood of obtaining a positive result for del(7q) and T8 in the cohort was unaffected by the methodology used. In contrast, the use of a sorted sample greatly increased the proportion of positive findings in del(5q) and, especially in del(20q), the two probes for which the basal positivity in full samples was lowest. The clinical value of this increased rate of detection of del(5q) and del(20q) remains unclear, since their prognostic utility has only been established in levels detectable by conventional karyotyping of a full sample.

SUCCESSFUL TREATMENT WITH DANAZOL FOR MYELODYSPLASTIC SYNDROMES AND APLASTIC ANEMIA REFRACTORY OR INELIGIBLE TO STANDARD THERAPY
F. Schimpf1,2, A.M. Pelizzari 1, E. Borlenghi 1, M. D’Adda 1, E. Cerqui 1, D. Marocolo1, G. Rossi1
1Hematology, ASST Spedali Civili di Brescia, Brescia, Italy

Background: The discovery of danazol potential activity on telomere elongation in bone marrow failure has renewed interest in this drug. The treatment of cytopenia in myelodysplastic syndromes (MDS) and aplastic anemia (AA) patients who fail or are ineligible to standard therapies is an unmet medical need; however only dated reports on danazol use in this setting are available.

Aims: We report the results of treatment with danazol in patients with MDS and AA at a single institution.

Methods: From Jun–11 to May–15, danazol was administered to 31 consecutive patients (20 MDS and 11 AA). Criteria for treatment were non-serious AA (8), severe AA ineligible/refractory to immunosuppressive therapy or allogeneic transplantation (3), transfusion dependent (TD) lower risk MDS refractory to red cell transfusions (5), MDS with isolated thrombocytopenia <50x10^9/L (6) or with bone marrow hypoplasia and bicytopenia (3). Diagnosis was defined by WHO 2008 for MDS and according to Camitta (Blood 1975) for AA; response was assessed by IWG 2006 criteria.

Results: The characteristics of the patients are shown in the Table. All MDS patients had low-risk disease according to IPSS and IPSS-R, except 2 and 3 patients respectively. Nineteen patients (12 MDS, 7 AA) received danazol at full dose (600mg daily). A 400mg daily dose was given to 12 patients, due to toxicity (4 MDS, 4 AA) or comorbidities (4 MDS). Median duration of treatment
was 19 months (mo) (1-66) in AA and 6 mo (1-60) in MDS. ORR was 73% and 50%, respectively. Age and hemoglobin levels impacted on response in AA. Hematological improvement was seen on all lines in 92% of cases, with a median time to best response of 3-5 mo on platelets and neutrophils and of 8-12 mo on hemoglobin. Interestingly, duration of response in MDS patients was significantly longer with a danazol dose of 600mg than with 400mg (p<0.001). Conversely, dosing did not impact on response to danazol in AA patients. Grade 2-3 toxicity was significantly higher in AA patients (p<0.05), 60% pretreated with IST. Adverse events included: hepatotoxicity (3 G1, 1 G2, 3 G3), muscle pain/CPK elevation (3 G1, 2 G2), transient renal impairment (1 G1), hypoxia (1 G1). Responders to danazol had a better survival in terms of OS and EFS in both groups (Figure 1).

Figure 1.

Summary/Conclusions: Danazol was proved both effective and safe as treatment of cytopenia in MDS and AA patients refractory or ineligible to standard therapies. The daily dose of 600mg was more effective for MDS patients, whereas a lower dose of 400mg may have a better risk/benefit ratio in AA. Younger AA patients with less severe anaemia were more likely to respond. Danazol use is particularly attractive in thrombocytopenic patients, where responses were rapid, but delayed responses may be expected also on anaemia by using dana- zol for prolonged periods, when tolerated. Response to danazol is also potentially associated to a survival advantage, although these data should be confirmed by larger prospective studies.

E1191

SURVIVAL OUTCOMES IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY

J. Bell1, A. Galaznik1, E. Farrell2, M. Blazer2, H.-C. Shih2, A. Raju2, A. Ogbonnaya2, M. Eaddy3, R. Fram3, D. Fallar4

1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, 2Xcenda, Palm Harbor, United States

Background: MDS is composed of multiple and rare hematological stem-cell disorders, resulting in cytopenias and disease-related complications and deaths. There are no robust trial data comparing the available treatment options for HR-MDS patients; and of the approved drugs, only azacitidine has demonstrated a statistically significant, but modest clinical impact on overall survival (OS).

Aims: We evaluated first-line treatment (1LT) choice and survival outcomes in a US cohort of HR-MDS patients engaged in routine care.

Methods: Newly diagnosed HR-MDS patients who were ≥18 years old and who had initiated 1LT were retrospectively identified from Optum, a large US claims database, between 1/1/2008 and 10/31/2015. HR status was based on ICD-10 codes: D46.20, D46.21, D46.22), or ≥2 outpatient claims with ICD coding: ≥1 inpatient claim with an HR-MDS ICD-9/10 code (ICD-9 code: E58.83). Among patients able to achieve transfusion independence, a trend toward increased 2-year PFS and OS rates was observed, although statistical significance was not reached. Characteristics that contribute to variations in PFS and OS outcomes within the HR-MDS population need further investigation.

E1192

DOSE-CONFIRMATION PK/PD STUDY OF ORAL ASTX727, A COMBINATION OF ORAL DECITABINE WITH A CYTIDINE DEAMINASE INHIBITOR (CDAI) E7727, IN SUBJECTS WITH MYELODYSPLASTIC SYNDROMES (MDS)

1UT MD Anderson Cancer Center, Houston, 2Roswell Park Memorial Institute, Buffalo, 3Cornell University Medical Center, New York, United States, 4Hospital Maisonneuve-Rosemont, Montreal, 5Sunnybrook Medical Center, Toronto, Canada, 6University of Chicago, Chicago, 7Dana Farber Cancer Institute, Boston, United States, 8Princess Margaret Cancer Center, Toronto, Canada, 9Hackensack University Medical Center, Hackensack, 10Massachusetts General Hospital, Boston, 11Medical College of Wisconsin, Milwaukee, 12Astex Pharmaceuticals Inc., Pleasanton, 13Vanderbilt University Medical Center, Nashville, United States

Background: We have previously shown that ASTX727, a combination of oral decitabine and the oral CDAI E7727, emulates the pharmacokinetics of a one hour intravenous decitabine infusion (IV-DAC) in a dose-escalation phase 1 study. (Garcia-Manero. Blood 2016 128:112)

Aims: To confirm pharmacokinetic (PK) and pharmacodynamic (PD) comparability of 20mg/m² IV-DAC administered D1-5 of a 28 day cycle with an entire hour intravenous decitabine infusion (IV-DAC) in a dose-escalation phase 1 study. (Garcia-Manero. Blood 2016 128:112)

Methods: Adult patients with Int-1/int-2 or HR MDS or Chronic Myelomonocytic Leukemia (CMML) were enrolled in a randomized cross-over Phase 2 study. Patients were randomized 1:1 to receive in the first 28 day cycle, either 5 days of IV-DAC or 5 days of ASTX727, followed by a cross-over to the other in Cycle
2. Cycles 3 Forward were with ASTX727. PD were assessed with LINE-1 methylation as measured on bone cells at baseline and days 8, 15, 21 and 28 in cycles 1 and 2. Full PK assessments of ASTX727 were performed on Days 1, 2 and 5 with sparse sampling on Days 3 and 4 and on Day 1 of IV-DAC. Modeling of 5 day exposures of ASTX727 and IV-DAC was created for each patient. Safety and clinical response were assessed on all patients.

Results: 50 patients were randomized, 46 had matched PK and 46 had matched PD sample sets for the first 2 cycles. No significant differences were seen when comparing the randomized sequences for any parameters, so all assessments comparing ASTX727 and IV-DAC were performed independent of sequence. The geometric mean maximum demethylation was 9.9% for ASTX727 and 7.1% for IV-DAC [Ratio of geometric mean AUC of IV-DAC vs ASTX727 = 1.21, 90% CI: 0.80-1.85] with a lower limit of 90% CI of 0.804. The geometric mean AUC for IV-DAC was 161 ng*h/mL. The 5 day total geometric mean of the AUC (ng*h/L) was 769 for ASTX727 and 805 for IV-DAC [(Ratio of geometric mean of ASTX727 and IV-DAC = 0.94, with a lower limit of 90% CI of 0.806). Demethylation Cmax was higher for IV-DAC (189 ng/ml) than after ASTX727 (295 ng/ml) and 5 h (129 ng/ml). The Day 5 adverse events regardless of grade or causality were febrile neutropenia 34%, neutropenia 28%, thrombocytopenia 16%, fatigue 16%, and hypomagnesaemia 18%. There were no reported GI adverse events greater than Grade 2 with ASTX727 regardless of relationship to treatment.

Summary/Conclusions: Patients treated with azacitidine (especially APL patients) at high risk of infection were further analyzed to determine if AZA as a monotherapy was associated with a lower infection risk. No further stratification analysis was done. Based on the analysis, the use of AZA in patients at high risk of infection was not independently associated with a lower infection risk. Further stratification analysis is needed to identify if AZA is associated with a lower infection risk in any specific patient population or subgroup.
suitable, but, at present, its safety is questioned in MDS patients. Furthermore, in clinical practice, danazol, an attenuated androgen, has been reported to have some ability to increase the platelet count in this context (Wattel 1994; Chan 2002).

Aims: To assess efficacy and toxicity of danazol employed to improve severe thrombocytopenia in lower-risk MDS setting.

Methods: We retrospectively reviewed twenty-four patients affected by MDS and treated with danazol for thrombocytopenia. The initial dose was 600mg/day for all patients. The IWG criteria of response (Cheson 2006) were adopted. The outcome was observed every 3 months till 12th month. The overall response rate and the average platelet count or each time of observation were described. Progression free survival was estimated with the Kaplan-Meier product limit method, followed by the logrank test and by the Cox proportional-hazard regression.

Results: Of the 24 patients, 3 patients had a therapy-related MDS. At the starting time of danazol therapy, the IPSS was “low” in 9, “int-1” in 13 and “int-2” in 2 cases respectively; the IPSS-R was “very low” in 2, “low” in 11, “intermediate” in 7 and “high” or “very high” in 4 cases. At baseline in 14 patients the platelet count was lower than 20x10^3/mL, the average was 20x10^3/mL and the maximum value was 38x10^3/mL. The median dose was 600mg (range 200-600) also maintained at least up to 3 months (range 400-600). At 6 and 12 months the median dose therapy was 400mg (range 400-600 and 200-600 respectively). The response rate was 79.1% (19 responders on 24 treated). The average count increased as shown in Figure 1, over 60x10^3/mL after 6 months from the beginning of therapy and so maintained after one year. Only 3 patients lost the response at 187, 600 and 633 days respectively. The median survival was not reached in the presented series, and the probability to maintain the response is over 75% after two years from the beginning therapy in the responder patients (Figure 2). Adverse events recorded were as follows: moderate (grade 3) (with subsequently drug suspension); severe (grade 3) but reversible renal failure in 1 case (the drug was stopped); moderate (grade 1 and 2) increase of serum creatinine in 6 case (with reduction of danazol to 400mg/day in 2 of these); reversible cutaneous rush in 3 cases; amenorrhea in 1 case (the only fertile woman in the series); weight loss and loss of appetite in 1 case, weight gain in 1 woman.

Summary/Conclusions: This series confirms the efficacy of danazol to improve platelet count in the most of patients with severe thrombocytopenia due to lower-risk MDS. In all patients with increased platelet count, the response was clinically significant. The median dose of 600mg should be maintained for at least 3 months to properly assess the effectiveness of therapy and then adjusted according to response and toxicity. The response may not be immediate, but seem to be reachable after 3-6 months of treatment. A responsive patients have short probability to loss the response, that may last for very long time. The toxicity profile of this drug is low. The mechanism of action of danazol in MDS patients remains unclear. Waiting for more information on the efficacy and safety of eltrombopag from the clinical trials in progress, danazol may be a good therapeutic option for these patients.

E1196
TREATMENT PATTERNS IN PATIENTS WITH HIGHER-RISK MYELODYSPLASTIC SYNDROMES (HR-MDS) IN ROUTINE CLINICAL CARE IN THE UNITED STATES (US) – A CLAIMS DATABASE STUDY

J. Bell1,*, A. Galaznik1, E. Farrell2, M. Blazer3, H.-C. Shih2, A. Raju2, A. Ogbonna2, M. Eaddy2, R. Fram1, D. Faller1

1Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge, MA, Xcenda, Palm Harbor, United States

Background: Treatment of patients with HR-MDS includes hypomethylating agents (HMAs) (azacitidine and decitabine), high-intensity induction chemotherapy (IC), and stem cell transplant (SCT). Given the rarity of disease, information available on how these treatments are applied in practice is limited.

Aims: We evaluated the treatment patterns of HR-MDS patients engaged in routine care within the US.

Methods: Newly diagnosed HR-MDS patients who were ≥18 years old were retrospectively identified from Optum, a large US claims database between 1/1/2008 and 10/31/2015. HR status was based on ICD coding: ≥1 inpatient claim or ≥2 outpatient claims with an HR-MDS ICD-9/10 code (ICD-9 code: 238.73; ICD-10 codes: D46.20, D46.21, D46.22). The first MDS claim served as the index date. Exclusion criteria included: absence of continuous enrollment in medical and pharmacy benefits for 12 months prior to index date (baseline period), presence of other primary cancer, or receipt of any chemotherapy or SCT during the baseline period. First-line therapy (1LT) was defined as an MDS-specific treatment (as defined by NCCN MDS Guidelines v2.2017)1 initiated on or after the index date. Patients were followed until death, end of continuous enrollment, or end of study (12/31/2015). For patients with progression to acute myeloid leukemia (AML), treatment pattern evaluation stopped at AML diagnosis.

Results: 335 newly diagnosed HR-MDS patients were identified; 209 (62.4%) were treated with 1LT with treatment initiated within 1 month of diagnosis (median: 17 days, interquartile range [IQR]: 9, 35). A higher proportion of untreated patients (n=126) was ≥75 years of age (71.4% vs 61.5%) and had certain comorbidities at baseline (congestive heart failure, 23.0% vs 16.3%; renal disease, 24.6% vs 16.3%; diabetes 31.0% vs 23.4%, diabetes with end organ failure, 16.7% vs 8.1%) than treated patients. For treated patients, 1LT with azacitidine predominated in 68.9% of patients (n=184), followed by decitabine in 20.6% of patients (n=43), and immunomodulators (lenalidomide or thalidomide) in 8.1% of patients (n=19) (Figure 1). A patients had only SCT and an additional 14 had SCT at some point during follow-up. With regard to HMA therapy, median duration was 4.5 months (IQR: 2.6, 9.5) for azacitidine and 4.8 months (IQR: 2.1, 11.6) for decitabine. A greater proportion of decitabine-treated patients...
received supportive care with colony-stimulating factors (CSFs) (39.5% vs 28.5%) and either erythrocyte or platelet transfusions (69.8% vs 57.6%) during 1LT vs azacitidine-treated patients. Second-line therapy (2LT) was administered to 30 (14.4%) patients; the HMAs again predominated in 63.3% of patients (n=19). Of patients not receiving 2LT, 65 (31.7%) progressed to AML; 47 (22.9%) had <30 days of follow-up due to proximity to end of study (38 [80.9%] of these were on 1LT at end of study data). 33 (16.1%) continued to receive some supportive care and, 21 (10.2%) died.

Summary/Conclusions: Most HR-MDS patients treated in routine care are treated according to guidelines, with the HMA, azacitidine, predominating. Underlying comorbidities and older age may influence whether or not to treat HR-MDS patients with 1LT. For treated HR-MDS patients, duration of 1LT did not differ with azacitidine and decitabine. However, use of certain MDS-related supportive care treatments varied by choice of HMA, with more decitabine-treated patients receiving CSFs and transfusions. Further research is needed to determine how these factors influence both clinical outcomes in a HR-MDS population.

E1197
APPRECI8: A PIPELINE FOR PRECISE VARIANT CALLING INTEGRATING 8 TOOLS
S. Sandmann1, M. Karimi2, A. de Graaf3, B. van der Reijden3, E. Hellström-Lindberg4, J. Jansen3, M. Dugas1
1Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden, 2Institute of Medical Informatics, University of Münster, Münster, Germany, 3Department of Medicine Huddinge, Karolinska Institutet, Stockholm, Sweden, 4Laboratory Hematology, RadboudUMC, Nijmegen, Netherlands

Background: For the use of next-generation sequencing in clinical routine (42,322bp) was analyzed. Validation was performed by re-sequencing on the Roche 454. In all cases the same target region consisting of 19 genes on Illumina HiSeq. The second test set covered 89 MDS patients, sequenced to train our pipeline, we analyzed two data sets covering data of 54 myelodys-

Methods: We developed appreci8, a variant calling pipeline combining the output of eight open-source variant calling tools: GATK HaplotypeCaller, Platypus, VarScan, LoFreq, FreeBayes, SVNver, SAMtools and VarDict. The pipeline performs several steps of filtration, including a final automatic characterization of all reported calls as artifacts, likely polymorphisms and likely mutations. To consider variant calling results in clinical routine, it consistently features lowest PPV as well (set 1: 0.99, set 2: 0.94). The PPV of the appreci8 output for both training sets is higher compared to each of the individual tools. Analysis of the independent test set 1 leads to comparable results. Sensitivity of the individual tools sensitivity ranges between 0.82 and 0.99, while PPV ranges between 0.02 and 0.91. Combining the output of all variant calling tools leads to sensitivity of 1.00 and PPV of 0.02. However, application of appreci8 leads to variant calling results with sensitivity of 0.98 and PPV of 0.99. To test the robustness of our approach, we analyzed Roche 454 data, although the pipeline was exclusively trained on Illumina data. Regarding the individual tools sensitivity ranges between 0.91 and 0.99, while PPV ranges between 0.07 and 0.68. By combining the output of all variant calling tools, sensitivity increases to 0.99, while PPV is 0.05. Application of appreci8 leads to sensitivity of 0.98 and PPV of 0.76.

Summary/Conclusions: To consider variant calling results in clinical routine, it does not seem appropriate to rely on the output of a single tool only. Instead, combining the output of several tools and applying a set of filters as it is done by our appreci8 pipeline leads to results with both high sensitivity and PPV. Nonetheless, variant calling results should, especially at allelic frequencies below 20%, always be viewed with criticism.

E1198
COMPARISON OF ADMINISTRATION OF HYPOMETHYLATING AGENTS EFFICIENCY OF ALLOGENEIC SCT IN ELDERLY PATIENTS WITH ADVANCED MDS
J. Cermak1,*, A. Vitek1, J. Maalouf-Soukupova1, M. Markova-Štastna1, P. Cetkovsky1, P. Matouš1
1Clinical Hematology, Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: Hypomethylating agents (HMA) have been introduced as a promising agent in the treatment of elderly patients with advanced myelodysplastic syndromes (MDS) leading to a response in approximately 50% of patients. However, most of the patients relapse and estimated years survival is below 10%. Stem cell transplantation (SCT) still represents the only curative treatment even in elderly patients with advanced MDS and it is connected with long-term survival in 35-40% despite relatively high risk of transplant related mortality (25-30%).

Aims: The aim of the study was a retrospective analysis of results of the treat- ment of 59 elderly patients (50 years of age or older) with MDS RAEB-2 or with acute myeloid leukemia with multilineage dysplasia with less than 30% of bone marrow blasts (MDS RAEB-T according to the FAB classification) who received either HMA or underwent allogeneic SCT.

Methods: In the HMA group, 34 out of total 38 patients received azacitidine (Vidaza®) in the dose of 75mg/m2x7 every 28 days and 4 patients were treated with decitabine (Dacogen®) in the dose of 20mg/m2x5 every 28 days. Median number of cycles administered was 10.4 (range 3-31). An age and diagnosis matched transplanted group consisted of 21 patients, 9 patients were transplanted upfront, 12 patients were pretreated either with combination chemotherapy (10 patients) or with HMA (2 patients) and achieved CR prior to SCT. Ten patients received myeloablative conditioning and 11 patients were transplanted after reduced conditioning regimen.

Results: A hematologic response to HMA (CR, PR, hematologic improvement) was observed in 22 out of 38 patients in HMA group (57.9%). CR was achieved in 10 patients (31.8%). In SCT group, engraftment was reached in 20 out of 21 patients, 11 patients died after SCT (6 on complications related to SCT, 5 patients relapsed). No difference was observed between both groups in 2 years estimated overall survival (OS), (42% for SCT vs 36% for HMA), a sig- nificant difference in favour of SCT was present in estimated 3 years and 5 years OS (42% and 38% for SCT vs 9% and 4% in HMA group, P=0.001). Median OS was 18.7 months in HMA treated group compared to 42.6 months in SCT group (P=0.02). In a recent analysis performed at 48 months after start- ing the treatment, 2 patients treated with HMA (5.3%) and 9 patients treated patients (42.8%) were alive, 23 patients in HMA group and 6 patients in SCT group relapsed. No significant differences in results and adverse effects of treatment were observed between patients aged 50-60 years and those older than 60 years in both HMA and SCT groups.

Summary/Conclusions: Our results confirm previous observations showing that despite a promising effect of HMA resulting in hematologic response in more than 50% of elderly patients with advanced MDS, allogeneic SCT still represents the only potentially curative treatment connected with long-term survival in a significant number of patients even in elderly MDS patients.

A MULTICENTER, OPEN-LABEL, PHASE I CLINICAL STUDY: SAFETY, EFFICACY, AND PHARMACOKINETICS OF ORAL RIGOSERTIB IN JAPANESE PATIENTS WITH RECURRENT/RELAPSED OR REFRACTORY MYELODYSPLASTIC SYNDROMES

K. Ishizawa1,2, K. Usuki3, K. Ando4, Y. Ueda5, T. Kiguchi6, N. Uko7,8, Y. Onishi9, H. Iida9
1Hematology and Cell Therapy, Yamagata University Faculty of Medicine, Yamagata, 2Department of Hematology and Rheumatology, Tohoku University Hospital, Sendai, 3Department of Hematology, NTT Medical Center Tokyo, Tokyo, 4Department of Hematology and Oncology, Tokai University School of Medicine, Isehara, 5Department of Hematology/Oncology, Kurashiki Central Hospital, Kurashiki, 6Department of Hematology, Chugoku Central Hospital, Fukuyama, 7Department of Palliative Care Medicine, Saga Medical Center Koseikan, Saga, 8Department of Hematology, National Hospital Organization Kyushu Cancer Center, Fukuoka, 9Department of Hematology, National Hospital Organization Nagoya Medical Center, Nagoya, Japan

Background: Rigosertib, a novel phosphoinositide 3 kinase pathway inhibitor, induces G2/M arrest leading to the apoptosis of cancer cells and myeloblasts and is safe for and well tolerated by pts with low, intermediate-1, intermediate-2, or high-risk myelodysplastic syndromes (MDS).

Aims: The aims of the study were to assess the safety, efficacy, and pharmaco-kinetics of oral rigosertib and to determine the recommended dose (RD) for a Phase II clinical study in Japanese pts with recurrent/relapsed or refractory MDS.

Methods: We conducted a multicenter, open-label, Phase I clinical study of oral rigosertib. The key eligibility criteria were as follows: recurrent/relapsed or refractory MDS; age ≥20 or older; ECOG PS of 0 to 2; and no major organ dys-functions. Rigosertib (280 and 560mg BID) was administered orally in one 21 day cycle (up to cycle 6) that consisted of the 14-day, twice-daily, oral admin-istration term, followed by 7-day monitoring. The primary endpoint was dose-limiting toxicity (DLT). The secondary endpoints were 1) safety as assessed with adverse events (AEs) and laboratory results, 2) efficacy as assessed with the International Working Group 2006 criteria, and 3) pharmacokinetics.

Results: Between March 2013 and November 2014, 6 male and 3 female pts (median age: 70; range 52-80) were enrolled. ECOG PS was 0 in 7 pts and was 1 in 2 pts, and 3 and 6 pts were eventually assigned to the 280 and 560mg BID arms, respectively. According to the FAB classification, 4, 2, 2, and 1 pts were categorized to RAEB, RARS, RA, and RAEB-1, respectively. The prog-nostic factor according to IPSS was Int-1 risk in 4 pts (1 and 3 pts in the 280 and 560mg BID arms, respectively) and was Int-2 in 5 pts (2 and 3 pts in the 280 and 560mg BID arms, respectively). DLT occurred in 1 pt in the 280mg BID arm and in 2 pts in the 560mg BID arm: the former consisted of type 2 dia-betes and grade 4 delirium, and the latter grade 5 urinary tract infection and grade 3 prolonged QT interval. Therefore, the RD for a Phase II clinical study in Japanese pts was determined to be 560mg BID. On day 11 of treatment, 1 pt in the 560mg BID arm died of grade 5 urinary infection whose relationship with the investigational drug was rated to “Definite”. The presumed cause of death was septic shock caused by a urinary tract infection. Six pts developed mean counts of leukocytes, neutrophils, lymphocytes, and reticulocytes in the 280mg BID arm did not decrease along with increases in the number of cycles delivered but decreased slightly in the 560mg BID arm. Any changes of note were not found in other hematological items. One case of grade 3 neutropenia developed in the 280mg BID arm, and 1 case each of grade 3 laboratory abnor-malities—increased alanine aminotransferase, increased aspartate aminotransferase, prolonged QT interval, neutropenia, and decreased hemoglobin—occurred in the 560 BID arm. The hematological remission rate was 11.1% (1 narrow CR; 1/9 pts), and the hematological improvement rate was 11.1% (1 HI-; 1/9 pts). Among the PK parameters, inter-individual variability was observed in the Cmax and AUC. However, changes suggesting the accumulation of rigosertib during repeated oral administration (e.g., consistent increases in the Cmax and AUC) were not found.

Summary/Conclusions: The present chemotherapeutic regimen of oral rigosertib was well tolerated. Our study indicates that the RD for a Phase II clinical study is 560mg BID in Japanese patients with recurrent/relapsed or refractory MDS.

NON-OVERLAPPING PROMOTER AND SUPERENHANCER DRIVEN PROCESSES SUPPORT MYELOMA CELL GROWTH AND SURVIVAL VIA DISTINCT REGULATORY AXES

M. Fucinati1,2, C. Lin3, M. Samur1, H. Avet-Loiseau3, K. Anderson1, J. Bradner4, N. Minna5
1Dana Farber Cancer Institute, Boston, 2Baylor college of medicine, Houston, United States, 3Cancer research center, Toulouse, France, 4Novartis, Boston, United States

Background: We have previously reported that E2F1 and its heterodimerization partner DP1 promote MM tumor proliferation both in vitro and in vivo; and observed an inverse correlation between their expression and patient survival suggesting a role in MM pathogenesis. Moreover, E2F2 functional impairment by a dimerization inhibiting stapled peptide significantly affects myeloma tumor cell growth while sparing effect on normal components of bone marrow as well as normal plasma cells, suggesting an E2F2 dependency in MM cells.

Aims: In this study, our aim was to defined the regulatory landscape of E2F in MM to better understand how E2F1 and DP1 drive myeloma cell proliferation; and to define the relationship between promoter proximal transcription factor-associated gene expression and super-enhancer-driven transcriptional programs.

Methods: We integrated genetic perturbation with functional omics to define E2F role in MM. Global occupancy of E2F1 and DP1 in MM was evaluated by Chip-seq analysis. E2F1 and DP1 genomic localizations were then integrated to MM reference epigenome. Enhancers and super-enhancers were mapped using Roadmap data and calculated using bamliquidator (github.com/bradnerlab/pipeline). Read densities were calculated using bamliquidator (github.com/bradnerlab/pipeline/wiki/bamliquidator).

Results: Integration of E2F1 and DP1 genomic localization to MM reference epigenome revealed specific co-occupancy of the factors at promoters of active genes marked by H3K4me3, with a strong positive correlation between E2F and RNA PolII occupancy at H3K4me3 peaks. Road map peaks were marked by H3K27ac and BRD4, showed virtually no E2F binding. Prompt by these observations, we explored the transcriptional and functional interrela-relationship between E2F and BETs to identify their individual contribution to event-ual functional effect in MM. Unbiased hierarchical clustering revealed distinct regulatory axes for E2F and BETs, with E2F predominantly localized to active gene promoters of growth/proliferation genes and BETs disproportionately at enhancer- regulated tissue specific gene expression confirming that these factors estab-lish distinct target gene programs. At the extremes, we found less than 10% of genes were among the top 500 in BRD4 enhancer signal (i.e. SE-regulated) and top 500 E2F promoter signal. We hypothesized that the presence of BETs and E2F in distinct regulatory axes divides active genes in MM into those that can be selectively influenced by BET inhibition or E2F perturbation, but not both. In line with this we have observed that dual E2F and BET inhibition is synergetic for MM cell growth, both in vitro and in vivo.

Summary/Conclusions: In conclusions, our results highlight the existence of non-overlapping promoter and super-enhancer-associated dependencies in multiple myeloma, suggesting a sequestered molecular control that may be perturbed in cancer with potential for development of a promising therapeutic strategy.

ANALYSIS OF THE GENOMIC LANDSCAPE OF MULTIPLE MYELOMA HIGHLIGHTS NOVEL CANDIDATE PROGNOSTIC MARKERS AND DISEASE SUBGROUPS

1Dana Farber Cancer Institute, Boston, 2University of Milan, Milan, Italy, 3Memorial Sloan Kettering Cancer Center, New York, United States, 4Wellcome Trust Sanger Institute, Cambridge, United Kingdom, 5Dana-Farber Cancer Institute, Boston, United States, 6Foundation IRCSS Istituto Nazionale dei Tumori, Milan, Italy, 7European bioinformatics institute, Cambridge, United King-dom, 8National and Kapodistrian University of Athens, Athens, Greece, 9Centre Hospitalier Universitaire de Nantes, 10Center for Cancer Research Nantes- Angers, Nantes, 11Centre de Recherche en Cancérologie de Toulouse, Toulouse, France

Background: In multiple myeloma (MM), next generation sequencing (NGS) has expanded our knowledge of genomic lesions, and highlighted a dynamic and heterogeneous composition. Despite a growing number of cases sequenced, the full potential of NGS studies has not been exploited so far.

haematologica | 2017; 102(s2) | 493

Madrid, Spain, June 22 – 25, 2017
Aims: We used a custom target pulldown (TPD) approach on a large cohort of MM samples at diagnosis, with homogeneous treatment and long follow-up, to further our understanding of the landscape of driver lesions in MM and how this can be used to improve prognostication and disease classification.

Methods: We used a custom-designed SureSelect pulldown strategy (Agilent Biotechnologies) to target 246 genes implicated in MM or cancer in general; 2538 single nucleotide polymorphisms; the immunoglobulin heavy chain (IGH) locus. We sequenced unmatched DNA from CD138-purified plasma cells from 418 patients with a median follow-up of 5.4 years using Illumina HiSeq2000 machines. We applied algorithms developed in-house to detect driver genomic events, filtering out potential artifacts and germline variants. We then ranked each mutation on its likelihood of being oncogenic.

Results: We identified 197 driver events including genes, aneuploidies and IGH translocations (IGH-Tx), median of 6 per patient. Gene mutations where found in >99% of patients. At least one oncogenic mutation of a known driver gene previously identified (KRAS, NHRAS, TP53, FAMM6C, BRAF, DIS3, TPAF3, SPH40, IRS4) was found in 64%, with a long tail of infrequently mutated genes with uncertain significance. Karyotypic class was assigned in 80% of patients, with 9% of hyperdiploid cases also showing an IGH-Tx (mostly t(4;14)). IGH-Tx and aneuploidies dominated the MM genomic landscape, KRAS and NHRAS being the only point mutations present in the 15 most frequent driver events. Multivariate analysis by sparse Cox regression highlighted only four driver events with significant prognostic impact for both progression-free (PFS) and overall survival (OS): t(4;14) (HR 1.88, CI 1.25-1.81), amp(1q) (HR2.63, CI 1.92-3.59), del(17p), del(17p) with monosomy 13 and novel oncogenic copy number changes such as the high level amplification of MAF in 1 case.

Summary/Conclusions: We have developed and demonstrated utility of a reliable workflow for genome-wide copy number assessment that can be implemented using existing targeted short read sequencing data, greatly extending the utility of this technology beyond the identification of driver mutations in patients with haematological malignancy. In the context of myeloma this can be used to report clinically relevant changes including deletions of 1p and 17p, and gains of 1q and 8q, as well as novel numerical chromosome aberrations.

E1202
THE MULTIPLE MYELOMA GENOME PROJECT: DEVELOPMENT OF A MOLECULAR SEGMENTATION STRATEGY FOR RISK STRATIFICATION OF MULTIPLE MYELOMA
1Celgene Corporation, San Francisco, 2Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, 3Dana Farber Cancer Institute, Harvard Medical School, Boston, 4Celgene Corporation, Summit, United States, 5Celgene Corporation, Seville, Spain, 6Centre de Recherche en Cancérologie de Toulouse Institut National de la Santé et de la Recherche Médicale, Toulouse, France, 7Newcastle University, Newcastle, United Kingdom

Background: Segmenting multiple myeloma (MM) into subgroups with distinct pathogenesis and clinical behavior is critical to implement a targeted therapy approach and improve prognostic for patients. Current technologies have elucidated major translocation groups and recurrent copy number changes with varying effects on prognosis. However, minor translocation and mutational groups remain poorly described due to limited sample numbers and small datasets. The availability of multiple sets of high quality genomic data associated with clinical information, cytogenetics, and outcomes provides an opportunity to create an integrative genomic predictor using mutational, chromosomal, and gene expression alterations to develop a classification system to segment MM into therapeutically meaningful subgroups.

Aims: The Multiple Myeloma Genome Project (MGP) is a global collaborative research initiative that aims to define the landscape of genomic and cytogenetic alterations for MM to inform development and deployment of clinically relevant tests that could improve diagnosis, prognosis, and treatment of patients with MM.

Methods: We have established a dataset representing 1766 MM patients for which whole exome sequencing (WES; n=1307), Whole Genome Sequencing (WGS; n=459), and expression data from RNAseq and CNA assays (n=1059) were available. Data were derived from the Myeloma XI trial, DANA-Faber Cancer Institute/Intergroupe Francophone du Myelome, The UAMS Myeloma Institute and the Multiple Myeloma Research Foundation (IA1 – IA9). Data were investigated for genetic abnormalities following preprocessing with standard methods and six clinical datasets. Results: Our analysis is focused on data from newly-diagnosed MM patients (n=1751), which is the majority of our dataset. We have begun to integrate genomic dataset with various correlates. Based on our data, we have at least
VCP (p97) is an ER-associated protein that belongs to the AAA ATPase family. It has a variety of cellular functions including ER-associated protein degradation, autophagy, and aggresome formation. Recent studies have elucidated emerging roles of VCP and its potential as a therapeutic target in several cancer subtypes including multiple myeloma (MM).

Aims: We screened approximately 2,000 small molecular compounds to find novel small compounds that suppress growth of MM cell lines, and found that OSSL_325096 has strong anti-proliferative activity on MM cell lines (IC50 100-500µM). In this study, we evaluated anti-MM activity of OSSL_325096 through VCP inhibition, in an ATP-competitive manner.

Methods: OSSL_325096 were purchased from Princeton BioMolecular Research, Inc. (Princeton, NJ, USA). His-tagged human VCP (hVCP) cDNA was cloned and utilized to generate hVCP protein in vitro as previously described (Chou et al., PNAS, 2011, vol. 108(12): 4834-4839) to evaluate the VCP inhibition by OSSL_325096. For in vivo analysis, MM xenograft model mice were intraperitoneally administered with vehicle or 50mg/kg of OSSL_325096 twice a week.

Results: OSSL_325096 inhibited proliferation of MM cell lines, including one bortezomib-resistant cell line (Figure 1). OSSL_325096 induces apoptosis in these cell lines and primary MM cells purified from patients but not in PBMCs from healthy donors. OSSL_325096 treatment leads to accumulation of poly-ubiquitinated proteins, cleavage of caspase-3, and up-regulation of CHOP in MM cell lines (Figure 2), suggesting this compound induces caspase-mediated apoptosis and ER-stress in MM cells. OSSL_325096 has a chemical structure similar to several known VCP inhibitors. Therefore, to evaluate the role of VCP in MM cell lines, we next performed knockdown of VCP. Knock-down of VCP induced apoptosis in MM cell lines, accompanied with accumulation of poly-ubiquitinated protein. In-silico protein-drug binding simulation suggests possible binding of OSSL_325096 to the ATP binding site in VCP’s D2 domain. Indeed, in the cell-free ATPase assay, OSSL_325096 showed dose-dependent inhibition of VCP’s ATPase activity (Figure 3). The IC50 of OSSL_325096 on ATPase activity was 7-10µM, while IC50 of cell survival in MM cells was 0.1-0.8µM, suggesting that OSSL_325096 may have other anti-myeloma function in addition to VCP inhibition. RNA-sequencing of MM cells treated with OSSL_325096 revealed that several pathways including mTRO1 signaling, TNFα signaling, and unfolded protein response, were activated by OSSL_325096. Finally, OSSL_325096 was administered to xenograft mice with MM cell tumors and inhibited the tumor growth in vivo (Figure 4).

Summary/Conclusions: The present data suggest that OSSL_325096 may be novel anti-myeloma drug candidate partially through its direct inhibition activity of VCP.

E1206
A NOVEL PREDICTIVE MODEL COMBINING LINCRNAS AND PROTEIN CODING GENES IN MULTIPLE MYELOMA
M. Samur1,2, A. Gulla1, M. Fulciniti1, R. Szalati1, A. Akatsur Samur1, M. Shamas1, F. Magranege1, S. Miniville1, K. Anderson1, G. Parmigiani1, H. Avet-Loiseau2, N. Munihi1

Background: We have established the largest repository of molecular profiling data in MM associated with clinical outcomes. Integrated analyses are enabling generation of clinically meaningful disease segments associated with differing risk that will inform development of clinical tests. ThempP intends to build a global network by expanding collaboration with global MM centers to incorporate additional datasets through current and new collaborations.

*The first 6 authors share co-first authorship. The last 3 authors share co-senior authorship.
Background: RNA has diverse sets of regulatory functions and a recent analysis of a large RNA repertoire has identified a large number of non-coding transcripts. One of which, long intergenic non-coding RNA (lincRNA) with transcripts longer than 200 nucleotides, are located between the protein coding genes and do not overlap exons of either protein-coding or other non-lincRNA genes. lincRNA genes have been considered to provide regulatory functions, however, their precise role and function remains unclear. Aim: Here we have studied lincRNAs using uniformly treated patients to show their impact on survival outcome in MM. Methods: We performed RNA-seq on CD138⁺ MM cells from 360 newly-diagnosed patients and 18 normal plasma cells (NPM) and analyzed for lincRNA and protein coding genes. MM patient data included morphologic characteristics, cytogenetic and FISH as well as clinical survival outcomes were also analyzed and correlated with lincRNA data. Results: Using only the expressed lincRNAs, we developed a risk prediction signature from EFS at 4 years was 53% (95% CI, 45.1% to 63.1%) and 32.6% (95% CI, 25.1% to 42.2%), and OS at 4 years was 93.2% (95% CI, 88.9% to 97.6%) and 71.1% (95% CI, 62.9% to 80.3%) in our patients having a low or high risk score, We then compared lincRNA signature with known expression signatures and improved the risk prediction for known expression signatures dramatically. We validated our results on independent large cohort with newly diagnosed MM RNAseq data. When applied to patient cohort separated by other risk categorization including minimal residual disease status (MRD), cytogenetic risk status (del17p, t(4;14) and t(14;16)) and International Staging System (ISS), lincRNA signature was able to further identify patients with significant differential survival outcomes. Summary/Conclusions: In summary, we report that lincRNAs have an independent effect on survival outcome in MM and provides rationale for its use in risk stratification as well as to understand biological impact. Combined prediction with other risk features improve the prediction power and helps to create better classification in MM.

DYNAMIC IMMUNOHISTOCHEMICAL EVALUATION OF MARROW MICROENVIRONMENT MODIFICATIONS IN PATIENTS WITH SMOLDERING MYELOMA

A. Mussetti1,*, A. Pellegrinelli2, N. Cieri3, M. Pennisi3, G. Garzone2, F. Dominoni2, A. Cabras2, P. Corradi2, V. Montefusco1

1Hematology and Adult Bone Marrow Transplantation, 2Department of Pathology and Laboratory Medicine, Fondazione IRCCS Istituto Nazionale Tumori, 3Università degli Studi di Milano, Milano, Italy. 4Department of Oncology and Hemato-oncology, Università degli Studi di Milano, Milano, Italy.

Background: In most cases, multiple myeloma (MM) is preceded by an asymptomatic status known as monoclonal gammopathy of unknown significance (MGUS) or smoldering multiple myeloma (SMM). The mechanisms of progression from SMM to MM are not well understood. Despite an increasing evidence of an immune system dysregulation in the setting of MM characterized by a tumor tolerating microenvironment, the immunosurveillance profile in the setting of SMM has never been investigated.

Aim: Our aim was to identify a progressive dysregulation of marrow microenvironment in sequential samples of SMM patients. Secondly, we hypothesized a difference in the microenvironment of the patients with progressed SMM versus those with stable SMM.

Methods: We performed extensive immunohistochemical analysis of bone marrow samples of 16 patients affected by SMM at time 0 (16 samples) and at +24 months (+/- 4 months, 16 samples). Half of these patients developed MM at 24 months (progressed SMM), the other half remained asymptomatic (stable SMM) at 24 months (+/−4 months, 16 samples). We aimed to characterise the immune landscape in the bone marrow of SMM and MM patients following ASCT, and to investigate the impact of residual disease on immune cell population. Results: At time 0, we found in SMM patients increased CD4+Foxp3− CD8 effectors, but high co-expression of LAG-3 suggests that these cells are functionally suppressed. Patients with larger amounts of residual disease have higher numbers of cytotoxic CD4 and CD8 cells, and the co-expression of the checkpoint protein LAG-3 may provide a rationale for blockade of this pathway.

Summary/Conclusions: The BM of MM patients following ASCT contains activated CD4 and CD8 effectors, but high co-expression of LAG-3 suggests that these cells may be functionally suppressed. Patients with larger amounts of residual disease have higher numbers of cytotoxic CD4 and CD8 cells, and the co-expression of the checkpoint protein LAG-3 may provide a rationale for blockade of this pathway.
Background: Bone marrow stromal cells (BMSCs) interact with multiple myeloma (MM) cells in the bone marrow, and also create a permissive microenvironment for MM cell growth and survival. Recent evidence indicated that MM cell-BMSC interactions are mediated by extracellular vesicles (EVs) plays an important role in the MM microenvironment.

Aims: In this study, we investigated the biological property of EVs and miRNAs in EVs derived from BMSCs, aiming to establish the emerging strategies to target MM microenvironment to prevent tumor growth and spread.

Methods: Bone marrow samples were obtained from MM patients (age 56 to 82, n=20) and monoclonal gammopathy of undetermined significance (MGUS) patients (age 44 to 82, n=13) in accordance with the Declaration of Helsinki and using protocols approved by the research Ethics Committee of Tokyo Medical University (IRB No. 2648), and BMSCs derived form MM patients (MM-BMSCs) and MGUS patients (MGUS-BMSCs) were isolated by the classical cell culture, and were homogeneously CD73+, CD90+, CD105+, CD34-, and CD45-.

Results: MM-BMSCs and mgUS-BMSCs had a fibroblast-like morphology in culture, and were homogeneously CD73+, CD90+, CD105+, CD34-, and CD45-. MM-BMSCs had a higher expression of α-smooth muscle actin (α-SMA) than mgUS-BMSCs. The nanoparticle size distribution of EVs derived from BMSCs was approximately 50 nm. We found high expression of miR-10a in the EVs derived from MM-BMSCs, while the expression of intracellular miR-10a was low in MM-BMSCs. We therefore hypothesized that low expression of cellular miR-10a might be important for survival of MM-BMSCs; As a result, miR-10a was packaged into EVs, and they were released to the extracellular space. To test the hypothesis, miR-10a mimic was transfected into BMSCs and the effect on EV secretion was investigated. Knockout of PBK was increased in cells expressing PBK and induced apoptosis of MM-BMSCs, while the cell proliferation and apoptosis of mgUS-BMSCs were not affected by the overexpression of miR-10a. We also found that inhibition of EV release with GW4869 promote the accumulation of intracellular miR-10a in MM-BMSCs, and EV-release inhibitor also can inhibited cell proliferation and induced apoptosis of MM-BMSCs.

Summary/Conclusions: Our findings indicate that expression of PBK and/or G9a/GLP represents new promising targets for the treatment of multiple myeloma. E. De Smedt1,*, J. Devin2, H. Liu3, A. Maes1, K. Maes1, K. De Veirman1, M. Menu1, K. Vanderkenken1, J. Moreaux2, E. De Bruyne1

E1210 SINGLE-NUCLEOTIDE POLYMORPHISM IN THE PBK GENE IS CLOSELY ASSOCIATED WITH MYELOMA CELL PROLIFERATION I. Hanamura1, A. Ota2, S. Karna2, M. Wahiduzzaman2, S. Mizuno1, K. Uchino1, J. Kanasugi1, T. Horio1, S. Murakami1, S. Suzuki3, R. Ueda3, S. Tsuzuki2, H. Konishi2, Y. Hosokawa2, A. Takami1

1Department of Hematology, Department of Internal Medicine, 2Department of Biochemistry, 3Department of Tumor Immunology, Aichi Medical University, Nagakute, Japan

Background: Elevated expression of PDZ binding kinase (PBK), which encodes a serine/threonine kinase, has been reported to be associated with a poor prognosis in a variety of cancers. The public gene expression profiling data also showed that higher expression of PBK was related with a poor prognosis in myeloma. However, the molecular mechanisms of PBK expression have never been investigated in myeloma.

Aims: The aim of this study is to elucidate PBK gene functions associated with myeloma cell growth in vitro and in vivo.

Methods: Eight human myeloma cell lines including ANBL-6, 8226, OPM2, and KMS-11 were used in this study. The expression levels of mRNA and protein of PBK were detected by real-time RT-PCR and western blotting, respectively. The human sequence of the whole PBK gene was determined using the dye terminator method. Knockout of PBK was performed using CRISPR-Cas 9 system. A single guide RNA sequence for PBK was selected by the CRISPR method. Knockout of PBK was confirmed by real-time RT-PCR and western blotting.

Results: In vitro, knockout of PBK significantly suppressed cell growth in vitro and in xenograft mice (Fig. 2). Moreover, exogenous expression of PBK increased cell proliferation in the PBK-deficient OPM2 cells, which carry PBK. Furthermore, Thr 9 phosphorylation on PBK was increased in cells expressing PBK compared with those cells expressing PBK. KMS-11 cells carrying PBK knockout by CRISPR-mediated knockout suppressed cell growth in vitro and in xenograft mice (Fig. 2). Moreover, exogenous expression of PBK augmented cell proliferation in the PBK-deficient OPM2 cells, which carry PBK. Furthermore, Thr 9 phosphorylation on PBK was increased in cells expressing PBK compared with those cells expressing PBK.

Summary/Conclusions: Our findings indicate that expression of PBK in myeloma cell proliferation, while PBK in MM was likely related to tumor suppression. Increased phosphorylation of Thr 9 on PBK might contribute to proliferation in cells with PBK. These results provide a novel insight into the mechanisms underlying myeloma cell growth and PBK is a potential stratification and therapeutic target for plasma cell dyscrasias.

E1211 THE HISTONE METHYLTRANSFERASES G9A/GLP REPRESENT NEW PROMISING TARGETS FOR THE TREATMENT OF MULTIPLE MYELOMA E. De Smedt1,*, J. Devlin2, H. Liu3, A. Maes1, K. Maes1, K. De Veirman1, M. Menu1, K. Vanderkenken1, J. Moreaux2, E. De Bruyne1

1Department of Hematology, 2Department of Monitoring Innovative Therapies, Institute of Human Genetics, CNRS, Montpellier, France, 3Department of Hematology, Tianjin Medical University General Hospital, Tianjin, China

Background: Multiple myeloma (MM) is a clonal plasma cell malignancy which mainly resides in the bone marrow. In cancer cells, the epigenetic landscape is known to be highly disturbed. In line, numerous epigenetic aberrations have been described in MM, resulting in deregulated gene expression, disease progression and drug resistance. Targeting deregulated epigenetic modifiers therefore represents an interesting therapeutic approach. G9a (EHMT2) and GLP (EHMT1) are 2 histone methyltransferases which catalyze mono- and dimethylation of histone 3 lysine 9 (H3K9). Importantly, G9a is overexpressed in several cancers, correlating with a poor prognosis.

Aims: Currently, data about the expression and role of G9a/GLP in MM is lacking. The aim of this study is therefore to investigate the functional role of G9a/GLP in MM pathogenesis.

Methods: The prognostic value of G9a/GLP in terms of overall survival was determined in the UAMS-TT2 cohort of newly diagnosed MM patients (n=345, 2012-2014) and survival was analyzed. In addition, we used a panel of 10 human cell lines, 3 murine cell lines and 5 primary patient samples to evaluate the effect of the small molecule inhibitors UNC0638 and BIX01294 on MM cell viability, cell cycle progression and apoptosis. We also assessed the in vitro anti-MM activity of BIX01294 in combination with bortezomib or ABT-199.

Results: In vitro anti-MM activity of therapeutic BIX01294 treatment was tested using the murine 5G1 cell line. Difference in overall survival between groups was assessed with a log-rank test and survival curves plotted using the Kaplan-Meier method.
E1212
CYTOTOXIC LYMPHOCYTES IN NEWLY DIAGNOSED MYELOMA HAVE REVERSIBLE FUNCTIONAL AND PHENOTYPIC ABNORMALITIES THAT MAY OFFER THERAPEUTIC OPPORTUNITIES
F. Seymour1,*, J. Cavenagh1, J. Gribben1
1Haematology-Oncology, Barts Cancer Institute, London, United Kingdom

Background: A bi-directional interaction exists between malignant cells and those of the immune microenvironment. This dynamic relationship results in gradual loss of clonal control associated with loss of cytotoxic lymphocyte (CTL) response. Mechanisms of immune escape are varied and include the induction of immunosuppression, notably the PD-1/PD-L1 axis. Multiple myeloma is a disease characterised by a pre malignant phase which can evolve into periods of asymptomatic and symptomatic disease. One possible mechanism for disease progression is progressive loss of immunological control. The malignant plasma cell has multiple potentially immune modifying effects including the expression of PDL1 and induction of a pro-tumour micro-environment. The role of CTLs is less well understood.

Aims: To undertake deep immune profiling of the CTL landscape in myeloma in order to establish whether features of immune dysregulation are present and to identify potential therapeutic opportunities.

Methods: Cryopreserved bone marrow from 18 patients with newly diagnosed and untreated myeloma and 9 controls were assessed using a 36 parameter mass cytometry panel. The panel was designed to assess 9 immune checkpoint regulators, 5 cytokines, and markers of proliferation and degranulation across multiple lymphocyte subsets. Samples were stimulated with CD3 and CD28 to assess functional capacity. Dimensionalisation clustering algorithmic analysis was used alongside traditional data analysis techniques to identify functional subpopulations characterised by expression of multiple markers.

Results: The cytokine profile in newly diagnosed myeloma is shifted towards a pro-tumour microenvironment with particularly marked elevation of TGFβ. The expression of G9a/GLP are associated with a worse disease outcome in newly diagnosed MM patients. Moreover, gene set enrichment analysis of patients with high G9a/GLP expression levels displayed a significant enrichment of genes involved in pathways associated with MM disease progression, including the RAS pathway, NF-kB canonical pathway, IRF4 multiple myeloma program and mRNA splicing. Sequencing data shows somatic mutations in specific G9a/GLP inhibitors BIX01294 and the UCN0138 significantly and potently reduced MM cell viability in vitro. Moreover, both inhibitors also induce cell cycle arrest and apoptosis. When comparing between both inhibitors, BIX01294 was found to be the most potent in inducing apoptosis.

Mechanistic studies for BIX01294 furthermore indicated that BIX01294 treatment altered the tumor microenvironment as evidenced by a strong increase in the formation of LC3B puncta and an increase in LC3II and beclin-1 protein levels. In addition, we found that BIX01294 sensitizes MM cells to the proteasome inhibitor bortezomib and the Bcl-2 inhibitor ABT199. Lastly, therapeutic treatment of 5TM1 inoculated mice with BIX01294 resulted in a clear antitumor effect, as evidenced by a clear decrease in tumor burden and a significant increase in the overall survival of BIX01294 treated mice compared to vehicle treated mice.

Summary/Conclusions: Altogether, our results demonstrate for the first time the importance of the histone methyltransferases G9a/GLP in MM pathogenesis. Furthermore, specific targeting of G9a/GLP induces MM cell apoptosis, enhances MM sensitivity to ABT-199 and bortezomib and significantly delays tumor progression in the murine 5TM1 model. Thus, G9a/GLP targeting represents a promising strategy to improve treatment of MM.

P53-RESTORING SMALL MOLECULE CP-31398 INDUCES APOPTOSIS VIA INDUCTION OF REACTIVE OXIDATIVE SPECIES IN HUMAN MULTIPLE MYELOMA
Y. Artimana1,2, K. Takada1, Y. Kawano1, N. Hayasaki1, H. Nakamura1, S. Kikuchi1, Y. Kamihara1, K. Murase1, H. Ikeda2, S. Iyama2, T. Sato2, K. Miyaniishi1, M. Kobune1,*, J. Kato1
1Department of Medical Oncology, 2Department of Hematology, Sapporo Medical University, Sapporo, Japan

Background: Reactive oxygen species (ROS) are normal byproducts of a wide variety of cellular processes. ROS have dual functional roles in cancer cell pathophysiology. At low to moderate levels, ROS act as signaling transducers to activate cell proliferation, migration, invasion, and angiogenesis. In contrast, high levels of ROS induce cell death. In multiple myeloma (MM), ROS overproduction is the trigger for apoptosis induced by several anticancer compounds, including proteasome inhibitors. However, no drugs that mainly affect oxidative stress are currently used for treatment of MM in the clinic. In MM, p53 status is an independent prognostic marker, since patients harboring p53 abnormalities are highly resistant to standard therapies, and the incidence of p53 mutations and deletions increases during disease progression. Therefore, restoration of p53 is an attractive strategy for treating advanced relapsed and refractory MM (RRMM) patients. CP-31398 (CP) is a small molecule that activates wild-type p53 or restores tumor-associated p53 mutants to wild type p53 function in multiple human cancer cell lines; this leads to cell cycle arrest and/or apoptosis. Although the growth of rhodomyeloblastoma cell lines can be inhibited by p53-dependent induction of ROS, but it is not clear whether CP-induced cytotoxicity proceeds via a similar pathway.

Aims: Our study was aimed at evaluating the anti-myeloma activity of CP.

Methods: MM cell lines (MM1S, RPMI8226, U266, KMS5, OPM2, Delta47, KMM15) and two primary myeloma samples were used. CP (200 nM) was added 48 h subsequent to treatment; consequently, the inhibitory effect of CP on MM cell line growth was assessed using a WST-1 assay. In order to elucidate the cytotoxic mechanism of CP, immunoblotting and flow cytometry analyses were performed. Measurements of cytosolic and mitochondrial ROS were performed with CellROX Deep Red or MitoSOX Red. For quantification of ROS, cells were analyzed by flow cytometry and fluorescence microscopy. The therapeutic potential of CP was evaluated by its ability to suppress tumor growth in vivo using the subcutaneous RPMI8226 murine xenograft model for human MM.

Results: In this study, we have demonstrated that the p53-activating small molecule CP-31398 effectively inhibited the growth of MM cell lines and primary MM isolates from patients with IC50 values in the range of 2.51–11.2 µM. CP also suppressed the growth of MM xenografts in mice. Mechanistically, CP was found to induce intrinsic apoptosis in MM cells via increasing mitochondrial and cytosolic ROS production. Interestingly, CP-induced apoptosis occurs regardless of the cells’ p53 status, suggesting that CP has additional mechanisms of action. In addition, we found that CP acted synergistic with the protease inhibitor carfilzomib (CFZ) in MM cells, providing a framework for further studies of CP alone and in combination with CFZ to improve the prognosis for MM patients.

Summary/Conclusions: Our findings indicate that CP could be an attractive candidate for treatment of MM even in patients with p53 abnormalities; this may satisfy an unmet clinical need, as such patients currently have a poor prognosis.

E1214
TUMOR MICROENVIRONMENT TRANSFORMATION FROMmUS TO MYELOMA IS ASSOCIATED WITH PRO-TUMORAL ACTIVATION OF MESOTHERMAL STROMAL CELLS (MSCS)
C. Giorgi1,*, D. Tilmio1, N. Parmelli1, P. La Cava1, G. Camiolo1, M. Tummino1, N. Caporarello1, C. Anfuso1, C. Conticello1, A. Romano1, F. Di Raimondo1, N. L. Parrinello1, 1Clinical and Molecular Biomedicine, section of Hematology, University of Catania, catania, Italy

Background: A well-recognized feature of MM is the intimate relationship between plasma cells (PC) and bone marrow microenvironment, characterized by a modified extracellular matrix, enhanced angiogenesis and presence of cells with immune suppressive activity, including tumor-associated macrophages and myeloid-derived suppressor cells (MDSC). Recently, we demonstrated that MM-MSC co-culture is able to convert normal immature myeloid cells in MM-derived MSC contributing to immune-escape mechanisms. Aims: We hypothesize that MSC derived from Smoldering myeloma (SMM) and MM are in an activated status that promotes tumor growth and tumor microenvironment transformation. Methods: Human peripheral blood mononuclear cells (PBMC) isolated from SMM and MM were co-cultured with healthy controls (HC)-mUS-, MM- or MM-MSC. After 6 days, neutrophils (N) were isolated using anti-CD66b magnetic microbeads and were tested in vitro for their ability to induce angio-genesis and suppress T cell proliferation.
Results: Only N educated by SMM- and MM-MSC (both from patients at diagnosis, relapsed and refractory) significantly up-regulated Arg1, NOS2 and TNFα and exhibited suppressive effect with a reduction of T cell proliferation (p<0.001). By co-culturing educated-N with Human Brain Microvascular Endothelial Cells (HBMEC), we observed increased both tube length and number of branch points only in conditions where HBMEC were incubated with MM-MSC (MM-MSC+HBMEC) vs. SMM-MSC+HBMEC (n=3, p<0.05). Adding Bortezomib, Lenalidomide or Pomalidomide during co-culture of PBMC with MM-MSC, isolated N showed a significant reduction of pro-angiogenic activity but did not lose immunosuppressive ability. To examine if PC play a role in MSC “activation”, before performing co-cultures with PBMC, we pre-treated HS-S or HC-SCM with MM cell lines. PC pre-treatment drives a healthy MSC to activate N in immunosuppressive and pro-angiogenic cells. Implantaion of mixtures of fluorescently labeled MM cells and healthy- or MM-MSC into zebrafish, animals cojected with PC and MM-MSC showed enhanced tumor colonization and growth compared with those injected with PC and healthy MSC.

Summary/Conclusions: Character of tumor microenvironment transformation frommmUS to MM is associated with progressive activation of MSC that have a pro-tumoral activity. Indeed SMM- and MM-MSC polarize N in immunosuppressive and pro-angiogenic N (NZ) in vitro. In addition, MM-MSC facilitate MM growth in vivo confirming their central role in tumor progression.

LONG TERM CR MULTIPLE MYELOMA PATIENTS STUDIED WITH NEXT GENERATION FLOW SHOW PREDOMINANTLY CURED VSmgUS-LIKE MINIMAL RESIDUAL DISEASE PATTERNS: A STUDY OF THE GTMM-TUSCAN GROUP FOR MULTIPLE MYELOMA

A. Gozzetti1,*, S. Sirianni1, V. Candi1, D. Raspadori1, C. Nozzoli2, M. Staderini2, M. Petrini3, A. Bosi2, M. Bocchia1

1Scienze della Salute, 2Oncologia ed emato-oncologia, Università degli Studi di Milano, 3Medicina interna e Oncologia clinica, Università di Bari, Bari, Italy

Background: Angiogenesis is a hallmark of tumors, and it is a peculiar characteristic in bone marrow (BM) of multiple myeloma (MM) patients. MM is still a incurable disease that strongly depends on interactions with BM microenvironment (TME). Endothelium of MM patients displays malignant behavior as compared to a healthy counterpart (1). MM displays a dysregulation of the Notch pathway due to Jaged ligands and Notch receptors overexpression. This condition brings about the generation of homotypic and heterotypic interaction loops that sustain MM growth. Moreover, Notch signaling is able to suppress BM resident cells, including osteoclast and BM stromal cells (BMSCs), although its role in the crosstalk of MM and endothelium is still to be clarified.

Aims: The aim of this study is to investigate Notch role in MM crosstalk with endothelium exploiting 2D assays and 3D organoid systems to mimic tumor microenvironment (TME).

Methods: The Notch ligands, Jaged1 and 2, were silenced in the MM cell line RPMI8226 (RPMI8226-TruJADG1/2 ) using an inducible lentiviral vector carrying two short hairpin RNAs targeting Jaged1 and 2. To mimic the endothelial compartment, both early and late endothelial cells (HAECs) were used and for the stromal compartment, the GFP+HSS cell line. Matrigel and collagen healing assays were set up to investigate Notch role in modulating the angiogenic potential of MM cells co-cultured with HAECs and HAECS motility in response to MM-derived soluble factors. To develop a TME-like system, a decellularized extracellular matrix (dECM) was used as a physiologic scaffold for organoid generation. dECM was produced by treating murine fibroblast NIH3T3 with ascorbic acid and was loaded with cells for organoids generation. We evaluated apoptosis of MM cells in single culture and co-culture with BMSCs or HAECS by flow cytometry.

Results: Matrigel assay of HAECs co-cultured with MM cells showed that direct contact increased angiogenic potential of HAECs to form a grid of tubes; this effect is significantly reduced when HAECs are co-cultured with RPMI8226-TruJADG1/2 cells, indicating a key role of Notch signaling in endothelial stimulation. Wound healing assay demonstrated that Notch signaling affects MM cells mobility, since it is reduced when Jaged ligands are ablated. Concerning the 3D-organoid generation, our results indicate that the handcrafted dECM was a suitable scaffold. Moreover, apoptosis assays indicated that MM cells displayed an increased survival when cultured in the presence of BMSCs, that consistently with their recognized protective role; no significant difference in MM cell apoptosis was observed in the presence of endothelial cells. On the contrary, we have observed that endothelial cells were protected by MM cells suggesting that MM cells improve angiogenesis by preventing endothelial cells apoptosis.

Summary/Conclusions: These results indicate a novel role for Notch pathway in MM-EC crosstalk suggesting that the Notch pathway activation in MM cells can increase their proangiogenic potential. 3D-organoid mimics BM microenvironment and may be used as a novel tool to recapitulate the interactions of BM and tumor cells beyond the animal models.

MIR-101-3P REGULATES BONE MARROW STROMA-INDUCED DRUG RESISTANCE IN MULTIPLE MYELOMA CELLS BY TARGETING SURVIVIN AND MODULATING CELL-CELL ADHESION

J. Abdi1,*, Y. Chen1, N. Rastgoo1, H. Chang2

1University Health Network, Toronto, Canada, 2Lab Hematology, University Health Network, Toronto, Canada

Background: In multiple myeloma (MM), bone marrow stromal cells (BMSCs) protect MM cells against cell death by direct or indirect interaction. This phenomenon is poorly understood. We partly explain de novo or acquired drug resistance in MM. Findings of relevant studies indicate activation of some oncogenic or survival pathways including PI3K/mTOR, Ras/MAPK, NFκB and Wnt. However, the potential regulatory mechanisms and druggable targets have not been clearly elucidated.

Summary/Conclusions: In conclusion NGF showed that MM patients with a CR can have long lasting remissions meaning disease control. Patients in sustained CR after 2 years can have high percentage of MRD negativity. Larger studies are warranted to identify patients who need treatment consolidation or continuous treatment based on MRD status vs others who could stay treatment free with social and economical benefits.
**Aims:** To understand the role of stromal induced drug resistance and to identify new therapeutic target in myeloma.

**Methods:** GFP-tagged human myeloma cell lines, 8226, U266 and MM.1s, were co-cultured with MM patient-derived BMMSCs or HS.5 cells with or without BTZ for 24 h. MM cells in monocultures were used as controls. Co-cultures were then applied to magnetic cell separation to isolate MM cells for downstream analyses including western blotting and mRNA or miRNA qPCR arrays. Furthermore, percent apoptosis of gated GFP+ cells was determined using FACS. In other experiments, MM cells were exposed to BMMSCs pre-treated with Brefeldin-A (BFA) or separated with a transwell (TW) insert. For functional analysis, miR-101-3p was overexpressed using lentiviral transduction and survival assays (BMMSCs) were then seeded on BMMSCs in presence or absence of BTZ. GFP fluorescence-based adhesion, cytotoxicity and annexin-V/PI apoptosis were applied.

**Results:** qPCR arrays showed that BMMSCs up- or down-regulated several miRNAs and mRNAs in MM cells. Survivin (BIRC5) was confirmed to be conserved in JNJ3 cell lines and mRNA and protein expression in monolayers. In contrast, miR-101-3p was confirmed to be significantly downregulated by stroma in MM cells. Moreover, suppression of miR-101-3p or upregulation of survivin was reversed partially when BMMSCs were pre-treated with BFA but highly significantly when they were separated from MM cells with a TW insert. The same trend was observed in in vivo results FACS analysis indicating that direct cell-cell adhesion was more effective in BMMSC-induced modulations in MM cells. Next we identified that survivin was a direct target of miR-101-3p, overexpression of miR-101-3p suppressed survivin mRNA/protein. As indicator of involvement in stroma-mediated drug resistance, survivin and miRNA-101-3p 3p inhibition of the bone marrow niche was thus effective in BMMSC 3p cultured. Furthermore, miR-101-3p overexpression or silencing of survivin increased BTZ-induced apoptosis in MM cells in the absence or presence of BMMSCs significantly overcoming stroma-mediated drug resistance. To test whether miRNA-101-3p could also regulate adhesion of MM cells to BMMSCs, we further showed that miR-101-3p significantly reduced adhesion of MM cells to HS.5 and primary MM BMSCs compared to scrambled control. This finding suggests that miRNA-101-3p regulates cell adhesion-mediated drug resistance (CAMDR) by modulation of BM-BMSC adhesion.

**Summary/Conclusions:** Our results identify a mechanism whereby BMMSCs induce drug resistance in MM cells by up-regulating survivin and down-regulating miRNA-101-3p which directly targets survivin. Overexpression of miRNA-101-3p or silencing of survivin sensitizes MM cells to BTZ significantly overcoming stroma-induced drug resistance. These findings disclose a role of survivin-miRNA axis in MM cell growth, progression and drug resistance.

**ARQ-197, A SMALL-MOLECULE INHIBITOR OF c-MET, REDUCES TUMOUR BURDEN AND PREVENTS TUMOUR-ASSOCIATED BONE DISEASE IN A MURINE MODEL OF MM**

A. Chantry1,*, E. Holly1, M. Fisher1, D. Jenny1, L. Michelle1, L. Darren1

1Oncology and Metabolism, University of Sheffield, Sheffield, United Kingdom

**Background:** The receptor tyrosine kinase c-Met, its ligand HGF, and their signaling have been implicated in the pathogenesis of myeloma. In myeloma patients with elevated levels of HGF its prognostic is known to be poor. Therefore, targeting these molecules or their pathway in such patients may be of great benefit. We hypothesised that ARQ-197 (Tivantinib), a small molecule c-Met inhibitor, would reduce myeloma cell growth and prevent myeloma-associated bone disease in a murine model.

**Aims:** 1. Assess effects of ARQ-197 on myeloma cell proliferation. 2. Assess effects of ARQ-197 treatment on tumour burden in murine models of myeloma and 3. Assess effects of ARQ-197 treatment on myeloma bone disease in murine models of myeloma.

**Methods:** In vitro we assessed the effects of ARQ-197 (0.1563 μM - 5 μM) on myeloma cell proliferation, cytotoxicity and c-Met protein expression in the JNJ3 human cell line. In vivo we intravenously injected NOD/SCID-γ mice with 10^6 JNJ3 cells and 1 week later treated mice with either ARQ-197 (200mg/kg/day, 5 times per week by oral gavage) or vehicle for 2 weeks. Response to drug resistance in MM cells by upregulating survivin and GSK3 in a significant inhibition of cell proliferation (p<0.001) and an induction of cell death (p<0.001), probably caused by significantly [SL1] reduced levels of phospho-c-Met. In vivo ARQ-197 treatment of JNJ3 tumour-bearing mice resulted in a significant reduction in tumour burden (p<0.001), where tumour infiltration by ARQ-197 was reduced by approximately 43% (864±9% vehicle vs 55±20% ARQ-197 treatment). ARQ-197 treatment also significantly prevented the formation of myeloma-induced bone lesions (P<0.001) and the loss of trabecular bone (p<0.01) compared to vehicle treated JNJ3-tumour bearing mice. Dynamic histomorphometry showed ARQ-197 treatment prevented bone loss in the mineralizing bone surface (p<0.001), the mineral apposition rate (p<0.01), the bone formation rate (p<0.01), and prevented complete loss of osteoblasts on the cortico-endosteal bone surface compared to the vehicle group.

**Summary/Conclusions:** In summary, these results suggest that ARQ-197 could be a promising therapeutic in myeloma patients who express high levels of HGF, leading to both a reduction in tumour burden and an inhibition of myeloma-induced bone disease.

**THE GENETIC LANDSCAPE OF THE MURINE 5T MODELS FOR MULTIPLE MYELOMA**

K. Maes1,*, B. Boeckx2, K. De Veirman1, E. Menu1, K. Vanderkerken1, D. Lambrechts3, E. De Bruyne4

1Hematology and Immunology, Vrije Universiteit Brussel, Brussels, 2Department of Oncology, VIB Center for Cancer Biology, 3Department of Oncology, VIB Center for Cancer Biology, Leuven, Belgium

**Aims:** Multiple myeloma (MM) is a plasma cell malignancy which remains incurable in most cases. This is mainly attributed to the large genetic and epigenetic heterogeneity of MM patients. However, to date, the genetic landscape of murine MM models have not been analyzed. Our aim of this study is to analyze the genetic landscape of the 5T murine models for MM.

**Methods:** In this study, we used the 5T2, 5T33vv and 5TGM1 murine models for MM. As control samples, we used C57BL/KeLwRj and C57Bl/6j germine DNA. We analyzed the copy-number alterations and the mutualional landscape using whole shell genome sequencing and whole exon sequencing.

**Summary/Conclusions:** Among the tested models, the 5T2 model displayed the most copy number alterations. Over the entire genome, 11% and 17% showed copy number alterations for the 5T33vv and 5TGM1 of which 6% is shared reflecting their clonal relationship. Overall, the copy-number alterations affects genes involved in RAS/MAPK, PI3K/AKT1 and JAK/STAT signaling. DNA damage response, cell cycle and epigenetic regulation. Exome sequencing revealed the presence of 417, 407 and 314 non-synonymous mutations and 8, 14 and 24 indels in the 5T33vv, 5TGM1 and 5T2 models, respectively. Moreover, a statistically significant overlap of mutated genes between the 5T33vv and 5T2 models was observed (p<1E-8). Similar to MM patients, we identified damaging mutations in Trp53, Rb1, Pik3ca, Fat3, Kdm6a and Nf1.

**CHARACTERIZING THE CONTRIBUTION OF BONE MARROW Stromal-derived IL-6 TO MYELOMA GROWTH AND RESISTANCE**

T. Csikos1,*, H.-J. Prins1, E. Drent1, P. Poddighe2, S. Zweegman1, T. Mutis1, R. Groen1

1Hematology, 2Clinical Genomics, VU University Medical Center, Amsterdam, Netherlands

**Background:** The bone marrow niche is a specialized microenvironment, which allows for the survival, growth and differentiation of hematopoietic stem and progenitor cells. This niche also provides the optimal growth conditions for multiple myeloma (MM). A complex interplay between cytokines, adhesion molecules, cell receptors and their ligands provides the MM plasma cells with survival signals and contribute to therapy resistance.

**Aims:** To unravel the role of the bone marrow mesenchymal stem/stromal cells (BMMSCs) in MM cell growth, progression and drug resistance.

**Methods:** Hypothesizing that the interaction between MM cells and the BMMSCs is bidirectional, we have compared BMMSCs from healthy individuals, mgUS, and MM patients and used our “humanized” bone marrow-like model to characterize the molecular impact of MM cells on BMMSCs. Finally, we have validated targets by generating HS-5 knock-out lines using CRISPR/Cas9 targeting.

**Results:** Analyzing the BMMSCs of healthy individuals, mgUS, and MM patients and used our “humanized” bone marrow-like model, allowed us to confirm established disease biomarkers (e.g. IL-
6, HGF, IGF and GDF15) and identify novel mediators of MM disease progression and bone disease. To further elucidate the role of IL-6 in BMSC-induced growth of MM plasma cells and drug resistance, we have established HSS stromal cell lines that upon CRISPR/Cas9 targeting have reduced or no expression of IL-6. RNA sequencing analysis of these cells revealed IL-6 to be a master regulator of cytokine production (e.g. IL-1β, CXCL8, CSF-2 and CSF-3). Disruption of the IL-6 gene did not result in a reduced growth rate of the IL-6 deficient stromal cells as compared to wildtype. Using the compartment specific bioluminescent imaging co-culture system, where luciferase gene-marked MM cells are co-cultured with non-marked stromal cells, we have documented a contribution of the stromal cells to both growth and drug resistance to known chemotherapeutics (e.g. bortezomib, doxorubicin) of MM cells. Using this same co-culture system we compared wildtype and IL-6 deficient stroma. Although disruption of IL-6 in the stromal cells resulted in a reduced proliferation of MM cells and stromal cell mediated drug resistance, it did not entirely reverse these stroma-mediated effects.

**Summary/Conclusions:** Taken together these data suggest that although IL-6 is one of the most deregulated genes in MM-derived BMSCs, it certainly is not the sole contributor to BMSC-induced MM cell growth and drug resistance.

**THE PAN-PIM KINASE INHIBITOR, PIM447, POTENTLY SYNTHETIZES WITH POMALIDOMIDE PLUS DEXAMETHASONE IN PRECLINICAL IN VITRO AND IN VIVO MODELS OF MULTIPLE MYELOMA**

T. Palino,1,2 L. San-Segundo,1,2 S. Hernández-García,1,2,3 L. González-Méndez,1,2 E.M. Algarín,1,2 M. Martín-Sánchez,1 M.V. Mateos,1,2 M. Garayoa,1,2 E.M. Ocio,1,2
1Centro de Investigación del Cáncer (CIC-IBMC), 2Completo Asistencial Universitario de Salamanca-IBSAL, Salamanca, Spain

**Background:** PIM kinases are a family of serine/threonine kinases recently proposed as therapeutic targets in multiple myeloma. Recent work from our group has shown the dual antitymoma and bone-protective effects of the pan-PIM kinase inhibitor, PIM447, and its in vitro synergism with current standards of care. Since myeloma remains an incurable disease, the preclinical evaluation of new drug combinations is of utmost importance, in order to support the development of future clinical trials. In this scenario, effective all-oral combinations are particularly attractive.

**Aims:** The aim of the present work has been the evaluation of the efficacy and mechanism of action of the all-oral triple combination PIM447 + pomalidomide + dexamethasone in preclinical in vitro and in vivo models of multiple myeloma.

**Methods:** In vitro cytotoxicity of PIM447, pomalidomide and dexamethasone alone or in double and triple combinations was evaluated on myeloma cell lines. The combination index (CI) was calculated with CalcuCyxus software based on results from MTT assay. Effects on apoptosis and cell cycle were evaluated by flow cytometry. Glucose uptake was analyzed by incubation with 2-NBDG. The mechanism of action was explored by analysis of different protein levels by western blot. Finally, a plasmacytoma model in CB17-SCID mice was employed for in vivo studies.

**Results:** Triple combination PIM447 + pomalidomide + dexamethasone showed a strong synergism (CI<0.3) in M15HS and RPMI-8226 cell lines. The cytotoxic effect was increased in the presence of PIM447 and pomalidomide, promoting a downstream reduction of the glucose metabolism-associated enzyme hexokinase II and also reduced glucose uptake by cells. Finally, the efficacy of this combination was confirmed in a plasmacytoma model in CB17-SCID mice, where it clearly reduced tumor growth as compared to single and double treatments.

**Summary/Conclusions:** Our preclinical data suggest that myeloma patients could benefit from treatment with the triple combination PIM447 + pomalidomide + dexamethasone and would support future clinical trials with this combination.

**E1224**

**TRIM33 IS A POTENTIAL TUMOR SUPPRESSOR IN MULTIPLE MYELOMA**

C.K. Johnston1,*, L.J. Crawford1, K.I. Mills1, A.E. Irvine1
1Centre for Cancer Research and Cell Biology, Queen’s University Belfast, Belfast, United Kingdom

**Background:** Multiple myeloma (MM) continues to be an incurable plasma cell neoplasm, regardless of recent therapeutic advances. The success of proteasome inhibitors in MM validates the ubiquitin proteasome system (UPS) as a therapeutic target. Using a UPS-specific microarray (PIQOR) we identified aberrant expression of an E3 ligase TRIM33 (tri-partite motif containing protein 33) in MM. TRIM33 has previously been identified as a tumor suppressor in chronic myelomonocytic leukemia and hepatocellular carcinoma.

**Aims:** The aim of this study was to examine TRIM33 expression and to investigate its role as a potential tumor suppressor in MM.

**Methods:** Western and/or immunofluorescence montage and in situ analysis of TRIM33 expression at basal level and following knockdown in four MM cell lines representing a range of MM translocations; JNJ3 (t(14;16), U266 (t(11;14), KMS-18 (t(4;14), OPM-2 (t(4;14)). TRIM33 knockdown was performed using shRNAs elicited with Lentivirus. The knockdown efficiency was verified by qPCR.

**Results:** Knockdown of TRIM33 expression was achieved in all cell lines, with varying levels of knockdown: J3N3 (p<0.0001) and U266 (p=0.015). Knockdown of TRIM33 expression did not alter cell viability in the (t(4;14) cell lines. However, cell viability was found to be increased in JNJ3 (p=0.001) and U266 (p=0.015). Knockdown of TRIM33 expression in patients with a t(4;14) compared to other MM subtypes, particularly (6;14) (p=0.004) and hyperdiploid cluster (p=0.05). Low TRIM33 expression has also been associated with poor overall survival (GSE2658; p=0.0034). Forty-seven patients were treated with TRIM33 expression in the non (t(4;14) and (t(4;14) MM were identified; these genes were analysed using QUADRATIC tools connectivity mapping to identify FDA approved drugs predicted to enhance the TRIM33 gene signature. One of the top enhancers identified was the tyrosine kinase inhibitor (TTK) Imatinib. The OPM-2 cell line showed greatly increased sensitivity to Imatinib compared with other MM subtypes (p<0.05) and U266 (p<0.005). Analysis of a publically available dataset to look at TRIM33 expression and correlation with survival in subsets of newly diagnosed MM; GSE19784 (N=320) and GSE2658 (N=551). qPCR was used to validate the changes in expression of the TRIM33 gene signature.

**Results:** Compared to normal bone marrow, lower expression of TRIM33 was observed at both gene and protein level (p=0.03) in the (t(4;14) cell lines, KMS-18 and OPM-2. Conversely, expression was found to be high in the non (t(4;14) cell lines, JNJ3 (p=0.001) and U266 (p=0.015). Knockdown of TRIM33 expression did not alter cell viability in the (t(4;14) cell lines. However, cell viability was found to be increased in JNJ3 (p=0.001) and U266 (p=0.015). Knockdown of TRIM33 expression in patients with a t(4;14) compared to other MM subtypes, particularly (6;14) (p=0.004) and hyperdiploid cluster (p=0.05). Low TRIM33 expression has also been associated with poor overall survival (GSE2658; p=0.0034). Forty-seven patients were treated with TRIM33 expression in the non (t(4;14) and (t(4;14) MM were identified; these genes were analysed using QUADRATIC tools connectivity mapping to identify FDA approved drugs predicted to enhance the TRIM33 gene signature. One of the top enhancers identified was the tyrosine kinase inhibitor (TTK) Imatinib. The OPM-2 cell line showed greatly increased sensitivity to Imatinib compared with other MM subtypes (p<0.05) and U266 (p<0.005). Analysis of a publically available dataset to look at TRIM33 expression and correlation with survival in subsets of newly diagnosed MM; GSE19784 (N=320) and GSE2658 (N=551). qPCR was used to validate the changes in expression of the TRIM33 gene signature.

**Summary/Conclusions:** We have shown that TRIM33 exhibits lower expression in (t(4;14) cell lines, compared to non (t(4;14) cell lines and that knockdown of TRIM33 increased the viability of non (t(4;14) cell lines. This suggests that TRIM33 may act as a tumor suppressor in MM and that expression is dysregulated in a subset of MM. Connectivity mapping identified Imatinib as an
enhancer of the TRIM33 signature that potently decreased the viability of the OPF2 cell line. This study suggests that enhancing the TRIM33 gene signature could potentiate the tumor suppressive effect of TRIM33 and identify novel therapies for this subset of MM.

LONG NON-CODING RNAs EXPRESSION HETEROGENEITY AND FUNCTIONAL INVOLVEMENT IN MULTIPLE MYELOMA
A. Carrasco1, T. Exponda1, G. Meydan2, M. Kulis3, R. Ordoñez1, V. Segura4, L. Garate1, D. Alignani5, B. Paiva6, J. San Miguel6, J. Martin-Subero3, A. Melnick2, F. Prósper6, X. Agirre1
1Onco-hematology, Center for Applied Medical Research (CIMA), Pamplona, Spain, 2Spain, 3Department of Medicine, Weill Cornell Medical College, New York, United States, 4Departamento de Fundamentos Clinicos, Universitat de Barcelona, Barcelona, Spain, 5Bioinformatics, 6Flow Cytometry Core, Center for Applied Medical Research (CIMA), 7Hematology, Clínica Universidad de Navarra, Pamplona, Spain

Background: Increasing amount of evidence indicates that deregulation of long non-coding RNAs (lncRNAs) is a common feature of cancer and therefore, its investigation may uncover new molecular oncogenic mechanisms. In multiple myeloma (MM), altered expression of small number of lncRNAs has been associated with decreased disease-free and overall survival, suggesting that these elements may play a more important role in MM than previously anticipated. Nevertheless, an extensive high-throughput analysis that characterizes the deregulation of lncRNAs in MM has not yet been performed.

Aims: We aim to characterize the IncRNA transcriptome of MM and its heterogeneity, and determine whether altered IncRNAs have a functional involvement in this disease.

Methods: Paired-end strand-specific RNA sequencing (ssRNA-seq) was performed in 38 purified plasma cell (PC) samples from MM patients, as well as in 5 tonsil PCs (TPCs) and in 3 bone marrow PCs (BMPCs) of healthy donors as controls. We also performed ssRNA-seq of populations from B cell differentiation (Naive, Germinal Center, Memory and PC). To study the heterogeneity of IncRNAs expression we performed sample level enrichment analysis (SLEA), in which each individual IncRNA was compared to BMPCs. To determine the epigenetic regulation of IncRNAs we used whole-genome bisulfite sequencing and CHIP-seq. shRNA-mediated knockdown using 2 different shRNAs and MET-INV conversion V (cell death) assays were utilized to study the functional effect of IncRNA overexpression.

Results: We identified 40.552 novel IncRNAs in MM samples that were present in at least 3 of the 38 patients. Principal component analysis demonstrated that TPCs and BMPCs cluster separately, suggesting that, in spite of being of the same cell type, their transcriptomes are very different. We observed that the expression of IncRNAs was more heterogeneous than that of coding genes. More importantly, SLEA showed 11.067 IncRNAs that were overexpressed and 5.601 underexpressed in >40% of patients. Thus, the number of deregulated genes analyzed by SLEA was much larger than the 70 IncRNAs that appeared as deregulated when all MM were compared to BMPCs, demonstrating the relevance of studying the heterogeneity in this disease. To determine the functional role of heterogeneously altered IncRNAs in the biology of MM cells we focused on the study of LINC-SMIL0 (Specific Myeloma Intergenic Long non-coding RNA), a IncRNA that it is overexpressed in ~ 40% of MM patients and not observed in the compartment of normal plasma cells (PCs) viability and movement. Finally, we analysed the in vivo effects of Eph3A/mAb in a MM mouse xenograft model.

Methods: Eph3A mRNA and protein where investigated in 15 MM BMPCs, 11 MM cell lines and 10 HCs by qRT-PCR and flow cytometry. The effects of Eph3A targeting by lentiviral RNA silencing (shRNA) and anti-Eph3A monoclonal antibody (Eph3AmAb) in vitro and in vivo were studied by adhesion assay on fibronectin on bone marrow stromal cells (BMSCs), invasion assays and proliferation MTS assay, respectively. Gene expression profiling (GEP) was performed in shEph3A versus shControl cells. Furthermore, the effects of Eph3AmAb were analysed in a MM xenograft model by measuring tumor size and by assessing angiogenesis, proliferation and apoptosis rate on tumor biopsies using immunohistochemistry (anti-CD31, anti-Ki67 and TUNEL assay, respectively). Statistical significance was determined by the t-test or One-way ANOVA analysis.

Results: Eph3A was found overexpressed in primary MM BMPCs and MM cell lines when compared with HCs (figure 1A-B). The Eph3A loss of function by siRNA and by Eph3AmAb significantly inhibited in vitro the ability of MM PCs to adhere to fibronectin, to BMSCs and to invade (figure 1C-E), without affecting cell proliferation and viability (data not shown). GEP showed that knockdown of Eph3A modulated some molecules that regulate adhesion, migration and invasion processes. Importantly, the treatment with Eph3AmAb in vivo significantly reduced tumor size and inhibited angiogenesis, as revealed by decrease of CD31+ vessels at immunohistochemistry (data not shown).

Background: The tyrosine kinase Eph receptor A3 (EphA3) has recently emerged as a potential therapeutic target, since it is overexpressed in many cancers, including some hematological malignancies (Keane et al. 2012). Furthermore, EphA3 has been found overexpressed not only in neoplastic cells, but also in the microenvironment of different human cancers, where its targeting inhibits tumor growth by disrupting supportive stroma and vasculature (Val et al. 2014).

Aims: Due to the absence of relevant information about the role of EphA3 in multiple myeloma (MM), we aimed to evaluate the expression of this molecule in primary bone marrow plasma cells (BMPCs) from MM patients and MM cell lines compared to healthy controls (HCs). In addition, using a "loss of function" approach by mRNA silencing and an anti-EphA3 monoclonal antibody (EphA3mAb), we studied in vitro plasma cells (PCs) viability and movement. Finally, we analysed the in vivo effects of EphA3mAb in a MM mouse xenograft model.

Methods: EphA3 mRNA and protein where investigated in 15 MM BMPCs, 11 MM cell lines and 10 HCs by qRT-PCR and flow cytometry. The effects of EphA3 targeting by lentiviral RNA silencing (shRNA) and anti-EphA3 monoclonal antibody (EphA3mAb) in vitro and in vivo were studied by adhesion assay on fibronectin on bone marrow stromal cells (BMSCs), invasion assays and proliferation MTS assay, respectively. Gene expression profiling (GEP) was performed in shEphA3 versus shControl cells. Furthermore, the effects of EphA3mAb were analysed in a MM xenograft model by measuring tumor size and by assessing angiogenesis, proliferation and apoptosis rate on tumor biopsies using immunohistochemistry (anti-CD31, anti-Ki67 and TUNEL assay, respectively). Statistical significance was determined by the t-test or One-way ANOVA analysis.

Results: EphA3 was found overexpressed in primary MM BMPCs and MM cell lines when compared with HCs (figure 1A-B). The EphA3 loss of function by siRNA and by EphA3mAb significantly inhibited in vitro the ability of MM PCs to adhere to fibronectin, to BMSCs and to invade (figure 1C-E), without affecting cell proliferation and viability (data not shown). In addition, using a "loss of function" approach by mRNA silencing and an anti-EphA3 monoclonal antibody (EphA3mAb), we studied in vitro plasma cells (PCs) viability and movement. Finally, we analysed the in vivo effects of EphA3mAb in a MM mouse xenograft model.
Summary/Conclusions: Our findings suggest that EphA3 is a novel regulator of MM PC trafficking, in part via effects on adhesion and invasion; its targeting using EphA3mAb inhibits tumor growth, possibly by reducing angiogenesis, though other possible mechanisms of tumor death cannot be excluded. These data, together with the favourable clinical properties of a humanized EphA3mAb reported in a phase I trial on acute myeloid leukemia and myelodysplastic syndrome (Swords et al. 2016), support EphA3 targeting as a new potential therapeutic opportunity for MM that would warrant to be further investigated.

PROGNOSTIC SIGNIFICANCE OF AMP1Q21 IN MULTIPLE MYELOMA
T. Abramova1, T. Obukhova1, L. Mendeleva1, O. Pokrovskaya1, E. Gribanova1, M. Nareyko1, L. Grebenyuk1, O. Votyakova1, M. Solovev1, M. F. Tirsova1, I. Nakastoev1, A. Grachev1, M. Kanaeva1, A. Danilina1, S. Kulkov1, M. Rusinov1, V. Savchenko1
1Hematology Research Center, 2N.Blokhin Russian Cancer Research Center, Moscow, Russian Federation

Background: Multiple Myeloma (MM) is a genetically heterogeneous and complex disease with widely diverging survival times from months to years. Amplification of locus 1q21 (amp1q21) is among the most commonly reported genetic abnormalities in MM, but its prognostic value remains unclarified.

Aims: To define the frequency of amp1q21 in MM and its correlation with other chromosomal abnormalities, clinical course and prognosis.

Methods: In 134 patients (pts) with newly diagnosed MM from December, 2009 to March, 2016, 67 male and 67 female, median age 57 years (30-81), we performed FISH with locus-specific and centromere DNA probes (XL 1p32/Iq21, XL IGH probe, XL t(11;14), XL t(4;14), XL t(14;16), XL t(14;20), XL t(6;14), XL cMYC BA, XL 5p15/9q22/15q22, XL P53 (MetaSystems), D13S25 (Cytocell). Induction therapy with bortezomib-based classes was initiated for 131 pts, 3 pts with smoldering MM remained under observation. Response was evaluated according to the IMWG criteria for 127 pts, because 4 pts died in induction. 48 pts were underwent ASCT. The median follow-up of group was 19.3 months (3.2 – 77.4). Progression was diagnosed in 69 pts, in 12 of them FISH-analysis was performed also in disease progression.

Results: Chromosomal aberrations were revealed in 133 of 134 (99%) pts. TlgH/Iq23 was detected in 42.5% (57/134), hypodiploidy in 57.5% (77/134), hypodiploidy in 2.4% (3/134) pts. In 11.2% (15/134) a concurrent tlgH/Iq23 and a trisomy were found. The IGH translocations t(11;14), t(4;14), t(14;16), t(14:20), t(6;14) were observed at a frequency of 16.4%, 12.7%, 3.7%, 2.2%, 0.7% respectively, chromosomal partner is not found in 6.7%. Del(13q) was detected in 40.3% (54/134), del(17p) in 12.7% (17/134), ttcMYC/8q24 in 17.2% (23/134). Amp1q21 was detected in 39.6% (53/134). We identified 3 copies of 1q21 in 60.4% (80/134), del(13q) was detected in 3% (4/134), 4-7 copies 1q21 (4-7) in 21 (39.6%) pts. Cases with amp1q21 had a high incidence of del(13q) (OR=2.71 (1.32-5.55); p=0.006) and as higher LDH levels (OR=2.27 (1.09-4.72); p=0.027). From 12 pts investigated in progression amp1q21 was found in 9 pts (75%); in 2 cases amp1q21 was not found at diagnosis and was revealed in disease progression only; in 7 cases - amp1q21 was detected at diagnosis and in progression, and its copy number did not change. The difference in response after induction between pts with or without amp1q21 was not statistically significant: OR – 11.8% versus 14.5%, VGPR – 39.2% versus 27.6%; PR – 37.2% versus 27.6%; therapy resistant 11.8% versus 30.3% (p=0.07). Pts with amp1q21 had significantly worse 5-year overall survival (OS) (43.5% vs 79.4%; p=0.07). According to copy number of 1q21 the 5-year OS pts carrying 3 or >3 copies of 1q21 were 67.3% and 20.9% (p=0.0016) (Figure 1). On multivariate analysis >3 copies of amp1q21 (HR=4.29, p=0.0094), TTCMYC/8q24 (HR=6.51, p=0.0082), del(13p) (HR=3.46, p=0.007) were found to be an independent adverse predictors of shorter OS.

Figure 1.

Summary/Conclusions: Our results show that amp1q21 has a significant impact on OS MM pts in cases of more than 3 copies of locus only. In cases of 3 copies of 1q21 OS pts is comparable with OS in group without amp1q21.

ADAPTIVE IMMUNE RESPONSE IN PLASMA CELL DysCRASIAS: IMMUNE PROFILING AND DETERMINATION OF CIRCULATING B CELL LEVELS AS A SURROGATE ASSAY FOR BONE MARROW TESTING
S. Drain1, P. Eggn1, I. Deighan2, P. Elder3, T. Bjerjson4, F. McNicholl5, M. Bowers6, C. Morris3, D. Alexander1
1Stratified Medicine, C-tric, Ulster University, 2Clinical Biochemistry, 3Haematology Department, Altnagelvin Hospital, Derry, 4Haematology Department, Ulster Hospital, Belfast, United Kingdom

Background: Immune paresis is commonly identified in patients with plasma cell dyscrasias (PCD). Often, in newly presenting multiple myeloma (MM), it is associated with intractable infections for which the patient first seeks medical help. Furthermore, recent evidence suggests the importance of assessing levels of bone marrow (BM) derived B cells for risk stratification of the MM patients as reduced levels of B-cells in the BM have been associated with poorer outcomes and reduced progression free survival1. This cellular measure of adaptive immune function (ie: B cell enumeration) is, however, seldom analysed in the peripheral blood (PB) of patients with PCD.

Aims: This study was designed to examine measures of the adaptive immune response in PCD patients, by measuring relative and absolute numbers of T, B cell subset, NK and NKT cells at different stages of PCD, and to determine if the PB B-cell component can act as a surrogate marker for B cell enumeration in MM.

Methods: PB and BM lymphocyte subset analysis was performed on samples obtained from a range of PCD patients (n=70) using directly conjugated monoclonal antibodies (MAB) and multicolour flow cytometry, carried out on a FACSAria III cell sorter (BD, Oxford, UK). Serum protein electrophoresis was performed to identify and quantify paraproteins, and uninvolved Ig levels were quantified using autoanalyzer and turbidimetric SFLC were performed using the Freelite assay on the SPARus instrument (Binding Site, Birmingham, UK).

Results: Data is presented on 102 PB samples obtained from 70 PCD patients at different stages of disease, including monoclonal gammapathy of undetermined significance (MGUS), smoldering myeloma (SMM), and MM at diagnosis (MMD), throughout treatment (MMT) and at relapse (MRR). Quantification of circulating lymphocyte subsets showed reduced, absolute, numbers of B cells (56/102), T cells (19/102), TCD8 cells (32/102), CTLs (17/102), NK cells (32/102) and NKT cells (72/102). Furthermore, these reduced B cell levels were more frequently seen in the MMD and MMT groups (50% of samples) compared with the other PCD groups (10-25% of samples). Lymphocyte subset analysis was also performed on paired PB and BM samples from 14 patients with MM and a significant, positive, correlation was seen between relative numbers of B cells in both PB and BM (r=0.0001, r=0.09). No clearcut correlations were found between reductions in uninvolved Ig or sFLC levels, and numbers of cells involved in the adaptive immune response.

Summary/Conclusions: The results presented here are further evidence of immune paresis in PCD with specific effects seen at the cellular level. The high frequency of reduction was in B lymphocytes and NKT cells, in keeping with reduced levels of circulating B cells, followed by T cells, particularly TCD8 cells which have a crucial role in B cell Ig production. Relative B cell levels in BM were significantly correlated with B cell levels in PB and we suggest that monitoring of B cell levels in the PB of PCD patients may serve as a surrogate assay for enumeration of B cells in BM.

NOVEL MONOClonAL ANTIBODY THERAPY TARGETING CD26 IN MULTIPLE MYELOMA
H. Nishida1, H. Suzuki1, M. Hayashi1, M. Sakamoto1, T. Yamada1
1Pathology, Keio University, School of Medicine, Tokyo, Japan

Background: Bone disease is a hallmark of multiple myeloma (MM) and targeting osteoclasts (OCs) to alleviate bone destruction is a component of the standard care for MM. CD26 is a 110-kDa cell surface glycoprotein with DPPIV enzyme activity and has well-defined roles in T cell activation and several tumor developments, including malignant lymphoma. However, little is known about the role of CD26 in regulating bone remodeling.

Aims: In this study, we examine the CD26 expression in human normal OCs and OCs of MM patients. We explore the function of CD26 in osteoclastogenesis of OCs and investigate the effects of humanized anti-CD26 monoclonal antibody (CD26mAb) on human OCG. We further define the molecular targets of CD26 signaling cascade in OCG and explore the therapeutic potential of CD26mAb for treating MM.
Methods: Human BM-MNCs derived from normal human subjects or MM patients were cultured with M-CSF plus sRANKL with or without GSK2606414 for OC formation for TRAP staining and functional assay. To assess the mechanisms of action of CD26Ab on OC, RANK signaling proteins were examined by immunoblotting.

Results: CD26 is expressed on normal human OCs and is intensely expressed on activated OCs in MM, M. msFH-01, and sRANKL induced human OC differentiation, in association with CD26 expression on monocyte-macrophage lineage cells. CD26 expression was accompanied by increased phosphorylation of MKK3/6 and p38MAPK, which is crucial for human OC differentiation with its downstream activation of microphthalmia-associated transcription factor (mitf). Mitf plays an important role in OC functions. CD26 expression was evidenced as the number of multineucleated OCs (>3 nuclei) by TRAP/CD26 staining and down-regulated the secretion of TRAP-5b and type 1 collagen. It decreased the size of OCs and the number of nuclei per OC, with significantly defective bone resorption activity. It was revealed that in the presence of CD26Ab, which blocked OC precursor cells (OCPCs) CD26 expression and phosphorylation pathway was specifically, rapidly inactivated and subsequently, its downstream mitf phosphorylation was persistently inhibited. Thus, OC maturation with its bone resorption was impaired by suppressing the expression of TRAP and OC fusion proteins. In contrast, MKK3/6-p38MAPK-mitf was not phosphorylated at all in immature OCs after RANKL stimulation, regardless of the absence or presence of CD26Ab. These results suggest that CD26Ab blocked RANKL induced p38MAPK phosphorylation in OC precursor cells, but not in OCs. The activation of other MAPKs including ERK and SAPK/JNK, or NFXB was rapidly induced in response to RANKL both in OC precursor cells and OCs. However, the absence of phosphorylation at CD26 in CD26Ab did not directly affect mature OC functions. Next, although CD26Ab did not demonstrate direct inhibition of proliferation of MM cells, to further investigate the role of CD26 in MM cells in the BM, co-cultures of 11 MM cell lines with CD26-stained OCs were performed. We examined the expression of CD26 in MM cells. Although CD26 expression was only slightly detected in any of MM cell lines in mono-culture, CD26 expression level was upregulated in all MM cell lines, co-cultured with OCs by flow cytometry and immunohistochemistry. CD26 protein level in these cell lines was also increased by immunoblotting or ELISA. To further explore the CD26 expression in the BM microenvironment, we performed the upregulation of CD26Ab on CD26Ab stained MM cells. We also found that CD26Ab impairs the development of human functional OCs. Targeting CD26 positive OCs and certain endothelial vascular cells in several cases. Anti-myeloma efficacy of CD26Ab on MM cells, co-cultured with OCs was also evidenced.

Summary/Conclusions: Our data imply that the blockade of CD26 signaling with CD26Ab impairs the development of human functional OCs. Targeting CD26 in both OCs and MM cells with CD26Ab may be a promising novel therapeutic strategy in MM-associated bone disease and MM progression.

THE ANTI-MYELOMA ACTIVITY OF PERK KINASE INHIBITOR IN TARGETING MORE THAN 50 UPR-RELATED GENES INVOLVED IN THE PROLIFERATION OF MM CELLS

T. Bagratin1,*, E. Kastritis1, N. Mavrianou1, C. Liacos1, E. Terpos1, M. Dimopoulos1

1National and Kapodistrian University of Athens, Athens, Greece

Background: Due to the immunoglobulin production, multiple myeloma (MM) plasma cells are dependent on the unfolded protein response process (UPR), which controls protein production and ensures its proper translation and folding. A study by Michallet et al (2011) showed that knockdown of one of the three well-known arms of the UPR, PERK (protein kinase R (PKR)-like ER kinase) in MM cells resulted in autophagic cell death. This outcome indicated the importance of PERK activation for the maintenance of plasma cell to myeloma cell but also its ability to impede the apoptotic effect. In this study we used a small ATP competitive molecular inhibitor, GSK2606414, that acts by targeting PERK enzyme activity in its inactive DFG conformation at the ATP-binding site domain while displaying ≥385 fold selectivity over c-kit, Aurora B, BRK and many other kinases.

Aims: In this study we aimed to use a small ATP competitive molecular inhibitor, GSK2606414, that acts by targeting PERK enzyme activity in its inactive DFG conformation at the ATP-binding domain, while displaying ≥385 fold selectivity over c-kit, Aurora B, BRK and many other kinases.

Methods: We initially screened 25 CD138+ MM patients and 6 human myeloma cell lines (HMCLs) for PERK mRNA expression. Our results showed that PERK mRNA is highly expressed in almost all patients (5-10 fold higher than the mean PERK expression of HMCLs).

Results: To test the effect of GSK2606414 on the proliferation of MM cells, 4 HMCLs were treated with different doses of GSK2606414 at two time points (24 and 48 hours). Treatment of cells with 3-30μM GSK2606414 resulted in a dose-dependent inhibition of cell proliferation in all HMCLs ranging for 20-95% reduction of proliferative activity, thus, indicating the dependency of these cells on PERK signaling. Treatment of KMS11 and KMS12 cells with 3-30μM GSK2606414 for 24 and 48 hours resulted 25% and 15% increase in apoptotic cells by Annexin-V staining, respectively compared to untreated cells. In the absence of PERK inhibition, the percentage of apoptotic cells was increased in 40% and 30% reduced cell proliferation in H929 and L363 cells respectively compared to control. The effect of GSK2606414 in combination with bortezomib in the proliferation of H929 and L363 cells was examined. As seen in the apoptosis assay, pre-treatment of these cells with 10μM bortezomib for 24 hours increased the percentage of apoptotic cells by 40-50%. In addition, GSK2606414 and 10μM bortezomib combined treatment resulted in 70% and 40% reduction of cell proliferation in H929 and L363 cells respectively compared to control.

A study by Michallet et al (2011) showed that knockdown of one of the three well-known arms of the UPR, PERK (protein kinase R (PKR)-like ER kinase) in MM cells resulted in autophagic cell death. This outcome indicated the importance of PERK activation for the maintenance of plasma cell to myeloma cell but also its ability to impede the apoptotic effect. In this study we used a small ATP competitive molecular inhibitor, GSK2606414, that acts by targeting PERK enzyme activity in its inactive DFG conformation at the ATP-binding domain while displaying ≥385 fold selectivity over c-kit, Aurora B, BRK and many other kinases.

Results: To test the effect of GSK2606414 on the proliferation of MM cells, 4 HMCLs were treated with different doses of GSK2606414 at two time points (24 and 48 hours). Treatment of cells with 3-30μM GSK2606414 resulted in a dose-dependent inhibition of cell proliferation in all HMCLs ranging for 20-95% reduction of proliferative activity, thus, indicating the dependency of these cells on PERK signaling. Treatment of KMS11 and KMS12 cells with 3-30μM GSK2606414 for 24 and 48 hours resulted 25% and 15% increase in apoptotic cells by Annexin-V staining, respectively compared to untreated cells. In the absence of PERK inhibition, the percentage of apoptotic cells was increased in 40% and 30% reduced cell proliferation in H929 and L363 cells respectively compared to control. The effect of GSK2606414 in combination with bortezomib in the proliferation of H929 and L363 cells was examined. As seen in the apoptosis assay, pre-treatment of these cells with 10μM bortezomib for 24 hours increased the percentage of apoptotic cells by 40-50%. In addition, GSK2606414 and 10μM bortezomib combined treatment resulted in 70% and 40% reduction of cell proliferation in H929 and L363 cells respectively compared to control.
**Summary/Conclusions:** In conclusion, given the on-target pharmacological effects of PERK inhibitor on MM, development of PERK inhibitors may offer a therapeutic advantage that would affect MM pathogenesis and treatment.

ENVIRONMENTAL CONTROL OF PLASMA CELL FITNESS IN MULTIPLE MYELOMA: MALIGNANT CO-OPTATION OF ARGININE AS NOVEL IMMUNE ONCO-METABOLIC CHECKPOINT

A. Romano1,2, J. M. Garcia Manteiga3, V. Simeone4, L. Parrinello5, L. Canziani1, E. Milan7, M. Ghizzinardi2, D. Tibulico6, G. Giallongo2, P. La Cava2, F. Cremaschi1, C. Concilio1, P. Musto7, F. Cicere7, F. Di Raimondo7, S. Cenci1

1Division of Genetics and Cell Biology, San Raffaele Scientific Institute, Milan, 2Division of Oncology, Ospedale Policlinico e Vittorio Emanuele di Catania, 3Center for Translational genomics and Bioinformatics, San Raffaele Scientific Institute, Milano, 4Laboratory of Pre-clinical and Translational Research IRCCS, CROB Referral Cancer Center of Basicaltiss, Rionero in Vulture (Pz), 5Division of Genetics and Cell Biology, Azienda Ospedaliero Poliominatoria e Vittorio Emanuele di Catania, 6Department of Oncology-Metabolism, San Raffaele Scientific Institute, Milan, Italy

**Background:** The bone marrow (BM) environment plays a crucial role in the incurable plasma cell (PC) malignancy multiple myeloma (MM). Our previous work showed that arginine deprivation (arginine/glutamine <1000:1000) was established long-term and PC fitness, regulating Blimp-1, immunglobulin (Ig) production and ATP availability (Penge, 2013) and that MM is addicted to the autophagy receptor SQSTM1/p62 (Miller, 2015). Among putative pro-tumoral patients are immunosuppressive BM-derived high-density neutrophils (HDNs), but the role of HDNs in MM is unknown.

**Aims:** We hypothesized that in MM HDNs sustain PC fitness sustaining p62 through environmental arginine deprivation.

**Methods:** We integrated diverse unbiased and hypothesis-driven approaches: (1) gene expression profiles (GEP) of patient-derived circulating HDNs (60 MM, 30 healthy, 30 healthy controls), (2) metabolomic profiling by UHPLC/GC-MS of ad hoc collected BM and peripheral plasma (16 MM, 17 smoldering MM, 30mgU, 29 controls), and (3) functional and expression in vitro studies on human MM cell lines. We validated our observations in primary MM cells using bioinformatic analysis of transcript expression levels detected by RNA sequenc- (RNA-seq) available from the open-access, public clinical and molecular database, the CoMMpass Researcher Gateway (RG, https://research.themm.org, v I8A, n=649).

**Results:** In vitro, selective and progressive arginine deprivation (range 1000-0 μM) in four MM cell lines (MS 1S, U266, OPM2 and RPMI828) activated the GCDN/CHOP axis, resulting in increased p62 and Blimp-1 expression, increased ATP availability and immunglobulin production. Conversely, stable lentiviral p62 silencing significantly reduced Blimp-1 and ATP, and led to complete extinction of MM cell lines within 10 days of culture. Bioinformatic analysis of MMRF-Encompass trial data showed a positive correlation between p62 and Blimp-1 expression and eGFR. The percentage of patients with abnormal eGFR decreased as p62 transcriptionally predicted shorter progression-free survival at 24 months (4.56 months versus 11.6 months, p<0.0001).

**Summary/Conclusions:** Taken together, our findings disclose a novel envi-ronmental circuit co-opted by MM pathway, wherein immunosuppressive HDNs sustain PC fitness through arginine depletion to increase p62 and Blimp-1 via the GCN2/CHOP pathway.

ESTIMATED GLOMERULAR FILTRATION RATE (eGFR) CALCULATED BY CKD-EPI EQUATION COMBINED WITH THE INTERNATIONAL STAGING SYSTEM PROVIDES A POWERFUL PROGNOSTIC MODEL FOR EARLY MORTALITY IN MYELOMA PATIENTS

E. Katodritou1,*, V. Palaska1, E. Giannopoulou1, S. Papadaki1, A. Gerofotis1

1Hematology Department, Theagenion Cancer Hospital, 2Hematology Department, Papageorgiou General Hospital, 3Hematology Department and Bone Marrow Transplantation Unit, G. Papanikolaou General Hospital, THESSA-LONIKI, 4Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, ATHENS, Greece

**Background:** During the last decades, the introduction of autologous trans-plantation and novel agents has improved early mortality rates (EM, henceforth defined as death within one year after diagnosis) in Multiple Myeloma (MM). However, the incidence of EM remains high. Data relating to prognostic factors for EM in MM are limited.

**Aims:** The aim of this study was to explore for possible prognostic factors for EM, which could be a useful tool for planning treatment strategy in MM.

**Methods:** We have studied the medical records of 479 patients with MM (MF: 258/221, median age: 68 years, range 29-88, IgG: 269, IgA: 123, light chain: 72, non-secretory: 15), diagnosed and treated in our Department between January 2001 and January 2016; 86 patients (18%) had EM. Comparisons of patients’ characteristics between the EM group and the rest of the patients were performed with χ², one-way ANOVA and Mann Whitney U test. Prognostic factors for EM and overall survival (OS) were studied by using logistic regres-sion and cox regression analysis, respectively; OS was plotted by Kaplan-Meier; p<0.05 was considered as statistically significant.

**Results:** Patients with EM were more often men with a higher median age; hemoglobin, platelets and albumin were lower whereas κ2 microglobulin, lactate dehydrogenase (LDH) and calcium were higher in the EM group compared to the rest of MM patients (p<0.05). The percentage of patients with abnormal estimated Glomerular Filtration (eGFR) calculated by chronic kidney disease epidemiology collaboration (CKD-EPI) creatinine equation (t<04ml/min/1.73m²) was higher in the EM group compared with the rest of the patients (69% vs 17%, p<0.001). In accordance with the International Staging System (ISS), advanced MM stage (i.e. ISS3) was observed more often in the EM group compared to the rest (65% vs 31%, p<0.001). High risk cytogenetics including t(4;14), t(14;16) and del17p were present in 48% of patients in the EM group vs 21% of the others (p<0.001). The percentage of patients included in the highest EM category (EMi: relapsed/refractory disease: 26%; other causes: 6%). Univariate logistic regres-sion analysis demonstrated that ISS, revised ISS (RISS), abnormal LDH, hemoglobin <10g/dl, high risk cytogenetics, and CKD-EPI <40ml/min/1.73m² were independent prognostic factors for EM. In the multivariate analysis ISS and abnormal eGFR were the only independent prognostic factors for EM. When we incorporated ISS and eGFR in a single prognostic model (CKD-EPI/ISS) we identified 3 distinct prognostic groups: 1) low risk group including patients with ISS1 and CKD-EPI <40ml/min/1.73m², 2) high risk group including patients with ISS3 and CKD-EPI <40ml/min/1.73m² and 3) intermediate risk group including patients that did not fit in either low or high risk group. The inci-dence of EM in each was group was 8.1% 39% and 15.3%, respectively (OR: 2.8, 95% CI:1.9-4.1, p<0.001). Multivariate cox regression analysis of prognostic factors for OS in the whole population demonstrated that CKD-EPI/ISS model was the strongest independent prognostic factor for OS (HR= 0:38, 95% CI: <0.03).

**Summary/Conclusions:** Based on our data, the combination of eGFR esti-mated by CKD-EPI with ISS (CKD-EPI/ISS) represents a powerful independent prognostic model for EM and OS, in the era of novel agents. The markers con-stituting eGFR and ISS are cheap and available for most of MM patients, there-fore the CKD-EPI/ISS prognostic model may be readily applicable. Never-theless, the establishment of CKD-EPI/ISS model requires further validation.

ACTIVATED AND EXPANDED NATURAL KILLER CELLS FROM MULTIPLE MYELOMA PATIENTS DESTROY TUMOR DRUG RESISTANT CELLS AND CLONOCENIC TUMOR CELLS

A. Leivas1,2, I. Rapado1,2, L. Fernández1, A. Pérez-Martínez3, J.J. Lahuerta2, J. M. Martínez-López1,2

1Hematologic Malignancies Clinical Research Unit, Spanish National Cancer Research Center, 2Hematology, Hospital Universitario 12 de Octubre, 3Pediatric, Hospital Universitario La Paz, Madrid, Spain

**Background:** Multiple myeloma (MM) remains an incurable disease. Novel therapeutic strategies targeting drug resistant cells (DRC) and clonogenic tumor cells (CTC) are needed. Our group has conducted a phase I clinical trial with activated and expanded autologous NK cells (NKAEs) in patients with refractory MM with a relevant clinical effect. Likewise, it has been possible to discriminate DRCs in MM by side population (SP) detection.

**Aims:** The aim of this study was to characterize DRC and to check the activity of NKAEs against these DRCs and CTCs while preserving the hematopoietic progenitor cell.

**Methods:** Flow cytometry of the side population was performed by Dye Cycle Violet efflux detection to characterize DRC of MM cell lines and bone marrow samples from MM patients. The side population was purified by sorting and characterized by RNaseq. NK cells from MM patients’ peripheral blood were obtained and cocultured with the genetically modified K562-mb15-41BBL cells in order to obtain NKAEs. The activity of NKAE cells against SP was evaluated by time lapse microscopy and the activity against CTCs was evaluated by methylcellulose assay. In vitro safety against CD34+ progenitors was evaluated by time-resolved fluorescence cytotoxicity with europium-TDA and cul-ture media of methylocellulose containing autologous bone marrow and Erythrocytes.

**Results:** SP cells from both cell lines and samples from different stages of MM showed overexpression of stemness markers. Patient NKAE cells were shown to have much higher adhesion, migration and detection capacity of MM tumor cells than NK cells from the same patient. After SP purification by sorting, NKAE cells were able to detect and kill MM cells without significant differences. NKAE cells were also able to destroy CTCs from different MM cell lines. Cyto-toxicity studies revealed that NKAE cells did not destroy mononuclear cells from healthy bone marrow, even at maximum ratios of 32:1 the mean cytotoxicity was 1.85% (range 0 - 4.47%). Experiments on CD34+ hematopoietic progenitor cell cultures also showed that NKAE cells do not destroy CD34+ clones from healthy bone marrow, confirming the safety of NKAEs.

**Summary/Conclusions:** NKAE cells have molecular characteristics of the tumor stem cell compartment in MM. Likewise, NKAE cells from MM patients could
destroy drug resistant MM cells and clonogenic tumor cells with high efficiency, preserving CD34+ hematopoietic cells, and thus constitute an effective and safe therapy against MM.

E1235
UNMASKING THE RETROTRANSPOSON-ORCHESTRATED PRODUCTION OF SOLUBLE RANKL IN MULTIPLE MYELOMA CELLS
S. Papamichos1,2
1Laboratory of General Biology, Aristotle University of Thessaloniki Medical School, Thessaloniki, Greece

Background: Growing evidence suggest that production of soluble receptor activator of nuclear factor-kappa B ligand (sRANKL) directly by myeloma cells is causally related to the generalized bone loss in multiple myeloma (MM). Notably, sRANKL may be produced either by proteolytic cleavage of membrane-bound RANKL or by alternative splicing of TNFSF11 gene (TNFSF11 variant 2, sRANKL mRNA). Recent analysis argues against proteolytic processing of the membrane-bound form being the main mechanism of sRANKL production by myeloma cells. Accumulative data indicate that sRANKL mRNA presents a restricted transcriptional pattern, namely is expressed predominantly in malignant cell types. Accordingly, sRANKL mRNA (over)expression in primary MM cells and human MM cell lines has been validated in three independent studies. Furthermore it was recently demonstrated that sRANKL mRNA proximal promoter and first exon are of retroviral origin, residing within a large genomic cluster of transposable elements (TEs).

Aims: To unmask the TE-shaped transcriptional and epigenetic apparatus impelling the expression of sRANKL mRNA in a cell type- and cell context-specific manner.

Methods: RepeatMasker software was used to reveal the presence of integrated TE in the genomic segment comprising TNFSF11, TNFSF11 RNA-Seq data, generated by the GTEx project across 51 normal human tissues, were analyzed via GTeX Portal. TNFSF11 RNA-seq data from 4 bone marrow samples and 8 white blood cells samples, generated from the PRJEB4337 and PRJNA182351 BioProjects, were analyzed via the NCBI portal. TNFSF11 transcription factor (TF) ChIP-seq data were downloaded from the UCSC Genome Browser Database. Data on TNFSF11 proximal promoter methylation status in 63 cell lines were downloaded from the HaIB Methyl450 ENCODE track.

Results: RNA-Seq data from 51 normal human tissues show that sRANKL mRNA is expressed in a cell context-dependent manner, which is in accordance with the retroviral origin of the transcript. Data analysis from the PRJEB4337 and PRJNA182351 BioProjects further validates the null expression of sRANKL mRNA in normal human bone marrow and white blood cells. Methylation status of sRANKL mRNA promoter in 5 lymphoblastoid cell lines (LCLs) signifies that the retroviral promoter remains heavily methylated in these cell types. TNFSF11 TF ChIP-seq data show that 5 of 161 TFs can bind to the TE-derived sRANKL mRNA promoter region. Four of the five TFs (EBF1, PAX5, IKZF1, and PU.1) bind to this genomic segment exclusively in LCLs, signifying a cell-type specific transcriptional regulation. Notably, all 4 TFs are known to play a major role in normal and/or malignant lymphopoesis. Furthermore, IKZF1 and PU.1 represent direct targets of immunomodulatory drugs (IMiDs) for down-regulation.

Summary/Conclusions: Transcription of sRANKL mRNA is driven by a retroviral promoter which remains heavily methylated, thereby inactive, in normal lymphocytes. Epigenetic derepression of this promoter during the course of myeloma development is a direct consequence of the (over)expression of sRANKL mRNA by myeloma cells represents a plausible scenario. Should the IKZF1 and the PU.1 TFs act as enhancers of sRANKL mRNA expression, directly contributing to upregulation of sRANKL production in MM, it is a tantalizing hypothesis that warrants further investigation because this type of transcriptional boost could be a target for new treatment strategies. That Lenalidomide treatment downregulates the amount of sRANKL in the serum of patients with MM through inhibiting PU.1 expression (Breitkreutz et al., Leukemia 2008) is in accordance with the above and further raises the interest on the mechanisms promoting the anti-osteoclastogenic properties of IMiDs.

E1237
ADENOSINE AS THE MYELOMA BONE Marrow Niche: IMMUNE REGULATION AND KEY PLAYER IN DISEASE PROGRESSION
A. Horenstein1,2,*, A. Chillemi1, V. Quarona1, F. Costa1, D. Toscani1, F. Morandi4, D. Marmipietro6, N. Giulian6, F. Malavasi1,2
1Medical Sciences, University of Turin, 2CERMS, A.O.U. Citta della Salute e della Scienza, Turin, 3Myeloma Unit, Department of Clinical and Experimental Medicine, University of Parma, Parma, 4Laboratory of Oncology, Istituto Giannina Gaslini, Genova, Italy

Background: The tumor microenvironment is rich in extracellular mono- and di-nucleotides (ATP, NAD) which are metabolized by cell surface ectoenzymes to produce adenosine (Ado), a nucleoside involved in the control of inflammation and immune responses. Multiple myeloma (MM), a plasma cell malignancy that develops within the bone marrow (BM) niche, overexpresses CD38, a molecule with complex functions. As a nucleotide-metabolizing enzyme, CD38 catalyzes the initial disassembly of NAD to CADPR and ADPR, which is followed by adenosinergic activity, providing that BM cells are able to recognize the presence of adenosine. (E203a and CD73).

Aims: To demonstrate that adenosinergic pathways contribute to customize hematosis in MM.

Methods: Evaluation of the expression of adenosinergic enzymes was assessed by immunohistochemical and flow cytometric analysis on cell lines, and primary myeloma cells and BM biopsies from patients with MM or with monoclonal gammopathy of undetermined significance. Flow cytometry and immunohistochemistry revealed that in the (over)expression of sRANKL mRNA by myeloma cells represents a plausible scenario. Should the IKZF1 and the PU.1 TFs act as enhancers of sRANKL mRNA expression, directly contributing to upregulation of sRANKL production in MM, it is a tantalizing hypothesis that warrants further investigation because this type of transcriptional boost could be a target for new treatment strategies. That Lenalidomide treatment downregulates the amount of sRANKL in the serum of patients with MM through inhibiting PU.1 expression (Breitkreutz et al., Leukemia 2008) is in accordance with the above and further raises the interest on the mechanisms promoting the anti-osteoclastogenic properties of IMiDs.

Summary/Conclusions: We confirm the clinical value of a simple, rapid, two-tubes FC quantification of the proportion of pathologic plasma cells in the evaluation of the risk and kinetics of disease evolution imgUS and SMM. It’s use allows identification of patients which require more frequent follow-up.
Myeloma and other monoclonal gammopathies - Clinical

Results: A total of 1493 pts were enrolled in Cohort 1 from Sep 2009 to Dec 2011; 1450 were treated, 81% (n=1173) in a community setting. Of those, 432 (29%) met analysis criteria. Median follow-up was 39.3 months. Median age was 60 y (range, 24-78); 60% were men; and 86% were white. A total of 165 pts did not receive maintenance. Of 267 pts receiving maintenance, 213 (80%) received LEN-based maintenance; 30 (11%) received BORT-based maintenance; and 16 (6%) received LEN+BORT maintenance. Of the maintenance groups, only data from LEN maintenance is presented; small sample sizes in the other maintenance groups limited interpretation. The median treatment duration was 35.2 months for pts who received LEN maintenance and 26.1 months for those who did not receive maintenance. Median PFS was significantly longer for pts who received LEN maintenance vs no maintenance (50.3 months vs 30.8 months; hazard ratio [HR]=0.62 [95% CI: 0.46, 0.82]; P=0.009; Table). OS was also significantly improved for pts who received LEN maintenance vs no maintenance (HR=0.54 [95% CI: 0.36, 0.83]; P=0.005). Second PFS (PFS for second-line treatment) was similar for both LEN and no maintenance groups. Exploratory analyses showed generally similar PFS and OS outcomes was performed.

Background: Randomized phase 3 clinical trials have shown that maintenance therapy after autologous stem cell transplant (ASCT) can extend time to progression, progression-free survival (PFS), and overall survival (OS) for patients (pts) with newly diagnosed multiple myeloma (NDMM) (Sonneveld, J Clin Oncol, 2012; McCarthy, N Engl J Med, 2012; Attal, N Engl J Med, 2012; Palumbo, N Engl J Med, 2014; Attal, ASCO, 2016). Connect MM is a largely community-based, US prospective observational cohort study designed to characterize diagnosis, treatment patterns and outcomes in pts with NDMM in clinical practice.

Aims: The Connect MM registry was used to assess impact of maintenance therapy on survival outcomes in pts with NDMM receiving ASCT. Methods: Adult pts with NDMM were eligible to enroll in the registry within 60 days of diagnosis. Pts were enrolled in 2 sequential cohorts and were treated at the clinician’s discretion as per standard of care. Cohort 1 pts receiving induction and ASCT were included in the analysis and characterized into 4 maintenance regimen subgroups: no maintenance, lenalidomide (LEN)-based maintenance, bortezomib (BORT)-based maintenance, and LEN+BORT maintenance. Duration was from 100 days post-ASCT (no maintenance group) or start of maintenance until progressive disease, death, discontinuation, or data cutoff of January 7, 2016. End points were PFS, second PFS, OS, and safety. An exploratory analysis of the impact of baseline characteristics on survival outcomes was performed.

DARATUMUMAB-BASED COMBINATION THERAPIES IN HEAVILY-PRE-TREATED PATIENTS WITH RELAPSED AND/OR REFRACTORY MULTIPLE MYELOMA

A. Lakshman1, J. Abeykoon2, S. Kumar1, V. Rajkumar1, T. Kourelis1, F. Buadi1, D. Dingli1, L. Martha1, W. Gonsalves1, A. Dispenzieri1, R. Kyle1, Y. Lin1, R. Go1, R. Warsame1, M. Hobbs1, A. Fonder1, Y. Hwa1, S. Hayman1, S. Russell1, N. Leung1, M. Gertz1, P. Kapoor1

1Division of Hematology, Internal Medicine, Mayo Clinic, Rochester, United States

Background: Daratumumab-based combination Therapies (DCT) with bortezomib (V)/ lenalidomide (R)/ pomalidomide (P) and dexamethasone (d) have shown exceptional activity in relapsed and/or refractory multiple myeloma (RRMM) in trials. Experience outside of trials since the approval of Daratumumab (D) in 2015 is limited.

Aims: We aimed to review the outcomes of patients who received DCT at our institution.

Methods: Records of RRMM patients seen at Mayo Clinic, MN from December 2015–December 2016 were reviewed. Patients who received ≥1 cycle of DCT were included. Time-to-event analyses were done from date of starting DCT using Kaplan Meier method. Common terminology criteria for adverse events vs

Results: Of 130 patients, 59% were males and median age at DCT initiation was 67 (43-93) years. ECOG performance score was 22% in 29%. Patients were classified as mSMART high (22%), intermediate (22%) or standard (56%) risk. Median time from diagnosis to initiation of DCT was 51.3 (5-156) months, and median number of prior therapies was 4 (1-14). Eighteen (14%) of patients were refractory to prior daratumumab monotherapy. Fifty-three (41%) patients received ‘other’ DCT. Median time to first response (≥ PR) was 3.1 months (95% CI: 17-4.6). Overall response rate was 46%, complete remission in 17%, with clinical benefit rate of 62%. Median estimated follow up from initiation of DCT was 5.4 months (CI 4.2-5.5). The median duration of response was 6.1 months (CI 5.1- not reached (NR)). Median progression-free survival (PFS) was 5.5 months (CI 4.1-7.8) (figure A) and median time to next therapy (TTNT) was 5.9 months (CI 4.6-9.4) (figure B). Median PFS for D/Pd, D/Rd and other DCTs were 4.6 (CI 2.7-NR), 7.8 (CI 5-NR), 3.9 (CI 2.1-4.8) and 3.9 (CI 2.8-8.2) months, respectively (p=0.3). Median overall survival (OS) from starting DCT was NR (CI 11.4-NR) (figure C). Median PFS for quadruple refractory (n=28) MM was 2.8 months (CI 2.2-5.3) vs 5.9 months (CI 4.9-NR) for the rest (p=0.008) (figure D). Grade 3 or higher hematological toxicities were seen in 42% of patients. Other toxicities included infections (37%), fatigue (31%), infusion reactions (16%) and diarrhea (10%).

Figure 1.

Summary/Conclusions: DCT are effective in RRMM, but the PFS remains short, particularly in quadruple refractory patients, reflecting the challenges encountered in managing heavily-petreated, and often less fit patients, in routine practice.

E1241

IMPACT OF METFORMIN USE IN THE OUTCOMES OF MULTIPLE MYELOMA PATIENTS POST STEM CELL TRANSPLANT

N. Duma1, J. Vera-Aguilera1, J. Paludo1, Y. Wang1, T. Anagnostou1

1Hematology, Mayo Clinic, Rochester, United States

Background: Metformin use was associated with a better progression-free survival and higher complete response rates after SCT in our MM cohort. A trend toward better overall survival was also noted in the Metformin group. Larger studies are needed to enhance our understanding of the clinical effect of metformin on MM.

Methods: All MM patients who underwent stem cell transplant (SCT) at the Mayo Clinic Rochester from 2007 to 2012 were reviewed. Patients were grouped based on metformin use. Initial diagnosis at our institution and ≥12 months of follow up were required. Kaplan-Meier method and Cox regression were used for time-to-event and multivariate analysis.

Results: Out of 687 patients, 78 (11.4%) patients were using metformin at the time of MM diagnosis. Baseline characteristics in the metformin and no-metformin groups were similar. Median metformin dose was 2000mg daily and median duration of metformin use from MM diagnosis was 22 months. Patients on the Metformin group achieved higher rates of complete response after SCT (41% vs 29% p<0.02). Median progression-free survival (PFS) after SCT was longer in the Metformin group, 31.3 months (95% CI: 10.4-52.2) vs 16.6 months in the no-metformin group (95%CI: 14.5-18.7) p<0.04. There was a trend toward longer overall survival in the Metformin group, but it was not statistically significant (170 vs 106 months, p<0.10). In a multivariate analysis of metformin use, age, sex, international staging system (ISS), LDH and cytogenetics/FISH, the former was an independent predictor of PFS after SCT (OR: 0.38, 95%CI: 0.20-0.88, p<0.001).

Figure 1.

Summary/Conclusions: Metformin use was associated with a better progression-free survival and higher complete response rates after SCT in our MM cohort. A trend toward better overall survival was also noted in the Metformin group. Larger studies are needed to enhance our understanding of the clinical effect of metformin on MM.

COMPARING WHOLE BODY MRI WITH PET-CT IMAGING AT DIAGNOSIS OF MYELOMA

J. Vidler1, G. Havariyoun2, G. Vivian3, I. Walker1, M. Streetly1, K. Cuthill1, R. Benjamin1, N. Mulholland3

1Department of Haematological Medicine, 2Department of Medical Engineering and Physics, 3Departments of Radiology and Nuclear Medicine, King’s College Hospital, London, United Kingdom

Background: Imaging in the diagnosis of myeloma is a rapidly developing field. First line imaging has traditionally been a skeletal survey with plain films, however new guidelines recommend whole body imaging to aid the diagnosis of myeloma. Whole body MRI (WBMRI) has shown exceptional activity in relapsed and/or refractory multiple myeloma. Whole body PET-CT (WBCT) is a well-established imaging modality in myeloma. The aim of this study was to compare WBMRI with PET-CT imaging at diagnosis of myeloma.

Methods: A retrospective cohort study was performed of all patients with multiple myeloma or plasmacytoma in 33 patients presenting to King’s College Hospital, London. The scans were reviewed independently by two consultants in Radiology.
and Nuclear Medicine, looking for focal bone lesions, bone marrow pattern and incidental findings. Details of the patients’ demographics, myeloma diagnosis and treatment were collected from the medical records.

**Results:** Of the 33 patients, 24 were male. The median age was 64 years (range=43-86 years). One patient had a solitary plasmacytoma, the other 32 had myeloma (21 IgG, 3 IgA, 2 non-secretory, 4 light chain disease, 2 biclonal myeloma, 1 had ISS stage 1 disease with a median paraprotein level of 17 (range 0.52-6). 21 patients had a bone marrow plasma cell burden of 10-60%, 10 patients >60% and 2 were unknown. Sixteen patients were diagnosed with smouldering myeloma and a ‘watch and wait’ policy was adopted. Eleven patients were treated with chemotherapy, 4 were entered into a clinical trial, one was offered palliative care and one was referred to our centre for autograft. WBMRI identified a focal lesion of disease in 30% of patients compared with 36% by PET-CT. This was not a statistically significant difference (p=0.18). In addition there was no statistically significant difference between PET-CT & MRI in detecting <3 or >3 lesions (p=0.705 and p=0.083 respectively). The apparent difference was in the detection ofvertebrae L5 (using diffusion weighted MR imaging) was measured. This showed a strong correlation with the degree of bone marrow infiltration by plasma cells (r=0.64). An ADC of <600mm²/s had a negative predictive value of 93% for a bone marrow plasma cell infiltrate of >60%. There was also a significant difference (p=0.012) in the ADC between those with smouldering myeloma and those with symptomatic disease. It was noted that 9 scans resulted in incidental findings including pneumonia, adrenal lesions and one case of colocoleral cancer.

**Summary/Conclusions:** We have shown no difference in PET-CT and WBMRI in detecting a myeloma defining focal bone lesion, or providing prognostic estimations of burden of disease. Using MRI, a measure of the ADC at vertebrab L5 has been shown to be a semi-quantitative parameter that correlates with bone marrow plasma cell infiltration and distinguished between those with smouldering and symptomatic disease. In addition it is noted that whole body imaging has led to incidental findings of further pathology, including an unrelated malignancy, which may lead to useful clinical information or to further investigations and imaging which may not be needed.

**PERSISTENCE OF MINIMAL RESIDUAL DISEASE BY MULTIPARAMETER FLOW CYTOMETRY CAN HINDER RECOVERY OF ORGAN DAMAGE IN PATIENTS WITH AL AMYLOIDOSIS**

P. Milan1,*, M. Massa1, M. Bassett1, F. Russo1, P. Bert2, A. Foli1, O. Annibali1, G. Palladini1, G. Merlini1
1Department of Molecular Medicine, Amyloidosis Research and Treatment Center, Fondazione IRCCS Policlinico San Matteo, University of Pavia, Pavia, Italy
2Hematology, Stem Cell Transplantation, Transfusion Medicine and Cellular Therapy, Research Unit, Università Campus Bio-Medico di Roma, Rome, Italy

**Background:** In multiple myeloma, Minimal Residual Disease (MRD) demonstrated by multiparameter flow cytometry (MFC) identifies subjects with significantly shorter survival typically among those who attain complete response (CR). The role of MRD in AL amyloidosis has not been assessed so far.

**Aims:** In the present study, we assessed the MRD by MFC in patients with AL amyloidosis who attained CR.

**Methods:** CR was defined as per current criteria (negative serum and urine immunofixation and normal free light chain ratio). For flow cytometry studies bone marrow samples were processed following the Euro Flow Bulk Lysis Standard Operating Protocol and stained with the EuroFlow/MF MM MRD panel. At least 5x10⁶ events were measured using a FACS Cantos II (USA) instrument. Data were analyzed using the Infinty software (Spain). Patients were identified as having residual disease if a discrepant population of plasma cells comprising ≥50 events was identified (10⁻⁵ limit of detection).

**Results:** Twenty-eight patients were tested (7 were found to have relapsed at the time of MRD assessment with monoclonal components detectable and MRD+) and 21 satisfied current criteria for CR. Nineteen (90%) had relapsed and 9 (45%) progressed by detection of smouldering disease. More than 2 lines of therapy were required to achieve CR in 7 subjects. Median time to CR was 10 months (range: 3-82). Five patients (62%) had achieved cardiac response and 9 (50%) renal response at the time of CR. The median time from CR to MRD was 30 months (range: 6-148), this was not different in the MRD positive and MRD- patients. Sixteen patients were diagnosed with smouldering myeloma and a ‘watch and wait’ policy was adopted. Eleven patients were treated with chemotherapy, 4 were entered into a clinical trial, one was offered palliative care and one was referred to our centre for autograft. WBMRI identified a focal lesion of disease in 30% of patients compared with 36% by PET-CT. This was not a statistically significant difference (p=0.18). In addition there was no statistically significant difference between PET-CT & MRI in detecting <3 or >3 lesions (p=0.705 and p=0.083 respectively). The apparent difference was in the detection of vertebrab L5 (using diffusion weighted MR imaging) was measured. This showed a strong correlation with the degree of bone marrow infiltration by plasma cells (r=0.64). An ADC of <600mm²/s had a negative predictive value of 93% for a bone marrow plasma cell infiltrate of >60%. There was also a significant difference (p=0.012) in the ADC between those with smouldering myeloma and those with symptomatic disease. It was noted that 9 scans resulted in incidental findings including pneumonia, adrenal lesions and one case of colorectal cancer.

**Summary/Conclusions:** We have shown no difference in PET-CT and WBMRI in detecting a myeloma defining focal bone lesion, or providing prognostic estimations of burden of disease. Using MRI, a measure of the ADC at vertebrab L5 has been shown to be a semi-quantitative parameter that correlates with bone marrow plasma cell infiltration and distinguished between those with smouldering and symptomatic disease. In addition it is noted that whole body imaging has led to incidental findings of further pathology, including an unrelated malignancy, which may lead to useful clinical information or to further investigations and imaging which may not be needed.

**ERRATUM**

**ERRATUM**

---

**A validation study in a larger cohort is ongoing.**

**Further investigations are needed in the area of whole body imaging.**

---

**Aims:** Carfilzomib (K), a novel irreversible proteasome inhibitor associated with a low incidence of PN, was evaluated in two recent phase 3 studies in RRMM patients. The possible impact of MRD on PN rate during the study (prespecified key secondary endpoint) was significantly lower with Kd vs Rd for patients with grade 2 PN at baseline. In ENDEAVOR, grade ≥2 PN rate during the study (prespecified key secondary endpoint) was significantly lower with Kd vs Vd (6.0% vs 32.0%, Table). Patients had significantly improved pain and neurotoxicity subscale scores with Kd vs Vd. PFS improved with Kd vs Vd in patients with baseline history of grade 2 PN (Table 1).

**Table 1.**

---

**Summary/Conclusions:** In ENDEAVOR, the rate of PN was significantly lower with Kd then with Vd: in ASPIRE, PN rate was similar for Kd and Rd. Improved pain and neurotoxicity subscale scores with K may be attributed to better disease control and/or lower PN rates.

---

**EARLY RELAPSE FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION IN MYELOMA IS A POOR PROGNOSTIC MARKER FOR OVERALL SURVIVAL AND IS DIFFICULT TO PREDICT AT DIAGNOSIS OR DURING INDUCTION TREATMENT**

I. Walker1,*, A. Coady2, I. El-Najjar 3, K. Wilson4, K. Cuthill1,5, W. Ingram4, M. Kazmi5, K. Raj1, R. Benjamin1, S. Schey1, A. Pagliuca1, G. Muth1, M. Streetly1,3, C. Bygraves5
1Department of Haematology, King’s College Hospital Foundation Trust, 2Guy’s, King’s and St Thomas’ School of Medical Education, King’s College London, 3Department of Haematology, Guy’s and St Thomas’ NHS foundation Trust, 4Department of Haematology, University Hospital Wales, Cardiff, UK, 5Department of Haematology, University Hospital of Cardiff, United Kingdom

**Background:** High dose chemotherapy followed by autologous stem cell transplantation (ASCT) remains the gold standard treatment in myeloma for young
patients at induction. A number of factors have been shown to correlate with overall survival (OS) and progression free survival (PFS) including depth of remission prior to ASCT, Initial ISS stage and high risk cytogenetics. Emerging evidence has demonstrated that early relapse following ASCT is associated with reduced OS, and is not correlated with depth of pre-transplant response.

**Aims:** To characterise myeloma patients who relapsed within 12 months of ASCT; through baseline characteristics and transplant engraftment, and assess the impact of this early relapse on OS and PFS.

**Methods:** We performed a multicentre retrospective analysis of patients who underwent ASCT at 3 centres between 01/2009 – 02/2016 (London) and 06/2006 – 03/2013 (Cardiff). Baseline characteristics were reviewed and ASCT engraftment was assessed by; time to neutrophils $\geq 50 \times 10^9/l$ and platelets $\geq 20 \times 10^9/l$. Post-transplant PFS & OS was calculated by time (months) from diagnosis to progression or death.

**Results:** 443 myeloma patients were identified, median age was 57 (r 31-73), 56% were male. 41% of patients were ISS stage 1, 34% stage 2, 25% stage 3. Cytogenetic data was available for 139 patients. 1st-line therapy prior to transplant was immunomodulatory drug (IMiD) based (THAL/LEN) for 318/443 patients & 72/443 were proteasome inhibitor (PI) based (BORT/CAF). In addition, 11 patients received combination PI and IMiD. Median time from start of therapy to ASCT was 10 months (r-3-109m). 67 patients progressed within 12m of ASCT (early progression). No statistical difference was found between $<12$m or $\geq 12$m relapse for; age, gender, 1st line therapy, ISS stage, Hb, LDH, Ca or cytogenetics, confirming that this group is difficult to predict at baseline. Median OS from time of diagnosis was 103 months (95% CI 101 -137), median OS from start of ASCT was not reached, however 5-year OS was 68%. Patients with progressive disease within 12 months of ASCT, has significantly reduced median OS. Median OS post ASCT was 31 months (95% CI 21-39) compared to non-progressive patients (median OS:103m 95% CI 89-117) $p=0.0005$. Median OS from ASCT was reduced in early progression median OS:18m (95% CI 14-22m) vs progression >12 months median OS:89m (95% CI 79-98m) $p=0.0005$. 1st line therapy did not influence likelihood of PFS<$\leq$12months, with no statistical difference between patients who received PIs, IMiDs or both 1st line ($p=0.484$). A significant difference was observed in median time to platelet engraftment between the 2 centres. Increased time for platelets to reach $>20 \times 10^9/l$ was associated with reduced OS from ASCT for each centre HR 1.14 & 1.20 ($p=0.046$ & 0.03) for Cardiff or London centres respectively (Cox’s Method).

**Summary/Conclusions:** Early relapse following ASCT is a significant predictor of inferior OS in myeloma and difficult to predict from standard baseline characteristics. From our analysis; 1st line treatment prior to ASCT did not influence OS or PFS. There was an association between slow platelet engraftment following ASCT and PFS and OS. Possible explanations include: residual occult disease, toxicity of chemotherapy or patient somoral factors which facilitate disease resistance and impair normal haematopoiesis. All of these factors have been shown to drive relapse. RCTs are required to standardise bone marrow response assessment post ASCT, quantify remission status (using laboratory and imaging techniques) and definitively predict early relapse. Additionally, these studies will investigate further biological or genetic mechanisms driving early relapse to help identify novel therapeutic approaches in this extremely poor prognosis group.

**E1246**

**PATIENT-REPORTED OUTCOMES (PROS) WITH IBRUTINIB: SUBSTUDY OF INNOVATETM FOR WALDENSTRÖM MACROGLOBULINEMIA (WM)**

1Haematology, Concord Repatriation General Hospital, Concord, Australia, 2National and Kapodistrian University of Athens, School of Medicine, Athens, Greece, 3Azienda Ospedale Niguarda Ca’ Granda Hospital, Milan, Italy, 4Colorado Blood Cancer Institute, Denver, 5Winship Cancer Institute of Emory University, Atlanta, United States, 6Royal Victoria Hospital at McGill University Health Centre, Montreal, Canada, 7Hospital Universitario de Salamanca, Salamanca, Spain, 8Dana-Farber Cancer Institute, Boston, United States, 9Hopital Pitie-Salpetriere APHP, UPMC Universite, Paris, France, 10Pharmacylics, LLC, and AbbVie Company, Sunnyvale, United States, 11University of Ulm, Ulm, Germany.

**Background:** Anemia and fatigue are frequent indications for WM treatment. To date, patient-reported outcomes (PROs) have not been used to quantify benefits of WM therapy. Ibrutinib (ibr), a first-in-class, once-daily inhibitor of BTK, is indicated in the EU for the treatment of WM after 1st prior therapy of first-line in patients (pts) unsuitable for chemoimmunotherapy.

**Aims:** To prospectively collect PROs from the INNOVATE substudy to assess patients’ perspectives of the therapeutic benefit of ibr.

**Methods:** INNOVATE has randomized (ibr+rituximab [RTX] vs placebo+RTX) with 2 components. Pts in the substudy received oral ibr 420mg daily until progressive disease (PD) or unacceptable toxicity. All pts provided informed consent. PRO assessments—FACT-An total score (TS) and FACT-An anemia subscale (AS), and EQ-5D-3L (EQ)—were performed regularly.

**Results:** Persistent fatigue was the main indication for treatment in 22/31 (71%) pts. Baseline PRO scores were lower for time study vs randomized pts (Table). With a median of 17 months (mo) of treatment, most pts had clinically meaningful improvement in TS (>7 points; 77%), AS (>6 points; 84%), and EQ utility scores (≥0.08 points; 68%). Time to clinically meaningful improvement was prompt (1 mo for TS and AS; 2 mo for EQ), corresponding with a 48% decline in median IgM (median 20 g/L) after 4 weeks. In pts with baseline anemia (hemoglobin [Hb] ≤110 g/L), sustained Hb improvement increased with depth of response. At week 65, Hb levels significantly correlated with TS ($r=0.507$, $P=0.01$) and AS ($r=0.519$, $P=0.008$), and were marginal for EQ ($r=0.39$, $P=0.054$). Although IgM levels did not significantly correlate with PRO scores, the benefit was similar in responders regardless of depth of response.

**Table 1.**

**Summary/Conclusions:** Clinical response, and associated anemia improvement induced by ibr, correlated with meaningful improvements in the well-being of heavily pretreated pts with RTX-refractory WM.

**E1247**

**INCIDENCE AND RISK FACTORS OF CARDIOVASCULAR ADVERSE EVENTS IN A LARGE POPULATION OF NEWLY-DIAGNOSED, TRANSPANT INELIGIBLE MYELOMA PATIENTS TREATED WITH CARFILZOMIB**

1Myeloma Unit, Division of Hematology, University of Torino, Torino, 2Italian Multiple Myeloma Network, GIMEMA, 3Unit of Clinical Epidemiology, AOU Città della Salute e della Scienza di Torino and CPO Piemonte, Torino, Italy, 4Myeloma Unit, Division of Hematology, University of Torino - Currently Takeda Pharmaceuticals Co., Torino, Zurich, Italy, Switzerland, 5Department of Hematology, Erasmus Medical Center, Rotterdam, Netherlands.

**Background:** Cardio-vascular (CV) toxicities in patients (pts) with multiple myeloma (MM) may derive from comorbidities, MM itself and its treatment. Carfilzomib, an irreversible proteasome inhibitor, is approved as single agent or in combination with dexamethasone or lenalidomide-dexamethasone for relapsed MM.

**Aims:** To prospectively collect CV outcomes in pts newly-diagnosed with MM treated with Carfilzomib in 3 phase III studies (IST-CAR-506, IST-CAR-508, IST-CAR-601).

**Methods:** All pts were treated with 9, 28-day induction cycles with carfilzomib, cyclophosphamide (300mg/m² on days 1,8,15) and dexamethasone (40mg weekly) (CCyd), followed by carfilzomib maintenance until progression or intel-
eral vascular disease (including hypertension in 13% patients), 19% diabetes and 5% chronic pulmonary disease. After a median follow-up of 21 months, at least 1 cardiovascular (CV) AEs occurred in 29% of patients; any grade hypertension was 34% of patients and those with at least 1 CV risk factor were at higher risk (odds ratio: 3.75; p=0.002) and grade 3-5 CV-AEs (34% vs 15%, p=0.01) were more frequent compared to those without CV-AEs (12% and 18%, respectively; p<0.001). A trend toward a shorter 2-year overall survival (adjusted for age) was observed among patients who experienced at least 1 CV-AE as compared with those who did not (74% vs 83%; HR: 0.51; p=0.066). Pts ≥75 years had a higher risk of any grade (58% vs 36%; p=0.002) and grade 3-5 CV-AEs (34% vs 15%, p=0.01) were more frequent compared to those younger in older patients (29%) than in younger ones (6%; p<0.001). Patients with at least 1 CV risk factor at enrolment had a 4-fold increased risk (odds ratio: 3.79; p<0.001) of developing a CV-AE during treatment as compared to patients with no CV risk factors; in detail, baseline hypertension (odds ratio: 4.12; p=0.012) and peripheral vascular disease (odds ratio: 3.75; p=0.002) conferred the highest risk of developing CV-AEs.

Summary/Conclusions: Among newly diagnosed MM pts treated with carfilzomib, cyclophosphamide and dexamethasone, at least 1 CV-affected event was more common in pts aged ≥75 years than in younger patients (8% vs 13%; HR: 0.67, p=0.05). CV toxicity may significantly impact on treatment compliance and survival. Therefore, to derive maximum benefit from Carfilzomib, all pts – particularly the elderly - should be carefully assessed to select the most appropriate treatment.

E1249 POMALIDOMIDE (POM) + LOW-DOSE DEXAMETHASONE (LODEX) AFTER SECOND-LINE LENALIDOMIDE (LEN)-BASED TREATMENT OF RELAPSED OR REFRACTORY MULTIPLE MYELOMA (RRMM): UPDATED PROGRESSION-FREE SURVIVAL ANALYSIS D.S. Siegel1, G.J. Schiller2, K. Song3, R. Agajanian2, K. Stockett-Goldstein6, H. Kaye4, M. Selagi2, F.J. Rivest2, E. Malek2, G. Talamaro1, J. Mouru1, W. Chung1, S. Sinnivasan1, M. Qian11, S. Rivulski1, A. Thakurta11, N.J. Bals12 1John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ, 2David Geffen School of Medicine at UCLA, Los Angeles, CA, 3United States, 4Virginia General Hospital, Vancouver, BC, Canada, 5The Oncology Institute of Hope and Innovation, Bronx, NY, 6McGill University Health Centre, Montreal, Quebec, Canada, 7Cleveland Clinic, 8University Hospitals Case Medical Center, Cleveland, OH, 9Penn State Hershey Cancer Institute, Hershey, PA, 10Cleveland Cancer Institute, Summit, NJ, 11United States, 12University of Calgary, Calgary, Alberta, Canada

Background: Most recent pivotal trials of triple therapy in second- and third-line treatment excluded patients (pts) whose multiple myeloma (MM) was refractory to LEN. This is not reflective of the standard of care in first and second line where LEN is given until progressive disease (PD). To address this, the MM-014 phase 2 trial enrolled pts with RRMM and second-line LEN-based treatment failure. Cohort A enrolled pts treated with POM + LoDEX. The study was amended to include cohort B (pts treated with POM + LoDEX + daratumumab).

Aims: To present updated safety and efficacy analyses only from cohort A, in which pts received POM + LoDEX immediately after relapsing or being refractory to second-line LEN-based therapy.

Methods: Pts aged ≥18 years had documented MM, measurable disease, 2 prior lines of treatment, and PD after ≥2 cycles of second-line LEN-based treatment. Pts received 28-day cycles of POM 4mg/day on days 1-21 + LoDEX 40mg/daily (1day/75 days) on days 1, 8, 15, 29 and 36; R=42% (cortenbrolins) was mandatory. The primary endpoint was overall response rate (ORR; ≥ partial response [PR]) assessed by modified IMWG criteria. Secondary endpoints included time to response (TRR), progression-free survival (PFS), secondary primary malignancies (SPMs), and biomarkers. All pts provided informed consent.

Results: Of 51 enrolled pts in cohort A, 59 (76.5%) discontinued treatment, mostly due to PD. Median age was 68.0 years, and 92.2% had an Eastern Cooperative Oncology Group performance status of ≤1. A total of 45 pts (88.2%) were refractory to their last treatment with LEN, and 37 (72.5%) had prior treatment with carfilzomib. Median duration of prior LEN-containing therapy was 24.6 months. With a median follow-up of 13.6 months, ORR was 29.4%, with 1 (2.0%) complete response, 5 (9.8%) very good partial responses, and 9 (17.6%) PRs. Minimal response (MR) was reached in 15.7% of pts. Median TTR was 1.9 months and 66% of pts had ongoing response at 1 year. Median PFS was 13.8 months. The 2-year PFS rate for the intent to treat population, 69.4% for pts with ≥ MR, and 69.1% for pts with PR. In addition, pts with ≥ MR had similar treatment durations as those achieving ≥ TRR (10.5 vs 11.5 months, Table). Common grade 3/4 adverse events (AEs) included anemia (25.5%), neutropenia (11.8%), and infections (19.6%; including pneumonia [9.8%]. No pts experienced SPMs. In the immune subset analysis, the proportions of CD3+ and CD3+/CD8+ T cells after treatment were significantly higher vs baseline (72.6% vs 67.8% and 36.9% vs 32.1%, respectively, P<0.05). Pts with response also had significantly elevated proportions of these T-cell populations, but pts with no response did not. Relative changes from baseline for CD3+ and CD3+/CD8+ T-cell populations were significantly greater in pts with response vs those with no response (10.4 vs −0.8 and 4.2 vs −3.5, respectively; P<0.05).

Summary/Conclusions: This update confirms the safety and efficacy of POM + LoDEX following second-line LEN-based treatment failure in pts with RRMM. Hematologic AE rates improved, and median PFS was longer with third-line use than previously reported with POM + LoDEX use in later treatment lines. In addition, achieving disease control of ≥ MR led to similar PFS rates as reaching ≥ PR.

E1249 “REAL WORLD” DATA ON THE EFFICACY AND SAFETY OF IZAXOMIB IN COMBINATION WITH POMALIDOMIDE AND DEXAMETHASONE IN RELAPSED/REFRACTORY MULTIPLE MYELOMA: A STUDY OF THE GREEK MYELOMA STUDY GROUP

E. Terpos1,2, E. Katodritou2, M. Kotsopoulou2, I. Ntanasis-Stathopoulos1, P. Lampropoulou3, S. Papadaki2, M. Papapathanasiou4, D. Stoumbos5, M. Gavriatopoulou1, P. Lampropoulou3, E. Kastritis1, M.A. Dimopoulos1

1Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, 2Department of Hematology, Theaghenion Cancer Hospital, Thessaloniki, 3Department of Hematology, Metaxa Cancer Hospital, Piraeus, 4Department of Hematology and Bone Marrow Transplantation Unit, G. Papankioiakou General Hospital, Thessaloniki, Greece

Background: The all-oral combination of ixazomib, lenalidomide and dexamethasone (IRd) has been recently approved as a novel standard of care for relapsed/refractory multiple myeloma (RRMM). Aims: The aim of this study was to evaluate the efficacy and safety of IRd in the “Real World” (RW) practice, where data are very limited.

Methods: This was a retrospective, non-interventional study, which recorded IRd treatment data from patients with RRMM who participated in the name-patient program of ixazomib in Greece. The primary endpoint was the evaluation of safety and efficacy; secondary endpoints included: treatment duration; time to response; duration of response; percentage of patients who experienced adverse events (AEs), needed dose modification or treatment discontinuation; evaluation of PFS and TTP.

Results: Forty-one patients were included in the present study. Of those, 35 (83%, median age 63-79 years) had received at least 3 cycles of IRd on the date of data analysis and thus they were included in the present report. The median line of previous therapies was one (range: 1-5); 71.4% (25/35) patients had received one prior treatment, while 20.0% (7/35),...
and 4 with other therapies. Baseline characteristics were balanced across those who were on treatment. 63 were treated with LEN, 6 with BORT, 0 with THAL, and 4.6 mos (range 0.2-36.9 mos) for THAL. At the time of analysis, 3557 patients (98.0%) had discontinued treatment. Of the 73 patients (2.0%) for BORT, and 4.6 mos (range 0.1-79.9 mos) for patients receiving LEN, 4.1 mos (range 0-61.4 mos) for patients receiving THAL. Data on long-term responders will be presented at this meeting.

Table 1.

Summary/Conclusions: LEN was generally well tolerated and the safety results were similar to published data. As expected, the occurrence of neuropenia, TCP, and VTEs were higher in patients in the LEN cohort, whereas neuropathy was more frequently reported in patients in the BORT cohort. VTEs were low in all cohorts. The occurrence of SPMs was generally low and comparable between cohorts.
Results: During the development process, a number of similarities and discrepancies between centers as well as evidence gaps were identified. Intense discussion and literature searches resulted in a concise, harmonized clinical pathway, released by all 14 Centers of Excellence. This is freely available on the website ccc-netzwerk.de and provides a very decisive insight according to the current state of knowledge on the CCC-level (e.g. on the diagnostic algorithm). The clinical pathway is well suited for informing patients and physicians about the most up-to-date, comprehensive medical treatment standards as well as innovative procedures. Furthermore, this project initiated the idea of developing a national evidence-based clinical practice guideline for MM in the frame of the German Guideline Program in Oncology.

E1252
WT1 HETEROCLITIC EPITOPPE IMMUNIZATION FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION IN PATIENTS WITH HIGH-RISK MULTIPLE MYELOMA (MM)
G. Koehne1,*, S. Devlin1, D. Chung1, H. Landau1, N. Korde1, S. Mailankody1, H. Hassoun2, A. Lesokhin1, N. Lendvai1, S. Giralt2, O. Landgren1
1Memorial Sloan Kettering Cancer Center, New York, United States

Background: The Wilms tumor 1 (WT1) protein is a tumor associated antigen that is a target for anticancer immunotherapy. We had previously demonstrated overexpression of WT1 in multiple myeloma (MM) cells by IHC, as well as formation of a WT1 peptide fragment (RMPFNPYLY-LHxA-01) on MM cells using the engagement interface between malignant plasma cells and T-cells in HL-A-A’1*11 MM pts using the high-affinity fully human IgG1 mAb ESK1. We report initial results from MM pts immunized with the WT1 heteroclitic peptide mixture galinepimut-S (GPS) after autologous stem cell transplantation.

Aims: To determine the safety and potential efficacy of the WT1 heteroclitic peptide immunizer GPS administered in patients with multiple myeloma following autologous stem cell transplantation.

Methods: 16 MM pts underwent autologous stem cell transplantation with melphalan conditioning followed by (fth) lenalidomide maintenance starting 3 months (mos) post SCT. 13/16 pts presented with high-risk (HR) cytogenetics [t(4;14), t(14;16), del17p, 1q21/25 gain and/or del13q]. GPS was administered with montanide s.c. starting autologous stem cell transplantation.

Results: 16 pts underwent autologous stem cell transplantation with melphalan conditioning followed by (fth) lenalidomide maintenance starting 3 months (mos) post SCT. 13/16 pts presented with high-risk (HR) cytogenetics [t(4;14), t(14;16), del17p, 1q21/25 gain and/or del13q]. GPS was administered with montanide s.c. starting autologous stem cell transplantation.

Summary/Conclusions: The first clinical MM pathway developed and released by all 14 German CCCs/Centers of Excellence translates scientific evidence and expert knowledge into precise suggestions for MM patients in clinical practice. These harmonized guidelines will increase the quality of care throughout Germany. To be up-to-date and to reflect latest research findings this clinical pathway will be updated every 18 months.

E1253
ANALYSIS OF MULTIPLE MYELOMA PATIENTS WITH PROGRESSIVE DISEASE AT TIME OF FIRST AUTOLOGOUS STEM CELL TRANSPLANTATION: PREDICTORS OF PROGRESSIVE DISEASE AND FACTORS AFFECTING SURVIVAL
J. Blocka1,*, H. Goldschmidt1, T. Hielscher2, M. Pritsch1, M. Raab1, J. Hillengass1
1University Hospital Heidelberg, 2German Cancer Research Center, Heidelberg, Germany

Background: The impact of response depth at time of autologous stem cell transplantation (ASCT) on the progression-free and overall survival (PFS and OS, respectively) of multiple myeloma (MM) patients has been an extensively investigated area. Rosirol et al. (2011) reported a significantly worse PFS and OS in patients with progressive disease (PD) compared to stable disease (SD) at time of ASCT; Pirris et al. (2015) stated a significantly shorter PFS, but not OS, in patients with PD in comparison to SD or minimal response (MR) at time of ASCT.

Aims: Our goal was to characterize MM patients with PD at time of first ASCT. We aimed to analyze the effects of PD on PFS and OS. Next, we intended to analyze the impact of PD on OS. Our research included the influence of PD on OS and the survival of patients with at least PD at time of ASCT (non-PD patients).

Methods: Non-trial MM patients who had undergone a single or tandem ASCT at the University Hospital of Heidelberg in the years 1992-2014 were analyzed regarding their impact on their response before 1st ASCT (d -100 or, if available, response as close to the date of ASCT as possible, i.e. until d-4). Of the 874 ASCT-patients, 829 were eligible for a PFS- and 832 for an OS-analysis. In 51 patients, PD was present at time of ASCT. PFS and OS of those patients were compared with the survival of patients with at least SD at time of ASCT (non-PD patients).

Results: Neither the clinical parameters at induction start; Parrish et al. (2015) stated a significantly shorter PFS, but not OS, in patients with PD compared to SD at time of ASCT. Furthermore, clinical factors at beginning of induction therapy, including age (< 65 years), ISS stage, elevated LDH, use of novel agents in induction therapy, high-risk FISH cytogenetics (at least one of the following: del17p, 1q21 gain, t(14;16)); response after ASCT, and maintenance therapy (yes vs no) were analyzed regarding their impact on PFS and OS of patients transplanted in PD. We also analyzed clinical factors at beginning of PD as well as use of novel agents in the induction therapy regarding their impact on the survival of PD before ASCT. Response was evaluated according to EBMT-criteria. PFS was calculated from date of 1st ASCT, except for prognostic impact of response assessment after 1st ASCT, where date of response assessment was used. Start of maintenance therapy was analyzed as time-dependent factor.

Summary/Conclusions: Non-trial patients transplanted in our center between 1992 and 2014 with ≥ 100 days before ASCT had similar PFS and OS as non-PD patients. Neither the clinical parameters at induction start, response after 1st ASCT, nor maintenance therapy had a significant effect on PFS in those patients. In the univariate analysis, high-risk cytogenetics as well as elevated LDH at induction start had a significantly negative effect on OS in patients with PD before ASCT (HR= 17.12, p = 0.0017; HR= 6.09, p = 0.01, respectively), compared to PD-patients with no high-risk cytogenetics or with normal LDH. Furthermore, ISS stage III was a significant predictor (OR= 3.35, p = 0.02)) of occurrence of PD before ASCT.

E1254
SEVERE INFECTIONS IMPACTS OVERALL SURVIVAL IN ACTIVE MULTIPLE MYELOMA PATIENTS
G. Barilla1,*, C. Nicolo1, A. Lipo1, A. Brancha1, L. Checuz1, E. De March1, Madrid, Spain, June 22 – 25, 2017

Figure 1.

Summary/Conclusions: The first clinical MM pathway developed and released by all 14 German CCCs/Centers of Excellence translates scientific evidence and expert knowledge into precise suggestions for MM patients in clinical practice. These harmonized guidelines will increase the quality of care throughout Germany. To be up-to-date and to reflect latest research findings this clinical pathway will be updated every 18 months.
E1255

EVALUATION OF CARDIOVASCULAR EVENTS ASSOCIATED WITH DIFFERENT TREATMENT MODALITIES OF MULTIPLE MYELOMA IN THE REAL-WORLD SETTING IN THE UNITED STATES

D. Lenihan1, R. Potluri2, H. Kanakamedala2, A. Dasgupta2, C. Chen1, C. Vanderbilt University Medical Center, Nashville, 2SmartAnalyst Inc., New York, 3Bristol-Myers Squibb, Lawrenceville, United States

Background: Multiple myeloma (MM) is a disease of the elderly. The prevalence of cardiovascular (CV) comorbidities in the MM population is high. Past research suggests that MM is associated with a range of cardiac risks, and emerging evidence shows that both proteasome inhibitors (PIs) and immunomodulatory drugs (IMiDs) can have important CV sequelae. The improved efficacy of PI plus IMiD combination therapy (PI+IMiD) has resulted in its widespread adoption, which suggests that CV events may become a prominent concern in patients receiving PI+IMiD as contemporary treatment for MM.

Aims: To assess the risk of developing CV events in patients receiving anti-MM treatment and to test if a specific treatment modality was associated with higher risk of a CV event.

Methods: Patients with ≥1 inpatient claim or ≥2 outpatient claims with a primary diagnosis code for MM who were treated with PI and/or IMiD drugs between Jul 2012 and Sep 2014 were identified in a large US claims database. The first claim for a PI or IMiD drug in this period was defined as the index date, which was preceded by 180-d continuous eligibility with no anti-MM treatment (baseline). Patients were divided into three cohorts based on the anti-MM treatment received: PI, IMiD, PI+IMiD. CV events of interest included cardiac arrhythmia, cardiac failure, venous thromboembolism (VTE), myocardial infarction, ischemic heart disease, angina, stroke and coronary atherosclerosis, and were measured during anti-MM treatment. Kaplan–Meier methods were used to estimate the occurrence rate of a CV event, and multivariate Cox regression models were developed to identify prognostic factors of each CV event among patients treated with anti-MM therapies.

Results: 4288 patients met the eligibility criteria for inclusion in the study (57% male, median age 66.4 ± 11.4 years). A review of MM comorbidities showed that both proteasome inhibitors (PIs) and immunomodulatory drugs (IMiDs) may be associated with incremental occurrence of specific CV events during treatment, and may result in specific CV events earlier during therapy than PIs or IMiDs alone. Given that severe comorbidities impact OS mostly in the setting of not neutropenia related infections, immunoglobulin replacement therapy or chemotherapy may possibly have a protective role in high risk old patients characterized by ISS and DS stage III, bone marrow PC >60% and aggressive disease at the time of diagnosis.

Figure 1.

Summary/Conclusions: PI+IMiDs may be associated with incremental occurrence of specific CV events during treatment, and may result in specific CV events earlier during therapy than PIs or IMiDs alone. These highlight a need for treatments that do not exacerbate CV risks and are appropriate for patients with pre-existing CV conditions. The lower prevalence of baseline CV comorbidities and lower mean age in patients on PI+IMiD suggest that prevalence of a CV comorbidity and age influences treatment choice. Further analysis may be necessary to better understand the impact of baseline CV comorbidities on choice of MM treatment.

E1256

LENALIDOMIDE PLUS HIGH-DOSE VERSUS LOW-DOSE DEXAMETHASONE FOR THE TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA: A SYSTEMATIC REVIEW

K. Kupas1, P. I. Kaspar, V. Baecker, K. Weise2, 3Bristol-Myers Squibb, Munich, 4Ecker + Ecker GmbH, Hamburg, 5University of Tübingen, Tübingen, Germany

Background: Lenalidomide in combination with dexamethasone is approved globally for the treatment of multiple myeloma (MM). Although older pivotal regimens used lenalidomide combined with low dose dexamethasone (LD), more recent studies have used lenalidomide plus low-dose dexamethasone (LD) for relapsed/refractory MM (RRMM), as the LD regimen demonstrated better survival with lower toxicity for the treatment of newly diagnosed MM.
Methods: We collected the clinical data of 169 patients qualified to HDT/autoSCT in routine clinical practice.

Aims: We performed a historical comparison based on a systematic review of literature describing low- vs high-dose dexamethasone in patients with MM to assess effects of LD vs LD on safety and efficacy outcomes.

Methods: We searched MEDLINE, EMBASE and Cochrane databases and key clinical trial registries for studies including adults with MMR who had received ≥3 prior therapies and had a symptomatic relapse on their last treatment.

Eligible studies evaluated LD (lenalidomide: 25mg on Day 1–21 of each cycle; dexamethasone: 160mg/cycle, not pulsated) or LD (Cycles 1–4: 480mg/cycle; Cycle 5+; 160mg/cycle, pulsed). Only those trials with designs and baseline patient characteristics similar to ELOQUENT-2 were eligible to ELOQUENT-2 to enhance reliability.

Studies with a follow-up of ≥16–25 months were evaluated separately from studies with a follow-up of >30 months; these observation periods approximately align with those of ELOQUENT-2.

Results: From an initial bibliographic search yielding 5155 non-duplicate results and 619 registry results, 7 studies (8 publications) met the inclusion criteria (4 LD studies, 3 LD studies). Data for overall survival and tolerability from 1153 patients in the LD group and 353 patients in the LD group were analyzed. The median age of patients was 63–88 years. Most patients were white, male and had an ECOG score ≤ 1. LD was not associated with loss of efficacy in terms of overall survival; after >30 months of follow-up, the hazard ratio for LD vs LD was 1.04 (95% CI 0.85–1.28). Tolerability was similar for LD vs LD; after 16–25 months of follow-up, LD was associated with a statistically significantly increased risk of Grade 3/4 adverse events (AEs; relative risk [RR]: 1.10 [95% CI 1.01-1.18]). However, after >30 months of follow-up, LD was not associated with an increased risk of Grade 3/4 AEs (RR: 1.05 [95% CI 0.97-1.12]) or serious AEs (RR: 1.08 [95% CI 0.97-1.20]); RR for AEs leading to discontinuation was 1.16 (95% CI 0.87-1.54).

Summary/Conclusions: Overall survival and safety are not significantly affected by different dosing of dexamethasone in combination with lenalidomide; thus, using LD is a reasonable alternative for patients in this patient population. Further studies may provide additional evidence to inform clinicians and revision of international guidelines for dexamethasone dosing in MM.

E1257

HIGH EFFICACY AND SAFETY OF VTD AS AN INDUCTION PROTOCOL IN NEWLY DIAGNOSED MM PATIENTS ELIGIBLE FOR HD/autOSCT – A REPORT OF POLISH MULTIPLE MYELOMA STUDY GROUP

1Clinical Transplantology, 2Hematology and Bone Marrow Transplantation, Medical University of Lublin; 3Department of Hematology, Collegium Medicum UMK, Bydgoszcz, 4Department of Hematology, Institute of Hematology and Transfusion Medicine, Warsaw; 5Department of Hematology, St. John of Dukla Lublin Region Cancer Center; 6Department of Hematology, Olszyn, 7Department of Hematology, Collegium Medicum UMK, Bydgoszcz, Poland

Background: Three drug bortezomib-based regimens are nowadays generally recommended standard induction therapy for transplant-eligible patients with newly diagnosed multiple myeloma (MM). The choice between different regimens depends on drug availability in particular countries, their toxicity profile and local preferences. Observations from routine practice might have though significant impact on the MM management in this patient population.

Aims: The aim of this retrospective analysis was to evaluate the efficacy and safety of VTD regimen in newly diagnosed MM patients eligible for HD/autOSCT in routine clinical practice.

Methods: We collected the clinical data of 169 patients qualified to HD/autOSCT who received VTD as induction, 105 patients (62%) received VTD as induction and 105 patients (62%) received VTD as induction. The patients were 12 men and 7 women, aged 60±4 years (37–73 years). 10 patients were diagnosed with lambda FLC MM and 9 with kappa type. A total of 244 sessions were conducted, with an average of 11.6 sessions per patient (range 3-27). In all cases reduction of serum FLCs concentration was successfully achieved. (90% of reduction). At the end of treatment with HCO-HD, the reduction of lambda and kappa FLCs concentrations was 85% (range 30-98%) and 85% (range 30-98%), respectively. The average reduction per dialysis session was 65% for lambda and 60% for kappa. 17 out of the 21 treated cases recovered sufficient renal function to become independent of dialysis (80.9% renal recovery). Renal recovery appears to be sustained over time. There was a significant association between the reduction of lambda and kappa FLCs concentrations and renal recovery. Our results confirm previous findings on the effectiveness of FLCs reduction by HCO-HD. Until randomized trials yield results, our highest percentage of improve renal outcome with respect to published studies leads us to recommend combined therapy of chemotherapy and HCO-HD in patients with MM-related renal failure.

Summary/Conclusions: In dialysis-dependent AKI secondary to MM, combination HCO HD with chemotherapy allows a sustained reduction of FLCs levels, representing an effective therapy in renal recovery.
E1259
IMPACT OF IMMUNOPARESIS IN PATIENTS WITH LIGHT CHAIN AMYLOIDOSIS
L.G. Rodríguez-Lobato1,2, C. Fernández de Larrea1, M.T. Cibeira1, N. Tovar1, J.I. Aróstegui2, L. Rosello1, M. Elena1, J. Yagüe4, J. Blażei1
1Department of Haematology, 2Department of Immunology, 3Department of Biochemistry, Hospital Clinic, Barcelona, Spain

Background: The presence of immunoparesis (IP) at diagnosis in several plasma cell disorders is a risk factor for progression, associated with an unfavorable outcome with reduced progression-free survival (PFS) and overall survival (OS). However, its impact in light chain (AL) amyloidosis has been evaluated only in few series, and when present it was associated with worst response and survival.

Aims: The aim of this study was to investigate the prognostic impact of IP in patients with newly diagnosed AL amyloidosis at a single institution.

Methods: We reviewed the clinical records of patients with AL amyloidosis diagnosed from January 2006 to December 2016. Sixty-nine patients (32F/37M; median age at diagnosis 62) with available immunoglobulin (Ig) measurements were the final study population. Initial baseline demographics, clinical and laboratory data, treatment and follow-up were collected. Median follow-up was 30.2 months. IP was defined as suppression of all uninvolved Ig below the lower reference value. PFS and OS were calculated from the date of diagnosis.

Results: Forty-three patients (62.3%) were transplant ineligible while 26 (37.7%) underwent an autologous stem cell transplantation (ASCT). The distribution of the monoclonal protein isotype by immunofixation at diagnosis was as follows: light chains only (46.4%), IgG (39.1%), IgA (10.2%) and IgM (4.3%). The predominant light chain isotype was lambda (79.7%). A very good partial response (VGPR) or better was achieved in 53.6% of patients. Three-year OS rate was 54.3%. IP was observed in 27.5% of the patients at diagnosis. Patients with IP had a higher bone marrow plasma cells (BMPC) infiltration (29 vs. 21.7%; P<0.001). Also a trend towards a higher difference between involved and uninvolved free light chains was observed in the group of patients with IP (360.2 vs. 221.7; P=0.015). The presence of IP was an independent risk factor for worse PFS and OS in multivariate analysis. PFS and OS were significantly different in patients with stage I and II Mayo12, incorporating ASCT, BMPC and IP, indicating that IP retained its independent prognostic factor for worse PFS (HR=12.05; 95% CI, 1.9-75.7; P=0.008).

Discussion: The presence of IP at diagnosis could be an additional powerful discriminatory prognostic indicator in the group of patients without advanced stage of the Mayo risk stratification system of 2012.

Figure 1.

Summary/Conclusions: The presence of IP has a negative impact on survival, especially in the sub-group of patients in early stages of the disease. The presence of IP at diagnosis could be an additional powerful discriminatory prognostic indicator in the group of patients without advanced stage of the Mayo risk stratification system of 2012.

Background: The introduction of novel agents, such as proteasome inhibitors (PSIs) and immunomodulatory drugs (IMiDs) approved in 2006 and 2010, respectively, and/or autologous stem cell transplantation (SCT) are associated with improved overall survival of 60.6 months in Japanese multiple myeloma (MM) patients (pts) (Ozaki et al. Blood Cancer Journal 2015). However, the disease still remains incurable with disease relapse being inevitable after frontline therapy (FLT). Data regarding treatment patterns and duration of treatment (DOT) of Japanese pts with relapsed and refractory (RR) MM in routine clinical practice is limited.

Aims: This retrospective study aims to describe the treatment patterns and DOT of second-line therapy (SLT) with PI- and IMiD-based regimens and to assess factors that influence treatment choice and DOT of SLT in Japanese MM pts.

Methods: This is retrospective cohort study in pts with MM diagnoses with ICD-10-CM (C900) codes between April 2008 and January 2016 in Japan. This study used Japanese health insurance data provided by Medical Data Vision. MM pts receiving SLT were included. Index date was defined as the first observed claim for MM treatment and SLT was defined as switch to another drug combination or retreatment following a treatment gap of 90 days after starting FLT. Pts with salvage SCT were excluded. Observations were censored at loss to follow up, death or the end of study period. Kaplan-Meier analyses were performed to calculate DOT from the start of SLT. Welch’s test was used to test for statistical significance between groups.

Results: Among 965 pts receiving SLT, mean age was 68.8 years of age (yo); 65.3% were ≥65 yo at start of SLT; 54.2% were male. Most pts received lenalidomide (L)-based SLT (35.4%), followed by bortezomib (B)-based regimens (29.4%) and other regimens not containing novel agents (35.2%); Other regimens include thalidomide, cyclophosphamide, etoposide, melphalan, vincristine, (liposomal) doxorubicin, interferon, panobinostat, single-agent steroid; only 1.2% received B+L combination therapy. L+d and B+d were the most common (35.2% vs. 21.7%) in SLT. Majority of Japanese pts received B-based regimen in FLT among those receiving L+d and B+d SLT (77.2% vs. 55.1%). Pts with peripheral neuropathy (PN) and renal insufficiency (RI) prior to SLT were 30.3% and 16.5%, respectively; those with PN were more likely to receive L+d compared to B+d (35.9% vs 21.3%, P=0.0047), but those with RI was not independently associated with treatment choice of SLT. Median DOT of L+d was longer than B+d (13.8 vs 6.9 months, P=0.0001); DOT was similar for those without a front-line SCT and receiving B+d FLT in both regimens (11.9 vs 11.9 months). PN and RI prior to SLT and age have not shortened the DOT in SLT. Additionally, 35.4% experienced PN during SLT among pts receiving L+d and B+d in SLT but there was no significant statistical difference of DOT between pts with and without PN. Median daily dose of L was 12.0mg; there was no significant difference of DOT between pts received at least and less than 12.0mg.

Summary/Conclusions: Among pts in SLT, 65% of Japanese pts obtained L- and B-based regimens. This observation is similar to the United States (Romanus et al. EHA 2016) and Europe (Raab et al. EHA 2015). Majority of pts did not receive triplet-based regimen. Pts experienced PN in FLT were more likely to initiate L-based therapy in SLT and regimen type in SLT was correlated with DOT. Future research is needed to better understand treatment changes in routine clinical practice and the impact on pts’ outcomes, especially, after integration of novel agent-based triplet combinations as new standards of care in RRMM in Japan.

ROLE OF HEAVY/LIGHT CHAIN RATIO IN MYELOMA PATIENTS ACHIEVING COMPLETE RESPONSE AFTER FIRST LINE THERAPY
F. D’auria1, F. La Rocca1, V. Simeon1, T. Statuto1, G. Pietrantuono1

Background: The presence of immunoparesis (IP) at diagnosis could be an additional powerful discriminatory prognostic indicator in the group of patients with advanced stage of the Mayo risk stratification system of 2012.
Background: Polyclonal antibodies against the conformational epitopes between the heavy and light chains (HLC) of immunoglobulin (lg) have been recently introduced as diagnostic tool in multiple myeloma (MM) and other monoclonal gammopathies. They separately identify the two different light chain types of each lg, allowing the quantification of the monoclonal component. HLC and HLC ratios may be particularly useful for monitoring the presence of monoclonal component in oligo-secretory MM or when it migrates in the β region, as frequently observed in IgA MM. The International Myeloma Working Group (IMWG) has published in 2016 new consensus criteria for assessing response and minimal residual disease (MRD) in MM, outlining the potential role of HLC assay in this setting and the need of its further investigation, particularly in patients achieving complete response (CR). Aims: We conducted a single center, prospective study of HLC ratio, in comparison with free light chain (FLC) ratio, for the evaluation of MRD and its prognostic role in MM patients achieving CR after first line treatments including novel agents.

Methods: Twenty-five consecutive patients were evaluated. Mean age was 63 years (range 43-92), fourteen patients were males. Ig isotype was IgG or IgA in 14 and 11 patients, respectively, with 20 patients showing kappa and 5 lambda light chains. According to International Staging System, seven patients had stage 1, ten stage 2 and eight stage 3. Fourteen patients not eligible to autologous stem cell transplantation (AuSCT) received a bortezomib-based treatment, mainly constituted by bortezomib, melphalan and prednisone combination (VMP), while eleven patients underwent AuSCT after induction therapy with bortezomib, thalidomide and dexamethasone (VTD). With a median follow-up of 52 months (range 21-92), overall survival (OS) of the entire cohort was 61 months (95% CI 52-80) and progression-free survival (PFS) was 26 months (95% CI 10-38). FLC assay normalisation in CR was significantly associated with better PFS (43 months, 95% CI 14-45) and fourteen samples (56%) with abnormal FLC ratio. Discrepancies and k/λ ratios were then calculated.

HLC ratio and fourteen samples (56%) with abnormal FLC ratio. Discrepancies and k/λ ratios were then calculated.

Results: At CR time, we found seven (28%) samples still showing abnormal HLC ratio and fourteen samples (56%) with abnormal FLC ratio. Discrepancies between the two assays occurred in 11 patients. FLC assay normalisation in CR was significantly associated with better PFS (43 months, 95% CI 14-45) respect to patients with persistent abnormal FLC ratio (12 months, 95% CI 9-22, p=0.049). In contrast, normalization of HLC ratio had no impact on PFS (26 months, 95% CI 52-80) and progression-free survival (PFS) was 26 months (95% CI 10-38).

Aims: To the best of our knowledge, this is the first study to analyze HLC ratios exclusively in MM patients in CR. While our preliminary data confirm the prognostic usefulness of FLC in this setting, currently they do not support a role for HLC as putative biomarker of MRD.

Summary/Conclusions: In this first real-world analysis we confirm that daratumumab monotherapy is able to induce response in one third of highly pretreated and double refractory RRMM patients. Regarding safety, in contrast to the SIRIUS trial where no treatment discontinuations due to AEs occurred, 3/26 pts (11%) treated with daratumumab in clinical practice had their therapy interrupted due to complications.

**E1263**
REAL-WORLD TREATMENT PATTERNS AND PATIENTS CHARACTERISTICS IN MULTIPLE MYELOMA ACROSS EUROPE

Summary/Conclusions: In this first real-world analysis we confirm that daratumumab monotherapy is able to induce response in one third of highly pretreated and double refractory RRMM patients. Regarding safety, in contrast to the SIRIUS trial where no treatment discontinuations due to AEs occurred, 3/26 pts (11%) treated with daratumumab in clinical practice had their therapy interrupted due to complications.
Background: Multiple myeloma (MM) is the second most common haematological malignancy after non-Hodgkin lymphomas, accounting for 13% of blood malignancies and 1% of all cancers1. The medical management of multiple myeloma has changed over the years and is influenced by multiple factors (e.g., evidence from clinical trials, drug approval status, level of drug reimbursement, guidelines), which vary across Europe. Information describing how patients are managed in the real world is needed. Aims: The aim of this analysis was to investigate real-world treatment patterns and patient characteristics in MM across Europe.

Methods: Physicians in Europe were requested to answer a series of questions on patient characteristics and treatment regimens of the last eight patients that they had treated during the month prior to answering the questionnaire, according to their patients’ medical charts. The questionnaire was conducted between January and June 2016. Data on 2564 patients with MM were available and are presented here. Countries were grouped into regions according to similar healthcare systems: Spain, Portugal, Italy and Israel (Southern Region, SR, n=1096); Austria, Netherlands, Belgium, Norway, Sweden, Switzerland and Finland (Central and Northern Region, CNR, n=776); Croatia, Estonia, Hungary, Latvia, Lithuania, Poland, Serbia, Slovakia (Eastern Region, ER, n=689). Analyses were descriptive.

Results: Patient characteristics were generally similar across regions, with the majority being <75 years old (69-76%), receiving frontline therapy at study inclusion (57-58%), and being eligible for autologous stem cell transplant (ASCT) (53-59%). The median time from MM diagnosis to the time that the physician answered the questionnaire was higher in ER (19.9 months) than other regions (9.7-11 months) (Table). The majority of frontline regimens contained bortezomib, although this was lower in ER (51%) than in other regions (66-70%). The median duration of frontline therapy was longer in ER (4.5 months) than other regions (3.2 months). This difference was mainly driven by ASCT eligible patients having longer duration of therapy in ER (4.5 months) than other regions (2-3 months). The number of patients who were treated with ASCT was higher in SR and CNR (24-25% of patients) than in ER (18%). The majority of second line regimens contained lenalidomide (57-64%) in all regions except ER, where bortezomib-based regimens were most frequent (38%). The median duration of second line therapy was shorter in SR and CNR than in ER (Table). Moreover, for second line therapy, ASCT eligible patients had shorter duration of therapy in ER and SR (3.2 months) than in CNR regions (4.5 months). The majority of later-line (≥3) regimens were based on therapies that did not include bortezomib, lenalidomide or pomalidomide for all regions (79-87%). Differences in treatment duration were noted between regions with the exception of SR where pomalidomide (29.4%), lenalidomide (12.6%) and bortezomib (14%) were preferred options. In this analysis conducted in Europe, treatment patterns differed in terms of regimens used and duration of therapies even though patient characteristics were generally similar across regions. This may in part be related to differences in healthcare systems. Further research is required to understand how new therapies can be integrated into current treatment patterns and how these treatment patterns impact patient outcomes.

Summary/Conclusions: In this analysis conducted in Europe, treatment patterns differed in terms of regimens used and duration of therapies even though patient characteristics were generally similar across regions. This may in part be related to differences in healthcare systems. Further research is required to understand how new therapies can be integrated into current treatment patterns and how these treatment patterns impact patient outcomes.

Table 1.

Summary/Conclusions: This study shows that the prevalence of frailty syndrome is high and has a profound impact in early death. It is also independently associated with a worse prognosis. Frailty should be considered as part of the clinical assessment when treating elderly patients with myeloma.

E1265

PROGNOSIS OF AL AMYLOIDOSIS WITH KIDNEY INJURY

A. Talbot1,2, X. Belfant2

1Immulogy, hospital Saint Louis, paris, 2Neprology, chig, montreuil, France

Background: AL amyloidosis is a rare disease related to excessive and uncontrolled secretion of monoclonal light chains. The consequence of this proliferation is an alteration of the affected organs due to deposition of free light chains. Despite therapeutic advances in recent years based, among others, on the finding of French studies, the prognosis of this disease remains poor in particular for patients with cardiac disease. Kidney involvement is also frequently observed, as diagnosis in the form of a classic kidney lesion is rare, but at present the prognosis of chronic renal failure in this context is unknown.

Aims: The study was interested in the prognosis of AL amyloidosis associated with endstage renal disease on dialysis in the era of treatment with bortezomib.

Methods: A total of 133 patients (61 from ile-de-France region register and 72 from reference center) were analyzed. Median survival was 66.7 months compared to 70.6 months for patients without dialysis (p=0.65). Within the group

E1264

FRAILTY AND MORTALITY IN ELDERLY PATIENTS WITH MULTIPLE MYELOMA

N. Schulz1,2, M. Smetiansk1, D. Fanti1, V. Otero1

1Medicina Interna - Hematología, Hospital Italiano, de Buenos Aires, CABA, Argentina

Background: Worldwide, life expectancy continues to rise. The treatment of elderly people with cancer poses special challenges that should be better addressed. Frailty is a geriatric syndrome associated with reduced functional reserve, impairment in multiple physiological systems, and reduced ability to regain physiological homeostasis.

Aims: To evaluate the impact of the level of frailty on early death and overall survival of elderly patients with multiple myeloma.

Methods: Retrospective study of a cohort of 150 patients older than 65 years with a recent diagnosis of multiple myeloma from January 2006 to December 2012. Patients were treated with IMIDs, alkylating or bortezomib based chemotherapy based on physician preference blind to the geriatric assessment. A check list for frailty burden measurement was used based on Edmonton frailty score and included: cognitive impairment, depressive disorder, polypharmacy, urinary incontinence, functional impairment, gait disturbance or falls, low weight or weight loss and previous hospitalization. Level of frailty was scored as the sum of each area involved. Record of all the variables were obtained from a retrospective review of the centralized and computerized medical records of the patients presented with Myeloma ISS 3. Sixty five percent of patients met at least one frailty criteria and 31% of patients were considered frail. The most common findings were polypharmacy, gait and functional impairment. Most patients were treated with IMIDs (47%); alkylating agents (33%) or bortezomib (14%) based chemotherapy. There was no difference in treatment according to frailty group (p=0.38). The median overall survival time was 75 months (95% CI 53-110), 39 months (95% CI 19-64) and 17 months (95% CI 5-37) for fit, vulnerable and frail patients respectively (log rank p 0.0002). Frailty was specially associated with early death [OR 8.2 (95% CI 1.9-34) p=0.007]. In the multivariate analysis a higher risk of death was observed related to age [HR 1.07 (95% CI 1.02-1.12) p=0.002], number of frailty criteria [HR 1.13 (95% CI 1.1-1.3) p=0.05] and ISS [HR 2.6 (95% CI 1.8-3.8) p=0.001]. The frailty criteria independently associated with death were incontinence polypharmacy and previous hospital admissions. Frailty was specially associated with early death [OR 6.2 (95% CI 1.9-34) p=0.0007].

Summary/Conclusions: This study shows that the prevalence of frailty syndrome is high and has a profound impact in early death. It is also independently associated with a worse prognosis. Frailty should be considered as part of the clinical assessment when treating elderly patients with myeloma.

FDG-PET IN MULTIPLE MYELOMA: DUAL TIME POINT FDG UPTAKE IN FOCAL LESIONS CORRELATE TO RESPONSE TO CHEMOTHERAPY

1Hematology, Odense University Hospital, Odense, Denmark, 2Radiology, Hospital of the University of Pennsylvania, Philadelphia, United States, 3Nuclear Medicine, 4Radiology, Odense University Hospital, Odense, 5Nuclear Medicine, 6Hematology, Vejle Hospital, Vejle, Denmark

Background: Dual Time Point (DTP) 18F-FDG PET imaging has been shown to be useful in differentiating malignant from benign lesions in that increasing uptake from 1 to 3 hours is a characteristic feature of malignancy in contrast to inflammation.

Aims: The aim of this study was to evaluate the predictive role of DTP 18F-FDG PET/CT imaging in assessing response to chemotherapy in multiple myeloma (MM).

Methods: 23 patients with MM (21 male, aged 53-75 years) underwent 18F-FDG PET/CT in a prospective study (RCT02187371) before start of treatment and two months after high dose chemotherapy with stem cell support. All scans were performed at 60 and 180 minutes after tracer injection at Odense University Hospital and Vejle Hospital. Thirteen patients with ≥3 focal lesions of at least 10 mm were selected for further analysis. Images were analyzed using an adaptive thresholding algorithm (ROVER software; ABX GmbH, Radeberg, Germany). Focal malignant lesions were localized in pre-treatment scans; maximum standard uptake value (SUVmax) and mean SUV (SUVmean) and partial volume corrected SUVmean (pvcSUVmean) were obtained for each lesion. The response to chemotherapy was classified as complete or partial in the post-treatment scan. A complete response was defined as a complete resolution of the lesion in the post-treatment scan. Lesions with partial response were present in the post-treatment scan. All statistical analyzes were done in SPSS 24 using repeated measurements-ANOVA.

Results: Three-five focal lesions were evaluated in each patient. In the pre-treatment PET studies, the increase in SUVmean from 1 to 3 hours was significantly higher for lesions with partial response compared to those with complete response (27.7% vs 11.4%; P=0.050). Additionally, the increase in pvcSUVmean was more significant than the increase in SUVmean (+42.23% vs +12.0%; P=0.003). The increase in SUVmax of delayed scans was not significant (P=0.082).

Summary/Conclusions: These preliminary data show that a more significant increase of FDG uptake in delayed scans of DTP PET before treatment correlates with better response to chemotherapy in patients with MM. The increase in pvcSUVmean is a better index than those of SUVmean and SUVmax for this purpose.

E1268
UNDERSTANDING THE CONTRIBUTE OF THE NOTCH PATHWAY IN MULTIPLE MYELOMA BONE MARROW NICHE: A FOCUS ON EXTRACELLULAR VESICLES-MEDIATED COMMUNICATION
M. Colombo1,2, F. Baccianti1, L. Cantone2, N. Moschini1, N. Platovna3, S. Garavelli1, M.T. Palano1, R. Adami1, A. Neri2, V. Bollati1, R. Chiaromonte4,5
1Dept. of Health Sciences, 2Dept. of Clinical Sciences and community health, 3Dept. of Oncology and Hemato-Oncology, Università degli Studi di Milano, 4Department of Hematology, Ag. Georgiou General Hospital, 5Department of Haematology, University of Athens, Athens, Italy

Background: Multiple myeloma (MM) is an incurable cancer stemming from malignant plasma cells. MM is characterized by a strong tropism to the bone marrow (BM), where tumor cells accumulate and establish complex interactions with the normal stroma, which in turn promotes tumour survival, drug resistance and the development of bone disease. The Notch oncopathic pathway provides a key contribute to the ability of MM cells to shape the BM niche, affecting both BM cell biology and the intra-tumoral extracellular vesicles (EVs) that are secreted by the cells. In this work we aimed to further elucidate the role played by the Notch pathway in the shaping of the BM microenvironment to provide a supportive milieu for MM cells, with a focus on the contribute of EVs to the crosstalk between MM cells and the BM stromal cells.
Methods: We established two MM cell lines stably retaining the doxycycline-inducible pTRIPZ vector containing anti-Jagged1 and Jagged2 shRNAs and a BM mesenchymal stromal cell line (BMSCL) expressing shRNAs for Notch1 and Notch2. EVs were isolated by ultracentrifugation and used for functional assays and molecular analysis. qPCR was performed using SYBR Green. Apoptosis analysis was performed by flow cytometry; evaluation of protein expression was conducted by Western blot analysis.

Results: We present evidences that EVs play a crucial role in the dysregulated interactions of MM cells with the BM microenvironment and that Notch regulates their release. Indeed, BMSCLs knocked down for Notch1/2 results in a decrease in EVs release and reduce their ability to induce Bortezomib resistance in MM cells and to stimulate their migration. On the other side, MM-derived EVs are able to increase the expression of pro-tumor factors by BMSCL (i.e., SDF-1α), promoting their ability to boost tumor growth; interestingly, this effect is lost when EVs are isolated from MM cells where the Notch pathway was inhibited. Finally, EVs released by co-cultures of BMSCLs and MM cells where the Notch pathway is blocked displays a reduced ability to increase osteoclastogenesis compared to EVs from the control culture. This is particularly relevant due to the crucial role played by bone disease in MM progression.

Summary/Conclusions: These new insights in the pathophysiology of the rearranged BM niche represent the rationale for a Notch-directed therapy aiming to uncouple the crosstalk of MM with the surrounding microenvironment by inhibiting Notch signaling.

E1269
THE USE OF CARFILZOMIB AND BORTEZOMIB IN ROUTINE CLINICAL PRACTICE: RESULTS FROM PREAMBLE, AN ONGOING, OBSERVATIONAL COHORT STUDY IN MULTIPLE MYELOMA
B. Dure1,2, G. Cook2, H. Goldschmidt3, D. Kuter4, T. Zyczynski5, S. Popov6, M. Goorash7, C. David8, R. Vill9, 1Cedars-Sinai Medical Center, Los Angeles, United States, 2University of Leeds, Leeds, United Kingdom, 3Heidelberg University Hospital, Heidelberg, Germany, 4Massachusetts General Hospital Cancer Center, Boston, 5Bristol-Myers Squibb, Lawrenceville, United States, 6Parexel, St Petersburg, Russian Federation, 7Washington University School of Medicine, St. Louis, United States

Background: Multiple myeloma (MM) remains largely incurable despite improvements in clinical outcomes following the approval of immunomodulatory drugs (IMiDs) and proteasome inhibitors (Ps) (Rajkumar et al 2010). Previous findings from PREAMBLE (NCT01838512) is an ongoing, observational, international cohort study exploring real-world treatment patterns and outcomes in pts with MM. Eligible pts were aged ≥18 yrs with diagnosis of RRMM, ≥1 prior treatment paradigm.

Aims: In this subsequent PREAMBLE analysis, treatment patterns in patients (pts) with RRMM receiving bortezomib (bort) and carfilzomib (carf) were evaluated to better understand the use of Ps in routine clinical practice.

Methods: PREAMBLE (NCT01838512) is an ongoing, observational, international cohort study exploring real-world treatment patterns and outcomes in pts with MM. Eligible pts were aged ≥18 yrs with diagnosis of RRMM, ≥1 prior therapy and follow-up and retrospective analysis.

Results: The outcome for patients with Multiple Myeloma (MM) is highly

E1270
ROLE OF SERUM FREE LIGHT CHAIN VS BENICE JONES MEASURE-
MENT IN LIGHT CHAIN MULTIPLE MYELOMA (LCMM) AT DIAGNOSIS,
DURING TREATMENT AND FOLLOW-UP FOR RESPONSE EVALUATION
M. Stadenni1, M. Berardi2, A. Caldin3, C. Nozoll3, E. Antonioli4, A. Bosi5
1Hematology Department, Azienda Ospedaliero-Universitaria Careggi, Flo-
rence, Italy, 2BMT Unit, Azienda Ospedaliero-Universitaria Careggi, Florence, Italy

Background: According to IMWG recommendations for response assessment in multiple myeloma (MM), serum free light chain (sFLC) measurement should be used to define a “stringent” complete response in symptomatic MM and, only in cases when Bence Jones protein (BJP) is deemed as not quantifiable (<200mg/24h), in light chain multiple myeloma (LCMM). However, data are available suggesting that sFLC could be a more sensitive tool than BJP for minimal residual disease assessment and an earlier indicator of progressive disease (PD). BJP measurement is usually performed within 2-8 months following the last treatment. This study aimed to assess sFLC and BJP as the primary markers of LCMM progression and the impact of these markers on outcome at diagnosis and follow-up.

Methods: Serum and urine samples were collected from pts affected with plasma cell dyscrasia referring to the Azienda Ospedaliero-Universitaria Careggi between 1st February 2012 and 31 December 2013. Serum and urine protein electrophoresis were performed using Capillary II, serum and urine immunofixation using Hydrasys II (both from Sebia), sFLC were measured on Immage 800 neph-
ometry (Beckman Coulter) using Freelite reagents (The Binding Site).

Results: We analyzed samples from 387 pts having positive serum and/or positive urinary immunofixation and/or abnormal sFLC ratio. Among them, 43 symptomatic LCMM pts were identified having both sFLC and BJP measurements at baseline (MM diagnosis or first relapse). Serum and urine lab tests results were evaluated at baseline, monthly during therapy and every 3 months during follow-up. Median duration of laboratory monitoring for the whole group was 42 months (range 3-120). Autologous stem cell transplantation was performed in 30% of pts previously treated with proteasome inhibitors (81%) and/or immunomodulating agents (40%) or chemotherapy (9%). 65% of sFLC or BJP were not available suggesting that sFLC could be a more sensitive tool than BJP for minimal residual disease assessment and an earlier indicator of progressive disease (PD). Bence Jones protein measurement was performed within 2-8 months following the last treatment. This study aimed to assess sFLC and BJP as the primary markers of LCMM progression and the impact of these markers on outcome at diagnosis and follow-up.

Summary/Conclusions: Both sFLC and BJP are useful in LCMMS pt for disease monitoring, however, sFLC measurement appears to be more sensitive in MDD and early relapse identification. These data suggest that plasmacytomas could be substituted by sFLC measurement in LCMMS. In our series only 1 case showed plasmacytoma occurring earlier than sFLC- PD but was considered not clinically significant. On the contrary 5 pts in both sFLC and BJP measurement was performed within 2-8 months following the last treatment. This study aimed to assess sFLC and BJP as the primary markers of LCMM progression and the impact of these markers on outcome at diagnosis and follow-up.

E1271
SUPPRESSION OF THE NON-MONOCLOAL PAIR AS NEW BIOMARKER FOR THE DIAGNOSIS OF MULTIPLE MYELOMA PATIENTS AT DIAGNOSIS
AND AFTER AUTOLOGOUS STEM CELL TRANSPLANT
J.L. Garcia De Veas Silva1, M.D.S. Lopez Velez1, C. Bermudo Guitarte2, R. Rios Tamayo3, M. Jurado Chacón3, T. De Haro Muñoz1
1Department of Laboratory Medicine, Complejo Hospitalario Universitario de Granada, Granada, Spain, 2Department of Clinical Biochemistry, Hospital Universitario Nuestra Senora de Candelaria, Santa Cruz de Tenerife, Spain, 3Department of Clinical Hematology, Complejo Hospitalario Universitario de Granada, Granada, Spain

Background: The outcome for patients with Multiple Myeloma (MM) is highly
variable. Understanding the prognosis for a particular patient can help when selecting the intensity of treatment to be used and the frequency of reviews. The quantification of heavy/light chains pairs by the immunosassay Hevylite (HLC) allows us a precise measurement of monoclonal and non-monoclonal immunoglobulins of the same isotype.

Aims: The aim of the study is to evaluate i) the impact of the “HLC ratio” defined as monoclonal immunoglobulin over isotype matched non-monoclonal immunoglobulin (involved/uninvolved HLC ratio or i/u HLC ratio), ii) the suppression on non-monoclonal pair denominated “HLC-matched pair suppression” and iii) the effect of “systemic immunoparesis” at diagnosis and at +100 days after autologous stem cell transplant (ASCT).

Methods: 85 patients (50 Male:35 Female) with a median age of 70 years (56-78) were followed (35 IgGK, 18 IgGL, 17 IgAK and 15 IgAL). The median follow-up of the patients was 19 (5-30) months. Sixteen patients (18%) presented ISS stage I, 15 (28%) with stage II and 54 (64%) with stage III disease. Thirty patients that reached ASCT were evaluated at +100 days after ASCT. Immunoglobulin heavy/light chain pairs (HLC) were assessed by Hevylite assays (The Binding Site). Clinical variables were evaluated for their impact on patient’s outcome. Overall survival (OS) and progression-free survival (PFS) were evaluated by Kaplan-Meier method and Cox regression. Statistical analysis was performed using GraphPad Prism 7.

Results: The median OS of the 85 patients was 54% and 26 patients deceased during the study due to MM. The median value of i/u HLC ratio was 80 (31.5-319.71). At diagnosis, an i/u HLC ratio>80 was significantly associated with worse OS (46 vs 61%, p=0.005) and shorter PFS (23% vs 42%, p=0.006). Severe HLC-matched pair suppression (i.e. more than 50% below the lower reference range) was identified in 68% of the newly diagnosed patients and was associated with significantly shorter OS (35% vs 81%, p=0.004) and PFS (21% vs 50%, p=0.013). Severe (>50%) systemic immunoparesis of non-monoclonal immunoglobulins was identified in 64% of the patients at diagnosis and was also associated with shorter OS (32% vs 81%, p=0.030) but not with shorter PFS (26% vs 44%, p=0.306). The evaluation of other clinical variables on patient’s outcome are shown in table (see Table). In multivariate analysis, severe HLC-matched pair suppression and albumin were found as independent risk factors for OS whereas creatinine and i/u HLC ratio>80 were found as independent risk factors for PFS. In the post-ASCT evaluation of the patients (n=30), normalization of HLC ratio was observed in 22 patients (73%). An altered HLC ratio was significantly associated with shorter PFS after ASCT (25% vs 70%, HR: 3.42, 95%CI: 1.12-11.97, p=0.039) and with a trend towards a worse OS (p=0.072). Severe HLC-matched pair suppression was found in 12 patients (40%) and was predictive of worse OS (0% vs 72%, HR: 10.63, 95%CI: 1.11-114.11, p=0.023) and shorter PFS (35% vs 71%, HR: 8.87, 95%CI: 1.72-45.92, p=0.002). On the other hand, the severe systemic immunoparesis observed in 17 patients (57%) was not associated with OS (p=0.644) and PFS (p=0.750).

Summary/Conclusions: Severe HLC-matched pair suppression and i/u HLC>80 are associated with worse OS and shorter PFS in MM patients suggesting a potential use of these parameters as prognostic biomarkers in newly diagnosed patients. Severe HLC-matched pair suppression is an independent risk factor for OS whereas i/u HLC>80 is independently associated with shorter PFS. In patients after ASCT, severe HLC-matched pair suppression reflects the persistence of clonal cells that is not associated with severe systemic immunoparesis.

E1272

SURVIVAL STRATIFICATION OF PATIENTS WITH MULTIPLE MYELOMA (MM) AFTER FIRST RELAPSE: SENSITIVITY ANALYSES OF A NOVEL RISK STRATIFICATION ALGORITHM (RSA)

R. Hajek1,*, M. Delforge 2, M. Raab 3, L. Pour 4, I. Špička 5, E. Gregora 6, J. Minařík7, S. Gonzalez-McQuire8, W. Bouwmeester9, V. Maisnar10

1Department of Haematoncology, University Hospital Ostrava, Ostrava, Czech Republic, 2Department of Hematology, UZ Leuven, Leuven, Belgium, 3Department of Internal Medicine V, University Hospital Heidelberg, Heidelberg, Germany, 4Department of Internal Medicine, Hematology and Oncology, University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, 51st Medical Department – Clinical Department of Haematology, 1st Faculty of Medicine and General Teaching Hospital, Charles University, 6Department of Internal Medicine and Hematology, University Hospital Kralovske Vinohrady, Prague, 7Department of Hemato-Oncology, University Hospital Olomouc and Faculty of Medicine and Dentistry, Palacky University Olomouc, Olomouc, Czech Republic, 8Amgen (Europe) GmbH, Zug, Switzerland, 9Pharmertil International, Rotterdam, Netherlands, 104th Department of Internal Medicine – Haematology, Charles University Hospital and Faculty of Medicine, Hradec Kralove, Czech Republic

Background: Established risk stratification tools in MM, such as the Interna- tional Staging System (ISS) and the revised ISS, have improved overall survival (OS) estimates by combining the strongest known predictors of survival at diag- nosis. There remains, however, a need for tools that use additional data avail- able at relapse to improve risk stratification. We previously used real-world data from the Czech Registry of Monoclonal Gammapathies (RMG) to develop a RSA for estimating risk of death in patients with MM starting second line (2L) treatment. A multiple Cox regression model identified predictors of OS at 2L (Table); hazard ratios (HRs) for each predictor were multiplied to obtain an overall score for each patient. A K-adaptive partitioning for survival (KAPS) algorithm stratified patients into risk groups based on these scores.

Aims: To investigate how our RSA is affected by: 1) removing cytogenetic abnormalities (CAs) at diagnosis as an OS predictor, as these are not routinely used, as they are not routinely used; 2) adding 2L treatment as a predictor, as 2L treatment type is likely to affect OS; 3) changing the number of stratification groups.

Methods: The analyses used data for 1418 patients aged ≥18 years who were diagnosed with symptomatic MM between May 2007 and April 2016 and who had started 2L. The Cox model was re-run for two sensitivity analyses: excluding CAs and adjusting for treatment received at 2L (adding bortezomib or lenalido- mide vs other treatments as a predictor). The impact of different numbers of risk groups was assessed using KAPS.

Table 1.
REAL-WORLD DATA ON MULTIPLE MYELOMA: A PROSPECTIVE NATIONAL REGISTRY IN URUGUAY ON 224 NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS FROM 2012-2015

E. Riva1,2, V. Bove3, F. Villano1, M. Mori2, A. Noria3, P. Petruskevicius4, C. Córdoba2, A. Gómez5, J. Díaz1

1Hematology Department, Hospital de Clínicas, Facultad de Medicina, 2Hematology, Centro Médico, Salto, 3Hematology Department, Asociación Nacional de Cerrados por Trasplante de Médula Ósea, 4Hematology, Centro Médico, Montevideo, 5Hematology, Centro Médico, Montevideo, Uruguay

Background: The Uruguayan National Myeloma Registry is the first observational prospective Uruguay registry designed to document clinical characteristics of newly diagnosed multiple myeloma (MM), treatment and outcomes in a real-world setting. It collects data from all institutions from all MM patients in Uruguay.

Aims: To document current strategies of clinical characteristics at diagnosis, management, outcomes and treatment adverse effects of non-selected newly diagnosed MM patients in a recent period.

Methods: This registry includes all MM diagnosed from January 2012 in all institutions, nationwide. Smoldering MM are not included. We present the analysis of the first 3 years of data collection. Information was obtained from medical records. The database includes clinical and laboratory characteristics, treatment, disease-related and treatment-related adverse events, response, progression free survival, overall survival and cause of death. Survival is obtained from the Uruguayan Ministry of Health database.

Results: With a 71% institutional coverage, 224 patients were included. Median age at diagnosis was 66 years (range 33-94 years), 54.5% were male; 10% were younger than 50 years and 34.5% older than 70 years. Distribution according Ig subtype was: IgG 50.4%, IgA 23.3%, Light chains 18.7%, non-secretory 2.2% and IgM <1%. Most patients had advanced disease: 79.6% Durie-Salmon stage III (176/221), 48.6% ISS (83/167). Anemia (hemoglobin <10g/dL) was present in 69% (31/45), osteolytic lesions in 86%, renal impairment (creatinine>2mg/dL) in 29.5% and hypercalcemia in 10%. Cytogenetics was evaluated in 150 patients; high risk features were detected in 6.3% by conventional cytogenetics and 19% by fluorescence in situ hybridization. First-line treatment included at least one of the new drugs (Thalidomide, Bortezomib or Lenalidomide) in 92% of patients ≤70 years and in 7% of ≤70 years. First-line response was available in 73%, Overall response rate (>PR) was 82.3%, VGPR= 23.2% and CR=15.2%; 9.8% patients achieved stable disease and 7.9% were refractory. (Fig 1.). Comorbidities and treatment-related toxicities were observed in 45.8% (47% in >70 y vs 41%). Most common adverse events were recurrent infections (28%), neuropathy (17%), thromboembolic events (5.4%) and grade 3-4 neutropenia (5%). Sixty out of 146 potential candidates have been transplanted as first line consolidation at the time of this analysis. After a median follow-up of 30 months, overall survival was 62.8% (median NR in ≤70 years and 32 months in >70 years) and median progression free survival (PFS) was 17 months.

Summary/Conclusions: This first national registry provides a thorough insight into the characteristics of MM patients in our country. With a high institutional coverage, we show MM characteristics at diagnosis are similar to other real-life reports.(1) MM is detected in advanced stage with a high percentage of renal impairment. Diagnosis is performed according to international recommendations. First-line treatment is defined by local policies which restrict Bortezomib to high-risk cytogenetic features and/or renal impairment and do not provide Lenalidomide. Reasons for 59% potential candidates not receiving ASCT should be addressed in future research. This analysis provides relevant real-life information to plan strategies to improve MM management and perform high quality population-based research on the field.

REPRESENTATION OF MINORITIES, THE ELDERLY AND WOMEN IN MULTIPLE MYELOMA CLINICAL TRIALS

N. Duma1,2, J. Vera-Aguiré1, M. Gonzalez3, Z. R. Parrondo3, J. Paludo4, V. Mariotti2, Y. Wang1, R. Warsame1, R. Go1, A. Adjei3

1Hematology, Mayo Clinic, Rochester, 2Internal Medicine, Rutgers University, Newark, 3Mayo Clinic, Rochester, United States

Background: Multiple myeloma (MM) accounts for approximately 1% of all cancers and 10% of hematologic malignancies in the United States (US). MM occurs in all races but the incidence in African Americans is two to three times higher than in non-Hispanic whites. Many clinical trials (CT) lack appropriate representation of specific patients populations, limiting the generalizability of the evidence obtained.

Aims: Determine the representation of ethnic minorities, the elderly and women in MM CT.

Methods: Enrollment data from all therapeutic trials reported as completed in clinicaltrials.gov from 2000 to 2016 were analyzed. CT including other hematologic malignancies and with recruitment outside of the US were excluded. Enrollment fraction (EF) was defined as the number of enrollees divided by the 2013 Surveillance, Epidemiology, and End Results (SEER) database MM complete prevalence. Chi-square test was used to estimate differences in categorical data.

Results: Out of 177 MM CT, 78 (44%) reported ethnicity with a total of 12,055 enrollees. Out of those 78 CT, 52 (67%) were phase II, 15 (19%) phase III and 11 (14%) phase I. Most of the results were published from 2012 to 2016 (74%). Distribution by race, gender, age and comparison with the SEER MM prevalence data are described on Table 1. Forty-six (59%) trials were sponsored by industry, 7% by NC1 and 25 (32%) were investigator initiated. Participation in CT varied significantly across ethnic groups, non-Hispanic Whites (NHW) were more likely to be enrolled in CT (EF of 0.23) than African Americans (AA) (EF of 0.08, p <0.0001) and Hispanics (H) (EF of 0.05, p <0.0001). Males had significantly higher enrollment than females (EF of 0.46 as compared to 0.29) with the difference being most pronounced in the elderly (EF of 0.40 as compared to 0.24) and females (EF of 0.25 as compared to 0.07).

Figure 1.
Background: Rearrangements of the immunoglobulin heavy chain (IGH) on chromosome 14 are identified by FISH in about 15-20% of patients (pts) with newly diagnosed multiple myeloma (MM). Historically, the immunoglobulin heavy chain on chromosome 14 have been associated with a worse outcome, but the clinical significance of these rearrangements is not yet clear. We evaluated a series of patients with newly diagnosed MM to determine the impact of t(11;14) on clinical outcomes and HRU in a largely community setting.

Methods: This analysis used the Connect MM registry to analyze the impact of maintenance or no maintenance of lenalidomide (LEN)-only or no LEN in the treatment of newly diagnosed multiple myeloma (NDMM) patients. The study included patients with newly diagnosed multiple myeloma (NDMM) who received lenalidomide maintenance (M) or no maintenance (N). The primary outcome was OS from diagnosis and post autologous stem cell transplant (ASCT) was 70% (p<0.0001).

Results: A total of 1493 patients with NDMM were enrolled in Cohort 1 from 2007-2011. Median age at diagnosis was 62 years, 49% pts (52%) were male, and 24% (67%) had ISS stage 3. A total of 1455 pts were evaluable for OS, and 1127 pts had OS data available. Overall, 180 (70%) pts achieved very good response (VGPR), and 243 (30%) pts achieved complete response (CR). The median OS was 30.5 months for M, and 15.6 months for N (p<0.0001). In multivariate analysis, ISS stage was an independent risk factor for mortality; pts with stage 3 had 7.3 times (CI: 1.16-36.4) and 5.7 times (CI: 1.63-20.0) the risk of mortality than pts with stage 1 and 2. Having an ASCT reduced mortality by 67% (CI: 0.04-0.41).

Conclusions: Despite the use of novel therapies the OS at 5 years of our pts with MM was not significantly improved compared to SEER data from 1992-2013 (51% vs 48.5%). Pts with t(11;14) who had ASCT had increased survival compared to those who did not. Our results suggest that t(11;14) may confer a worse prognosis. Further prospective studies evaluating the risk of t(11;14) are warranted.

E1275
EVALUATION OF TREATMENT INDUCED PERIPHERAL NEUROPATHY IN MULTIPLE MYELOMA AND ITS INFLUENCE ON PHYSICAL AND ROLE FUNCTIONING

B. Sidi Mohamed El Amine1,*, H. Asma1, O. Fouzia1, S. A. Najet1, Z. Zahia1
1Hematology department, University hospital of Sidi Bel Abbés, Sidi Bel Abbés, Algeria

Background: Peripheral neuropathy (PN) is a major dose limiting and potentially disabling adverse event of commonly therapeutic drugs used in the management of multiple myeloma (MM), including the immunomodulatory drugs (IMIDS, Thalidomide and Lenalidomide), and the proteasome inhibitor (Bortezomib).

Aims: The aims of this study were to (1) perform a psychometric evaluation of PN and (2) examine the prevalence of this complication and its influence on physical and role functioning of MM patients.

Methods: The FACT/GOG-Neurotoxicity (Ntx) subscale for assessing treatment induced PN was evaluated. The 11-item of this questionnaire was administered to patients with MM treated with IMIDS and/or Bortezomib. The subscale was evaluated in 32 patients for internal reliability, construct validity, criterion validity, and comparison with other neuropsychological and functional assessment tests (CTCAE version 3). Spearman rank correlation was calculated to determine the impact of PN on functional, physical and role functioning of MM patients, assessed by EORTC quality of life scale (EORTC QLQ-C30). A Cronbach alpha coefficient ≥ 0.8 is good. Spearman rank correlation is significant if p < 0.05 or r > 0.5.

Results: Cronbach alpha coefficient for internal consistency of FACT/GOG-Ntx subscale was 0.92, and its correlation with the full CTCAE scale as follows: P=0.0001. All the 11 items exhibited high correlations with the NTX subscale score (r= 0.65- 0.79), and the Construct validity of NTX was good. According to FACT/GOG-NTX and NCI-CTCAE, 24 (75%) patients presented PN secondary to IMIDs or Bortezomib. The PN was severe in 14 (43, 7%) patients, especially those who received Bortezomib associated with IMIDS (71, 4%). PN did not influence the achievement of a very good response of MM to therapy (P=0.0005, P=0.0001 respectively).

Summary/Conclusions: PN and (2) examine the prevalence of this complication and its influence on physical and role functioning of MM patients, assessed by EORTC quality of life scale (EORTC QLQ-C30). A Cronbach coefficient ≥ 0.8 is good. Spearman rank correlation was calculated to determine the impact of PN on functional, physical and role functioning of MM patients, assessed by EORTC quality of life scale (EORTC QLQ-C30). A Cronbach coefficient ≥ 0.8 is good. Spearman rank correlation is significant if p < 0.05 or r > 0.5.

E1276
PROGNOSTIC SIGNIFICANCE OF T(11;14) EXPRESSION BY FISH IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA IN THE ERA OF NOVEL THERAPIES

1Internal Medicine, Rutgers NJMS, Newark, 2John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, 3Mayo Clinic, Rochester, United States

Background: Rearrangements of the immunoglobulin heavy chain (IGH) on chromosome 14 are identified by FISH in about 15-20% of patients (pts) with newly diagnosed multiple myeloma (MM). Historically these rearrangements have been associated with a worse prognosis. Further prospective studies evaluating the risk of these rearrangements are warranted.

Methods: This study (Kaufman et al, Leukemia. 2016 30:633-9) suggests that t(11;14) may confer a worse prognosis. Further prospective studies evaluating the risk of t(11;14) are warranted.

Summary/Conclusions: Despite the higher incidence of MM in African Americans and the elderly, the former only represented 8.6% of the study participants and 66% of these were less than 65 years of age, perhaps lacking data in the tolerability of these new agents in our aging MM population. We also observed industry studies were less likely to recruit AA patients. Future trials should take extra measures to recruit participants that adequately represent the United States MM population.

E1277
ANALYSIS OF THE CONNECT MM REGISTRY: TREATMENT OUTCOMES AND HEALTHCARE RESOURCE UTILIZATION IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA WHO RECEIVED LENALIDOMIDE MAINTENANCE OR NO MAINTENANCE

1US Oncology Research, Rocky Mountain Cancer Centers, Denver, 2Mount Sinai Hospital, New York, 3Cedars-Sinai Samuel Oschin Cancer Center, Los Angeles, 4MD Anderson Cancer Center, Houston, 5US Oncology Research, Maryusland Oncology Hematology, Columbia, 6Providence Cancer Institute, Southfield, 7Duke University Medical Center, Durham, 8Steeplechase Cancer Center, Somerville, 9University of South Carolina, Columbia, 10Wake Forest University School of Medicine, Winston-Salem, 11Celgene Corporation, Summit, 12Indiana University Simon Cancer Center, Indianapolis, United States

Background: Maintenance therapy post autologous stem cell transplant (ASCT) has been shown to improve clinical outcomes, including time to progression, progression-free survival (PFS), and overall survival (OS) in patients with newly diagnosed multiple myeloma (NDMM) (Sonneveld, J Clin Oncol, 2012; McCarthy, N Engl J Med, 2012; Attal, N Engl J Med, 2012; Palumbo, N Engl J Med, 2014; Attal, ASCO, 2016). However, the effect of continued treatment on healthcare resource utilization (HRU) is mostly unknown. Connect MM is a largely community-based, US prospective observational cohort study designed to characterize diagnosis, treatment patterns, and outcomes in patients with NDMM in clinical practice.

Aims: This analysis used the Connect MM registry to analyze the impact of maintenance therapy post ASCT on clinical outcomes and HRU in a largely community setting. The study (Kaufman et al, Leukemia. 2016 30:633-9) suggests that t(11;14) may confer a worse prognosis. Further prospective studies evaluating the risk of these rearrangements are warranted.

Methods: Adult patients with NDMM were eligible for enrollment in the registry within 60 days of diagnosis. Patients who completed induction and single ASCT were men, and 86% were white. Baseline patient characteristics except serum
creatinine, calculated International Staging System stage, history of monoclonal gammopathy of unknown significance, presence of del(17p), and induction regimen were similar across groups. LEN-only maintenance significantly extended PFS compared to no maintenance (median 54.5 months vs 30.8 months; hazard ratio [HR]=0.98 [95% CI: 0.43, 0.79]; P=0.0005; Table). OS was also significantly improved with LEN-only vs no maintenance (HR=0.45 [95% CI: 0.29, 0.73]; P<0.001). HRU results are detailed in the Table. The rate of hospitalization/100 person-years (PY) was similar across groups (P=not significant [NS], all comparisons) at the end of years 1 and 2. The median duration of hospitalization was numerically longer for patients who received no mainte-
ance. Procedures/surgeries and concomitant medication use were similar across both groups at the end of years 1 and 2.

Table 1.

| Serum FLC (Freelite, The Binding Site, Birmingham, UK) | GEM/PETHEMA clinical trials (GEM05menos65, GEM05MAS65, GEM2010MAS65 and GEM2012 | Results: Serum FLCs were measured by the sFLC assay (SAS-3 and SAS-4, Helena Bioscience Europe) and were performed on an automated nephelometer (BNII, Dade Behring / Siemens, Marburg, Germany). The electrophoretic study of the monoclonal component (CM) was performed by capillary electrophoresis (V8, Helena Biosciences Europe), and immunofixation was performed for the Ig, y, k and l chains (SAS-3 and SAS-4, Helena Biosciences Europe). Results: From a total of 168 patients with NDMM (68 patients with Bence Jones kappa / 76 Bence Jones lambda), 146 (86%) had FLC data at diagnosis, with 139/146 (95%) evaluable by FLCs [involved sFLC ≥100]. In addition, 68 of the 169 patients also had detectable MP in serum and 7 of the 169 had non-evaluable MP in urine (MP <0.200 g/24h). We studied the correlation of both techniques’ MP quantification results (uPEP vs sFLC) and we observed a low correlation (Pearson’s r =0.293, p =0.003), that should be partly explained by the low prof-

Summary/Conclusions: For patients with NDMM, LEN-only maintenance sig-
ificantly improved PFS and OS vs no maintenance with no apparent impact on HRU.

E1278

SERUM-FREE LIGHT-CHAINS (sFLC) INSTEAD OF URINE PROTEIN ELECTROPHORESIS (uPEP) FOR MONITORING LIGHT-CHAIN MULTIPLE MYELOMA (LCMM)

L. Lopez Anglada Fernandez1, C. Cueto-Felquieros2, M.V. Mateos3, L. Rosiño6, A. Oriol6, A.I. Tereul6, L. Palomera6, F. Arinta6, J.J. Bargay6, J.M. Hernández10, Y. Gonzalez11, B. Maria Jesus12, A. Valeri6, M. Granell13, R. Garcia Sanz6, Á. Lopez de la Guía14, J. Besalduc15, R.B. Martínez16, M.T. Hernández17, P. Puerta2, J. Bladé4, J. San Miguel18, J.J. Lahuerta1, J. Martínez-López1, Hema-tology, Hospital Germans Trias y Pujol de Badalona, Badalona, 4Haematology, Hospital Clínico de Valencia, Valencia, 5Haematology, Hospital Lozano Blesa, Zaragoza, 6Haematology, Hospital Morales Meseguer, Murcia, 7Haematology, Hospital U Son Llatzer, Mallorca, 8Haematology, Hospital General del Norte, Seviglia, 9Haematology, Hospital U San Carlos, Madrid, 10Haematology, Hospital U Son Espases, Mallorca, 11Haematology, Hospital U San Carlos, Madrid, 12Haematology, Hospital Universitario de Canarias, Tenerife, 14Haematology, Hospital Universitario de Salamanca, Salamanca, 15Haematology, Hospital Clinic i Provincial de Barcelona, Barcelona, 16Haematology, Hospital Germans Trias y Pujol de Badalona, Badalona, 17Haematology, Hospital General de Segovia, Segovia, 18Haematology, Hospital U Son Llatzer, Mallorca, 19Haematology, Hospital Universitario de Canarias, Tenerife, 20Haematology, Clínica Universitaria de Navarra, Pamplona, Spain.

Background: Response and follow-up criteria in multiple myeloma (MM) are still based on the protein electrophoretic (PEP) quantification of the monoclonal protein (MP) in serum (s) and/or urine (u). Monitoring MP by urine (u) PEP has a very low sensitivity for evaluating variations of small amounts of MP. In this work, we try to validate the use of sFLC assay in the context of GEM/PETHEMA clinical trials in order to evaluate the responses and its advan-
tege in comparison to standard quantification of MP by PEP in serum (s) and/or urine (u). Monitoring MP by urine (u) PEP has a very low sensitivity for evaluating variations of small amounts of MP.

Methods: We included 169 patients with Bence Jones (BJ) MM with measur-
able urine disease who have being treated according to GEM/PETHEMA clin-
ical trials in order to evaluate the responses and its advantages in comparison to standard quantification of MP by PEP in serum (s) and/or urine (u). Monitoring MP by urine (u) PEP has a very low sensitivity for evaluating variations of small amounts of MP.

Results: From a total of 168 patients with NDMM (68 patients with Bence Jones kappa / 76 Bence Jones lambda), 146 (86%) had FLC data at diagnosis, with 139/146 (95%) evaluable by FLCs [involved sFLC ≥100]. In addition, 68 of the 169 patients also had detectable MP in serum and 7 of the 169 had non-evaluable MP in urine (MP <0.200 g/24h). We studied the correlation of both techniques’ MP quantification results (uPEP vs sFLC) and we observed a low correlation (Pearson’s r =0.293, p =0.003), that should be partly explained by the low prof-

Summary/Conclusions: There is an acceptable agreement between both methods for response evaluation. The SFLC assays provide a greater sensitivity than the urine protein electrophoresis for monitoring low levels of disease in certain cases with measurable disease at diagnosis (isFLC ≥100) being useful for its follow-up, and also provide prognostic value as a predictor of progres-

E1279

TOPSPIN: A NOVEL ALGORITHM TO PREDICT TREATMENT SPECIFIC SURVIVAL IN CANCER

J. Uebels1,2,3, E.H. van Beers1, A. Brojzl2, P. Sonneveld3, M.H. van Vliet4, J. de Ridder4

1Center for Molecular Medicine, UMC Utrecht, Utrecht, 2Department of Hema-
tology, Erasmus MC Cancer Institute, 3SkylineDx, Rotterdam, Netherlands

Background: In recent years many novel treatments have been introduced for Multiple Myeloma (MM), leading to an improved survival. However, this has also led to the situation where many different treatment combinations are used, without a clear indication which patient will benefit most from which treatment. It is increasingly recognized that genetic heterogeneity between tumors influ-
ence treatment response. Patient outcomes may be improved by selecting the right treatment for the right patient at the moment of diagnosis. This requires the discovery of predictive markers, for example gene expression signatures, that can aid in this treatment decision. Here we present TOPSPIN (Treatment Outcome Prediction using Similarity between PatieNts), a novel algorithm to discover such markers from tumor gene expression data. We use it to identify patients more likely to benefit from bortezomib.

Aims: This algorithm aims to develop a classifier that identifies a subset of patients that will benefit more from a treatment of interest than similar patients who receive a different treatment.

Methods: TOPSPIN aims to predict whether a patient will benefit (class 1) or not benefit (class 0) from a certain treatment of interest based on the gene expression profile of the patient. This algorithm relies on the idea that geneti-
cally similar patients who received a different treatment should have a large difference in survival, given that genetic similarity is defined in a manner that is relevant to treatment response. This principle is used to identify prototype patients: patients who received the treatment of interest and have a larger than expected survival difference with the genetically most similar patients who received another treatment. Genetic similarity is defined separately for 10 581 gene sets based on Gene Ontology (GO) annotation. These prototype patients are used to define a classifier: new samples who exhibit a similar gene expres-
sion profile as the prototype patients will be classified as likely to benefit from the treatment of interest. Here we use TOPSPIN to predict which patients will ben-
et from the proteasome inhibitor bortezomib. We combine tumor gene expres-
sion data from the Total Therapy 2, Total Therapy 3 and HOVON-65/GMMG–

HD4 phase III clinical trials into one dataset comprising 910 patients, split into a bortezomib arm (n=407) and a non-bortezomib arm (n=503). Progression free survival is used as outcome measure. This dataset was split in a training set (n=606) and a test set (n=304). The test set is not used at any point in the training procedure and is only used for independent validation.
Results: We successfully identify gene sets that enable us to predict which patients will benefit most from bortezomib. The top 8 performing GO sets based on Hazard Ratio (HR) were combined to achieve the final classification. In the training set 28.4% of patients are classified a class 1, resulting in an HR of 0.13 (p=7.1*10^{-11}) between the two treatment arms. More importantly, in an independent test set an HR of 0.47 (p=0.03) was found, as shown in Figure 1.

Figure 1. Kaplan-Meier plot of survival for patients treated with bortezomib and in the control arm. The survival was calculated from the date of diagnosis to the date of death or last follow-up.

Summary/Conclusions: TOPSPIN is successful in predicting bortezomib specific survival in independent data. TOPSPIN can be applied to any dataset with two treatment arms and a continuous outcome measure. In a disease like MM, where many different treatment are available, selecting the right treatment is critical and TOPSPIN can aid in this decision.

**E1280**

**AMYLOIDOSIS RESEARCH CONSORTIUM CARDIAC AMYLOIDOSIS SURVEY: RESULTS FROM PATIENTS WITH AL AMYLOIDOSIS AND THEIR CAREGIVERS.**

I. Lousada1,*, M. Maurer2, S.D. Guthrie3, K. Hsu1, M. Grogan4
1Amyloidosis Research Consortium, Boston, 2Columbia University, New York, 3Prothena Biosciences Inc, South San Francisco, 4Mayo Clinic, Rochester, United States

Background: Cardiac amyloidosis is a severe disease that can lead to cardiac dysfunction and death. Amyloid light chain (AL) amyloidosis, hereditary transthyretin (hATTR) amyloidosis, and wild-type transthyretin (wtTTR) amyloidosis may result in cardiac amyloidosis. AL amyloidosis is caused by an accumulation of misfolded light chain and often involves organs other than the heart (eg, kidneys, nervous system). Initial symptoms are often nonspecific (eg, weight loss, fatigue). Consequently, a diagnosis is frequently made only after the disease has become advanced. Previous patient-directed research found that despite patients being initially referred most often to cardiologists (as opposed to hematologists and nephrologists), cardiologists diagnosed the condition much less frequently than other specialists.

Aims: To understand delays, errors, and inconsistencies in the diagnostic pathway for patients with AL cardiac amyloidosis and validate using caregiver responses.

Methods: An online survey consisting of 36 questions (for patients) and 37 questions (for caregivers) was developed by the Amyloidosis Research Consortium (ARC) and distributed to the patient mailing lists of ARC, the Amyloidosis Foundation, and Amyloidosis Support Groups in January 2017. The survey was designed for patients with all forms of cardiac amyloidosis and their caregivers; however, the present analysis is limited to AL amyloidosis.

Results: In this subanalysis, 137 patients and 115 caregivers completed the survey. Most patient respondents were >55 years of age (n=111; 81.0%); of those, 16.1% (n=22) were >70 years of age. Composition of the population was 81.8% white/Caucasian (n=112), 2.2% Asian (n=3), 4.4% African American (n=6), 2.2% Latino (n=3), 5.1% other (n=7), and 3.6% unknown (n=6). Most patients had lived with their diagnosis for >1 year (17.5% [n=24] <1 year; 23.4% [n=32] 1-2 years; 29.2% [n=40] 3-5 years; 21.2% [n=29] 6-10 years; 8.8% [n=12] >11 years). A significant percentage of patients had multorgan involvement (54.7% [n=75] kidney; 29.9% [n=41] nerve; 14.6% [n=20] liver; 43.8% [n=60] GI; 14.6% [n=20] skin; 22.2% [n=49] other site). Before diagnosis, 43.8% (n=60) of patients were incorrectly diagnosed with one or more other conditions, predominantly by cardiologists and general practitioners (Table 1). Furthermore, more than 75% of patients visited 3 or more different physicians before diagnosis. Nearly all misdiagnosed patients (83.3%; n=50/60) reported receiving treatment for their misdiagnosed condition. Both patients and caregivers reported correct diagnoses being made most frequently by cardioligists and hematologists (Table 1). Caregivers echoed the multitude of distinct physicians visited before diagnosis (Table 1). Patients reported that biopsy of fat pad, kidney, or heart was the predominant diagnostic test performed (Table 1). Hospitalization was prevalent; 55.5% (n=76) patients reported amyloid-related cardiac hospitalization. Moreover, 31.3% (n=43) of patients reported the need for air travel for physician consultation.

Summary/Conclusions: This represents the first survey compiling both caregiver and patient experiences with AL amyloidosis. Alignment of caregiver with patient responses validates our patient-directed research. Patients with AL cardiac amyloidosis frequently receive misdiagnoses and sometimes receive incorrect treatment for the misdiagnosed condition. Disease awareness among all specialists is vital, especially among those to whom patients are initially referred due to the nature of their initial symptoms.
immunomodulatory agent (IMiD)-free regimens. Analysis using a fixed-effects model found that DRd compared with other IMiD-containing regimens in Network 1, and DVD compared with other IMiD-free regimens in Network 2 prolonged PFS and OS among patients with RRMM (see Table 1).

**Summary/Conclusions:** In the absence of prospective head-to-head trials, NMA provides potentially important information on comparative effectiveness of different treatments. This NMA suggests that the combinations of DRd and DVD are more effective than PFS in patients with RRMM with similar trends found for OS when compared with other established and new regimens.

## E1282

**TRENDS IN TREATMENT PATTERNS AND SEQUENCING IN PATIENTS WITH MULTIPLE MYELOMA DIAGNOSED 2011-2016 IN THE UNITED STATES USING AN ENHANCED ELECTRONIC HEALTH RECORDS DATABASE**

### Background:
Over the past few years, the multiple myeloma (MM) treatment (Tx) landscape has changed considerably. Immunomodulating (IMiD) drugs and proteasome inhibitors (PI) have emerged as mainstays of MM Tx. However, the limitations and lag time of available administrative claims databases make it difficult to assess current real-world trends in the Tx of MM.

### Aims:
The study aimed to describe trends in demographics, Tx patterns, and sequencing for newly diagnosed MM (ndMM) patients (Pt) in the United States (US) using an enhanced Electronic Health Records (EHR) database.

### Methods:
A retrospective observational study of ndMMPts was conducted utilizing EHR from a nationally-representative database (Flatiron Health). The Flatiron MM provider network comprises over 260 clinics throughout the US. Pts with an ICD-9 (203.0x) or ICD-10 (C90.xx) diagnosis of MM between 01/01/2011–12/31/2016 were randomly selected into the study. Pts were excluded if they did not have ≥2 documented clinical visits during the study period. Diagnosis of MM was confirmed through review of unstructured chart data. Index date was defined as the Pt’s date of diagnosis with MM. ndMM Pts were defined as those without a MM Tx more than 14 days prior to their first diagnosis date. Start of first-line (1L) therapy was defined as the 1st episode of an eligible systemic Tx given after or up to 14 days before the index date. Regimens were defined using the 1st eligible drug episode plus other eligible drugs given within 28 days of each other. A maximum gap of 90 days was allowed within a given line of therapy (LOT) and was considered concluded the day before the start date of the next LOT.

### Results:
For the 3367 ndMM Pts identified, mean(SD) age was 68.5(11) years at the time of diagnosis, 45.9% were female, 57.6% were white, 14.7% African American, and 11.1% other race. The most common immunoglobulin (ig) classes at diagnosis were IgG (51.8%) and IgA (18.9%). Median follow-up time for ndMM Pts was 15.9 months. During the study period, 1611 received only 1 line (L), 1037 were treated with 2 L, 325 with 3 L, 252 with 4 L; while 442 (13%) remained on treatment with other IMiD-containing regimens at diagnosis. Start of first-line (1L) therapy was defined as the 1st episode of an eligible systemic Tx given after or up to 14 days before the index date. Regimens were defined using the 1st eligible drug episode plus other eligible drugs given within 28 days of each other. A maximum gap of 90 days was allowed within a given line of therapy (LOT) and was considered concluded the day before the start date of the next LOT.

A maximum gap of 90 days was allowed within a given line of therapy (LOT) and was considered concluded the day before the start date of the next LOT.
Results: At a median follow-up of 9.8 months in a protocol-specified interim analysis, 67 patients had disease progression or death were observed (in 18 of 66 patients (27.2%) in the group B vs 28 of 68 (41.1%) in the control group (p=0.001)). A significantly higher rate of overall response was observed in the group B than in the group A (88.7% vs 62.9%, p<0.001), as was a higher rate of complete response or better (39.2% vs 16.1%, p<0.001). The most common adverse events during the treatment was myelotoxicity (neutropenia in 68.6% of the patients in the therapy group B vs 42.1% of those in the control group A), anemia (in 21.5% vs 13.6%) and thrombocytopenia (in 13.8% vs 8.7%).

Summary/Conclusions: In patients with relapsed multiple myeloma, the addition of daratumumab to lenalidomide and dexamethasone appeared active and resulted in significantly improved progression-free survival. However it was associated with a higher risk of myelotoxicity.

COMPARISON BETWEEN IMMUNOFIXATION NEGATIVITY AND NORMAL FREE LIGHT CHAIN RATIO WITH MULTICOLOUR FLOW CYTOMETRY FOR THE ASSESSMENT IN PATIENTS WITH MULTIPLE MYELOMA WITH VGPR OR BETTER

K. Narita1*, H. Takamatsu2, Y. Abe1, Y. Usui1, M. Takeuchi1, K. Matsue1
1Department of Medicine, Hematology/Oncology Kameda Medical Center, Kamogawa, 2Department of Hematology and Respiratory, School of medicine, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, Japan

Background: Urine and serum Immunofixation electrophoresis (uIFE and sIFE, respectively) and free light chain assay (FLC) are widely accepted as standard tests for diagnosis and monitoring of multiple myeloma (MM). However, there is significant discordance between the electrophoretic method and FLC test for response assessment. Despite this discordance, previous studies did not address the differences in assessment of response treatment between the intact immunoglobulin MM (IIMM) and light chain only MM (LCMM/oligosecre- tory MM (OSMM)). uIFE results are poorly correlated with the serum FLC level, however, treatment response of LCMM has still been recommend to assess by 24-hour uIFE by International Myeloma Working Group guideline. However, MRD levels on uIFE negativity or normal FLC ratio (rFLC) in patients with various types of MM have not been studied.

Aims: To explore the relationship between uIFE, sIFE negativity and normal rFLC for MRD assessment in patients with IIMM and LCMM.

Methods: We initially selected 162 patients with MM (LCMM and OSMM, n = 41; IIMM, n=21) that received treatment at Kameda Medical Center, Kamogawa-shi, Japan and Kanazawa University Hospital, Kanazawa-shi, Japan between April 2008 and January 2016. Among them, 126 patients (LCMM/OSMM 40, IIMM 86), who achieve VGPR or better response, were selected on the basis of the availability of simultaneous serum and urine test, FLC data, and bone marrow MRD. To explore the relationship between uIFE and sIFE negativity and normal rFLC, MRD levels were compared by multi-colour flow-cytometry (MFC) in patients with LCMM/OSMM, and IIMM that obtained VGPR or better. MRD negativity was defined as MRD <10^-4. Complete response (CR) was divided into conventional CR (cCR, CR but MRD-positive) and MRD- CR (CR and MRD-negative).

Results: One hundred and sixty-four complete IFE, FLC, and MFC data set of 126 patients (LCMM/OSMM 40, IIMM 86) with >2 VGPR were analysed. Normal FLC at VGPR, cCR and MRD- CR was 65.0%, 78.4% and 78.6% in IIMM, and 12.5%, 50.0%, and 100% for negative uIFE, and 0%, 11.5% and 100% for normal rFLC, respectively. These figures in IIMM were 23.0%, 41.6%, 81.4% for negative sIFE, and 53.8%, 75.0% and 88.8% for normal rFLC, respectively. Positive/negative predictive value (PPV/NPV) of uIFE and rFLC for MRD in LCMM/OSMM was 100%/45.8% and 100%/85.0% in IIMM, respectively.

Summary/Conclusions: Our observations confirmed that FLC test has greater sensitivity than uIFE for detection of the monoclonal component, and that normalization of sFLC ratio is highly predictive of MRD negativity in patients with LCMM/OSMM. The proportion of negative sIFE samples increased with depth of MRD, but the FLC response did not appear to parallel with the depth of response in IIMM. We recommend that FLC test should be incorporated into routine assessment in IIMM/OSMM as an alternative to 24-h uIFE, and both negative sIFE and normal rFLC are still useful for response assessment of residual clonal PCs in IIMM.

DARATUMUMAB IS AN EFFECTIVE AND SAFE SAVAGE THERAPY IN RELAPSED/REFRACTORY PATIENTS WITH MULTIPLE MYELOMA AFTER AUTOALLIATEHIC STEM CELL TRANSPLANTATION

E. Klyuchnikov1,2,3, U.-M. von Pein1, F. Ayuk1, M. Christoplet1, R. Adjaille1, A. van Randenborg1, C. Wolschke1, N. Kroeger1
1Department for Stem Cell Transplantation, University Cancer Center Hamburg-Eppendorf, Hamburg, Germany

Background: Daratumumab is a human monoclonal antibody that targets CD38, a cell surface protein that is overexpressed on multiple myeloma cells. The drug became the first monoclonal antibody as single agent therapy approved by the FDA for the treatment of multiple myeloma. The role of allo-SCT in myeloma patients (pts) remains unclear; nevertheless, the registry study of EBMT suggests an increasing rate of allografts in Europe in last years. Despite the potentially curative potential of this approach, the increased relapse rate and low PFS remain a central clinical problem.

Aims: In this single center retrospective analysis, we report on our experience on the use of daratumumab in relapsed/refractory myeloma pts after allo-SCT.

Methods: A total of 16 pts (male, n=9) with median age of 66 years (39-72) relapsing after allo-SCTs that had been performed during a period 2008-2015 at the University of Hamburg and received daratumumab as single agent sal- vage therapy. Before allografting 9 pts received one and 7 pts 2 autologous, respectively. All but one pt received at least 1 salvage therapy line prior to the allo-SCT. The allografts were performed from unrelated donors (MUD, n=9; MMUD, n=4) or matched related donors (MRD, n=3). The median of salvage lines post-transplant and prior to first daratumumab infusion was 3 (1- 4). The salvage regimens included bortezomib, lenalidomide, pomalidomide and carfilzomib. Daratumumab infusions were started at a median of 21 months (0-30) after relapse/progress.

Results: The median number of infusions was 13 (3-22). A total of 16 and 15 pts were available to safety and efficacy evaluation, respectively. The safety was assessed according to the Common Toxicity Criteria (CTC). A total of 20 adverse events were observed in 16 pts: dyspnea (CTC1, n=3; CTC2, n=1), bronchospasm (CTC2, n=2) shivering (CTC1, n=3), cough (CTC1, n=1; CTC2, n=1), muscle/skeletal pain (CTC1, n=4), acute coronary syndrome (CTC3, n=1), skin rash (CTC2, n=1), pressure on eyes (n=1). Two patients developed late onset infections (pneumonia and infection of urinary tract) followed by temporarily therapy interruption. We observed a decrease of Treg (CD4+CD25(high)Foxp3+flow) number from a median of 5.05% at start to 0.65% at day 21 after first daratumumab infusion in four pts. There were no cases of GvHD. The adverse events appeared in all pts after the first infusion, with improved tolerance of following infusions. There were no cases, where the therapy had to be stopped due to adverse events. Within a median follow-up of 32 months (1-45) from the relapse/progression 12 of 16 pts remain alive. Two pts died due to progress of myeloma and another 2 pts died due to severe infection/sepsis. A total of 9 of 15 evaluable pts responded (60%, PR, n=7, vgPR, n=2). The responses (decrease of paraprotein and/or free light chains; reduction of extramedullary tumor in 2 pt) occurred at a median of 7 days (7-75) after the first administration of daratumumab. The median response duration is 4.5 mo (1.5-8). Six pts show ongoing responses. All responding and 2 non-responding pts (stable disease) showed clinical improvement of constitutional symptoms.

Summary/Conclusions: Daratumumab demonstrated encouraging efficacy in relapsed refractory pts with myeloma after allo-SCT. The administrations of the drug in these heavily pre-treated pts were associated with good safety profile and development mostly non-severe adverse events mostly after the first infusion. Further studies on the use of daratumumab in post-transplant setting are warranted.

E1287

PROGNOSTIC RELEVANCE OF VEGF AND VEGFR EXPRESSION IN CD138+\CD19- AND CD138+\CD19+ PLASMA CELLS FROM PATIENTS WITH MONOCLONAL GAMMOPATHIES

C. Geraldes1,2,*, A.C. Gonçalves2, R. Alves2,3, E. Cortésao1,2,3, L. Ribeiro1, J.M. Nascimento Costa2,4, A.B. Sarmento-Ribeiro2,3

Mediha, Spain, June 22 – 25, 2017

haematologica | 2017; 102(s2) | 527
Background: Vascular endothelial growth factor (VEGF) is a potent angiogenic peptide with biologic effects that include regulation of extracellular matrix remodeling and inflammatory cytokine generation with an important role in the bone marrow microenvironment of multiple myeloma (MM). Angiogenesis is heightened in the bone marrow of MM patients in parallel with tumor progression. Myeloma and stromal cells secrete angiogenic factors that include VEGF. Previous studies showed an increase in the expression of VEGF between plasma cells (PCs) from the same MM patient. However, no clear association with expression levels, phenotypic subtypes of PCs and prognosis was demonstrated.

Aims: The present study aimed to evaluate the expression levels of VEGF and VEGF receptor (VEGFR) on phenotypic subtypes of PCs in patients with monoclonal gammopathies and to explore its role as diagnostic and prognostic biomarkers.

Methods: We include 128 patients with monoclonal gammopathies, 60 patients with newly diagnosed symptomatic MM and 68 with monoclonal gammopathy of uncertain significance (MGUS) and also from 11 non-neoplastic controls (Chronic anemia). The expression levels of VEGF and VEGFR by flow cytometry in the two populations of bone marrow PCs, identified by gating CD138+/CD19- (clonal PCs) and CD138+/CD19+ (non-clonal PCs). The results are presented as percentage of PCs expressing VEGF/VEGFR and as expression levels of this antiangiogenic molecules expressed in mean intensity of fluorescence (MIF). The effects of these parameters on progression-free survival (PFS) and overall survival (OS) were analyzed with Kaplan-Meier method. For statistical analysis, software IBM SPSS Statistics v22 was used. ROC curves were performed to assess the VEGF and VEGF receptor accuracy as diagnostic and prognostic biomarkers.

Results: In our cohort of patients, median age was 70 (39-86) years, 52% were male. We found increased expression levels of VEGF in CD138+/CD19- PCs from MM (80±7.5 MIF) compared tomgUS patients (61±7.6± MIF) (p=0.011), and also higher to the observed in CD138+/CD19+ PCs (39.92±1.74 MIF) in both populations of patients (p<0.01 and p=0.02, respectively). No differences were observed in the expression of VEGF in CD138+ in MM compared tomgUS patients from MM (39.92±1.74 MIF),mgUS patients (41.18±1.92 MIF) and controls (32.8±1.5 MIF). However, the percentage of CD138+/CD19+ cells expressing VEGF was significantly higher in mgUS (39.4±4.4%) and in MM patients (48.7±5.5%) compared to Ch (13.5±5.5%) (p=0.019 and p=0.003, respectively). The differential expression of VEGF showed that MM patients with VEGF levels higher than constant patients (23.5 MIF in CD138+/CD19- PCs have higher probability to progress to MM [AUC 0.688 (95%CI 0.592-0.784), p<0.001, 90% sensitivity, 56% specificity, 65% PPV, 84% NPV]. In MM patients, we also found an association between increased VEGF expression levels in CD138+/CD19- PCs (11%) and survival (in the maintenance setting for example) when some inherent immune burden (in the maintenance setting for example) when some inherent immune recovery has occurred. However this has yet to be confirmed in a prospective clinical trial.

Aims: To evaluate the effect of maintenance with POM alone (Arm 1) versus POM-LoDEX (Arm 2) on progression free survival (PFS), overall survival (OS), and kinetics of response (overall response rate (ORR)) in relapsed myeloma (MM) patients refractory to lenalidomide (RELEN) demonstrating stable disease (SD) or better after salvage treatment with pomalidomide (POM) and low dose dexamethasone (LoDEX) induction.

Methods: Multicentre, open-label, randomized phase 2 study of relapsed RLEN patients who had received 2 prior lines of therapy. POM 4mg days 1-21 (28 day cycle) was administered alone or in combination with LoDEX (40mg weekly) as maintenance following an induction with 4 cycles of POM and LoDEX. Treatment continued until toxicity or progression. Peripheral blood samples for immune studies were collected pre-induction and prior to cycles 1, 3, 6 and 10 of maintenance.

Results: 154 patients from 15 centers were enrolled on to the study (M:F 80:74), with a median age of 67 years (range 35-85). Median number of prior lines of therapy was 4.5 (2-14). All patients had failed LLEN (100%), 127 (82.5%) were also refractory to bortezomib (double refractory) and 94 (61%) had received a prior autologous stem cell transplant. 72 (47%) patients achieved SD or better with LoDEX induction. The ORR for LoDEX induction was 35 to POM (Arm 1) and to 37 to POM-LoDEX (Arm 2). After a median follow-up of 19 months, median PFS for all patients from study entry was 4.2m (IQR 2.1 – 8.6m). PFS for randomised patients (from time of randomisation) was 2.7m for POM (arm 1) versus 3.5m for POM-LoDEX (arm 2) (p=0.39). The PFS hazard rate for Arm 2 was relatively constant compared to Arm 1 which started with a hazard rate double that of Arm 2 but dropped to less than half of the rate in Arm 2 by 15 months, suggesting that with longer follow-up, there may be an emergent advantage to maintenance with POM versus POM-LoDEX (Figure 1.). Median OS for Arm 2 was relatively constant compared to Arm 1 which started with median OS of 12.7m for POM-LoDEX (arm 2) (p=0.39). The PFS hazard rate for Arm 2 was relatively constant compared to Arm 1 which started with a hazard rate double that of Arm 2 but dropped to less than half of the rate in Arm 1 by 12 months, suggesting that with longer follow-up, there may be an emergent advantage to maintenance with POM versus POM-LoDEX (Figure 1.). Median OS for Arm 2 was relatively constant compared to Arm 1 which started with median OS of 12.7m for POM-LoDEX (arm 2) (p=0.39). The PFS hazard rate for Arm 2 was relatively constant compared to Arm 1 which started with a hazard rate double that of Arm 2 but dropped to less than half of the rate in Arm 2 by 15 months, suggesting that with longer follow-up, there may be an emergent advantage to maintenance with POM versus POM-LoDEX (Figure 1.). Median OS for Arm 2 was relatively constant compared to Arm 1 which started with median OS of 12.7m for POM-LoDEX (arm 2) (p=0.39). The PFS hazard rate for Arm 2 was relatively constant compared to Arm 1 which started with a hazard rate double that of Arm 2 but dropped to less than half of the rate in Arm 2 by 15 months, suggesting that with longer follow-up, there may be an emergent advantage to maintenance with POM versus POM-LoDEX (Figure 1.). Median OS for Arm 2 was relatively constant compared to Arm 1 which started with median OS of 12.7m for POM-LoDEX (arm 2) (p=0.39). The PFS hazard rate for Arm 2 was relatively constant compared to Arm 1 which started with a hazard rate double that of Arm 2 but dropped to less than half of the rate in Arm 2 by 15 months, suggesting that with longer follow-up, there may be an emergent advantage to maintenance with POM versus POM-LoDEX (Figure 1.). Median OS for Arm 2 was relatively constant compared to Arm 1 which started with median OS of 12.7m for POM-LoDEX (arm 2) (p=0.39). The PFS hazard rate for Arm 2 was relatively constant compared to Arm 1 which started with a hazard rate double that of Arm 2 but dropped to less than half of the rate in Arm 2 by 15 months, suggesting that with longer follow-up, there may be an emergent advantage to maintenance with POM versus POM-LoDEX (Figure 1.). POMALIDOMIDE IS MORE EFFECTIVE IN REAL CLINICAL PRACTICE THAN IN RANDOMIZED TRIAL – AN OBSERVATIONAL STUDY OF THE CZECH MYELOMA GROUP
L. Pour1, L. Brozova1, I. Spicka3, V. maisnar4, F. Zagouri1, A. Gerofotis2, G. Christopoulou1, M. Gavriatopoulou1, D. Christoulas4, A. Kourakli3, P. Konstantinidou2, E. Kastritis1, M.A. Dimopoulos1
1Department of Clinical Therapeutics, National and Kapodistrian University of Athens, School of Medicine, Athens, 2Department of Hematology, Theagenion General Hospital, Thessaloniki, 3Department of Internal Medicine, Division of Hematology, University of Patras Medical School, Patras, 4Department of Hematology, 251 General Air-Force Hospital, Athens, Greece

Background: The combination of pomalidomide and low-dose dexamethasone (Pom-Dex) is a perspective option for patients with end-stage relapsed/refractory multiple myeloma (RRMM). We analyzed efficacy and toxicity of Pom-Dex in all patients from the Czech Republic treated from june 2013 to december 2016.

Methods: Patients were eligible if they had been diagnosed with RRMM and had failed at least two previous treatments with bortezomb and lenalidomide. They were treated with start dose of Pom (4mg/day on days 1-21, orally) plus low-dose dexamethasone (40mg/day on days 1, 8, 15, and 22, orally) until disease progression or unacceptable toxicity. We analyzed TTP and OS together with toxicity. Also, univariate Cox proportional hazards model for OS was done for standard risk factors. One hundred and twenty-two patients with median age of 67 treated with Pom-Dex were evaluated. Median follow-up was 8.7 months. Median of previous treatment lines was 4.

Results: Median TTP of Pom-Dex treatment was 7.1 months (95% CI 5.3-8.6). Median OS was 19.0 months (95% CI 13.2-25.8). The most common grade 3-4 adverse events were neutropenia in 44%, anemia in 22% and thrombocytopenia in 24% of patients. Grade 4 infections were observed in 19% of patients. Patients with ECOG worse than 2, B2microglobulin higher than 5, ISS stage 3, low hemoglobin, low platelet count and presenting extramedullary mass had worse OS according to univariate Cox proportional hazards model.

Summary/Conclusions: Our analyses show that Pom-Dex treatment of Czech RRMM patients is effective, well tolerated and had better results than the registration study. Performance status and tumor burden seem to be main prognostic factors according to our model. Thus, our suggestion for clinical practice is to start pomalidomide treatment as soon as possible in case of MM relapse.

E1291
UNDERSTANDING THE REAL-WORLD CLINICAL CHARACTERISTICS OF MULTIPLE MYELOMA PATIENTS IN EUROPE
T. Bacon1,2, M. Gaudiè, T. Ito, A. Hadfield4, A. Rider4
1Janssen Health Economics & Market Access EMEA, Dublin, Ireland, 2Janssen-Cilag, Neuss, Germany, 3Janssen Health Economics & Market Access EMEA, High Wycombe, 4Adelphi Real World, Bollington, United Kingdom

Background: Multiple myeloma is a heterogeneous disease that accounts for approximately 10% of all haematological malignancies. While European treatment guidelines exist for multiple myeloma, there is limited understanding about the characteristics of patients with multiple myeloma in Europe and how these characteristics vary by disease stage. Numerous patient and disease-related factors can have an impact on treatment choice. Data surrounding these factors would help to better characterise European patients and inform management and treatment practices in multiple myeloma.

Aims: The aim of the current study is to describe multiple myeloma patients from 5 European countries (France, Germany, Italy, Spain, and the UK) across the disease continuum.

Methods: Data were drawn from the Adelphi Real World Multiple Myeloma Disease-specific Programme (DSP), which was conducted across France, Germany, Italy, Spain and Myeloma UK in Q1 2015. The Multiple Myeloma DSP is a real-world, cross-sectional survey that involves haematologists and haematologists who completed patient record forms for the next 8 multiple myeloma patients with whom they consulted. Study variables included patient demographics and background clinical information.

Results: A total of 262 physicians reported on 2,024 patients with multiple myeloma. Of these patients, 73.2% were receiving first-line treatment; the remaining 26.8% were receiving second-line treatment or later. The median age of multiple myeloma patients was 70 years, 58.4% were male, and most patients (88.5%) were white/Caucasian. Only 4.3% of patients had a family history of cancer. Patients had a mean height of 168.8 cm, a mean weight of 72.8 kg, and a mean body mass index of 25.5 kg/m2. In terms of performance status, 79.8% of patients had an Eastern Cooperative Oncology Group (ECOG) status of 0 or 1, whereas 20.2% had an ECOG status of 2. While 12.9% of patients had smouldering myeloma, 47.5% of patients had advanced stage III disease. The most common symptoms experienced by patients were anaemia (31.0%), bone pain (32.4%), fatigue/weakness (28.4%), and kidney impairment or failure (12.6%). Furthermore, 34.6% of patients had bone complications at some point in time. Overall, 51.1% of patients had complications of these. 22.8% had hypertension and 12.5% had diabetes. Overall, 33.7% of patients were considered ineligible for transplant. Variances in patient characteristics, both by country and by line of therapy, were observed.

Summary/Conclusions: Results from this analysis provide valuable insight into multiple myeloma patients in European countries. These findings can help to inform future treatment practices in Europe.
stable disease and one progressed during the 4th cycle of treatment. After ASCT the ORR was 84.4% (613.3%) patients achieved CR, 13 (28.9%) VGPR and 19 (42.2%) PR. Adverse events of grade 3 or 4 included mainly anemia (4 patients), neutropenia (3, 6.6%) and febrile neutropenia (one patient). After a median follow-up of 19.1 months (range: 11.0-24.9), 11 patients have progressed and 4 died (all had achieved less than VGPR post-ASCT). The PFS, TTP and OS rates at 12 months were 88.6%, 88.6% and 100%, respectively. Forty (89%) patients had adequate stem cell collection post-ASCT (mean±SD: 8.9±4.6±10^6/kg CD34+ cells). Patients at baseline had elevated levels of CTX, TRACP-5b, sRANKL/OPG, Dkk-1, Ang, VEGF, VEGF-A, bFGF and reduced levels of Ang-1/Ang-2, bALP and P1NP compared to 30 healthy subjects of similar age and gender (p<0.01 for all comparisons). RAD therapy resulted in a reduction of circulating CTX (p=0.03), TRACP-5b (p=0.01), Ang (p=0.02), VEGF (p=0.01) and bFGF (p=0.01). Moreover, RAD increased serum levels of bALP (p=0.036), P1NP (p=0.028) and Ang-1/Ang-2 ratio (p=0.022). These alterations occurred irrespective of response, although patients who achieved at least VGPR tended to have more profound differences in the above parameters.

Summary/Conclusions: RAD resulted in successful induction for NDMM patients with an ORR of approximately 67% pre- and 84% post-ASCT. With a median follow-up of >1.5 year, the 12-month PFS rate and OS rates are high, as expected. RAD reduced bone resorption and increased bone formation; the latter has not been previously described with lenalidomide-based regimens. Furthermore, RAD reduced angiogenic cytokines and this supports the action of the regimen also through the disruption of the interactions between myeloma and stromal cells.

E1293
MULTIPLE MYELOMA IN THE REAL WORLD: HOW THERAPEUTIC LANDSCAPE HAS CHANGED IN THE LAST 15 YEARS
F. Cocito1,*, V.V. Ferretti 1, S. Mangiacavalli 1, C.S. Cartia 1, M. Ganzetti 1, E. Fugazza 1, B. Landini 1, M. Catalano 1, M. Cazzola 1, A. Corso 1
1Hematology, Policlinico S. Matteo, Pavia, Italy

Background: Therapeutic Multiple Myeloma (MM) scenario has completely changed in the last 30 years: conventional chemotherapy (CT) has been gradually abandoned and autologous stem cell transplantation (ASCT) is currently the gold standard treatment of multiple myeloma. Despite the clinical effectiveness of immunomodulatory drugs (IMiDs), their use in clinical practice is not homogenous and many patients do not receive a new drug and 90% after 2007 (p=0.002). Median PFS in pts >65 vs ≤65 yrs was 1.7 vs 2.4 yrs (p=0.001); median PFS in pts ≤65 yrs receiving or not ASCT was 3.2 vs 1.9 yrs (p=0.001); of note, PFS was not different when considering pts undergoing to ASCT after a CT-based or a Bor-based induction (3 vs 2.5 yrs, p=0.2). Time to next treatment (TTNT) in pts receiving ASCT or not was 30.1 months (5-122.7) vs 10.3 months (0.7-70.5) (p=0.001) from 1st to 2nd line tx and 11.2 months (0.3-121.9) vs 6.3 months (1.4-11.6) from 2nd to 3rd line tx (p=0.028). The early mortality (within the first year) was 5.9% (31/525), in details only 1/258 of those eligible to ASCT (0.4%) and 30/267 of those not candidate to transplant (11.2%). When considering this last group before and after the 2007, we observed a significant higher incidence of early mortality in the first period [21 (17.2%) vs 9 (6.2%)] (p=0.006). About new drugs toxicity: with Bor-based tx 30% of pts complaint neurological, 20% gastrointestinale and 18.2% hematologic toxicity; with Len-based tx 36.4% infective events and 28.9% hematologic toxicity. Median OS in pts ≤65 vs >65 yrs was 7 vs 4.8 yrs (p=0.001), of note considering pts ≤65 vs >65 yrs treated before 2007 median OS was 5.5 vs 3.1 yrs (p=0.001) and after 2007 median OS was not reached vs 7.5 yrs (p=0.034).

Summary/Conclusions: Our real life data show how MM therapeutic scenario has changed during the last 15 yrs. The tremendous improvement observed in this study was mainly evident in older pts with a strong reduction of early mortality and median OS reaching, in the second time frame after year 2007, 7.5 yrs. For younger pts ASCT confirmed to be of great benefit in term of TTNT and PFS. Thus, considering the real advantage of new drugs a palliative approach is not anymore justified even in very old pts.

CUL4A EXPRESSION AS A POTENTIAL PROGNOSTIC MARKER IN MULTIPLE MYELOMA PATIENTS TREATED WITH IMMUNOMODULATORY DRUGS
A. Malanda1,*, J. Barankiewicz1,2, A. Szumera-Cieckiewicz3, M. Prohorec-Sobieszek3, K. Warzocha1, P. Juszczyński4, E. Lech-Maranda1,2
1Department of Hematology, Institute of Hematology and Transfusion Medicine, 2Department of Hematology and Transfusion Medicine, Centre of Post-graduate Medical Education, 3Department of Diagnostic Hematology, 4Department of Experimental Hematology, Institute of Hematology and Transfusion Medicine, Warsaw, Poland

Background: Despite the clinical effectiveness of immunomodulatory drugs (IMiDs) in multiple myeloma (MM), neither their mechanisms of action nor the biomarkers that could identify patients who would benefit from IMiD treatment are yet known. While the identification of the IMiD action via cereblon (CRBN), IKaros (IKZF1) and Aiolos (IKZF3) was a milestone, the role of other pathways including CRBN and E3 ubiquitin ligase complex proteins (CUL4A, DDB1, Roc1) is not fully understood so far.

Aims: The aim of this study was to: 1) evaluate CUL4A, IKZF1, IKZF3, MUM1 and IRF4 expression in bone marrow trephine biopsies obtained from multiple myeloma patients before treatment with thalidomide, 2) analyze the associations between the expression of these proteins and clinical characteristics and outcomes.

Methods: IHC staining for CUL4A, IKZF1, IKZF3, IRF4 and MYC expressions were performed in trephine biopsies obtained from 25 patients with multiple myeloma before the treatment initiation. The patients (20 females, 5 males, median age 68 years) were treated with thalidomide based regimens as a first line treatment. The patterns of proteins’ expression were scored independently by two hematopathologists on a 0-3 scale and a positive sample was defined as ≥ 30% positive cells. Associations between studied proteins’ expression and clinical parameters were assessed using Fisher’s Exact Test for categorical variables and Mann-Whitney-Wilcoxon Test U for continuous variables. Survival (PFS and OS) were estimated using the Kaplan-Meier method and censored using the log-rank test.

Results: Prior to treatment with thalidomide, 13 patients (52%) showed high expression (≥ 30%) of CUL4A protein. No associations between expression of CUL4A and other proteins were seen. Patients with high CUL4A expression more often presented low disease stage according to Durie-Salmon classification (p=0.02), beta-2-microglobulin level within normal ranges (P=0.07) and higher median platelet count (P=0.003) compared to patients with low CUL4A expression. Moreover, patients with high CUL4A expression before treatment showed longer PFS compared to those with low CUL4A expression (P= 0.03). Additionally, a significant association between high Aiolos expression and high progression free survival of CD138+ cells in bone marrow was observed (p=0.01) compared to low Aiolos expression, however no other associations with clinical course of MM patients were seen. No associations between IKZF1, IKZF3, IRF4, MYC expression and patients’ characteristics or outcome were revealed.
Summary/Conclusions: In conclusion, our results suggest that CUL4A expression could serve as a prognostic marker for patients assigned to IMiDs containing regimens. Further analysis of the expression of other E3 ligase complex proteins in a larger patient cohort is in progress.

MAINTENANCE THERAPY WITH BORTEZOMIB IN PATIENTS WITH MULTIPLE MYELOMA (MM) AFTER ASCT AND MINIMAL RESIDUAL DISEASE (MRD)

M. Solovev1, L. Mendeleeva1, O. Pokrovskaya1, E. Gendzhian2, I. Galtseva3, J. Davydova3, M. Firsova1, M. Nareyko1, T. Abramova4, V. Savchenko4
1Dept. of High-Dose Chemotherapy of Paraproteinemic Hemoblastosis, 2Bio-statistics Laboratory, 3Immunophenotyping of Blood Cells and Bone Marrow Laboratory, 4Research Center for Hematology, Moscow, Russian Federation

Background: MRD-negativity status in patients with MM after autologous stem cell transplantation (ASCT) directly correlates with higher Relapse-Free Survival. It remains unclear whereas these patients should all receive maintenance therapy with its toxicity and cost.

Aims: To assess efficacy of maintenance therapy with Bortezomib in patients with MM, who have achieved complete remission after ASCT with MRD positive and negative status.

Methods: From January 2014 to February 2016 52 patients with MM (19 male and 33 female) ages from 24 to 66 years (median 54 years) who have achieved complete remission after ASCT were randomized for a year-long maintenance therapy with Bortezomib. On 100th day after ASCT and after completion of maintenance therapy samples bone marrow from all patients were assessed using 6-color Flow Cytometry to detect MRD. We chose Relapse-Free Survival (RFS) as the indicator of maintenance therapy efficacy. Kaplan-Meier survival curves were compared using log-rank test. Statistical analysis was performed using SAS 9.4.

Figure 1.

Results: 2-year Relapse-Free Survival in patients with MRD-negative status after ASCT was higher (p=0.05) than that in MRD-positive patients - 52,9% (95% CI: 35.5–70.8%) vs 37.2% (95% CI: 25.4–49.3%). The MRD-positivity significantly increases the risk of relapse (HR=1.7; 95% CI: 1.2–3.4; p=0.005).

Two year cumulative probability of relapse after ASCT in patients with MRD-negative status, who had (n=15) and hadn’t received (n=37) maintenance therapy with Bortezomib was not different (p=0.58). Average time of relapse in MRD-positive patients who received maintenance therapy with Bortezomib was 5 months longer than in the group of patients without maintenance therapy - 17.3 months vs 12.3 months. In the group of MRD-positive patients who did not completed maintenance therapy, relapse was diagnosed in 6 patients. After the end of the treatment 42% of MRD-positive patients achieved MRD-negative status. RFS in this group of patients was significantly higher than in the group of treated MRD-positive patients who retained that status after maintenance therapy (MT) - 100% vs 20% (p=0.02, Fig 1).

Summary/Conclusions: In cases when MRD-negative status was achieved after ASCT, maintenance therapy does not increase the RFS. In comparison – patients with positive MRD status after ASCT require maintenance therapy to improve their survival rate.

E1296
LONG-TERM OUTCOME OF MULTIPLE MYELOMA (MM) PATIENTS TREATED UP-FRONT WITH SINGLE OR TANDEM AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT) - SINGLE CENTRE EXPERIENCE WITH 334 PATIENTS

J. Batinic1,2,*, S. Basic-Kinda1, B. Dreta1, I. Hude1, A. Ostojic1, D. Sertic1, R. Servedi-Seiwert1, P. Roncovec1, I. Bojanic1, K. Gajdrov-Kuvezdic4, K. Dubravcic2, I. Illic1, I. Auer1,2, D. Nemec1,2
1Division of Hematology, Department of Internal Medicine, University Hospital Centre Zagreb, 2Medical School, University of Zagreb, 3Department of Transfusionology, 4Department of Pathology and Cytology, 5Department of Laboratory Diagnostics, University Hospital Centre Zagreb, Zagreb, Croatia

Background: ASCT after induction treatment has been standard of care for MM for almost 30 years. Some centers routinely perform two transplantation up-front (so-called tandem transplants), while others advocate postponing the second transplant until after progression. In recent years novel antimyeloma agents have significantly improved the prognosis of MM patients, thus casting further doubts on the value of the more aggressive tandem ASCT approach.

Aims: To describe long-term outcomes of MM patients treated with ASCT (single and tandem) in a single centre. allled tandem transplants), while others advocate postponing the second transplant until after progression. In recent years novel antimyeloma agents have significantly improved the prognosis of MM patients, thus casting further doubts on the value of the more aggressive tandem ASCT approach.

Methods: This was a retrospective analysis of outcomes of 334 MM patients who underwent 470 ASCT procedures at our center between 1993 and 2014. During that period treatment policies changed from single to tandem to salvage second ASCT, as data from different clinical studies became available.

Results: 296 patients received VAD (vincristine, doxorubicin, dexamethasone) as induction therapy and 38 regimens based on immunomodulatory drugs or proteasome inhibitors. All received high-dose melphalan for pretransplant conditioning, 32 in combination with total body irradiation. Tandem ASCT (defined as second transplantation performed within 6 months after the first) was performed in 136 patients, single ASCT in 168 and salvage second (after relapse/progression) in 30 patients. Transplant related mortality was 1.5%. Median follow up is 70 months (range 4 – 238). Median overall survival (OS) for the entire group is 123 months and median progression free survival (PFS) 40 months. Tandem ASCT in comparison to single and second salvage transplantation resulted in superior OS (203 vs 86 vs 68 months respectively, p<0.0001) and PFS (60 vs 38. vs 25 months respectively, p<0.0001) (figure). Seventeen percent of patients who underwent tandem ASCT are alive and progression-free more than 10 years after the procedure. Seventeen patients developed secondary malignancies.

Figure 1.

Summary/Conclusions: Our results suggest that tandem ASCT is a very effective treatment modality that can partially substitute for the absence of expensive novel agents with low long-term and lethal toxicities. Tandem ASCT seems to result in superior OS and PFS in comparison to single or salvage second ASCT. More than 10% of patients treated with tandem ASCT experience very prolonged PFS.
showed an association of EMD with other adverse prognosis factors and unfavorable outcomes. Our study evaluated EMD in pts undergoing autologous hematopoietic stem cell transplantation (ahSCT) are scarce.

Aims: We aimed to evaluate the clinical and laboratory characteristics of pts with EMD as well as its impact in outcomes of MM pts submitted to ahSCT (response to treatment, overall survival [OS] and progression-free survival [PFS]).

Methods: We analysed 155 MM pts submitted to ahSCT in our centre between January/2007 and December/2015, excluding second procedures. The assessment of response to treatment was based in the International Myeloma Working Group consensus criteria (2016).

Results: The median age of the cohort was 58 years (27–69), with 58% of males; the most common subtype was IgG (45%). In our cohort, 27% presented EMD at diagnosis, which was significantly higher compared to reports in the literature (p<0.001; 95%CI 0.22–0.37). The more common involved sites were vertebral column (49%), ribs (13%) and pelvis (13%). EMD occurred more frequently in males (38 vs 18%; p=0.012) and in pts with bone disease (51% vs 40%; p<0.001). EMD was more common after 46 months (21% vs 12%; p=0.022) and without anaemia at diagnosis (28 vs 11%; p=0.023).

No other significant differences in characteristic of patients with relapse were found between with and without EMD. Pts with EMD achieved lower complete response (CR/VGPR) proportions previously to ahSCT (30.4 vs 53.2%; p=0.009), as well as at 100 days after ahSCT (D100) (41.3 vs 59.6%; p=0.037). However, no differences were found concerning refractoriness to first line therapy or proteasome inhibitor (PI) treatment, despite EMD pts received a higher mean number of therapeutic lines previously to a 1L and 2L treatment (12.0 vs 10.8; p=0.023). After a median follow-up of 46.6 months, the median OS was not reached for global cohort and both groups, and there was no difference between them (p=NS). The median PFS was 51.3 months for global cohort, with no differences seen between pts with and without EMD (50.2 vs 54.1; p=NS). Pts with EMD treated with a PI (57%) presented a higher OS (NR vs 1.4; p=0.025). After a median follow-up of 48.6 months, the median an OS was not reached for global cohort and both groups, and there was no difference between them (p=NS). The median PFS was 51.3 months for global cohort, with no differences seen between pts with and without EMD (50.2 vs 54.1; p=NS). Pts with EMD treated with a PI (57%) presented a higher OS (NR vs 1.4; p=0.025). After a median follow-up of 48.6 months, the median an OS was not reached for global cohort and both groups, and there was no difference between them (p=NS). The median PFS was 51.3 months for global cohort, with no differences seen between pts with and without EMD (50.2 vs 54.1; p=NS).

Summary/Conclusions: In our cohort, EMD prevalence was significantly higher than usually described in the literature. This observation was probably associated to more carefully surveillance of EMD in ahSCT candidates. EMD was associated with a lower proportion of CR/VGPR previous to ahSCT and at D100 evaluation, even after a higher number of therapeutic lines, although we failed to demonstrate that EMD was an independent prognosis factor for PFS and OS. PI seem also to be the best first-line therapeutic approach for EMD pts. In conclusion, our study suggests that EMD is underestimated in MM pts. It is necessary to achieve a better knowledge of the physiopathology of EMD, in order to define better treatment options that may overcome its negative impact in therapeutic response.

E1298
DIFFERENCES IN PATIENT AND DISEASE CHARACTERISTICS OBSERVED AT INITIATION OF FIRST-LINE AND INITIATION OF SECOND-LINE TREATMENT IN PATIENTS WITH RELAPSED MULTIPLE MYELOMA IN THE CZECH REPUBLIC

V. Maisnar1,2, Z. Szabo3, W. Bouwmeester4, L. DeCosta5, L. Pouët6, E. Zucchi6, P. Minařík9,10, S. Gonzalez-McOuire11, R. Hájek12
1Faculty of Medicine, Charles University Hospital, 24th Department of Medicine – Haematology, Charles University Hospital and Faculty of Medicine, Hradec Králové, Czech Republic, 3Amgen (Europe) GmbH, Zug, Switzerland, 4Pharmatin International, Rotterdam, Netherlands, 5Amgen Ltd, Uxbridge, United Kingdom, 6Department of Internal Medicine, Hematology and Oncology, University Hospital Brno, 7Faculty of Medicine, Masaryk University, Brno, 8Department of Internal Medicine and Hematology, University Hospital Olomouc, 9Department of Hematology, University Hospital Hradec Králové, 10Department of Haematology-Oncology, University Hospital Olomouc and Palacky University Olomouc, 11Department of Medicine and Dentistry, Palacky University Olomouc, 12Department of Haematology-Oncology, University Hospital Ostrava, 12Faculty of Medicine, University of Ostrava, Ostrava, Czech Republic

Background: Tools such as the International Staging System (ISS) and the revised ISS (R-ISS) are used to stratify risk of relapse in patients with multiple myeloma (MM), enabling assessment of survival expectations. These tools are based on factors measured at diagnosis only; understanding the role of these factors at relapse is less clear. Patient characteristics change over time; tools that rely on patient characteristics measured at diagnosis only may therefore, become less relevant than other tools that consider factors measured at relapse. The Registry of Monoclonal Gammopathies (RMG) is a large hematological disease registry, collecting data from patients in the Czech Republic and Slovakia. Data from the RMG can be used to explore real-world characteristics of the patients at diagnosis and during the course of disease.

Aims: To explore how key characteristics of patients with relapsed MM evolve between initiation of 1L treatment and initiation of 2L treatment to better understand drivers of disease progression and death.

Methods: This non-interventional, observational, retrospective study used data collected prospectively from Czech patient charts available in the RMG. Adults (218 years old) initiating 1L treatment for MM between May 2007 and April 2016 were included (N=3027); those with smoldering MM were excluded. Patient and disease characteristics were extracted at initiation of 1L and of 2L treatment. Repeated measurements were available only for those who initiated 1L and 2L treatment (1L+2L group; N=1418); patients who did not start 2L treatment may have been in remission, lost to follow-up or had died. Pts who received 1L+2L treatment, their health status improved between initiation of 1L and of 2L treatment. At 2L, patients tended to have a lower ISS stage (re-measured at 2L) than when they started 1L (stage I at 1L: 26.6%; at 2L: 41.1%). Similarly, the proportion of patients with R-ISS stage III disease was lower at start of 2L (24.6%) than at start of 1L (31.1%) treatment. Eastern Cooperative Oncology Group performance status scores were also better for patients when they started 2L than when they started 1L treatment (stage 3–4 at 1L: 8.7%; at 2L: 5.5%). Laboratory measurements indicated that patients were in better health at the start of 2L treatment than at initiation of 1L treatment: median M protein levels decreased from 31.2 g/L at 1L to 17.7 g/L at 2L, and elevated calcium and creatinine levels were less common at 2L than at 1L. Median lactate dehydrogenase levels were slightly elevated at start of 2L vs start of 1L treatment (184.4 U/L vs 206.6 U/L).

Table 1.

Summary/Conclusions: Patient health was better at initiation of 2L treatment than at initiation of 1L treatment. At relapse, patients are likely to be closely monitored and are able to initiate the next treatment line while in relatively good health; at initiation of 1L, patients may have experienced deterioration in health which could have triggered their diagnosis. These findings illustrate how patient characteristics change over time and that the underlying treatment survival may evolve; therefore, restaging patients at relapse may be beneficial and could contribute to improved predictive tools that can better define survival estimations at first relapse by considering patients' experiences at 1L.

E1299
AN EARLY GOOD RESPONSE AFTER BORTEZOMIB-BASED INDUCTION REGIMENS REPRESENTS A SIGNIFICANT PREDICTOR FOR IMPROVED PFS IN NDMM PATIENTS

G. Rivoli1,2, M. Cea1, S. Aquino2, A. Dego1, N. Di Felice1, N. Bisso1, D. Avenoso1, R. M. Lemoli1, M. Gobbi1, L. Canepa1
1Clinica Ematologica, 2Ematologia 1, IRCCS San Martino IST, Genova, Italy

Background: Introduction of triplets-based induction regimens containing proteasome inhibitors (PIs) in clinical practice have led to higher response rates and prolonged life expectancy in newly diagnosed multiple myeloma (NDMM)
patients. Different studies have linked complete response (CR) with better PFS (progression free survival), but not always with prolonged overall survival (OS), most likely due to the impact of novel agents in the management of relapsed-refractory patients. Overall, these observations suggest PFS as a more reliable predictor of clinical outcome. Also, the biological aggressiveness is emerging as a pivotal disease characteristic which affects clinical behavior and response to therapy. In this context, little is known about the association of response kinetic with survival outcomes.

Aims: In order to evaluate whether early achievement of a good quality response impacts on outcome, we retrospectively analyzed 87 NDMM patients treated at our institution with bortezomib containing regimens (BRs).

Methods: From 2004 to 2016, 87 patients with NDMM and measurable disease (serum and/or urine M protein) were treated with BRs. Both patients eligible and non-eligible for ASCT were included in the study; patients undergoing ASCT were censored at the time of transplant. Median age was 66 (range 32-87); males were 51 (59%); 72 (83%) patients were in III stage; median follow up was 30.7 months; median number of administered courses was 5 (range 2-9). PFS was defined according to IMWG criteria. Cytogenetic risk evaluation performed by a standardized FISH panel, including del17p, del13q, t(11;14), t(4;14), was available in 37 patients (42.5%). Among these high risk abnormalities were identified in 20 patients. Early good response (EGR) defined an M protein reduction ≥75% after 2 courses of therapy. Survival curves were calculated for PFS and OS by Kaplan Meyer method, using log-rank test.

Results: PFS and OS were both assessed in patients who achieved EGR as well as in patients who did not. No significant differences were observed in terms of OS between the two groups, whilst PFS was significantly longer in patients achieving EGR (p=0.036, median PFS 44.7 vs 29 months, respectively). Next, we analyzed patients with high risk cytogenetic. Among these, EGR vs non-EGR patients reached a PFS of 43.7 and 18.7 months, respectively. Remarkable PFS differences between these two groups were not significant (p value=0.11).

Methods: Individual patient-level data (IPD) were reconstructed from the published Kaplan-Meier PFS curves from the ELOQUENT-2 (ERd), ASPIRE (KRd), and TOURMALINE-MM1 (NRd) randomized, controlled, Phase III trials using digitization software and the methods described by Guyot, et. al. Using the reconstructed IPD, Kaplan-Meier survival curves were estimated for each arm within each trial. PFS curves were digitized by two independent researchers and the reconstructed curves were overlaid with the published data to validate the IPD. In each trial, the relative PFS benefit over time was calculated as the difference in the Kaplan-Meier PFS estimate of each triplet regimen and the Kaplan-Meier PFS estimate of Rd divided by the Kaplan-Meier PFS estimate of Rd: rPFS(t)= (S_E(t) - S_R(t)) / S_R(t). Where S(t) denotes the Kaplan-Meier PFS estimate at time t, and L and X denotes E, K, or N, respectively.

Results: IPD from the three randomized controlled trials was successfully reconstructed and validated. Numerically, ERd had the highest relative PFS over the initial 10 months of treatment and showed sustained benefit from month 24 onwards (Figure 1). At 12 months, the relative PFS benefit was 17.9% for ERd, 21.7% for KRd, and 9.7% for NRd. At 24 months, the relative PFS benefit was 45.1% for ERd, 34.3% for KRd and 24.1% for NRd. At 36 months, the relative PFS benefit was 39.9% for ERd and 19.1% for KRd. ERd had a higher relative PFS than NRd for almost the entirety of RRMM treatment. At the end of data availability, NRd and KRd showed no additional PFS benefit relative to Rd, while ERd showed a sustained benefit through 40 months. Data will be updated for the conference, where available.

Figure 1.

Summary/Conclusions: For the treatment for RRMM, ERd showed an early and sustained benefit in relative PFS which was maintained through 40 months. KRd and NRd showed initial benefits which faded by the end of data availability.

E1301

POMALIDOME WITH LOW-DOSE DEXAMETHASONE IN PATIENTS WITH RELAPSED OR RELAPSED AND REFRACTORY MULTIPLE MYELOMA: A PROSPECTIVE ANALYSIS IN A POPULATION-BASED REGISTRY

R. Wester1,*, A. Dinmohamed1,2,3, P. Sonneveld1, A. Brojii1, N. Blijlevens4
1Department of Hematology, Erasmus Medical Center Cancer Institute, Rotterdam, 2Department of Research, Netherlands Comprehensive Cancer Organisation (KNL), Utrecht, 3Department of Public Health, Erasmus University Medical Center, Rotterdam, 4Department of Hematology, Radboud umc, Nijmegen, Netherlands

Background: Patients with relapsed and/or refractory multiple myeloma (RRMM) have limited treatment options and a poor prognosis. Previous trials showed that pomalidomide combined with low-dose dexamethasone is effective in these patients with improvement in response and survival. These studies led to the approval of pomalidomide as third line treatment in patients with RRMM. A retrospective analysis in a population-based registry was conducted to assess response and survival in patients with RRMM treated with a pomalidomide-based regimen. Also, we defined subgroups who benefit most of this treatment regimen.

Methods: Patients were eligible for pomalidomide if they received ≥2 prior lines of therapy including bortezomib, lenalidomide and/or an immunomodulatory therapy and developed progressive disease on their last therapy. This is a prospective analysis of patients registered at the nationwide Netherlands Cancer Registry. Treatment consisted of 4mg pomalidomide, day 1-21, combined with corticosteroids. Treatment was discontinued in case of progressive disease or unacceptable toxicity. The primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), overall response rate (ORR), toxicity, response per risk group (based on cytogenetics and ISS at initial diagnosis) and response per age group (<65 vs >65 years).

Summary/Conclusions: For the treatment for RRMM, ERd showed an early and sustained benefit in relative PFS which was maintained through 40 months. KRd and NRd showed initial benefits which faded by the end of data availability.
Results: A total of 82 patients (median age 68 years [range: 43-88]) were included in this analysis. CRAB criteria included anemia in 23 patients (28%), renal insufficiency in 8 (9.8%), hypercalcemia in 13 (16%) and bone lesions in 54 (66%). Median time from diagnosis to start pomalidomide was 5.75 years [range: 0.8-18.4]. median number of treatment cycles was 3 [range: 1-17]. At time of analysis 59 patients had stopped pomalidomide treatment: 24 patients had progressive disease, 10 had unacceptable toxicity, 6 patients were refractory, 4 patients died during treatment and 15 patients stopped due to various other reasons. Grade ≥3 hematological adverse events occurred in 11% of patients, 4% had neutropenic fever. Grade ≥3 non-hematological toxicities occurred in 57% of patients, including infection in 22%, gastrointestinal disorders in 5% and renal disorders in 5%. Of 69 patients evaluable for response ORR was 41%, with a partial response (PR) rate and a very good partial response (VGPR) rate of 36% and 4% respectively. Response based on age was not significantly different (p=0.426). Median PFS for all patients was 3.8 months (95% confidence interval [CI] 2.3-6.6). Patients >65 years had a longer PFS of 5.7 months (95% CI 2.3-8.0) versus 2.8 months (95% CI 1.9-6.6) in patients ≤65, however, this was not statistically significant (p=0.427) (figure 1). For patients achieving ≥PR, median PFS was 9.6 months (95% CI 5.7-not reached [NR]). Median PFS in patients diagnosed more than ten years prior to initiation of pomalidomide treatment was 9.6 months (95% CI 5.7-NR), as compared to 2.2 months (95% CI 1.3-6.8) among patients treated within 5 years after diagnosis (p=0.05). Data about previous treatment, ISS stage, cytogenetics at diagnosis and an update of OS will be presented at EHA.

Summary/Conclusions: Our results show that older patients and patients with a long interval between initial diagnosis and pomalidomide treatment (indicating a less aggressive myeloma) may benefit from this treatment.

E1302

INVOLVED/UNINVOLVED HEAVY/LIGHT CHAIN INDEX CAN PREDICT PROGRESSION IN MULTIPLE MYELOMA PATIENTS AFTER AUTOLOGOUS PERIPHERAL BLOOD STEM TRANSPLANT. PRELIMINARY EXPERIENCE

1Immunoimmunology, University Hospital Ramon y Cajal, Madrid, Spain
2Clinical Analisis, 3Haematology, University Hospital La Princesa, 4Haematology, University Hospital Ramon y Cajal, Madrid, Spain

Background: High-dose therapy followed by autologous peripheral blood stem transplant (APBSCT) has demonstrated to improve overall survival and progression free survival with a high complete remission rate in multiple myeloma (MM) patients. However, most patients eventually present progression or relapse (P/R). Detection of P/R is mainly based on a significant increase of monoclonal protein (MC) or free light chains (sFLC). The identification of new biomarkers to early predict P/R might be clinically useful for an anticipated therapy.

Aims: The aim of our study was to evaluate the potential role of the Involved/Uninvolved Heavy/Light Chain index (I/Ui) in this setting.

Methods: We prospectively followed 44 MM transplanted patients: 19 with IgG-kappa isotype, 11 with IgG lambda, 9 with IgA-kappa and 5 with IgA-lambda. They were followed for 29.0±3.8 months (mean±standard error [SE]). Serial serum samples from each MM patients were collected periodically after APBSCT. Relapse or progression was defined according IMWG criteria. To identify factors that predict disease progression in MM transplanted patients, we studied heavy/light chains (HLC) par quotient quantification, sFLC and total immunoglobulins levels in serial serum samples collected during the follow-up. Involved/uninvolved index (I/Ui) was calculated using the monoclonal chain (Involved) as numerator and the polyclonal chain of the same class (Uninvolved) as denominator. The HLC ratio (HLC) was calculated as IgGx/IgGA or IgAx/IgAA with normal reference ranges established in 1.3-3.7 for IgG and 0.7-2.2 for IgA.

Results: In IgG MM patients, values of I/Ui were significantly increased in pre-relapse compared to basal samples (8.49±4.01 vs 2.23±0.67 p=0.012). By contrast, this index remained stable along follow-up in patients in complete remission (CR) or with a partial response (PR). However, the later showed higher values of I/Ui ratio, suggesting that the presence of an M-component induces immunosuppression in the uninvolved chain. Regarding IgA MM, we established a cut-off value of 2.0 for I/Ui that allowed the discrimination of patients at high risk of early progression (values above 2.0) from those in CR, whose levels of I/Ui are always below 2.0 (p=0.02).

Summary/Conclusions: Our results show that HLC-par measurement could detect progression or relapse and the increase of MC in transplanted MM patients earlier than other methods. Future studies will need to demonstrate the real value of the I/Ui index as a biomarker to anticipate progression in MM patients subjected to APBSCT.

Figure 1.

Summary/Conclusions: In this analysis the experience in clinical practice of patients with RRM treated with a pomalidomide-based regimen is reported. These data support results shown in clinical trials. Preliminary data presented here suggest that older patients and patients with a long interval between initial diagnosis and pomalidomide treatment (indicating a less aggressive multiple myeloma) may benefit from this treatment.

MULTIPLE MYELOMA IMMUNOPHENOTYPIC REMISSION IS A SIGNIFICANT PREDICTOR OF PROGRESSION FREE SURVIVAL AFTER FIRST AUTOLOGOUS STEM CELL TRANSPLANTATION - PILOT STUDY

K. Beranova1, J. Radocha1, O. Soucek2, K. Machaikovala1, J. Hanousek1, P. Zak1, V. Maisnár1

1IV. interni hematologicka klinika, 2Institute of Clinical Immunology and Allergology, Fakultni nemocnice Hradec Kralove, Hradec Kralove, Czech Republic

Background: Minimal residual disease in multiple myeloma assessed by multiparameter flow cytometry has become an increasingly important predictor of progression-free survival (PFS).

Aims: Our primary endpoint was to evaluate PFS in myeloma patients after stem cell transplantation who reached immunophenotypic CR (iCR) versus those who have not.

Methods: We prospectively evaluated prognostic importance of minimal residual disease detection by multiparameter flow cytometry (MFC) in multiple
myeloma patients who underwent autologous stem cell transplantation from January 2014 until December 2016. All patients were uniformly treated with bortezomib based induction therapy followed by high dose chemotherapy (Melphalan 200mg/m²) and autologous stem cell transplantation. Minimal residual disease (MRD) status was determined by 8-colour MFC 1 month after autologous transplantation from bone marrow aspirate in all patients who achieved at least conventional VGPR or CR.

Results: We identified 56 patients who fulfilled the above mentioned criteria, 30 were males and 26 females, median age was 61. 62.5% of patients (35/56 patients) achieved iCR, 37.5% of patients (21/56) did not. Median follow up of the cohort was 19 months (6-59), 32.1% of patients (18/56) relapsed during the follow-up period, 16.1% of patients (9/56) died. 22.9% (13/56) patients in iCR and 47.6% (10/21 patients) not in iCR relapsed during the follow up. Patients in iCR showed significantly longer PFS with median 42 months than those in less than iCR with PFS median 29 months (p=0.0196, log-rank test). This was reflected in a hazard ratio of relapse (0.3865) lower in iCR compared to CR. The 5 year OS was 91% in iCR and only 75% in CR. An improvement of PFS and OS was also noted in patients achieving iCR versus CR (26.3% vs 16.1% respectively).

Summary/Conclusions: Achieving immunophenotypic CR is clearly associated with longer progression free survival compared to conventional CR. Reaching iCR should be a goal of myeloma treatment.

E1304
REGULATION OF NORMAL AND MONOCLONAL IMMUNOGLOBULIN SECRETION BY CYTOKINES (S-SYNDECAN-1, BLYS & TGF-BETA-1) IN PATIENTS WITH IG-SECRETING B-CELL DISORDERS AT PRESENTATION.

PROGNOSTIC IMPLICATIONS

E. Koulieris1, P. Papaiannouni1,1, E. Nikolaidou, K. Sarris1, D. Maltzetas, S. Harding2, N. Kafassi3, K. Tsalimalma3, K. Bitsani1, T. Tzenou1, V. Bartzi1, P. Patsis1, S. Kotsanti1, A. Koudouna1, E. Kastritis4, S. Sachanas5, P. Panayiotidis1, M.-C. Kyrtsonis1

1Hematology Section - 1st Department Of Propaedeutic Internal Medicine, Laikon General Hospital, Athens, Greece; 2Binding Site Ltd, Birmingham, United Kingdom; 3Immunology Laboratory, Laikon General Hospital, 4Therapeutic Clinic, Alexandra’s Hospital, 5Hematology Clinic, Medical Center Psychico, Athens, Greece

Background: The most common neoplastic lymphoproliferative diseases that secrete paraprotein are multiple myeloma (MM), Waldenstrom’s Macroglobulinemia (WM) and chronic lymphocytic leukemia (CLL). The two first entities secrete paraprotein by definition, while serum free light chains (sFLC) are increased in 50% of CLL cases. Microenvironmental factors, such as soluble Syndecan-1 (ssynd-1) and BlyS normally promote lymphoplasmacytic differentiation as well as their secretory activity, whereas, like TGFBeta1, inhibit them. Determination of Ig is necessary in MM and WM for diagnostic purposes and for monitoring patients, while in CLL, sFLC has prognostic value. The total amount of secreted Ig does not really reflect disease burden. The heavy chain Ig can be accurately determined with the ‘Heavylite’ method (that measures the amount of secreted Ig does not really reflect disease burden. The heavy chain Ig can be accurately determined with the ‘Heavylite’ method (that measures the amount of secreted Ig). However, the light chain isomer (kappa or lambda), thus allowing exact quantification of the amount of pure monoclonal fraction but also the degree of suppression of polyclonal lgs, both being reflected by the corresponding ratios (HLCR).

Aims: To determine any possible relationship between the amount of lgs secreted and the degree of suppression of polyclonal lgs and TGFBeta1, as well as with disease outcome.

Methods: We studied 269 patients: 105 with MM (79 IgG and 26 IgA, of whom 33%, 31%, and 36% were staged ISS 1, 2 and 3 respectively), 64 suffering from WM (44%, 28%, 28% staged WM-ISS 1, 2, 3 respectively), and 100 with CLL (67%, 23%, 10% staged Binet 1, 2, 3 respectively). Patients were regularly followed up at least last visit or (median follow up 5 months). sFLC/sFLC R and HLCR/HLCR R were determined by nephelometry (Freelite™ and Heavylite™, the Binding Site Birmingham, UK) while sSynd1, BLYS and TGFBeta1 by ELISA, either in fresh or in frozen sera sample drawn at the time of diagnosis. Statistical analysis was performed by standard methods using the SPSS v22.0. software.

Results: The main correlations observed between the lg levels secreted in the 3 diseases and cytokines studied, as well as their impact with regard to patients’ outcome, are shown in table.

Summary/Conclusions: sSynd1 in MM and BLYS in WM and CLL correlated with disease progression. By inhibiting both monoclonal and polyclonal lg, TGFBeta1 correlated in MM with both HLC and FLC ratios and differences. In addition, the aforementioned variables are prognostic with regard to patients’ outcome.

E1305
PATIENTS WITH MULTIPLE MYELOMA (MM) IN LONG TERM COMPLETE REMISSION (LT-CR) AFTER AUTOLOGOUS TRANSPLANT (APBSCT) EXPRESS A DISTINCTIVE IMMUNE PROFILE WITH POTENTIAL PROGNOSTIC VALUE

A. Arteche-Lopez1,1, A. Alegre Amor2, A. Kreutzmann3, B. Aguado2, M. Espinistra2, LM. Villan2, P. Sanz1, A. Arriero3, C. Muñoz-Calleja4

1Clinical Analysis, 2Haematology, 3Immunology, University Hospital La Princesa, 4Haematology, Immunology, University Hospital Ramon y Cajal, Madrid, Spain

Background: A small fraction of patients with MM could be considered potentially cured as long as they remain for more than six years in long term complete remission (LT- CR). Evaluation of the immune status of these patients could highlight interesting information.

Aims: Here we present an observational study that evaluates the numbers and phenotype of T- and B-cells subsets in the peripheral blood (PB) of MM-LTCR patients.

Methods: After approval by the ethics committee, we selected 13 patients diagnosed with MM, in sCR according to IWG criteria for at least six years after APBSCT, and 15 healthy adults (HA) of similar ages as a comparative group. Group MM: 7 males and 6 females; median age: 61. Mibian follow up. B-cells after APBSCT was 8 years (range 6-19). Group HA: 5 females and 10 males, median age 60 (36-78). Immune phenotypic characterization was done using a comprehensive 8-color flow cytometry panel. Subpopulations of CD4+ and CD8+ T-cells from PB were quantified, including naïve, central and effector memory T-cells, as well as subpopulations of B-cells: naïve, transitional, marginal zone-like, class-switched memory and plasmablasts. In order to confirm their specific immune signature, the analysis was repeated in the same LT- CR-MM patients one year after the first analysis was done. A Kruskal-Wallis test was used to evaluate differences among the studied groups. A posteriori test was done to compare the control group with the two patient’s group (patients and patients +1 year), independently of each other. A Wilcoxon matched test was used to compare a patient under group “patients” with the status of the same patient in the same group “patients +1 year”. Statistical analysis was done using GraphPad Prism software.

Results: The patients had a lower percentage of total CD4+ T-cells (p=0.0004) together with a decrease in the naïve CD4+ T-cells (CD27-CCR7+CD45RA+; p=0.0004) and an increment of the effector memory CD4+ T-cells (CD27CCR7+CD45RA-; p=0.0028). In addition, both CD72CCR7CD45RA+ and CD72CCR7CD45RA+ similar results were found within the CD8+ T-cells. No differences were observed in the Tregs defined as CD4+CD25+ICD127. The mean percentage of total B-cells in the patients was within the normal range and no significant differences were found when compared to HA. However, naïve B-cells (CD22-CD19-CD7+) proportion was higher in patients and a corresponding reduction of marginal zone-like B-cells (CD22-CD19CD7-CD23+) and plasmablasts (CD27++CD38++)(p=0.0047) was observed. No differences were observed in the percentage of transitional B-cells (CD27-CD10-CD38+) or plasmablasts (CD27+ CD38++) in the PB of the two groups. When the analysis was repeated in the same LT- CR-MM patients one year after the first analysis, no changes were detected neither when analysed as a group nor when analysed individually.

Summary/Conclusions: The MM-LTCR patients seem to express a distinctive immune “footprint” characterized by a decreased proportion of naïve T-cells and an increased percentage of effector T cells, which probably exert a competent immune surveillance. Conversely, the increase in naïve B cells may guarantee the humoral response homeostasis, inhibiting the recognition of normal plasma cells that might compete with myelomatous cells for normal bone marrow niches. The precise role of these refined immunological studies in the monitoring and therapeutic decisions in MM patients, and also in the duration of sCR, should be defined in the future.

Study partially performed with research grants from the spanish Leukemia and Lymphoma Foundation and Grant P110/00494P from the Fondo de Investigaciones Sanitarias and FEDER funds.

IMPACT OF THE AFFORDABILITY OF NOVEL AGENTS IN PATIENTS WITH MULTIPLE MYELOMA: REAL WORLD DATA ON CURRENT CLINICAL PRACTICE IN MEXICO

L. Tarín-Arzaga1,1, V. Martínez-Pacheco1, A. Gomez-De Leon1, P. Colunga

1Clinical Analysis, 2Haematology, 3Immunology, University Hospital Ramon y Cajal, Madrid, Spain
 agents and transplantation settings in public health services.

**Methods:** We analyzed records of 148 patients diagnosed with MM in two health sectors in Monterrey, Mexico, from October 2007 to July 2016; 77 (52%) from PubC, with the most common induction therapy was cyclophosphamide-thalidomide-dexamethasone, followed by thalidomide maintenance, and 71 (48%) from PrivC wherein bortezomib or lenalidomide-based induction and lenalidomide maintenance were used. We compared demographics, disease stage, response rate and survival among both groups.

**Results:** Median age, gender and frequency of immunoglobulin isotype did not differ significantly between the two groups. Patients treated in PubC were more likely to be diagnosed with advanced stage disease (ISS III 42% vs 26% p<0.05). Median follow-up was 36 months (range 3-120 months). Autologous transplantation was performed in 80% of the transplantation-eligible patients in PrivC and only in 31% of PubC. At least a very good partial response to induction therapy was achieved more often in the PrivC among transplantation-eligible (65% vs. 42%, p<0.05) and ineligible patients (66% vs. 41%, p<0.05). Overall survival was significantly higher in PrivC for transplantation-eligible (median 84 vs. 42 months, p<0.05) and ineligible patients (median 79 vs. 46 months, p<0.05). After controlling for disease stage and transplantation factors, the risk of mortality was still higher in PubC (HR 1.49; 95% CI:1.0-2.2, p<0.05).

**Summary/Conclusions:** Stage at diagnosis, induction therapy and autologous stem cell transplantation were contributors to survival disparities between patients treated in public vs private health care facilities in Mexico. These findings underscore the need for more efforts to improve the affordability of novel agents and transplantation settings in public health services.

**BASAL CALCIUM, AN IMPORTANT ELEMENT IN THE DEVELOPMENT OF CALR MUTANT MPNS**

M. Morian Mairal1,1,1 P. Papadopoulos2, M. Krstic-Demonacos 1, 1 A. Aziz4

1Salford University, Manchester, United Kingdom, 2Hospital Clinico San Carlos, Madrid, Spain

**Background:** Calreticulin (CALR) is a calcium (Ca²⁺) buffering chaperone mutation of which has recently being associated with essential thrombocythemia and primary myelofibrosis without JAK2 mutations. These mutations have been suggested to impair the Ca²⁺ buffering activity of Calreticulin due to a change of the negative charge in its C-terminal domain. Ca²⁺ is known to be important during megakaryocyte activity; however its role during megakaryopoiesis and the possible link of CALR mutations and abnormal megakaryocyte production due to impaired Ca²⁺ buffering activity in myeloproliferative neoplasms (MPNs) remains unclear.

**Aims:** Here we aim to understand how basal Ca²⁺ fluctuates during normal megakaryopoiesis and how CALR mutations could affect the basal Ca²⁺ levels in megakaryocytes in MPNs.

**Methods:** Ca²⁺ staining was performed using Fluoro-8 dye and Ca²⁺ basal levels were measured by flow cytometry. Changes in basal Ca²⁺ during megakaryopoiesis using two cellular systems, K-562 cells and mouse bone marrow cells, were measured each 24 hours. Further studies using CALR mutant cellular models were performed using the same methodology.

**Results:** Our results showed a characteristic behaviour of fluctuations of basal Ca²⁺ in MPNs affected by basal Ca²⁺ reduction which could be essential for megakaryopoiesis. In order to understand how CALR mutations affect basal Ca²⁺, Marimo cells and Dami cells expressing CALR mutations were analysed. Here we show a decrease in basal Ca²⁺ in Marimo cells and Dami-CALR type2 mutation compared to the controls. Moreover, Dami–CALR type1 did not show any significant reduction, suggesting possible differences in Ca²⁺ behaviour in MPNs. We are currently working in the analysis of basal Ca²⁺ fluctuations during megakaryopoiesis in the presence of CALR mutations and preliminary results show abnormal basal Ca²⁺ levels throughout all the process of megakaryocyte differentiation.

**Summary/Conclusions:** Altogether, our findings indicate that basal Ca²⁺ could be an important element during megakaryopoiesis and CALR mutations found in MPN could impair the normal production of megakaryocytes due to changes in cellular Ca²⁺. However, further analysis need to be done in order to understand the role CALR mutations and their effect in the Ca²⁺ buffering activity of CALR in MPNs.

**THE INHIBITION OF JAK/STAT SIGNALING IS COMPENSATED BY ACTIVATION OF MAPK PATHWAY IN MYELOPROLIFERATIVE NEOPLASMS**

T. Suboticki1, B. Belesin Cokić2, D. Djilic1, S. Majstorovic1, D. Šefer1, S. Bješica1, J. Santićanež1, V. Cokić1

1Laboratory of neuroendocrinology, Institute for Medical Research, University of Belgrade, 2Clinic for endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, 3Laboratory of experimental hematology, Institute for Medical Research, University of Belgrade, 4Clinic of Hematology, Clinical Center of Serbia, Belgrade, Serbia

**Background:** Myeloproliferative neoplasms (MPN) remain incurable regardless of advancement in the use of JAK2 inhibitor Ruxolitinib, which competence is unrelated to the JAK2V617F mutation.

**Aims:** We want to explore JAK1/2 inhibition dependency in correlation with activated JAK/STAT3 signaling and cell cycle in MPNs.

**Methods:** The immunoblotting has been used to analyze activation of JAK/STAT3, PI3K/AKT and MAPK signaling in JAK2V617F mutated HEL cells and granulocytes of MPN. The cell cycle and apoptosis of granulocytes are studied by flow cytometry.

**Results:** Concerning myeloproliferation, JAK1/2 inhibitors reduced the percentage of cells in G2M phase and increased apoptosis in JAK2V617F mutated HEL cells. Comparing to polycythemia vera (PV), the percentage of granulocytes is decreased in S and G2M phases of essential thrombocythemia (ET) and primary myelofibrosis (PMF) that demonstrated increased apoptosis. Hexa-bromocyclodexane increased percentage of granulocytes in GoG1 phase of JAK2V617F positive, but reduced in JAK2V617F negative PMF, the later one similar to Ruxolitinib. JAK1/2 inhibitors reduced percentage of apoptotic granulocytes in JAK2V617F positive, but increased in JAK2V617F negative PMF. JAK1/2 inhibitors could not impair constitutive activation of JAK/STAT3 signaling in HEL cells as well as in granulocytes of JAK2V617F positive ET and PMF. Absence of JAK2V617 mutation supported dephosphorylation of JAK/STAT3 pathway by JAK1/2 inhibitors in ET, but not in PMF. JAK1/2 inhibitor
Ruxolitinib largely activates MAPK signaling in MPN, while slightly PI3K/AKT signaling in PV and JAK2V617F negative PMF. Specific JAK2 inhibitor Hexabromocyclohexane activates PI3K/AKT signaling in JAK2V617F positive ET, but reduced in JAK2V617F negative ET and PMF.

**Summary/Conclusions:** This observation support cross-talk between examined pathways, where inhibition of JAK/STAT3 signaling is compensated by activation of MAPK pathway irrespective of JAK2V617F mutation, while PI3K/AKT signaling demonstrates JAK2V617F dependence in MPN.

**CIRCULATING PLATELET AND MEGAKARYOCYTE-DERIVED MICROPARTICLES OF JAK2V617F MUTATED PATIENTS WITH MYELOFIBROSIS ARE DISRUPTED: A NOVEL LIQUID BIOPSY TOOL OF RESPONSE TO RUXOLITINIB?**

1Department of Experimental, Diagnostic and Specialty Medicine, Institute of Hematology, University of Bologna, Italy, 2Serafini Cancer Institute, 3Immuno-Hematology and Blood Bank Service, Azienda Ospedaliero-Universitaria S. Orsola-Malpighi, Bologna, Italy

**Background:** Microparticles (MPs) are small vesicles (0.1-1 micron) deriving from plasma membrane budding during homeostasis and cell activation. MPs express agonists and contain constituents from cell of origin and are increased in conditions that are characterized by high cell turnover or death, particularly inflammatory, autoimmune and neoplastic diseases. Myelofibrosis (MF) is a clonal neoplasia of the hematopoietic stem/progenitor cells characterized by distinct abnormalities in megakaryocytic (MK) development and platelet (PLT) activation. Mutations in 3 genes (JAK2, CALR, MPL) and chronic inflammation are the main pathogenic drivers of MF. Ruxolitinib (RUX), a JAK1/2 inhibitor, suppresses both clonal myeloproliferation and release of proinflammatory cytokines, reducing spleenomegaly and constitutional symptoms in about 50% of patients (pts). We hypothesized that, as mediators of inflammation, could be overexpressed in MF and possibly predict responses to RUX.

**Aims:** This study aims to: 1) enumerate circulating MK and PLT-derived MPs of MF pts; 2) evaluate the effect of RUX on MPs production by PLT and MK; 3) investigate whether circulating MK and PLT- MPs may be a biomarker of response to RUX.

**Methods:** EDTA-antiagglutinated peripheral blood from healthy donors (HD, n=10) and JAK2V617F positive MF pts (n=12) at intermediate-2/high IPSS criteria was collected at baseline and 3 and 6 months after RUX therapy and immediately centrifuged. Microparticles in megakaryocytic (MK) development and platelet (PLT) activation. Microparticles were qualitatively and quantitatively assessed by flow cytometry (CytoFLEX, Flow Cytometry- Beckman Coulter). The instrument was calibrated with MEGAMIX Beads (Beckman Coulter) with various diameters to cover the MPs (0.5 and 0.9μm).

**Results:** At 3 and 6 months, 5 out of 12 pts achieved a spleen response (R) according to 2013-IWG-MRT criteria. At baseline, the mean percentage of MK-derived MPs was significantly decreased (29±6 vs 72±5; p<0.001) while that of PLT-derived MPs significantly increased (49±7 vs 11±1; p<0.001) in MF pts compared to HD. However, the mean percentage of MK-derived MPs from pts not achieving a spleen response (NR) was significantly decreased compared to R (72±5; p<0.001) and HD (57±4 vs 72±5; p<0.001). By contrast, the mean percentage of PLT-derived MPs was significantly increased in NR compared to R (64±7 vs 37±9; p<0.05) and HD (64±7 vs 11±1; p<0.001). Of note, NR pts had significantly lower PLT number as compared to R (220±29 vs 422±98 p<0.05) and HD (72±5; p<0.0001). No correlation was observed at baseline between the percentages of MK/PLT-derived MPs and platelet number, allele burden, spleenomegaly and constitutional symptoms. At 3 and 6 months, RUX did not significantly modify the mean percentages of MK- and PLT-derived MPs compared to baseline values.

**Summary/Conclusions:** At variance with HD, the majority of circulating MPs in JAK2V617F mutated MF pts at intermediate-2/high IPSS risk derived from PLTs. RUX therapy did not modify the MK/PLT-derived MPs pattern, suggesting that JAK1/2 inhibition does not seem to affect the pathways of MK/PLT MPs production or closure. Most importantly, MPs evaluation at baseline is significant, especially when associated with subsequent spleen response. Specifically, NR pts had increased percentages of PLT-derived MPs with a concomitant reduction of PLT number. This could be related to a state of PLT hyper-activation with hyper-aggregation responses. Further studies are needed to confirm whether MPs may actually be considered a biomarker of disease activity and response to RUX.

**E1310**

**A COMPARATIVE FUNCTIONAL AND PHENOTYPIC PLATELET ANALYSIS AMONG GENETIC GROUPS OF ESSENTIAL THROMBOCYTHEMIA PATIENTS**

1Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Klinikos, 2Department of Innovative Medical Technologies and Health Research State Science, 3Research Institute Centre for Innovative Medicine, 4Department of Internal, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, Vilnius, Lithuania

**Background:** A number of genomic abnormalities have been associated with primary myelofibrosis (PMF). Non-coding region sequencing (NGS) and single-nucleotide polymorphism array (SNP-A) methods are currently used for PMF genomic studies and certain cytogenetic and genomic abnormalities have been determined. To better characterise the genomic landscape of PMF we performed comprehensive analysis of gene mutations and chromosomal aberrations in a population-based cohort of PMF patients.

**Aims:** To characterize genotypic variations in PMF using SNP-A and NGS methods.

**Methods:** PMF peripheral blood samples were screened by Infinium HD whole-genome genotyping assay with the HumanCytoSNP-12 BeadChips (Illumina Inc., CA). NGS analysis was performed using TruSight Myeloid 54 gene panel (Illumina). SNP-A and NGS data analyses were performed using Illumina BaseSpace Informatics suite (Illumina). JAK2, CALR, MPL mutations were additionally confirmed with Sanger sequencing while small indels – with DNA fragment analysis.
Results: 110 patients diagnosed with PMF according to WHO criteria between years 2013 and 2014 were included into this study. SNP-A analysis identified 77 chromosomal abnormalities in 61 patients (55.4%). These comprised the loss of heterozygosity (LOH) (59.7%), hemizygous deletions (23.4%) and copy number gains (16.9%). The most common aberrations in affected patients were: 5q loss (55.7%), 20q deletion (11.5%), 1q duplication (4.9%), 19p deletion (2.4%), 1p deletion (3.2%) and 6q LOH (3.2%). NGS analysis detected 219 gene mutations (in a total of 27 genes) in 108 patients (98%). The most frequently mutated genes were: JAK2 (62.9%), CALR (27.8%), ASXL1 (20.3%), TET2 (16.6%), MPL (7.4%), <5% ZRSR2, EZH2, DNMT3A, U2AF1, ET6, SF3B1, IDH1, IDH2. Recurrent specific mutations were identified in 10 genes. Sixty-two patients (57.4%) had more than one somatic mutation. Six patients (5.5%) had no JAK2, CALR or MPL mutations and were defined as “triple-negative”. Previously not described ZRSR2 gene 12 bp insertion was indentified in four patients (3.7%). The correlation analysis showed significant associations between 5q LOH and JAK2(V617F)mutation (p=0.010); ASXL1 mutations (p=0.011); 19p deletion and CALR mutations (p=0.004). Notably, the affected genes are located in core-sponding affected chromosome regions, indicating disruption of both alleles by different biological mechanisms. KRAS and ET6 mutations were statistically associated with ASXL1 mutations (p<0.001 and p=0.005, respectively) while JAK2 and CALR mutations were mutually exclusive in all cases (p=0.001).

Summary/Conclusions: A number of associations between gene mutations and chromosomal aberrations was revealed in PMF. Co-presence of 5q LOH with JAK2(V617F) and CALR mutations with 19p deletion indicate that further deregulation of these key signaling pathways may take place disrupting the second allele of the affected genes by different biological mechanism – LOH or deletion.

FREQUENCY OF CONCURRENT BCR-ABL1, JAK2, CALR AND MPL MUTATIONS IN A COHORT OF 5,545 CASES WITH SUSPECTED MPN BY A DEEP SEQUENCING APPROACH

S. Jeromin1,*, M. Meggendorfer1, A. Fasan1, C. Hafnerl1, W. Kern1, T. Hafner1
1MLL Munich Leukemia Laboratory, Munich, Germany

Background: Chronic myeloid leukemia (CML) is a myeloproliferative neo-plasm which is characterized by a bcr-abl1 rearrangement in almost 90% of BCR-ABL1-negative MPN a mutation in CALR, JAK2 or MPL can be detected. These genetic alterations are thought to be nearly mutually exclusive, however, an accurate frequency is still missing.

Aims: To determine the incidence of genetic markers occurring in parallel in a large cohort of patients with suspected MPN and characterize double mutated cases.

Methods: From July 2016 till January 2017 5545 samples were sent to our laboratory with suspected MPN. The male:female ratio was 1:1, and the median age was 60 years (range: 18-98 years). Median white blood cell count was 9x109/L, hemoglobin level (Hb) was 15g/dl, and platelet count was 328x109/L. All of these cases were analyzed by an amplicon deep sequencing approach for mutations in JAK2 (exon12, exon14), CALR (exon9) and MPL (exon10) with a sensitivity of 1%. 3070 patients were additionally screened for BCR-ABL1 fusion by a multiplex PCR approach. Samples that were double mutated for JAK2, CALR and MPL were analyzed by amplicon deep sequencing for additional mutations in 13 myeloid genes.

Results: In total 1775/5545 (32%) of suspected MPN patients showed JAK2, CALR and/or MPL mutations. 1438 (26%) were JAK2, 267 (5%) CALR, and 89 (1%) MPL mutated. Of note, the analysis of a subgroup (n=3070) for BCR-ABL1 fusion identified 123 (4%) as CML cases. The JAK2 mutated cases presented mainly with Va817PhE (99%) and rarely with JAK2 exon12 mutations (1%). CALR mutations were primarily type 1 (54%) and type 2 (30%). MPL mutations were located at amino acid Trp515 in 96% of cases. Double mutated cases were present in 19/1775 (1%) cases: JAK2/MPL (63%), JAK2/CALR (32%) and CALR/MPL (6%). In nearly all CALR mutated cases (67%) the CALR mutation was detected with the higher load, whereas in JAK2/MPL double mutated cases the ratio was equal. Most of the patients (18/19) had one mutation with a load below 10% and could have been missed by other approaches. BCR-ABL1 together with JAK2 or CALR mutation was found in one patient, each (0.21%). In 64% of the 267 patients, out of the 267, dated the previous 2-3 years, 8 patients had already received treatment for CML but were suspected to have independent BCR-ABL1-negative MPN. For two of these patients, samples 1 and 6 years prior to diagnosis of CML were available. Both showed CALR mutations already at this former time-point at high loads. In 10/19 (53%) double mutated patients the CALR mutations were detected in 8 different genes. SRSF2 and TET2 were the most frequently mutated ones (n=3, each). No significant difference in mutation frequency was detected to the overall frequency in MPN patients with single mutations. The JAK2, CALR and/or MPL mutated vs wild-type cases showed higher age (mean: 67 vs 56 years, p<0.001) and higher platelet count (480 vs 260x109/L, p<0.001). Interestingly, out of the 267, overall, the p-value was significantly different according to the presence of mutations as follows: triple-negative (56 years), CALR (63 years), JAK2 (67 years), MPL (71 years) and double mutated (74 years).

Summary/Conclusions: One-third of the cases can be diagnosed having BCR-ABL1 fusion in an unselected cohort with suspected MPN. The frequency of double mutated JAK2, CALR and MPL cases is 1%. In CML cases BCR-ABL1 fusion and JAK2 or CALR mutation were detected in 2% of the patients. The impact of these parallel genetic events on the clinical course of the disease has to be evaluated in the future.
was 0.9 years in TANSLX1mut. 3.6 years in TANSLX1wt, 13.8 years in DM(+)TANSLX1wt and was not reached in DM(+)TANSLX1mut (with follow up period of 10.3 years) group (p<0.0001). Differences in OS depending on the ASXL1 status were statistically significant in the TN (p=0.007) but not for DM(+) group (p=0.788). The better OS was observed in ASXL1 wt pts with low risk (LR) karyotype (Me 6.4 years, р=0.0005). There were no differences in OS of ASXL1 wt- HR, ASXL1 mut-LR and ASXL1 mut-HR pts (1.4 vs 1.6 vs 1.2 years, р=0.493).

Summary/Conclusions: The differences in OS were more statistically relevant in groups divided by TN/ASXL1 and karyotype/ASXL1 status. The presence of ASXL1mut significantly worsens OS in the TN group. OS in pts with any of the findings: HR karyotype or ASXL1 mut – was significantly shorter than in cytogenetically favorable ASXL1 wt counterparts.

JAK2 HAPLOTYPE 46/1 (GGCC) HAS NO EFFECT ON THE PRIMARY RISK OF JAK2 V617F MUTATION, BUT IT STRONGLY POTENTIATES THE PROGRESSION OF GROWN ALLELE BURDEN IN MYELOPROLIFERATIVE NEOPLASMS

M. Stolyar1,2,*, O. Klimova3,4, A. Gorbenko1, S. Titov3,4, I. Ïîêîëîâîâ1,5

Background: Several research groups have determined that the JAK2 46/1 (GGCC) haplotype in multiple ethnic groups is strongly associated with a predisposition to acquiring JAK2 V617F-positive MPNs. The role of the JAK2 46/1 haplotype in the natural evolution of the mutant JAK2V617F allele burden in PV but not ET or PMF has been shown [Alvarez-Larrán A e.a. Leukemia Research 2012, 36(3):324-326]. However, the data on the impact of the haplotype on the JAK2V617F allele burden do not always agree. Using a highly sensitive test allowed to reveal a high prevalence JAK2 V617F among persons without symptoms of hematological disorders [Krichesky S e.a. Blood Cells, Molecules and Diseases., doi: 10.1016/j.bcmd.2017.01.001]. Influence of haplotype 46/1 for such cases is not known. There are two competing hypotheses of "hypermutability" and "fertile ground" explaining the causes of the higher frequency of mutations of JAK2V617F in haplotype 46/1 carriers. The "hypermutability" hypothesis refers to an increased risk of a primary mutation in carriers of haplotype 46/1. In this case, the increasing frequency of the haplotype in patients with low allele burden (<5%) must also be observed, including those individuals without evidence of hematological disorders. Aims: Studying the relations of haplotype 46/1 and JAK2 V617F allele burden Methods: The diagnosis of chronic myeloproliferative neoplasms was based on the WHO (2008) criteria. The cohort included patients with JAK2 V617F mutation: 100 patients with PV, 51 with ET, 14 with MF, 41 patients with unclassifiable MPN, 51 with PMF. Patients with JAK2V617F allele burden of 100% were excluded. The JAK2V617F allele burden was evaluated by a quantitative real-time allele-specific PCR test using "in-house" kit (0.01% sensitivity). Associations between JAK2 V617F mutation and haplotypes of JAK2 were assessed using the Chi-squared test. The odds ratio (OR) and 95% confidence interval (CI) were also calculated for each comparison of JAK2 46/1 haplotype frequency and ranges of allele burden.

Results: The JAK2 46/1 haplotype (GG and CG) was present in 170 patients (80.6%) with MPN, in 25 (52%) patients with suspected MPN, in 23 (49%) asymptomatic JAK2 V617F+ patients and in 42 (42%) cases of control group. G variant of rs10974944 was more frequent in all JAK2 V617F-positive MPNs, than in the control population (χ²=46.5, p<0.0001). These results were similar to findings of previous studies, which have shown that the 46/1 haplotype predisposes to the acquisition of JAK2 V617F mutation. JAK2V617F allele burden was significantly higher in patients with PV than in patients with ET (p<0.001), but no differences were observed with from patients with the PMF. 46/1 haplotype was closely associated with MPN patients if the allele burden exceeds 5% (Fig. 1) regardless of the phenotype or the treatment. In this case with an increase in JAK2V617F allele burden the JAK2V617F allele burden significantly increased. However, there was no significant difference in the JAK2 46/1 haplotype frequencies between patients with allele burden less than 5% and the control group.

Summary/Conclusions: No significant differences of the carrier haplotype frequencies between control group and patients with minimal allele burden (less than 5%) JAK2 2V617F have been observed. This is evidence against primary "hypermutability" hypothesis. A further increase in allelic load is more pronounced in carriers of haplotype 46/1 that supports the "fertile ground" hypothesis. We hypothesize that DNA mutation JAK2V617F repair is down-regulated in 46/1 haplotype carriers.

E1315

MINIMAL RESIDUAL DISEASE MONITORING BY DIGITAL PCR FOR JAK2V617F DETECTION IN PATIENTS WITH MYELOFIBROSIS (MF) OR ACUTE MYELOID LEUKEMIA SECONDARY TO MF AFTER ALLOGENIC STEM CELL TRANSPLANTATION (ASCT)

M. Stolyar1,2,*, O. Klimova3,4, M. Ivanov3,4, A. Gorbenko1, S. Titov3,4, I. Olkhovskiy1,5

Background: Myelofibrosis (MF) is one of the BCR-ABL1-negative Chronic Myeloproliferative Neoplasms (MPNs), characterized by clonal expansion of abnormal hematopoietic progenitors and gradual replacement of normal bone marrow with fibrous tissue. MF patients' prognosis is widely variable and the disease can vary from mild to many patients to a very aggressive form. Allogeneic Stem Cell Transplantation (ASCT) is the only curative treatment option for these patients. The most frequent phenotype-driving mutation in MF is the V617F mutation in the JAK2 gene. A high sensitive quantification of JAK2V617F mutation load can be useful to assess Minimal Residual Disease (MRD) in treatment directed to eradicate the malignant clone, such as ASCT. Droplet Digital PCR (ddPCR) is a quantitative approach for the detection of rare allele characterized by a high level of sensitivity and specificity.

Aims: To evaluate the efficacy of ddPCR JAK2V617F mutation detection assay in monitoring the MRD level at consecutive time-points in a small cohort patients who underwent an ASCT for MF or MF-derived Acute Myeloid Leukemia (s-AML).

Methods: DNA from 9 patients affected by primary, secondary MF or s-AML were serially collected during the follow-up after ASCT (50-2500 days). These samples were investigated for hematologic chimerism by PowerPlex System (Promega USA) and were evaluated both by conventional allele specific PCR (ASO-PCR) and by a validated ddPCR mutation detection assay (Bio-rad, USA). Results were expressed as percentage of JAK2V617F mutated alleles on total evaluated alleles.

Results: The JAK2V617F ddPCR mutation assay was able to detect low muta- tion load (up to 0.006%), confirming to be much more sensitive than ASO-PCR (0.5-2%). In 4 patients, early after transplantation, we observed by ddPCR a low level of MRD that progressively increased during the follow-up and antici- pated a decrease in donor chimerism level and a worsening of clinical situation. In 2 patients, who showed a full donor chimerism and complete hema- tologic remission of the disease, very low levels of MRD (ranging from 1% to 0.06%) could be detected by ddPCR in the 2 years after ASCT. With a longer follow-up, a full molecular remission was achieved as demonstrated by ddPCR. In 2 other patients, we observed a very early achievement of full donor chimerism and JAK2V617F molecular negativity (within 90 days post HSCT), also when evaluated by ddPCR. These patients entered a complete hematologic remission of the disease which still persists (after 1 and 5 years after transplantation, respectively). Interestingly, in one patient whose post-transplant hematopoiesis proved full donor and negative for JAK2V617F mutation for 2 years, a weak positive signal revealed by ddPCR (0.075%) became apparent at 12 months after ASCT and anticipated an extra-hematologic relapse (skin and bone). A subsequent second allogeneic transplant from the same sibling donor restored clinical and molecular remission.

Summary/Conclusions: The ddPCR proved to be a sensitive and accurate method in detecting JAK2V617F mutation. Therefore, this assay can be a valid tool for MRD monitoring in MF and a candidate for ASCT. However, the use of this highly sensitive PCR should be considered with caution in the clinical management of transplanted patients to avoid inappropriate use of donor leukocyte infusion (DLI) and tampering of immunosuppression. A large,

Figure 1.
number of patients have to be studied with ddPCR to better understand the clinical significance of low mutation load.

**S100A8/9 ACTIVATION OF MAPK PATHWAY IS SUPPORTED BY ITS RECEPTORS RAGE AND TLR4 IN POLYCYTHEMIA VEREA**

M. Kovačić1, C. Mitrović-Ajić1, B. Belešlini-Cokić2, M. Diklić3, T. Subotićk1, D. Djiljic1, S. Momčilović1, D. Leković45, M. Gotić45, V. Čokić1

1Laboratory of neuroendocrinology, Institute for Medical Research, 2Clinic for Endocrinology, Diabetes and Metabolic Diseases, Genetic laboratory, Clinical Center of Serbia, 3Laboratory of experimental medicine, Institute for Medical Research, 4Clinic of Hematology, Clinical Center of Serbia, 5Medical Faculty, University of Belgrade, Belgrade, Serbia

**Background:** S100 proteins have been shown to regulate cell proliferation, excessively augmented in myeloproliferative neoplasms (MPN). S100A8/9 is produced by cells of myeloid origin as mediator of inflammation, while AKT excessively augmented in myeloproliferative neoplasms (MPN). S100A8/9 is involved in signal transduction, cell transformation and cell growth. It has been shown that S100A8/9 factor, further on ameliorated by TLR4 inhibition in PMF. Inhibition of TLR4 reduced S100A8/9 mediated MAPK activation has been significantly augmented by TLR4 and RAGE activation of AKT and MAPK pathways by S100A8/9 proteins in healthy controls and MPNs: polycythemia vera (PV), essential thrombocythemia (ET), primary myelofibrosis (PMF), according to JAK2V617F and calreticulin (CALR) mutation status.

**Methods:** S100A8/9 factor is examined in granulocytes of MPN using immunoblotting, while its influence on cell proliferation of granulocytes is determined by flow cytometry. Mutations of JAK2V617F and CALR exon 9 are analyzed by DNA sequencing. Besides JAK2V617F+ PV patients, we formed per three groups of patients: JAK2V617F+, JAK2V617F-/CALR+, and JAK2V617F-/CALR- for ET and PMF. Results: S100A8/9/Anteiles demonstrated a common significant increase in plasma of MPN patients, whereas the presence of CALR mutation augmented S100A8/9 levels in granulocytes of ET and PMF patients. Activation of AKT pathway is generally reduced by S100A8/9 factor, further on ameliorated by inhibition of the receptor for advanced glycation end products (RAGE) in granulocytes of JAK2V617F+ and JAK2V617F-/CALR+ groups of ET and PMF patients, while it has been prevented by Toll-like receptor 4 (TLR4) inhibition in PV patients. MAPK pathway is significantly inhibited by S100A8/9 only in JAK2V617F+ ET patients and JAK2V617F-/CALR- PMF patients, partially prevented by TLR4 inhibition in PMF. Inhibition of TLR4 reduced S100A8/9 mediated AKT and MAPK activation, while in contrast, S100A8/9 mediat ed MAPK activation has been significantly augmented by TLR4 and RAGE inhibition in PV patients. S100A8/9 stimulated granulocyte cycle arrest in G2M phase has been stopped by JAK2/1 inhibition.

**Summary/Conclusions:** S100A8/9 protein levels demonstrated stable elevation in MPNs, while inhibition of AKT pathway has been controlled by TLR4, whereas MAPK pathway activation by TLR4 and RAGE in PV, during treatment with S100A8/9.

**MUTATIONAL PROFILE STUDY OF DOUBLE-NEGATIVE ESSENTIAL THROMBOCYTHEMIA BY HIGH-DEPTH NEXT GENERATION SEQUENCING (NGS)**

G. Carreno-Tarragosa1,1, I. Rapado1, R. Ayala1, A. Arenas1, J. Martínez-López1

1Haematology, Hospital Universitario 12 de Octubre, Madrid, Spain

**Background:** Essential thrombocythemia is one of the three classical phae- noma negative myeloproliferative neoplasms. It is frequently difficult to diagnose and some molecular markers are used as diagnostic criteria according to WHO classification. Despite this, a significant proportion of patients do not present a clonality marker.

**Aims:** To identify the mutational profile of ET negative for V617F and CALR mutations and to correlate it with clinical data of the patients.

**Methods:** A cohort of 22 ET negative for mutations in JAK2 (qPCR) and CALR (GENESCAN) was selected. Median age at diagnosis was 46 years (range: 14-88), male:female ratio 9:13; 2 patients had a record of thrombotic event prior to diagnosis, 4 patients had symptoms at the time of diagnosis, 3 patients suffered thrombotic event after diagnosis, 1 patient suffered transformation to AML. Median Hb, WBC and platelets at diagnosis were respectively 14.75±0.5; 8.5±0.1x109/L and 720±10x109/L. We performed targeted gene sequencing by NGS (Ixon Torrent Proton System–Life Technologies) using a panel of 33 genes implicated in leukemia progression. X2 and t-student tests were used to find association between mutations and clinical data.

**Results:** On average, 97.94% of the target sequence showed a mean depth coverage around 2500. We discovered 17 non-synonymous mutations which were used to find association between mutations and clinical data.

**Conclusions:** 540 patients have been regulated to state cell proliferation, excessively augmented in myeloproliferative neoplasms (MPN). S100A8/9 is produced by cells of myeloid origin as mediator of inflammation, while AKT excessively augmented in myeloproliferative neoplasms (MPN). S100A8/9 is involved in signal transduction, cell transformation and cell growth. It has been shown that S100A8/9 factor, further on ameliorated by TLR4 inhibition in PMF. Inhibition of TLR4 reduced S100A8/9 mediated MAPK activation has been significantly augmented by TLR4 and RAGE activation of AKT and MAPK pathways by S100A8/9 proteins in healthy controls and MPNs: polycythemia vera (PV), essential thrombocythemia (ET), primary myelofibrosis (PMF), according to JAK2V617F and calreticulin (CALR) mutation status.

**Methods:** S100A8/9 factor is examined in granulocytes of MPN using immunoblotting, while its influence on cell proliferation of granulocytes is determined by flow cytometry. Mutations of JAK2V617F and CALR exon 9 are analyzed by DNA sequencing. Besides JAK2V617F+ PV patients, we formed per three groups of patients: JAK2V617F+, JAK2V617F-/CALR+, and JAK2V617F-/CALR- for ET and PMF. Results: S100A8/9/Anteiles demonstrated a common significant increase in plasma of MPN patients, whereas the presence of CALR mutation augmented S100A8/9 levels in granulocytes of ET and PMF patients. Activation of AKT pathway is generally reduced by S100A8/9 factor, further on ameliorated by inhibition of the receptor for advanced glycation end products (RAGE) in granulocytes of JAK2V617F+ and JAK2V617F-/CALR+ groups of ET and PMF patients, while it has been prevented by Toll-like receptor 4 (TLR4) inhibition in PV patients. MAPK pathway is significantly inhibited by S100A8/9 only in JAK2V617F+ ET patients and JAK2V617F-/CALR- PMF patients, partially prevented by TLR4 inhibition in PMF. Inhibition of TLR4 reduced S100A8/9 mediated AKT and MAPK activation, while in contrast, S100A8/9 mediated MAPK activation has been significantly augmented by TLR4 and RAGE inhibition in PV patients. S100A8/9 stimulated granulocyte cycle arrest in G2M phase has been stopped by JAK2/1 inhibition.

**Summary/Conclusions:** S100A8/9 protein levels demonstrated stable elevation in MPNs, while inhibition of AKT pathway has been controlled by TLR4, whereas MAPK pathway activation by TLR4 and RAGE in PV, during treatment with S100A8/9.
Background: We already demonstrated augmented proinflammatory IL-6 and angiogenic vascular endothelial growth factor (VEGF), hypoxia inducible factor-1α (HIF-1α) and endothelial nitric oxide synthase (eNOS) levels in myeloproliferative neoplasms (MPN).

Aims: To observe IL-6 activated signaling pathways during stimulation of angiogenic factors and their JAK-STAT dependence in MPN.

Methods: We analyzed phosphorylation of JAK/STAT3, PI3K/AKT and MAPK signaling by immunoblotting in HEL 92.1.7 cells (with JAK2V617F mutation) and granulocytes of MPN. The granulocyte cycle phases have been studied by flow cytometry.

Results: We demonstrated IL-6 stimulated angiogenic factors in HEL cells and HEL-derived macrophages, blocked by JAK-STAT inhibition for eNOS and HIF-1α. IL-6 stimulated JAK-STAT3 and angiogenesis related PI3-AKT signaling pathways in HEL cells, the later one prevented by JAK1/2 inhibition. Opposite to primary myelofibrosis (PMF), IL-6 activation of JAK-STAT3 and PI3-AKT pathways has been prevented and enhanced by JAK1/2 inhibition, respectively in granulocytes of polycythemia vera (PV). Moreover, IL-6 inhibition of JAK-STAT3 and PI3-AKT pathways in essential thrombocythemia (ET) has been prevented by JAK2 inhibitor in JAK2V617F positive ET granulocytes. JAK1/2 inhibitor Ruxolitinib upregulated IL-6 activators of MAPK pathway in MPN, in contrast to specific JAK2 inhibitor Hexabromocyclohexane. IL-6 mediated reduction in the percentage of HEL cells in G2M phase was reversed by Ruxolitinib that potentiated apoptosis and reduced the cell percentage in GO/G1 phase both in HEL cells and granulocytes of PMF. It has been detected the cell cycle arrest of MPN granulocytes in S phase (DNA replication) after treatment with IL6, completely diminished by JAK1/2 inhibition.

Summary/Conclusions: Therefore, we concomitantly revealed that inflammation stimulated angiogenic factors and signaling pathways involved in cell proliferation, apoptosis and angiogenesis are regulated by JAK-STAT inhibition.
than pts felt that MPN symptoms have an impact on pt quality of life (92% vs 76%) and that pts had a substantial emotional burden associated with their disease. For instance, 34%, 29%, and 26% of pts with MF, PV, or ET reported feeling anxious or worried compared with 70%, 46%, and 36% of physicians reporting that their pts experience substantial anxiety or worry. Some pts did not recognize that their symptoms could be MPN related; for example, one-fifth of pts did not think that their night sweats could result from their MPN (16% MF, 21% PV, 25% ET). Consistent with this, 60% of physicians indicated that pts could identify only few or some of their symptoms as MPN related. Pts and physicians were both concerned about reducing symptoms (pts: 70% MF, 61% PV, 53% ET; physicians: 80% MF, 55% PV, 60% ET); however, pts were also concerned about delaying MPN progression (58% MF, 57% PV, 66% ET; physicians: 43% MF, 28% PV, 37% ET; Figure 1). Compared with pts, physicians indicated a greater focus on prevention of vascular/thrombotic events in PV (66% vs 48%) and ET (80% vs 60%). Overall, only 27% of physicians felt they completely agreed with their pts on treatment goals; 66% felt they somewhat agreed. However, most pts (87%) were satisfied with their physician’s disease management/communication.

Summary/Conclusions: This study revealed a potential disconnect between physician and pt perceptions relating to communication and disease management, and an apparent lack of standardization in symptom assessment. Of note, some pts did not recognize that their symptoms could be MPN related and had different treatment goals than their physicians, indicating a need for improved pt education and pt-physician communication and a treatment plan that includes standardized monitoring of symptoms and agreement on treatment goals.

Methods: Data from the COMFORT-I trial of ruxolitinib (Verstovsek 2012) versus placebo was obtained from Incyte® for independent analysis. Association of total symptom burden (TSS; divided by the sample quartiles) and QOL (divided by the sample median) at baseline with OS among MF patients was estimated using the Kaplan-Meier method and tested using log rank tests and Cox regression. Symptom burden and QOL were assessed using the 5-symptom MF-SAFv2.0 (Mesa 2009) and EORTC QLQ-C30 Global Health/QOL scale (Aaronson 1993). In this population-based study, pts were not included in this symptom burden assessment and may represent an independent factor associated with increased survival.

Results: A total of 309 patients were available for analysis including 155 ruxolitinib-treated and 154 placebo-treated MF patients. Baseline demographics, disease-related variables, and calculated overall survival were similar to previous published results (Verstovsek 2015). Symptom Burden: When comparing OS by TSS quartiles at baseline, no significant associations in OS were observed (Figure 1A). Individual symptoms of bone or muscle pain, feeling full, pain under ribs on left side, abdominal discomfort, itchiness, or night sweats did not demonstrate significant associations when comparing OS by quartile symptom score. Baseline fatigue score demonstrated no difference in OS when stratified by median or quartiles. Global Health Status/QOL: To determine if treatment had an impact on QOL, the EORTC QLQ-C30 (Cella 2007) was administered. QOL components that showed significant differences between treatment groups included global health status (p < 0.01), fatigue (p < 0.001), nausea and vomiting (p < 0.02), and appetite (p < 0.03). Cox Proportional Hazards Modeling: Cox regression analysis reached significance for items of age (p < 0.001), sex (p < 0.001), and QOL (p < 0.009) when taking into consideration TSS, IPSS prognostic risk score, age, sex, COMFORT treatment arm, and QOL. When censoring for placebo patients at crossover, this analysis demonstrated that the same items remained significant (age p < 0.001, sex p < 0.001, and QOL p = 0.002).

Summary/Conclusions: For the patients prospectively evaluated in the COMFORT-I trial, pre-treatment QOL is strongly prognostic for overall survival and mp-MF high IPSS. This study suggests using QOL as a prognostic tool for symptom burden, disease risk, age, sex, and treatment. Prior literature has confirmed the importance of QOL in prognosticating survival in other cancer types. However, this is the first study that has identified the key correlation among individuals with MF. Neither individual nor combined symptom scores at baseline appeared prognostic for overall survival, emphasizing the importance of QOL assessment in addition to symptom assessment. Weight loss (a prognostic factor for DIPSS scoring) was not included in this symptom burden assessment and may represent an independent factor associated with increased survival.

Background: Quality of life (QOL) is a critical aspect of cancer treatment and survival. A strong association exists between QOL and overall survival (OS) for numerous malignancies including breast, gastro-esophageal, colorectal, lung, prostate, ovarian, and head and neck cancer (Sloan 2012, Montazeri 2009, Nils- 

Aims: To evaluate the prognostic relevance of QOL and symptom burden among patients with MF from the COMFORT-I study.

Methods: We identified a total of 3,367 pts with primary myeloid fibrosis (PMF, ICD-O-3 morphology code as 9961/3 and primary site code as C420, C421 or C424) diagnosed between January 2000 to December 2013. Pts with missing survival status (n=753), pts lost to follow up (n=4), and pts with missing age record (n=1) were excluded. Kaplan-Meier analysis was performed to determine overall survival (OS) and cancer specific mortality. The effects of specific covariates on OS were analyzed using a Cox proportional hazards model.
Results: The final study cohort comprised of 2,619 PMF pts. Median follow up period was 28 months (interquartile range (IQR) 11-56). Median age at diagnosis was 68 years (interquartile range 59-77 years) with 60.6% (n=1,586) ≥ 65 years old. More than half of the pts were male (58.5%; n=1,531); 82.2% (n=2,153) were white, and 16.4% (n=430) were diagnosed between 2012 and 2013. The geographic distribution was as follows: East 14.8%, South 18.4%, West 54.2% and Midwest 12.6%. Median OS was 42 months (Figure 1). The hazard ratio of all-cause mortality for age was 1.05 (95% Confidence interval (CI) 1.04-1.05), for female vs male was 0.72 (CI 0.64-0.80), for nonwhite vs white 1.01 (CI 0.87-1.16), for unmarried vs married was 1.04 (CI 0.94-1.16), for patients diagnosed 2012-2013 vs 2000-2011 was 0.95 (CI 0.75-1.20). Compared to West, the hazard ratio of OS for East, South and Midwest was 1.05 (CI 0.90-1.22), 1.28 (CI 1.12-1.47), 1.03 (CI 0.88-1.19) respectively.

Summary/Conclusions: This population based study showed that the overall survival of pts with PMF was short. Older and male pts were associated with higher mortality risk. There were significant differences across geographic regions of the United States. Although there is a trend of improvement in the period of 2012 to 2013, the result is not statistically significant, partially due to short follow up. These findings underscore the continuing need for effective therapies for pts with MF.

SERUM ALBUMIN IS A STRONG PREDICTOR OF SURVIVAL IN MYELOFIBROSIS, INDEPENDENT OF IPSS, DIPSS, AND DIPSS+ SCORES

A.T. Kuykendall 1,*, C. Talati 1, D.A. Sallman 2, K.L. Sweet 2, E. Padron 2, J.E. Lancee 2, A.F. Liss 2, K.S. Zuckerman 2, R.S. Komrokji 2

1University of South Florida/Moffitt Cancer Center, 2Moffitt Cancer Center, Tampa, Florida, United States

Background: Albumin is the main protein in human plasma. Serum albumin (SA) is used as a surrogate marker of nutritional status and inflammation. The prognostic role of SA has been studied in many diseases, including hematologic malignancies. In myelofibrosis (MF), ruxolitinib has been shown to improve SA levels in addition to other metabolic parameters. SA holds particular significance in MF given its ability to capture both nutritional status and inflammation level in a disease hallmarked by hyperactive inflammatory pathways and constitutional symptoms.

Aims: We aim to closely evaluate the significance of SA in MF patients as it pertains to clinical presentation, laboratory correlations, disease genomics, comorbidities and outcomes.

Methods: We retrospectively reviewed an institutional database of 376 MF patients who presented to Moffitt Cancer Center between 1/1/1998 and 12/31/2012 and available SA levels within 30 days of presentation. Laboratory values and prognostic scores were determined at time of first presentation. Overall survival (OS) was measured from time of first presentation until date of death or censored at time of last follow-up. Progression free survival (PFS) was defined as time from first presentation to development of acute myeloid leukemia (AML).

Figure 1.

Results: Our cohort of MF patients had median age of 67 and 69 at diagnosis and presentation, respectively. Most patients had primary MF (73%) with 11% and 16% having post-PV MF and post-ET MF, respectively. First, we looked at the correlation between SA and other clinical factors. SA was positively correlated with hemoglobin (p<0.01) and platelet count (p<0.01), and negatively correlated with age (p<0.01), peripheral blast percentage (p=0.03), ferritin (p<0.01), prognostic scoring models (p<0.01 for IPSS, DIPPS and DIPSS+) and pack-year smoking history (p<0.01). SA did not correlate with spleen size or any specific somatic mutation, but negatively correlated with somatic mutation burden (p=0.03). On univariate regression, SA was associated with inferior PFS (HR: 0.31 [0.13-0.72]; p<0.01) and OS (HR: 0.25 [0.17-0.36]; p<0.01). Four cohorts were created based on SA: cohort I-SA 2.5-3.5 g/dL (n=31); cohort II-SA 3.6-4.0 g/dL (n=98); cohort III-SA 4.1-4.5 g/dL (n=182); and cohort IV-SA=4.5 g/dL (n=84). OS increased with increasing SA with median OS (in months) of 9.34, 25.3, 48.4, and undefined in cohorts I-IV, respectively. On focused comparison, each cohort was significantly different than all others. On multivariate analysis, the influence of SA on OS remained significant after controlling for prognostic scores (IPSS, DIPSS, DIPSS+) and comorbidities. For PFS, SA remained significant when controlling for IPSS and DIPSS (p=0.01) but lost significance (p=0.08) when controlling for DIPSS+. Multivariable analysis was performed on a cohort of patients with available molecular data (n=138). SA significantly influenced OS after controlling for prognostic systems, comorbidities and mutations of SRSF2 and ASXL1. Lastly, it has independent prognostic value in incorporation into previously existing prognostic systems (IPSS, DIPSS, and DIPSS+). Patients were assigned 0, 2, 3, and 3 points for low (LR), intermediate-1 (int-1), intermediate-2 (int-2), and high risk (HR), respectively. Patients were then assigned -1, 0 and 1 point for SA ≥4.3, 3.8-4.3, and <3.8 g/dL, respectively. Risk groups were defined as LR (<1.0 points), int-1 (1 point), int-2 (2 points), and HR (3-4 points). Survival curves and histograms displayed better capture of LR and HR prognostic groups with median OS similar to standard prognostic modeling (see figure).

Summary/Conclusions: SA level is independently prognostic in MF and correlates with variables known to hold prognostic value. Its representation of nutritional status, inflammation, and comorbidities imbues it with special status in predicting outcome. Its incorporation into known prognostic scoring systems provides an improved ability to accurately capture low and high-risk subgroups.

CLINICAL UTILITY OF NEXT-GENERATION SEQUENCING IN THE MANAGEMENT OF MYELOPROLIFERATIVE NEOPLASMS

W. Alduaij1,*, C. McNamara1, A. Schuh2, A. Arruda1, M. Sukhai3,4, M. Thomas3, V. Gupta1

1MPN program, Princess Margaret Cancer Centre, 2Hematology- Princess Margaret Cancer Centre, 3Advanced Molecular Diagnostics Laboratory, Princess Margaret Cancer Centre, 4Applied Molecular Oncology, Ontario Cancer Institute, University Health Network, University of Toronto, Toronto, Canada

Background: The new classification of myeloproliferative neoplasms (MPNs) according to World Health Organization (2016) has been developed to improve clinical outcomes and risk stratification of patients. In addition to mutational testing, clinical utility remains not well defined. Funding for NGS testing by healthcare systems or third party payers is variable due to the lack of data on its utility in a routine care setting. At our centre, targeted sequencing (TAR-seq) is offered to all new patients referred for myeloid malignancies as part of the Advanced Genomics in Leukemia (AGILE) program.

Aims: In this study, we evaluate the impact of TAR-seq on the management of patients with a diagnosis of MPN or post-MPN acute myeloid leukaemia (MPN/AML).

Methods: All consenting patients referred to the MPN program at the Princess Margaret Cancer Centre between February 2015 and December 2016 with a suspected or confirmed diagnosis of MPN were evaluated (n=188). TAR-seq was performed on DNA extracted from peripheral blood (n=159, 85%) or bone marrow (n=29, 15%) using the TruSight Myeloid Sequencing Panel (illumina), a targeted NGS panel of 54 genes (39 hotspot region; 15 complete coding region coverage) implicated in myeloid malignancies. Repertoire was expanded to high quality exonic nonsynonymous, intronic splice site, frameshift, nonsense and known pathogenic synonymous variants. Variants with global mean allele frequency >1% were identified using multiple population databases (1000 genomes, ESP, ExAC) and excluded. Each patient’s TAR-seq results were reviewed alongside their clinical information systematically by at least two hematologists with expertise in MPN, and disagreements were resolved by consensus.

Results: 179 patients fulfilled the 2008 WHO diagnostic criteria for MPN: 107 were diagnosed with myelofibrosis (MF), 26 with polycythemia vera (PV), 21 with Essential Thrombocythemia (ET) and 32 with unclassifiable MPN. MF was unclassifiable and 12 with MPN/AML. In 6 patients with ‘triple negative’ MPN, who lacked mutations in the driver genes JAK2, CALR and MPL, TAR-seq confirmed the diagnosis of MPN in 13 patients. Variants were subsequently confirmed in 159 patients using a combination of Sanger sequencing, targeted panel and whole exome sequencing. In total, 60 patients were referred for mutation testing and 94 mutational analyses were performed. In 17 patients referred for NGS testing, mutations were identified in both new and known genes. Most mutational events were new and were confirmed in 15 patients. The most frequently mutated genes were JAK2, CALR, MPL and ASXL1. Lastly, given its independent prognostic value, TAR-seq results were used to modify patient management and changed patient care in 11 patients. In 6 patients with triple negative MPN, mutations in the driver genes JAK2, CALR and MPL were also detected. In total, TAR-seq identified 159 patients with MPN, 107 with MF, 26 with PV, 21 with ET, 32 with MPN/AML. In 6 patients with ‘triple negative’ MPN, who lacked mutations in the driver genes JAK2, CALR and MPL, TAR-seq confirmed the diagnosis of MPN in 13 patients. Variants were subsequently confirmed in 159 patients using a combination of Sanger sequencing, targeted panel and whole exome sequencing. In total, 60 patients were referred for mutation testing and 94 mutational analyses were performed. In 17 patients referred for NGS testing, mutations were identified in both new and known genes. Most mutational events were new and were confirmed in 15 patients. The most frequently mutated genes were JAK2, CALR, MPL and ASXL1. Lastly, given its independent prognostic value, TAR-seq results were used to modify patient management and changed patient care in 11 patients. In 6 patients with triple negative MPN, mutations in the driver genes JAK2, CALR and MPL were also detected.
IMPACT OF COMORBIDITIES AND BODY MASS INDEX ON SURVIVAL IN PATIENTS WITH MYELOFIBROSIS TREATED WITH RUXOLITINIB

Ematologia, Ospedale Nuovo Regina Margherita, Roma, Italy

Background: Charlson Comorbidity Index (CCI) and body mass index (BMI) are significantly associated with outcome in patients (pts) who receive continue treatment with tyrosine kinase inhibitors. Ruxolitinib (RUX) is the first JAK1/2 inhibitor that may induce spleen/symptom responses and improve quality of life in pts with myelofibrosis (MF). No data are yet available on the impact of comorbidity and BMI on pts treated with RUX.

Aims: To evaluate the impact of CCI and BMI on overall survival (OS) in a cohort of RUX-treated MF pts.

Methods: A multicenter observational study on WHO-defined MF treated with RUX according to standard clinical practice was conducted in 20 Italian Hematology Centers. Response to RUX was evaluated according to 2013 IWG-MRT criteria. OS was calculated from the date of RUX start to the time of death or last follow-up. Baseline parameters evaluated for correlation with OS were: blood cell count, spleen ≥10cm, marrow fibrosis grading, time from MF diagnosis to RUX start, transfusion dependency, mutation status, Total Symptom Score (TSS), CCI, and BMI.

Results: Between June 2011 and Apr 2016, 343 pts with PMF (51.9%), or post-ET (20.1%) / post-PV (28.0%) were treated with RUX in participating Centers. At RUX start, median age was 76.5 years (range 35.6-89.0) with a male prevalence (57.1%); International Prognostic Score System (IPSS) was intermedium-low (37.5% intm-1, 47.5% intm-2, high 18.4%), transfusion dependency and spleen enlargement were present in 23.8% and 74.7% of pts, respectively (62.4% with spleen ≥10 cm). TSS was <20 in 131 pts (38.2%); 62 (18.1%) pts had a BMI<21 (corresponding to lower quartile). CCI was zero in 105 pts (30.6%), one in 74 pts (21.6%), two in 58 pts (16.9%) and ≥3 in 106 pts (30.6%). OS from MF diagnosis was 3.6 yr (range 0.4-28.6) and median RUX exposure was 21.2 months (3-56.2). In multivariable Cox regression analyses of 845 patients with PMF, PET-MF and PPV-MF treated in 35 German hematology centers – a retrospective field study

B. Kragl,1*, C. Wassenberg2, H. T. Steinmetz3, G. Springer4, K. Jentsch-Ulrich5, A. Gaumann6, J. Dengler7, C. Junghanss1
1Department of internal medicine 3, Hematology, Oncology, Palliative Care, University-Hospital Rostock, Rostock, 2Gefos Dortmund mbH, Dortmund, 3Gemeinschaftspraxis für Onkologie und Hämatologie, Köln, 4Hämato-Onkologische Schwerpunktpraxis, Stuttgart, 5Schwerpunktpraxis für Hämatologie und Onkologie, Magdeburg, 6Institut für Pathologie, K aufbeuren, 7Schwerpunktpraxis Onkologie, Heilbronn, Germany

Background: Primary myelofibrosis (PMF) as well as secondary post essential thrombocythemia (pet)-MF and post polycythemia vera (pPV)-MF are considered rare diseases associated with significant morbidity. Diagnostics and therapeutic options have significantly improved during the last decade by development of novel drugs, improvement of allogeneic stem cell transplantation (SCT) procedures and supportive care. Whereas the characteristics of PMF, pET-MF and pPV-MF patients (pts) participating in clinical trials are well analyzed, data are rare for the general MF population including patients not included in or eligible for clinical trials.

Aims: In order to gain a broader, more comprehensive data set on the general MF population we performed a questionnaire poll in 35 German hematology centers gathering characteristics on 845 pts who were currently under care.

Methods: A questionnaire asking for general patient and disease specific data as symptoms, v-cfemalgia, prognostic factors, past/current treatment and blood count, degree of MF in bone marrow and transfusion frequency was designed. It was distributed to participating centers (n=35, mostly private offices) throughout Germany and analyzed centrally. Time period of collection at 3 years was 91.8%, 65.6% and 34.8% in group 1, 2 and 3, respectively (log rank p<0.001) for a median OS of undefined, 66.7 and 22.8 months. Notably, while 88.7% of high IPSS risk pts clustered in group 3, only 60.5% of pts in group 1 were at intm-2 IPSS risk, and 48.6% of pts in group 2 were at high IPSS risk. The achievement of a spleen response at 6 months (39.2% vs 36.4%, p=0.71) was not influenced by lower BMI. However, pts achieving a spleen response at 6 months had significantly increased OS (Fig. 1A). Also, a higher CCI did not correlate with lower spleen response at 6 months (44% vs 34% of pts with CCI<3, p=0.11). The impact of higher CCI on survival was only mildly affected by the achievement of a spleen response at 6 months (Fig. 1B).

Figure 1.

Summary/Conclusions: Together with transfusion requirement, CCI and BMI may influence survival in RUX-treated MF pts. Taking into account these additional parameters may allow to better define survival probability beyond IPSS risk assessment. Unfavorable CCI and BMI did not hamper responses to RUX; also, the achievement of a spleen response counterbalanced the negative prognostic effects of a lower BMI.
CALR Mutation Type Influences the Risk of Thrombosis in Essential Thrombocythemia According to a Cooperative Study Between Two Spanish Centers

Aims: The objective of this study is to define the clinical meaning of CALR mutation type in ET.

Methods: We analyzed 309 ET patients from two hospitals: H.C.U. Santiago and H.U. of Gran Canaria Dr. Negrín. Dates of diagnosis were between 1-11-90 and 1-10-2016, and the median follow up was of 6.88 years. Patients were treated according to local protocols. We collected clinical data of patients at diagnosis and during follow-up as well as events such as thrombosis, transformation to myelofibrosis (MF) or acute leukemia (AL). Thrombosis associated with diagnosis refers to those events happening from two years before to diagnosis until diagnosis. The statistical analyses were performed with R Core Team (2016) and IBM SPSS 21.0.

Results: JAK2V617F mutation was present in 60.5% of the patients, 1.9% had MPL mutations, 14.5% were CALR type-1 like, 11% were CALR type-2 like and 11% were CALR wild type. In three cases, we were not able to classify CALR mutation as type-12 like. With regard to the clinical events: 21 patients (6.8%) had thrombosis associated with diagnosis, and 34 (11%) at least 1 thrombosis per center. Results: Gender was equally distributed (50%/50%). Pts ages at initial diagnosis were as follows:<50 years (y) (11%), 50–60y (19%), 61-70y (31%), and >70y (40%). Current age was >65y in 70% of all pts. PMF represented the largest MF cohort (77%), followed by pet-MF (10%), ptyr-MF (7%) and unspecified (6%). Most pts (75%) had bone marrow fibrosis (10%) and decreased cellularity (36%), <1y (15%), unknown (1%). Key current blood values at time of diagnosis included abnormal thrombocyte counts (<500GPT/L; 6%) <100GPT/L (10%); ≤450GPT (28%) and elevated WBC>25.000/μL (11%). Presence of circulating blasts in the peripheral blood was documented in 11% of pts. Hemoglobin [g/dL] was ≥10.0 (68%), 8–10.0 (68%), <8.0 (8%) and unknown for 3% of the pts. Constitutional symptoms were present in 20% of the pts. Common symptoms included splenomegaly (60%), decreased fitness (41%) and weight loss (16%). Pruritus was present in 5% and night sweats in 9% of all pts. An individual Dynamic prognostic Scoring System (DIPPS) score was calculable in 495 pts: 19% low risk, 52% intermediate risk, 23% high risk disease. Concomitant thrombosis were common, most often cardiac (56%). Most common medical treatments included cytostatic (37%), anticoagulation (25%), JAK-inhibitors (23%) and none (24%). Non-medical treatments were rare: stem cell transplantation (3%), splenectomy (2%) and spleen irradiation (3%). Only 31% of all pts received red blood cell transfusions, however 7% had received >90 units.

Summary/Conclusions: Daily practice MF pts share several characteristics with MF trial cohorts (e.g. COMFORT). As expected the diseases were not as progressed as in the trials. Interestingly gender was equally distributed in our study. SCT was a rarely used treatment within this cohort whereas JAK2 inhibitors were frequently used.

Figure 1.

Summary/Conclusions: The type of driver mutation is associated with a different risk of thrombosis. Among the two types of CALR mutation, patients have similar clinical characteristics except for the risk of thrombosis which seems lower in CALR type-2 like compared to type-1 like. This finding shows the importance of studying the CALR mutation type in ET.

CALR Mutation Type Influences the Risk of Thrombosis in Essential Thrombocytemia According to a Cooperative Study Between Two Spanish Centers

Aims: We prospectively analyzed the levels of leukocyte-platelet (Le-Plt) aggregates, together with levels of soluble selectins, in a group of pts with Ph MPN with diagnosis and during therapy.

Methods: Our study included 90 consecutive de novo Ph MPN pts (37 polycythemia vera, 27 essential thrombocythemia, 26 primary myelofibrosis), diagnosed according to WHO criteria. According to therapy, pts were assigned as: hydroxyurea (HU) 7.8%, aspiron (ASP) 55.6%, hydroxyurea+aspirin (HU+ASP) 31.1%, although 5.6% of pts were without therapy. Neutrophil-platelet (Neu-Plt) and monocyte-platelet (Mo-Plt) aggregates were determined in whole blood samples (EDTA/CTAD) by flow cytometry. Aggregates were estimated as fraction (%) of CD42b+CD61+ neutrophils and monocytes. Plasma levels of E-, L- and P-selectins were determined by enzyme immunoassay. All analyses were performed on 9 pts with thrombosis and 9 pts without thrombosis.

Results: In all pts, mean levels of Neu-Plt and Mo-Plt aggregates at diagnosis were significantly elevated in comparison to control values (22.9% vs 8.9% and 13.0% vs 5.2% respectively, p<0.01). Mean concentration of soluble E-, L- and P-selectins were also significantly higher in Ph MPN than in control group (34.2 ng/mL vs 19.0 ng/mL; 2748.7 ng/mL vs 1322.0 ng/mL and 294.0 ng/mL vs 69.8 ng/mL, respectively, p<0.01). Mean levels of Neu-Plt and Mo-Plt aggregates in response to therapy were significantly reduced compared to baseline levels (Figure). Significant reductions were observed for E-selectin levels in HU+ASP group, for L-selectin levels in all three therapy groups and for P-selectin levels in HU and HU+ASP groups (Table). During the median follow up of 39 months from diagnosis of Ph MPN, thromboembolic events occurred in 13.3% of pts (12/90), particularly: 0/7 on HU, 3/50 on ASP, and 9/28 on HU+ASP. In this subgroup we observed increased baseline levels of Neu-Plt and/or Mo-Plt aggregates in 9/12 pts, while all 12 pts had increased at least one soluble selectin, predominantly P-selectin. Resting revealed that all 9 pts with thrombosis and increased aggregates level at baseline, normalized those levels after therapy, while only 4/12 pts normalized soluble selectin levels.
HEAT SHOCK PROTEIN 27 EXPRESSION IS INCREASED IN PATIENTS WITH PRIMARY AND SECONDARY MYELOFIBROSIS AND MAY BE AFFECTING THEIR SURVIVAL

Background: Increased heat shock protein 27 (HSP27/HSPB1) expression and phosphorylation were observed in a large number of neoplastic diseases and they have mostly been associated with aggressive disease features and poor prognosis. There are only few reports investigating HSP27 in primary myelofibrosis (PMF), a myeloproliferative neoplasm characterized by high inflammatory state reflecting in debilitating clinical symptoms.

Aims: To analyze HSPB1 mRNA expression in patients with PMF and secondary myelofibrosis (SMF) and to correlate it with clinical and hematological features.

Methods: We analyzed HSPB1 relative expression in bone marrow aspirates of 26 patients with PMF, four patients with SMF and 13 controls using quantitative real time polymerase chain reaction (RT-PCR). Spleen size was assessed by palpation. Association with overall survival was analyzed in 27 PMF and SMF patients evaluated at the time of diagnosis. The Kusak-Walls one way analysis of variance, The Mann Whitney U test, the Chi squared test, the Spearman rank correlation, the log-rank test and the Cox regression analysis were used, cut-off point for survival analyses was determined using the ROC curve analysis.

Results: Relative expression of HSPB1 differed significantly between diagnoses (P=0.011); it was significantly higher in patients with PMF and SMF than in control group (P=0.05 for both comparisons), but did not differ between PMF and SMF patients (non significant). Increased expression was associated with increase in the spleen size (P=0.009) and JAK2 V617F mutation (P=0.073). We did not detect significant associations with other disease specific features. Lower HSPB1 expression was associated with inferior overall survival in both univariate (HR 3.2; P=0.04) and multivariate analysis (HR 6.12; P=0.034) where effect was independent of age (non significant), gender (non significant) and the International Prognostic Scoring System (IPSS) score (HR 3.31; P=0.033).

Summary/Conclusions: We have found elevation of blood and endothelial cell activation markers at baseline in Ph-MPN. Cytoreductive and antiaggregatory therapy reduced the mean level of Le-Plt aggregates and concentration of soluble selectins. In subset of pts with thrombosis, therapy lead to normalization of Le-Plt aggregate levels, with incompletely normalized soluble selectin levels. Even with normal Le-Plt aggregates, observed elevated selectin levels can explain persistent thrombotic risk due to intrinsic changes in relationship between blood and endothelial cells as a part of biology of Ph-MPN itself.

E1329

NON-DRIVER MUTATIONS IDENTIFIED BY A 190-GENE NEXT GENERATION SEQUENCING PANEL IN PATIENTS WITH PRIMARY MYELOFIBROSIS AND POST-POLYCYTHEMIC/ESSENTIAL THROMBOCYTHEMIA MYELOFIBROSIS

B. Li1,2, Z. Xu1, T. Qin1, Y. Zhang1, J. Liu1, Z. Xiao1
1MDS and MPN Centre, Institute of Hematology and Blood Diseases Hospital Chinese Academy of Medical Sciences, Tianjin, China

Background: It is a consensus that the driver mutation is an independent prognostic factor in PMFs. Moreover, some non-driver mutations are found associated with initiation, progression and prognosis in PMFs. However, a recent study from the AGIMM (AIRC- Gruppo Italiano Malattie Mieloproliferative) group showed that the type of driver mutation did not influence prognosis in post-PV/ET MF. These observations proved that there were indeed some differences in these two types of MF.

Aims: The aim of current study was to describe the non-driver mutation landscape and the molecular differences between the patients with PMF and those with post-PV/ET MF.

Methods: Targeted gene sequencing was carried out at diagnosis. We sequenced 190 genes across 62 patients, resulting in 229 high-confidence mutations. The average gene coverage was 99%. The average read depth was 540×. Also, 92% of targeted regions were covered with >20×. Every mutation identified in this study was then compared against these expected patterns and categorized into “oncogenic,” “possible oncogenic variants,” or “unknown significance”. Using copy number-adjusted VAF, we reconstituted the clonal architecture to establish whether a mutant gene was an ancestral or subclonal mutation. According to the statistically differences in VAF among gene mutations, subjects were classified as two different clonal architecture, namely clone+subclone(s) (P<0.05) or clonal.

Results: In PMFs, 42 (93.3%) patients had at least one non-driver mutation. Within the 17 patients lacking the driver mutations in JAK2(V617F)Exon 12, MPLW515 and CALR 2 had mutant genes (SH2B3 and PIAS3) involving in JAK-STAT pathway, 13 had mutations in other genes and 2 had no mutations. In Post-MFs, non-driver mutations were detected in 16 (94.1%) patients. There are no differences in the median number of non-driver mutations in PMFs vs. post-PV/ET MFs (3 vs. 3.18, P=0.865) and PMF patients vs. without driver mutations (3 vs. 3.18, P=0.668). In PMFs, 12 non-driver genes were mutated in >5% of patients, namely ASXL1 33.3%, U2AF1 22.2%, TET2 15.6%, FAT1 15.6%, SETBP1 13.3%, SRSF2 8.9%, CUX1 8.9%, EP300 8.9%, FAT2 6.7%, NOTCH3 6.7%, EZH2 6.7%, and GATA3 6.7%. In post-PV/ET MFs, ASXL1 (41.2%) was the most frequent mutation, followed by TET2 (29.4%). U2AF1 and SRSF2 mutations were significantly more frequent in PMF than in post-PV/ET MF. Moreover, SETBP1 and FAT1 were mutated in PMF more often and not mutated in post-PV/ET MF. Figure 1A-C show 3 illustrative patients. Clonal architecture was significantly different between PMFs and post-PV/ET MFs (Figure 1D). About 50% PMF patients were classified as clonal, however, most (87.5%) post-PV/ET MF patients were clone+subclone(s). In PMFs, driver mutation was an ancestral mutation with other non-driver mutations in 14 (31.1%) subjects as 2015-R02413 in Figure 1A. Moreover, driver mutation even was a subclonal mutation in 9 (16.7%) subjects as 2015-R02406 in Figure 1D.
Baseline TSS, a 3-level grouping factor for GH/QOL change (deterioration vs stable vs improvement), and an interaction term between baseline TSS and the GH/QOL grouping factor.

Results: 301 patients randomized to ruxolitinib [N=149] or placebo [N=152]
completed TSS at baseline (45% female, median age 68 [range 40-91]). Median baseline TSS was 16.8 (range 0 to 52.7). Pooled SD at baseline and week 24 in TSS was 11.4 and 11.6, respectively, resulting in estimated meaningful changes of 3.6-5.8 points. For change and percentage change from baseline at week 24 in TSS, the pooled SDs were 9.8 and 75%, respectively, resulting in estimated meaningful changes of 3.3-4.9 points or 25%-38%. Among patients with TSS and QLG-C30 data at baseline and week 24, 51 (23%) patients had deterioration, 81 (27%) were stable, and 110 (50%) had improvement based on QLG-C30 GH/QOL changes. Mean (95% CI) changes in TSS for the three groups were 0.8 (-2.5 to 4.2), -1.4 (-3.8 to 0.8), and -6.8 (-9.0 to -4.6), and for percent changes 20% (-6% to 46%), 17% (-11% to 44%) and -34% (-45% to -22%). ANCOVA revealed that baseline TSS statistically significantly impacted p=0.02. Figure 1 demonstrates how group change in estimated mean (95% CI) changes in TSS for the improved group of -20.8 (-26.4 to -15.1), -11.7 (-14.3 to -9.0), and -2.6 (-5.1 to -0.1) for baseline TSS of 50, 30, and 10.

Summary/Conclusions: Distribution- and anchor-based approaches suggest that changes as small as 3-6 points on a 0-60 scale of the MFSAF v2.0 TSS may be meaningful to patients. However, estimates of meaningful change appear to increase in magnitude for higher baseline scores, though in a way that a static percentage change criterion would either require too much change for lower baseline TSS or not enough change for higher baseline TSS. All analyses suggest that some changes in symptoms which do not meet a 50% improvement may still be meaningful to patients.
response duration were 4 and 31 months respectively. 23% of patients lost response after a median time of 16 months. Seventy-five percent of patients responded to ruxolitinib in terms of spleen size, of whom 86.4% also achieved an erythropoietin response to ESA. A spleen increase during ESA treatment in patients responding to ruxolitinib was observed in 2 patients only.

No thrombotic events and no toxicity were reported over treatment with ESA. Survival was improved in improving anemia in MF patients treated with ruxolitinib. We observed a high response rate in this patients series without significant toxicities. In particular no thrombotic event was reported in response to ruxolitinib was reported. This results may be partially explained by the selection of patients with endogenous erythropoietin level below 250 IU/l, but they could also suggest synergistic activity of ESA and ruxolitinib.

E1333 COMPARING THE SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN PATIENTS (PTS) WITH DIPSS LOW/INTERMEDIATE-1–, INTERMEDIATE-2–, AND HIGH-RISK MYELOFIBROSIS (MF) IN JUMP, A PHASE 3B, EXPANDED-ACCESS STUDY

1University of Insubria, Varese, Italy, 2Princess Margaret Cancer Centre, Toronto, Ontario, Canada, 3Azienda Ospedaliera Bianchi-Melacrino-Morelli, Reggio Calabria, Italy, 4St. Paul’s Hospital, University of British Columbia, Vancouver, British Columbia, Canada, 5Federal Almazov Medical Research Center of the Russian Ministry of Health, St. Petersburg, Russian Federation, 6University Hospital of Halle, Halle (Saale), Germany, 7University Federale de Goiania, Goiania, Brazil, 8Ospedale di Circolo e Fondazione Macchi, Varese, Italy, 9Rabin Medical Center, Petah Tikva, Israel, 10Miguel Servet University Hospital and Centro de Investigación Biológica en Red de Enfermedades Raras (CIBERER), Zaragoza, Spain, 11Johannes Wesling Clinic, Minden, Germany, 12Novartis Pharma AG, Basel, Switzerland, 13Novartis Healthcare Pvt. Ltd, Hyderabad, India, 14GIMMS, Center for Research and Innovation of Myeloproliferative Neoplasms, AOI Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

Background: RUX is a potent JAK1/JAK2 inhibitor that led to improvements in splenomegaly and symptoms and increased overall survival in pts with intermediate (Int)-1– and high-risk MF by the International Prognostic Scoring System (IPSS) in the phase 3 COMFORT studies. JUMP is a large, phase 3b, expanded-access trial in countries with no access to RUX outside a clinical trial and includes pts with IPSS Int–1–, Int–2–, and high-risk MF. To further evaluate RUX, we conducted an analysis assessing safety and efficacy of RUX by Dynamic IPSS (DIPSS) prognostic risk.

Aims: To compare the safety and efficacy of RUX in pts with DIPSS low/Int–1– vs Int–2– vs high-risk MF

Methods: Eligible pts had IPSS high- or Int–2–risk MF, or Int–1–risk MF and a palpable spleen (≥25 cm). Starting dose was based on baseline platelet (PLT) count (<200×109/L), platelet count (<50×109/L), and could be titrated during treatment. The primary endpoint was safety and tolerability of RUX. Changes in palpable spleen length and symptom scores were also assessed. DIPSS scores were determined using pt characteristics at baseline.

Results: Based on available pt data, DIPSS status was determined for 1840 of 2233 enrolled pts. JUMP included 893 low/Int–1–, 754 Int–2–, and 193 high-risk pts (primary MF, 57%, 63%, 62%) who started treatment ≥1 y before data cutoff (01 Jan 2016). Pts with higher-risk MF were older (62, 68, and 72 y), had lower Hb (<10 g/dL, 3%, 64%, 100%), and had higher blast counts (≥1%, 18%, 44%, 85%). Disease duration (50, 51, and 55 mo) and spleen size (12, 13, and 14.5 cm) were similar in all 3 groups. Most pts started at 20mg bid (68%, 57%, 59%) or 15mg bid (20%, 11%, 23%), but these rarely led to discontinuation. Overall rates of nonhematologic grade 3/4 AEs were <2%, except for pneumonia (4.5%), pyrexia (2.5%), asthenia (2.2%), and dyspnea (2.2%). Infections in ≥5% of pts were pneumonia infection (7.3%), urinary infection (6.1%), and nasopharyngitis (5.3%). Herpes zoster was reported in 4.8% of pts. At wk 48, 64% (226/355), 52% (121/232), and 50% (26/52) of pts had a ≥50% reduction from baseline in spleen length; 19% (68/355), 19% (43/232), and 23% (12/52) had ≥50% reductions. Median response in spleen length by wk 72 is shown in the Figure: 69%, 57%, and 51% of pts achieved ≥50% reductions. Median time to response was 4.7 wk (2.5–7.5 wk), 5.3 wk (2.6–8.0 wk), and 8.1 wk (3.1–72.3 wk). From wk 4 to 48, 39%, 43%, 41%–44%, and 48%, and 48% of pts achieved a clinically meaningful response on the FACT-Lym TS: proportions of responders on the FACT-Fatigue were 42%–49%, 46%–49%, and 55%–61%.

Summary/Conclusions: RUX was safe and generally well tolerated. Interestingly, lower-risk pts received higher starting doses yet had lower rates of hematologic AEs. Additionally, lower-risk pts remained on treatment longer than higher-risk pts, with fewer discontinuations due to AEs. Lower-risk pts also achieved slightly better spleen size reductions and symptom improvement than higher-risk pts, suggesting that earlier RUX treatment may lead to greater benefits in pts with MF.

E1334 SAFETY AND EFFICACY OF RUXOLITINIB (RUX) IN PATIENTS WITH MYELOFIBROSIS (MF) WHO STARTED TREATMENT AT 10mg BID AND HAD THE DOSE UPTITRATED IN THE PHASE 3B EXPANDED-ACCESS JUMP STUDY

1St. Paul’s Hospital, University of British Columbia, Vancouver, British Columbia, Canada, 2Azienda Ospedaliera Bianchi-Melacrino-Morelli, Reggio Calabria, Italy, 3University of Florence, Florence, Italy, 4St. Paul’s Hospital, University of British Columbia, Vancouver, British Columbia, Canada, 5Federal Almazov Medical Research Center of the Russian Ministry of Health, St. Petersburg, Russian Federation, 6University Hospital of Halle, Halle (Saale), Germany, 7University Federale de Goiania, Goiania, Brazil, 8Ospedale di Circolo e Fondazione Macchi, Varese, Italy, 9Rabin Medical Center, Petah Tikva, Israel, 10Miguel Servet University Hospital and Centro de Investigación Biológica en Red de Enfermedades Raras (CIBERER), Zaragoza, Spain, 11Johannes Wesling Clinic, Minden, Germany, 12Novartis Pharma AG, Basel, Switzerland, 13Novartis Healthcare Pvt. Ltd, Hyderabad, India, 14GIMMS, Center for Research and Innovation of Myeloproliferative Neoplasms, AOI Careggi, Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy

Background: The most common hematologic grade 3/4 AEs were anemia (22%, 44%, 55%) or 15mg bid (26%, 32%, 33%). Median exposure was 16, 11, and 14.5 cm) were similar in all 3 groups. Most pts started at 20mg bid (68%, 57%, 59%) or 15mg bid (20%, 11%, 23%), but these rarely led to discontinuation. Overall rates of nonhematologic grade 3/4 AEs were <2%, except for pneumonia (4.5%), pyrexia (2.5%), asthenia (2.2%), and dyspnea (2.2%). Infections in ≥5% of pts were pneumonia infection (7.3%), urinary infection (6.1%), and nasopharyngitis (5.3%). Herpes zoster was reported in 4.8% of pts. At wk 48, 64% (226/355), 52% (121/232), and 50% (26/52) of pts had a ≥50% reduction from baseline in spleen length; 19% (68/355), 19% (43/232), and 23% (12/52) had ≥50% reductions. Best response in spleen length by wk 72 is shown in the Figure: 69%, 57%, and 51% of pts achieved ≥50% reductions. Median time to response was 4.7 wk (2.5–7.5 wk), 5.3 wk (2.6–8.0 wk), and 8.1 wk (3.1–72.3 wk). From wk 4 to 48, 39%, 43%, 41%–44%, and 48%, and 48% of pts achieved a clinically meaningful response on the FACT-Lym TS: proportions of responders on the FACT-Fatigue were 42%–49%, 46%–49%, and 55%–61%.

Figure 1.
Methods: in pts with MF. The presence of a subset of JUMP pts provides information on this approach. Further evidence from clinical practice suggests that starting RUX at 10 mg bid and subsequently titrating may reduce the risk of cytopenia development. An ad hoc analysis of a subset of JUMP pts provides information on this approach.

Aims: To assess the safety and efficacy of RUX at a starting dose of 10 mg bid in pts with MF.

Methods: Pts with high-, Int-2-, or Int-1–risk MF were eligible. Int-1–risk pts had a palpable (≥25 cm) spleen. Protocol starting doses (5, 15, or 20 mg bid) were based on baseline platelet (PLT) counts (<50 to <100×10^9/L, 100 to 200×10^9/L, >200×10^9/L, respectively). Although not per protocol, some pts started RUX at 10 mg bid. The primary endpoint was safety. Secondary end-points included changes in spleen length and symptoms.

Results: A total of 48 pts (primary MF, 60%) started RUX at 10 mg bid ≥1 y before data cutoff (01 Jan 2016). Mean baseline characteristics were: median age, 65.5 y (range, 20-83 y); male, 44%; spleen length, 12.3 cm; time since diagnosis, 56.6 mo; hemoglobin (Hb), 112.1 g/L (<100 g/L, 33.3%); PLT count, 351×10^9/L (<100×10^9/L, 10.4%). Pt characteristics were similar to those of the overall population and did not indicate an increased risk of developing cytopenias. At data cutoff, most pts remained on treatment or had completed treatment per protocol (58.3%). Primary reasons for treatment discontinuation included adverse events (AEs), disease progression, and death (8.3% each). Overall, 41.7% of pts had dose modifications (AEs, 33.3%); 20.8% had interruptions (all due to AEs). Median exposure time to RUX was 25.8 mg/d (SD, 10.1) and was comparable to those (33.2 and 23.3 mg/d) of patients starting at higher doses (20 and 15 mg bid).

The most common hematologic grade 3/4 AEs were anemia (27.1%; overall, 34.1%) and thrombocytopenia (14.6%; overall, 16.3%). Hb and PLT dynamics were also similar. AEs (all-grade [grade 3/4]) in >10% of pts included pyrexia (14.6% [4.2%]), asthenia (12.5% [0%]), weight increase (12.5% [0%]), abdominal pain (10.4% [0%]), headache (10.4% [2.1%]), and peripheral edema (10.4% [0%]). Infections in >2 pts included herpes zoster (8.3%), gastroenteritis, nasopharyngitis, and septic shock (6.2% each). At wk 24, 69.9% of pts (14/23) had a ≥50% reduction from baseline in spleen length and 26.1% (6/23) had ≥50% reductions; rates were similar at wk 48 (58.3% [7/12] and 25.0% [3/12]). Most pts (56.3%) achieved a ≥50% reduction at any time. Pts also experienced significant improvements in symptoms. From wk 4 to 48, 43%-59% (3/12) experienced significant improvements in symptoms.

Summary/Conclusions: A small cohort of pts in JUMP started at 10 mg bid, and had the dose uptitrated during the first 8 wk to a mean average daily dose comparable to those of pts starting at higher doses, leading to safety and efficacy outcomes consistent with those in the overall JUMP population. This alternative approach will be prospectively evaluated in anemic MF pts in the REALISE study (NCT029666353).

E1335

HYDROXYUREA IS ASSOCIATED WITH SKIN TOXICITY IN MYELOPROLIFERATIVE NEOPLASMS: RESULTS FROM A PROSPECTIVE NON-INTERVENTIONAL STUDY

F. Stegelmann1,2, K. Wille3, S. Schauer1, H. Döhner1, M. Griesshammer2,3

1University of Heidelberg, Ulm, 2University of Bochum, Minden, Germany

Background: Until today, hydroxyurea (HU) remains the most commonly used cytoreductive drug in patients (pts) with classic myeloproliferative neoplasms (MPN), i.e. essential thrombocythemia (ET), polycythemia vera (PV), and myelofibrosis (MF). However, mucosal lesions, cutaneous ulcers, and pre-carcinomatous skin alterations such as actinic keratoses are being considered as potential side effects of HU.

Aims: We sought to investigate the occurrence of skin toxicity in MPN pts under HU compared to other (non-HU) cytoreductive drugs in routine clinical practice.

Methods: Classic MPN pts regularly presenting at the outpatient centers of the University Hospital of Ulm and Johannes Wesling Clinic Minden were included in our non-interventional study after having given informed consent. Skin alterations were evaluated prospectively between December 2010 and November 2016.

Results: In total, 151 MPN pts under cytoreductive therapy were included (ET, n=55; PV, n=55; MF, n=41). Primary MPN diagnosis was made between 1979 and 2012 at a median age of 55 years (range, 22-82). Median duration of the disease at the baseline of the study was 6.3 years (0-32.6). Median prospective observation time for the total cohort within the study period was 5.3 years (0.4-6.2). Most frequently used cytoreductive drugs were HU in 120 pts, followed by ruxolitinib in 59, anagrelide in 39, and pegylated Interferon-alpha (IFN-a) in 28 pts. Median cumulative HU exposure was 46 months (1-252), while the median cumulative treatment time for the corresponding drug was 24 months (1-267) [ruxolitinib: 22 months (2-64); anagrelide: 19 months (1-216); IFN-a: 64 months (1-267)]. Of 120 pts exposed to HU, 52 pts (43%) presented with skin abnormalities during the observational period occurring after a total HU treatment time of median 46 months (1-252). Sixteen of 120 pts (13%) discontinued HU due to skin toxicity (basal cell carcinoma, n=3; malignant melanoma, n=1). Although pts of the HU cohort were exposed longer to the drug compared to pts of the non-HU group, numbers of skin events in non-HU treated pts were as following: n=5 under IFN-a (local reaction after subcutaneous injection, n=3; actinic keratoses, n=3), dry skin / xerostomia (n=2). Of note, four malignant skin diseases were reported under HU therapy (basal cell carcinoma, n=3; malignant melanoma, n=1). All pts of the HU cohort were exposed longer to the drug compared to pts of the non-HU group, numbers of skin events in non-HU treated pts were as following: n=5 under IFN-a (local reaction after subcutaneous injection, n=3; actinic keratoses, n=1), and none under ruxolitinib. In 3/126 (2%) non-HU treated pts, occurrence of skin toxicity led to discontinuation of the corresponding cytoreductive drug. Interestingly, both skin ulcers as well as the single events ‘basal cell carcinoma’ and ‘actinic keratosis’ occurred under combination therapy with HU. Taken together, skin alterations occurred more frequently under HU compared to non-HU treatment (52/120 [43%] vs 9/126 [7%]; p=0.0001), and the same was true for treatment discontinuations due to skin toxicity (16/120 [13%] vs 3/126 [2%]; p=0.014).

Summary/Conclusions: According to our prospective observation, skin toxicity was clearly associated with HU treatment compared to other cytoreductive drugs. This resulted in a higher rate of HU treatment termination due to skin toxicity. However, median exposure time to HU was clearly associated with HU treatment compared to other cytoreductive drugs.

E1336

THE NEGATIVE PROGNOSTIC IMPACT OF BASOPHILIA, EOSINOPHILIA AND MONOCYTOSIS AT DIAGNOSIS IN PRIMARY MYELOFIBROSIS

M. Pardina1,2, K. Hundraova2, J. Carda2, E. Cortesão2, R. Guilherme1,2, L. Ribeiro1,2

1Clinical Hematology Department, Coimbra University Hospital Centre, 2Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Primary myelofibrosis (PMF) is a myeloproliferative neoplasm (MPN) with a variable clinical presentation, from asymptomatic disease to rapidly progressive bone marrow failure and/or leukemic transformation; prognostic stratification using the DIPSS-plus score isolates patient cohorts with median survival ranging from 16 months to 185 months. The development of monocytosis during the course of PMF has been associated with a worse outcome, and absolute monocyte counts have been shown to be of prognostic value in other MPNs. Basophilia and eosinophilia are frequent findings in BCR-ABL-...
negative. Median age at BP was 71.3 years (range 46.3-86), being higher in PV (median 73 years, range 46.3-84.7) compared to ET (median 66.8 years, range 54.4-86, P = 0.0318) and PMF (median 67.9 years, range 48.1-84.9, P = 0.016). The complete blood count at leukemic evolution was not influenced by the initial diagnosis. At the time of BP, 31 out of 44 patients (70%) for whom cytogenetic analysis was available showed an abnormal karyotype (22 patients with complex karyotype or high risk aberrations). JAK2 mutated MPN can evolve into JAK2 wild type AML (9 of 28 patient with blasts DNA available), while CALR mutation was identified also in AML blasts in all 6 patients for which DNA was available. Time to leukemic evolution was shorter in PMF (35.3 months, range 3.6-141.1) compared to ET (176.7 months, range 14.4-362.3, P <0.001) and PV (129.1 months, range 17-367.8, P<0.001). According to chronic phase driver mutation, time to leukemic evolution was shorter in JAK2 V617F mutated PMF compared to CALR mutated PMF (30.6 vs 138 months, P =0.024), but not statistically different in JAK2 mutated ET compared to CALR mutated ET (123.4 vs 203.2 months, P =0.121). Outcome was dismal, independently from the diagnosis at BP: overall survival (OS) in PMF patients with monocytosis was 27.3 months, and for patients with eosinophilia the OS was 28.5 months, compared to 46.4 months for patients under the cut-off. Considering the whole cohort, 61.8% of patients had normal monocytosis, eosinophil and basophil ACs; the median OS in these patients was 56.1 months, compared to 28.5 months in patients with an increase in at least one AC. Applying the new cut-off, this difference in OS increased to 27.9 vs 64.4 months. Progression-free survivals were not calculated, since only 2 patients had BM- or PB-documented progression during follow-up.

Summary/Conclusions: We observed that the presence of monocytosis at diagnosis in PMF was associated with a halving of the median OS, while eosinophilia decreased the median survival to one-fifth; basophilia also associated with a reduction in survival, of approximately 20%. The application of specific cut-offs calculated for the cohort improved the differentiation and stratification of patients, with moderate to high specificity, further clarifying the negative prognostic impact of these three variables, at diagnosis, in PMF. Our results show that even simple, inexpensive and readily available parameters can be used to predict survival in PMF patients, and suggest that their integration into established scores could further increase the prognostic accuracy of the latter.

E1337 BLAST PHASE IN PH-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS: A SINGLE INSTITUTION RETROSPECTIVE ANALYSIS OF 85 PATIENTS

E. Roncoroni1,2, M. Bellini1, E. Rumil1, V. Ferretti1, D. Pietra1, C. Cavalloni1, M. Ciboddo2, I. Casetti1, P. Zappasodi1, P. Benvenuti1, C. Astoni1, M. Cazzola1,2
1Department of Hematology Oncology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; 2Department of Molecular Medicine, University of Pavia, Pavia, Italy

Background: Classic Ph-negative myeloproliferative neoplasms (MPN) include essential thrombocythemia (ET), polycythemia vera (PV) and primary myelofibrosis (PMF). Chronic evolution can lead MPN patients in chronic phase (CP) to develop acute myeloid leukemia (AML), called blast phase (BP); this event occurs at rates of approximately 1% in ET, 4% in PV and 20% in PMF over the first decade from MPN diagnosis.

Aims: To evaluate differences in clinical features and outcome in 85 patients with Ph-negative BP who presented with monocytosis (AC >0.75 G/L), basophilia (AC >0.2 G/L) and eosinophilia (AC>0.6 G/L) in BM and peripheral blood (PB) analyses dating from the time of diagnosis, and have complete charts with no missing data. After the exclusion of reactive causes, monocytosis was defined as an absolute count (AC) >1.0 G/L, eosinophilia as an AC >0.6 G/L and basophilia as an AC >0.2 G/L.

Results: We studied 55 evaluable patients (73% male) with a median age at diagnosis of 70.1±11.7 years old. At diagnosis, 20% of patients had monocytosis, with no significant differences according to gender or age. The median overall survival (OS) in PMN patients with monocytosis was 27.3 months, and two-thirds of these patients with monocytosis had a cut-off of 0.75 G/L. The reason of death was not available, but they presented with Ph-negative MPN. The median survival in Ph-negative ET patients of whom 15 presented with Ph-negative MPN was 85 months who progressed to BP, with a known monocytosis cut-off of 0.75 G/L. Patients with monocytosis had a median OS of 27.9 months, compared to 64.4 months for patients under the cut-off. We identified 12.7% of patients with eosinophilia at diagnosis, with no differences according to gender or age. PMF patients with eosinophilia had a five-fold lower median OS compared with patients without (6.1 vs 32.5 months, respectively). We obtained a new cut-off of 0.25 G/L of eosinophils, which separated patients with a specificity of 77.8% (95% CI: 57.7-91.4%), 29.1% of patients had an eosinophil AC above the cut-off, with a median OS of 17.3 months, compared to 43.8 months for patients under the cut-off. A total of 30.9% of patients had basophilia at diagnosis, with no differences according to gender or age. The median OS in patients with basophilia was 25.6 months, and 32.5 months in patients without. With a new cut-off of 0.25 G/L of basophil, with a specificity of 88.9% (95% CI: 70.8-97.6%), 20.0% of patients had an AC above the cut-off and a median OS of 19.7 months, compared to 46.4 months for patients under the cut-off. Considering the whole cohort, 61.8% of patients had normal monocytosis, eosinophil and basophil ACs; the median OS in these patients was 56.1 months, compared to 28.5 months in patients with an increase in at least one AC. Applying the new cut-off, this difference in OS increased to 27.9 vs 64.4 months. Progression-free survivals were not calculated, since only 2 patients had BM- or PB-documented progression during follow-up.

Summary/Conclusions: We observed that the presence of monocytosis at diagnosis in PMF was associated with a halving of the median OS, while eosinophilia decreased the median survival to one-fifth; basophilia also associated with a reduction in survival, of approximately 20%. The application of specific cut-offs calculated for the cohort improved the differentiation and stratification of patients, with moderate to high specificity, further clarifying the negative prognostic impact of these three variables, at diagnosis, in PMF. Our results show that even simple, inexpensive and readily available parameters can be used to predict survival in PMF patients, and suggest that their integration into established scores could further increase the prognostic accuracy of the latter.

E1338 TELOMERE LENGTH IS REDUCED IN ESSENTIAL THROMBOCYTHAEMIA PATIENTS COMPARED TO AGE AND GENDER MATCHED HEALTHY CONTROLS

S. Alliman1, J. Jie2, D. McLornan2, D. Radia1, G. Muffs2, C. Harrison1
1Haematology, Guys and St Thomas’ NHS Foundation Trust, 2Haematology, King’s College London, London, United Kingdom

Background: Essential thrombocythaemia (ET) is a clonal stem cell disorder, commonly diagnosed in the 6th or 7th decade of life. ET is associated with risk of thromboembolic events, hemorrhage, constitutional symptoms, progression to myelofibrosis and acute myeloid leukemia. In over 85% of patients a clonal driver can be identified with mutations in JAK2 (50-60%), Caletriculin (CALR) (25-30%) or the thrombopoietin receptor (MPL) (3-5%); the remainder of patients are termed "triple negative" (TN). Telomeres are non-coding regions of DNA consisting of thousands of repeated sequences (TTAGGG) and are considered central to chromosomal integrity and genomic stability. In healthy adults, telomere length (TL) progressively shortens with age; therefore, TL is considered as a marker of aging and genomic stability. Telomerase activity in several hematological malignancies have been shown to be characterized by shortened TL.

Aims: Determine if there is TL shortening in patients with ET when compared to age and gender matched controls and establish the effects of cyto-reductive treatment.

Methods: 100 patients were included in the study (27 with CALR, 35 JAK2V617F and two MPL515W mutations. 36 patients were TN). Most patients were female (70% 70/100); median age was 45 years (range 20 - 86 years).
Background: Nutritional status declines in most patients with myelofibrosis (MF). Sixty-seven percent of patients with MF lose weight over time and 27% of patients have a BMI decrease of at least one body mass index (BMI) category vs healthy controls, have shortened TL. This shortening is more pronounced in HC treated patients indicating that there may be a therapy effect as has been observed after HC treatment in sickle cell disease. Of note IFN treated patients had more normal TL suggesting that the disease related TL effects may be reversed by this agent.

E1339
NUTRITION IN MYELOFIBROSIS: CORRELATES FROM THE COMFORT-1 STUDY
R. Scherber1,2,*, H. Kosiorek3, H. Geyer4, S. Verstovsek5, B. Langlais6, L. Padmos1, J. Palmer1, A. Dueck3, A. Fleischman6, R. Mesa1
Hematology and Oncology, Mayo Clinic, Scottsdale, Arizona, 2Department of Hematology, Medical College of Wisconsin, Milwaukee, Wisconsin, 3Department of Hematology, Arizona HealthCare, Phoenix, Arizona, 4Department of Hematology, University of California Irvine, Irvine, California, United States

Methods: Data from the COMFORT-1 trial of ruxolitinib versus placebo was obtained from the Incyte for independent analysis. Data was analyzed for correlations with symptom burden and survival along with other variables. Symptom burden was assessed by the MF-SAF v2.0 (Mesa et al. Blood 2008;112(11):5224). MF also leads to deficient LDL and cholesterol levels compared to age matched controls (Mesa R A et al. Blood 2007;110(11):2548). Both hypocholesterolemia (p<0.001) and weight loss>10% (p=0.001) have been associated with decreased survival in PMF patients (Mesa et al. Blood 2009 114:3918). JAK inhibitor therapy has been found to improve nutritional markers including weight, cholesterol, albumin, and leptin compared to placebo in the COMFORT-1 study (Mesa et al. Clin Lymphoma Myeloma Leuk. 2015 Apr; 15(4): 214–221; Verstovsek et al. N Engl J Med 2012; 366:799-807). However, the correlation of these factors with other disease related variables and overall survival has not been established.

Aims: To evaluate the correlation, if any, between nutritional markers other variables collected in the COMFORT-1 study.

Methods: From the COMFORT-1 trial of ruxolitinib versus placebo cohort; for the 18 patients, whose TL was below the first centile, 55% (10/18) were CALR positive, p=0.0009; JAK2V617F positive patients (8/18) had prior exposure to HC; 34/100 were not on cytoreductive therapy. Remaining treatments were ruxolitinib (5), busulphan (4), andanagrelide (1) and vorinostat (1). Independent of mutational status there was significant TL shortening in untreated patients, p=0.05; however, upon evaluating the impact of cytoreductive therapy on TL we noted that ET patients currently on IFN but with either current or prior exposure had significantly shortened TL, p= 0.0015 and p=0.0001 respectively. Strikingly, there was no significant difference in TL in IFN patients who had no previous exposure to HC, p=0.2 but those ET patients currently on IFN but with prior HC exposure still had shortened TL.

Summary/Conclusions: We document for the first time that ET patients, when compared to age and gender matched healthy controls, have shortened TL. This shortening is more pronounced in CALR and JAK2V617F positive patients. Concerning therapy whilst present in untreated patients TL shortening was more pronounced in HC treated patients indicating that there may be a therapy effect as has been observed after HC treatment in sickle cell disease. Of note IFN treated patients had more normal TL suggesting that the disease related TL effects may be reversed by this agent.

E1340

Background: To evaluate the prognosis of patients with Essential Thrombocytemia (ET) the first decade of the century we assessed retrospectively the thrombosis free survival (TFS) and the overall survival (OS) of the patients diagnosed from 01/01/2000 to 31/12/2009 and collected on the database of our group. Aims: Diagnosis of ET was performed with PVSG, WHO 2001 or 2008 criteria, according to the date of the first observation. The whole population of 757 patients was then divided in two groups: the first (group I) with the diagnosis performed between 01/01/2000 to 31/12/2005 (334 patients), presented a median follow-up of 111.9 months, the second (group II) diagnosed between...
01/01/2006 to 31/12/2009 (385 patients), with a median follow-up of 58.2 months.

**Methods:** The characteristics of two groups of patients are reported in the Table 1. No differences could be found between the two groups according age, gender, platelet and WBC count and Hb level, Cardio-Vascular Risk Factors (CVRF), spleen enlargement and the occurrence of previous thrombotic events. The frequency of the JAK-2 V617F mutation resulted significantly different (49.1% vs 68.4%) but in the group I the search of the mutation was never performed at the diagnosis. TFS and OS were calculated from the date of diagnosis of ET to the date of event with Kaplan-Meier product limit method; the comparison of proportions and median values was computed with the Chi-squared and the Mann-Withney tests, as indicated.

**Results:** No significant differences emerged neither for TFS (p = 0.09, HR 1.42, 95% C.I. 0.89-2.30) nor for OS (p = 0.15, HR 1.34, 95% C.I. 0.87-2.06). We also evaluated the type of treatment used in the two groups to assess the potential link between the therapy and TFS or OS (Table 2). No difference emerged between the two groups as for anti-aggregating (mainly ASA), equally utilized in both groups, 287/369, 77.8%, and 330/383, 78.3%, respectively (p = 0.95). As for the cytodestructive therapy, Hydroxyurea was used in 74.8% vs 67.9% (p = 0.60) and alkylating agents in 1.9% vs 2.1% (p = 0.85), whereas the Anagrelide resulted utilized in 10.6% vs 3.9% (p = 0.001) and Interferon in 9.5% vs 5.2% (p = 0.037), respectively. The more frequent use of Anagrelide and Interferon in the first group (2000-2005) didn’t modify the prognosis (as for TFS and OS) of the patients.

**Summary/Conclusions:** Unfortunately, no improvement, neither as the TFS nor the OS was observed (Fig. 1 and 2): more efforts to better identify the groups at risk and, hopely, the introduction of new drugs as JAK-2 inhibitors could change the prognosis of ET patients.

**E1341**

**CUTANEOUS INVOLVEMENT IN PHILADELPHIA-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS—SINGLE-CENTER EXPERIENCE**

J. M. Sanchez-Raga1,2,*, N. Knöpfel3, M.D.M. Escudero-Góngora3, F. Sartori2, B. Lopez1,2, I. Herraez2, M.D.C. Ballester2, M. Torres2, A. Martin-Santiago3, A. Sampol2, M.A. Durán2

1Hematology and Hemotherapy, Fundación de Investigación Sanitaria de las Islas Baleares Ramon Llull, 2Hematology and Hemotherapy, 3Dermatology, Hospital Universitari Son Espases, Palma de Mallorca, Spain

**Background:** Philadelphia-negative chronic myeloproliferative neoplasms (MPNs) may present clinical dermatological manifestations at the time of diagnosis, as well as during the course of the disease. On the other hand, also its treatments can present skin side effects.

**Aims:** We have performed a dermatological review of a cohort of patients we follow-up at our center with the aim of assessing the cutaneous manifestations.

**Methods:** A randomized selection of patients with a diagnosis of essential thrombocythemia and polycythemia vera was performed. We create a specific consultation in which a detailed history of each patient (sex, age, diagnosis, signs and symptoms, treatments and its duration) as well as a deep dermatological examination was done. All data was collected in an Excel database and analyzed using the SPSS system.

**Results:** 63 patients (54 ET and 9 VP) were reviewed. The most frequent skin lesions were xerosis and/or keratosis pilaris (76.2% patients), nail changes (41.3%), actinic keratosis (39.7%), hyperpigmentation of the skin (23.8%), pruritus (23.8%) and non-melanoma skin cancer (22.2%). In figure 1 we detail all the skin alterations that we have found.

**Summary/Conclusions:** Cutaneous involvement in MPNs is more frequent than expected and it is usually underdiagnosed. Some of these lesions could be prevented with the correct treatment of their pathology and adequate photoprotection measures. The results obtained support the recommendation of an annual review by a dermatologist in a systematic way, especially in patients with higher risk factors: low phototype, high sun exposure, past dermatological history and prolonged cytodestructive therapy.

**HEMOGLOBIN AND WHITE CELL COUNT IN PATIENTS CLINICALLY SUSPECTED TO HAVE ESSENTIAL THROMBOCYTHEMIA MAY HELP IN PREDICTING EARLY PRIMARY MYELOFIROSIS OR UNCLASSIFIABLE MYELOPROLIFERATIVE NEOPLASM**

S. Sirhan1,*, C. Ross2, A. Oraz2

1Jewish General Hospital Montréal, Montreal, 2McMaster University, Hamilton, Canada, 3Weill Cornell Medical College, New York, United States

**Background:** Classification of myeloproliferative neoplasms (MPN) in patients presenting with thrombocytosis can be challenging. Relying only on clinical features may lead to misclassification of patients in the early stages of primary myelofibrosis (PMF) as essential thrombocythemia (ET). Although bone marrow (BM) biopsy examination is the gold standard necessary for accurate classification, in clinical practice it might be helpful to identify among patients with a working diagnosis of ET those most likely to have early PMF or unclassifiable MPN (MPN-U). To this end, Carobbio et al. (Am J Hematol. 2012;87:203-4) developed a simple algorithm based on presence of anemia (hemoglobin <120 g/L for females and <130g/L males) and/or leukocytosis (leukocytes ≥13×10^9/L) or elevated LDH (>200 mU/mL). For an accurate classification of the clinical and laboratory features need to be correlated with BM findings, thus collaboration between hematologists and pathologists is essential.

**Aims:** To examine applicability of the Carobbio algorithm in routine practice and its potential use in identifying among patients presenting with thrombocytosis and clinically suspected to have ET, those with early PMF or MPN-U. To identify unfit needs in the diagnosis of MPNs in daily practice upon which further educational initiatives can be built which stress the importance of hematologist-pathologist collaboration.
presentation with thrombocytosis. No central pathology review was planned for this stage of the study.

Results: A total of 122 patients (58 males and 64 females; 54% >60 years of age; 65% with LDH ≥200 mU/mL) with a clinical history indicative of ET were initially assessed. A majority of patients (76%) presented with suspected ET within the last 5 years, likely because it was more difficult for clinicians to identify patients with SM by biopsy collected within a year of presentation with thrombocytosis if they presented more than 5 years ago. Out of 122 patients, 48 met the hemoglobin and/or leukocyte criteria outlined in the Carobbio algorithm, Figure. The BM examination was performed on 33 patients who met pre-specified criteria for the timing of bone marrow biopsy. About one third of the 33 patients were not classified for ET or one third for PMF. While 2 of the remaining patients met criteria for PV, the rest were uncertain whether to represent true ET or early PMF, i.e. represented MPN-U (Figure 1).

Summary/Conclusions: Despite its methodological limitations, this initiative confirms that in real world clinical practice the Carobbio algorithm can be used to identify patients with early PMF and MPN unclassifiable among clinical scenarios currently suspected to have ET. It suggests a need for educational initiatives on using diagnostic algorithms to separate ET from PMF. It confirms the importance of hematologist-pathologist collaboration in reaching a final integrated diagnosis based on the WHO classification. These findings warrant further investigation in larger prospective studies.

E1343
PK/PD MODELING COMPARING DIVIDED DOSING (200mg TWICE-DAILY [BID]) VS SINGLE DOSING (400mg ONCE-DAILY [QD]) OF PACRITINIB (PAC) IN PATIENTS WITH MYELOFIBROSIS (MF) ON THE PERSIST-2 PHASE II STUDY

1CTI BioPharma Corp., Seattle, WA, 2Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, 3University of Michigan, Comprehensive Cancer Center, Ann Arbor, MI, 4Cleveland Clinic, Cleveland, OH, 5Northwestern University, Feinberg School of Medicine, Chicago, IL, United States, 6Princess Margaret Cancer Center, University of Toronto, Toronto, Canada, 7Albany Medical Center, Albany, NY, 8Beatson West of Scotland Cancer Centre, Glasgow, United Kingdom, 9Ryanz’s Clinical Hospital, Ryzan, Russian Federation, 10Stanford Cancer Institute, Stanford, CA, 11University of California-San Diego, La Jolla, CA, United States, 12Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom, 13Mayo Clinic, Scottsdale, AZ, 14MD Anderson Cancer Center, Houston, TX, United States

Background: MF is a life-threatening hematologic malignancy characterized by splenomegaly and debilitating constitutional symptoms. At the present, the JAK1/2 inhibitors ruxolitinib, only therapeutic option (pts) with hematologic response, has garnered regulatory approval. Although ruxolitinib has been shown to reduce splenomegaly and symptoms in pts with MF, it is associated with dose-limiting cytopenias, and not indicated for pts with platelets <50,000/µL. PAC is an oral kinase inhibitor with specificity for JAK2, FLT3, IRAK1, and CSF1R. Using data from prospective, open-label studies, population PK modeling and simulations predicted that BID dosing would result in higher steady-state AUC and lower Cmax from early-phase PAC studies, population PK modeling and simulations predicted that BID dosing would result in higher steady-state AUC and lower Cmax from early-phase PAC studies, population PK modeling and simulations predicted that BID dosing would result in higher steady-state AUC and lower Cmax from steady-state PAC trials.

Methods: In total, PK samples were collected up to week 24 from 144 PAC-pts for PK analysis only at weeks 12 and 24 (pre-dose). At the remaining sites, blood samples were collected from PAC-treated pts for PK and PD analysis at a prespecified subset of trial sites. Blood samples were collected on day 1 of week 1 (4 h post-dose), week 3 (pre-dose and 4 h post-dose), week 12 (pre-dose), and week 24 (pre-dose). At the remaining sites, blood samples were collected from PAC-treated pts for PK analysis only at weeks 12 and 24 (pre-dose).

Results: Blood samples were collected up week 24 from 144 PAC-treated pts (78 BID, 64 QD). The PK of PAC was described by a 2-compartment model with first order absorption, first order elimination from the central compartment, and an absorption lag time. PAC QD was associated with higher Cmax and lower Cmin vs PAC BID (Table). Median PAC plasma concentrations during weeks 12 to 24 with QD were similar to those with BID, whereas Cmin (Cminss) at weeks 12 and 24 were higher vs QD dosing by 10% and 15%, respectively. Also, median observed steady-state 4h concentration at week 3 (coincides with Cminss) was 12% higher with QD vs BID dosing.

Summary/Conclusions: As predicted by PK modeling and simulations analyzing PAC 400mg QD was associated with higher Cmax and lower Cmin vs PAC 200mg BID in pts with MF from the PERSIST-2 trial. These differences appear to translate into an improved benefit/risk profile of PAC BID vs QD regimens.

E1344
ZMYM2-FLT3 IS A RARE, RECURRENT, CYTOGENICALLY CRYPTIC FUSION IN MYELOID/LYMPHOID NEOPLASMS WITH EOSINOPHILIA THAT IS RESPONSIVE TO FLT3 INHIBITION

M. Jawhar1, N. Naumann1, M. Knut2, B. Schneider3, M. Ghazzawi4, K.-A. Kreuzer5, M. Hallek5, A. Fabarius1, J. Score6, A. Chase2, W. Tapper7, A. Reiter8, N. Cross9

1Department of Hematology and Oncology, Medical Faculty Mannheim of University of Heidelberg, Mannheim, Germany, 2Faculty of Medicine, University of Southampton, Southampton, United Kingdom, 3Department I of Internal Medicine, University Hospital of Cologne, Cologne, Germany

Background: Myeloid/lymphoid neoplasms with eosinophilia are characterised by diverse tyrosine kinase (TK) fusion genes, many of which can be effectively targeted by small molecule inhibitors. More than 70 TK fusions have been described, most of which are associated with visible cytogenetic abnormalities. However these fusions are rare, and the pathogenesis of the great majority of myeloid/lymphoid neoplasms with eosinophilia (MPN-eo) remains unexplained. We hypothesized that some MPN-eo cases may be driven by hitherto undetected cryptic TK fusion genes.

Methods: To screen cases with MPN-eo for TK fusion genes and evaluate the significance of any novel fusions

Results: Of 20 cases tested by RNAseq analysis, just one cryptic TK fusion was identified: ZMYM2-FLT3, predicted to arise as a consequence of an 8Mb inversion at 13q12. Unusually, both breakpoints fell within exons (ZMYM2 exon 20 and FLT3 exon 14, respectively) resulting in an in frame fusion. To test whether this might be recurrent, we analysed 105 additional cases by RT-PCR. One additional positive case was detected, with similar but not identical breakpoints to the initial case. Case 1, a 48 year old female, presented with leucocytosis (30x10^9/L), eosinophilia (2x10^9/L), elevated serum tryptase (37µg/l), splenomegaly and a hypercellular bone marrow (BM). Cyto genetics was normal and FIP1L1-PDGFRα, KIT D816V and JAK2 V617F were all negative. Subsequent FISH analysis identified a normal karyotype, and no pathogenetically relevant mutations were identified by a myeloid NGS panel (28 genes). After 10 months, she progressed to myeloid blast phase. Therefore the disease was resistant to AML-induction chemotherapy (FLAG-Ida), an allo-HSCT was performed. At 12 months after allogeneic PBSCT. The ZMYM2-FLT3 fusion gene was identified post mortem. Case 2, a 47 year old male, presented with eosinophilia (4.7x10^9/L), 47% elevated serum tryptase (42µg/l) and a hypercellular BM. Cyto genetics was normal and FIP1L1-PDGFRα, KIT D816V and JAK2 V617F were all negative. There was no response on steroids or hydroxyurea. Following the finding of ZMYM2-FLT3 positivity, treatment with sunitinib was commenced. Blood counts started to improve from day 4 and normalized after 3 weeks. During a pause of 3 weeks due to pulmonary infection, leukocytes/eosinophils rapidly increased, but normalized again within weeks after restart of sunitinib. The patient has been maintained on sunitinib for 10 months (since re-start) and remains in complete hematologic remission.

Summary/Conclusions: ZMYM2 is the fourth gene reported to fuse to FLT3 in myeloid neoplasms but the first FLT3 fusion that is cytogenetically cryptic. Given ZMYM2-FLT3 is a rare, recurrent fusion in myeloid neoplasms with eosinophilia that is potentially responsive to FLT3 inhibition, these findings will become the method of choice to detect rare TK fusions.
**E1345**

**COMPLETE HEMATOLOGIC AND CYTODERGIC RESPONSE IN A PATIENT WITH FIBROBLAST GROWTH FACTOR RECEPTOR 1 ACTIVATED MYELOPROLIFERATIVE NEOPLASM RECEIVING INCB054828**

N. Dallaire,1 E. Orofino,2 A. Iurlo2

1MD Anderson Cancer Center, Houston, TX, United States, 2Incyte Europe, Geneva, Switzerland

Background: Fibroblast Growth Factor Receptor (FGFR) inhibitors have demonstrated efficacy in solid tumors with FGFR pathway activation. INCB054828, a novel, highly selective FGFR1, FGFR2, and FGFR3 inhibitor, is being assessed for the treatment of several advanced malignancies (AACR 2015; Abstract 77). 8p11 myeloproliferative syndrome is an aggressive myeloproliferative neoplasm (MPN) associated with FGFR1 translocation on chromosomes 8p11.

Aims: To describe the characteristics of a patient with FGFR1 activated MPN who achieved a complete hematologic and cytogenetic response with INCB054828 in an ongoing phase 1/2 trial (NCT02393248).

Methods: In this 3-part, phase 1 dose-escalation and expansion trial, eligible adults had any advanced solid tumor (parts 1 and 3) or malignancy with FGFRs/FGFR alteration (part 2). Patients had Eastern Cooperative Oncology Group performance status score ≤1 (part 1) or ≤2 (parts 2 and 3), and were refractory to prior therapy with no known effective standard therapy available to them. Patients received INCB054828 orally on a 21-day cycle (2-weeks on/1-week off) starting at 9mg QD and increasing to 13.5mg QD.

Results: This 51-year-old male patient with 8p11 translocated MPN diagnosis (currently the only patient with MPN enrolled in this trial), presented with abnormal white blood cell (WBC) count (eosinophils, 15%; peripheral blood [PB] blasts, 4%) and abnormal platelet count (68 x 10^9/L). The patient had prior therapy with hydroxyurea. Bone marrow (BM) biopsy at study entry showed 95% cellular marrow, 5% damaged megakaryocytes (8/9,11/2,0,13) in 15% of 20 metaphases, and European Myelofibrosis Network grade MF-1. After 6 weeks of treatment with INCB054828 at a dose of 9mg QD in part 2 of the study, WBC count normalized with disappearance of eosinophilia and PB blasts. BM biopsy demonstrated a normalization of bone marrow differential with 50% cellularity, 1% BM blasts, adequate trilineage hematopoiesis, MF-1 fibrosis, and a complete cytogenetic response. After 4 months of treatment the patient was hospitalized for pneumonia and study treatment was held. The patient progressed to AML shortly after therapy interruption, with BM blasts increasing to 83% and evidence of clonal evolution (47,XY:+8,8(9,11;2;33) [3]/48 idem, +19 [17]). The patient was taken off study at this time (end of cycle 6) and subsequently achieved a complete remission on intensive chemotherapy with fludarabine, cytarabine, idarubicin, and allogeneic BM transplantation. The patient is currently alive and in complete remission.

Summary/Conclusions: INCB054828 showed efficacy in this patient with FGFR1 activated MPN using a 21-day (2-weeks on/1-week off) regimen. Continuous treatment may be necessary to sustain response and avoid rebound as has been seen with other kinase inhibitor therapies. A phase 2 trial has been initiated to evaluate INCB054828 in patients with myeloid/lymphoid neoplasms with FGFR1 rearrangement (NCT03011372).

**E1346**

**THE GRADE OF STROMAL CHANGES IMPACTS ON PROGNOSIS IN PATIENTS WITH PRIMARY MYELOFIBROSIS**

U. Gianelli1,2, S. Fiori1,2, D. Cattaneo2, A. Bossi3, I. Cortinovis3, C. Bucelli2, N. Orofino2, A. Iurlo2

1Division of Pathology, IRCCS Ca’ Granda - Maggiore Policlinico Hospital Foundation and University of Milan, 2Oncohematology Division, IRCCS Ca’ Granda Maggiore Policlinico Hospital Foundation, 3Department of Clinical Sciences and Community Health, University of Milan, Milano, Italy

Background: Recently, a detailed grading system for the assessment of bone marrow stromal changes has been proposed in primary myelofibrosis, proved as follows: bone marrow fibrosis: MF-0 in 9 cases, MF-1 in 60, MF-2 in 31 and MF-3 in 22; collagen deposition: Co-0 in 64 cases, Co-1 in 23, Co-2 in 21 and Co-3 in 14; osteosclerosis: Ost-0 in 72 cases, Ost-1 in 24, Ost-2 in 19 and Ost-3 in 7. Patients’ population was composed of 56 males and 66 females (MF-0=1/2) with a median age at diagnosis of 68 years (range 30-85). Clinically, at presentation, anemia was always present in 20 (16%) patients, leukocytosis more than 25 x10^9/L was identifiable in 4 (3%) patients, and platelets count less than 100 x10^9/L in 7 (6%) cases. AKT2617F mutation was detected in 81 cases (66%). Among the remaining 41 JAK2-negative patients, 4 and 27 carried MPL and CALR mutations, respectively; 10 out of 122 resulted “triple-negative”. According to the International Prognostic Scoring System, 38 cases were stratified as low risk, 51 as intermediate-1 risk, 21 as intermediate-2 risk, and the remaining 12 as high risk. By the time of the analysis, 21 (17%) patients had died: leukemic evolution occurred in 14 (11.5%) patients, whereas thrombotic or hemorrhagic events occurred in 25 (20.5%). Subsequently, a comprehensive grade of bone marrow stromal changes ranging from 0 to 9 allows us to distinguish 68 (72%) cases with low-grade stromal changes (total score: 0-4) and 34 (28%) with high-grade stromal changes (total score: 5-9). Clinically, patients with high-grade stromal changes presented more frequently with anemia, thrombocytopenia, leukocytosis, peripheral blood blasts and increased lactate dehydrogenase levels. The grade of bone marrow stromal changes resulted strictly associated with the International Prognostic Scoring System and the overall mortality (low-grade: 10 dead out of 88 vs high-grade: 11 dead patients out of 34; p=0.013). Finally, the grade of bone marrow stromal changes was effective in discriminating the overall survival of the patients with low-grade and high-grade stromal changes (Log-Rank test: p=0.0002).

Summary/Conclusions: A detailed evaluation of the bone marrow stromal changes has important prognostic implications and can be used at diagnosis in the clinical stratification of the patients affected by primary myelofibrosis. Further studies are needed to test if the prognostic significance of this grading system remains during the follow-up.

Background: Studies reveal that patients with inflammatory bowel disease (IBD) may have increased risk of haematological cancers. Moreover, Philadelphia negative chronic myeloproliferative neoplasms (MPNs) have previously been associated with autoimmune diseases, including IBD. Nevertheless, to our knowledge, the risk of IBD has not been investigated in patients with MPN.

Aims: We undertook a nationwide population-based matched cohort study, and estimated the risk of the MPN-IBD association.

Methods: We used valid Danish national registries, covering more than 5 million individuals, and included all patients diagnosed with either essential thrombocythemia (ET), polycythemia vera (PV), myelofibrosis (MF), or unclassifiable myeloproliferative neoplasm (MPN-U).

Results: INCB054828 showed efficacy in this patient with FGFR1 activated MPN using a 21-day (2-weeks on/1-week off) regimen. Continuous treatment may be necessary to sustain response and avoid rebound as has been seen with other kinase inhibitor therapies. A phase 2 trial has been initiated to evaluate INCB054828 in patients with myeloid/lymphoid neoplasms with FGFR1 rearrangement (NCT03011372).
ESSENTIAL THROMBOCYTHEMIA WITH AQUAGENIC PRURITUS: AN ENTITY WITH MORE AGRессIVE CLINICAL AND BIOLOGICAL PROFILE AT THE DIAGNOSIS AND A HIGH MORBIDITY DURING THE FOLLOW-UP
C. Le Gall-Ianotto1,2,*, R. Le Calloch3, L.-M. Mollard4, L. Misery1, J.-C. Ianotto4
1Service dermatologie, CHU Brest - Hôpital Augustin Morvan, 2Laboratory of interactions epithelium-neuropil, université of Brest, Brest, 3Service Hémato-
cologie, CHIC, Quimper, 4Service Hématologie, CHU Brest - Hôpital Augustin Morvan, Brest, France

Background: Polycythemia vera (PV) and essential thrombocythemia (ET) are Ph-negative myeloproliferative neoplasms in which arterial or venous thromboses and phenotypical evolutions (leukemia, myelofibrosis) are the most recurrent complications. Aqueagenic pruritus (AP), induced by water contact, is a typical symptom of PV. However, we showed recently that ET patients also suffered from AP with clinical characteristics quite different from those observed in PV patients. In 2008, the presence of AP was associated with a lower risk of arterial thrombosis in PV patients.

Aim: It seemed particularly interesting to analyse the clinical relevance and the prevalence of the presence of AP in ET patients for such a risk.

Methods: In this study, we used the OBENE observatory (Observatoire Brestois des Neoplasies myeloprolifératives), a register of MPN patients followed in our University Hospital in which biological and clinical data of 396 ET patients have been collected. This register was approved by a local ethical committee and registered in clinicaltrials.gov (NCT02897297). To avoid masked polycythemia Vera diagnostics, all JAK2 positive cases were tested for isotopic red mass cells if appropriate.

Results: Among the 396 ET patients, 42 (10.6%) suffered from AP. Interestingly, the median age at diagnosis of these patients was lower (51.6 vs 63.8%, p<0.0001). Furthermore, they presented more symptoms as erythrocytosis, hyperviscosity, constitutional symptoms and splenomegaly (p<0.01). ET patients with AP were more proliferative (more polycythemic but less thrombo-
cythemic, p<0.005), and were more difficult to treat (2.2 vs 1.1 treatment lines, p=0.005). Concerning the occurrence of thrombotic events (arterial or venous) at diagnosis, no significant difference between patients with or without AP was found. In contrast, the presence of AP induced an increase of throm-
bolic events during the follow-up (30.9 vs 17.2%, p=0.03). But surprisingly, these events appeared in the delayed timing. The arterial/venous rate of thrombosis was also different with 50/50 vs 2/3:1. Furthermore, we observed that about one-third of the patients with AP had phenotypic evolutions against 13.3% in the other group (p=0.0007); the most frequent evolutions were PV and secondary myelofibrosis (16.7 vs 5.4%, p=0.005 and 19 vs 4.8%, p=0.0003, respectively). Concerning the overall survival of the patients, we have noted that there was less death in the group with AP than without AP (11.9 vs 32.5%, p=0.006) in spite of a longer follow-up (12.1 vs 7.7 years, p=0.002).

Summary/Conclusions: AP is classically associated to PV. But we confirmed here that AP is also present in ET. Furthermore, ET patients suffering from AP were more proliferative, more symptomatic at diagnosis but also had higher risk of thromboses and phenotypic evolutions than ET without AP. Despite that these patients have a higher overall survival. So, the presence of AP in ET with ET characterizes patients with high risk of morbidity (thromboses, pheno-
typic evolutions).So as in PV, the presence of AP in ET patients at the time of diagnosis should be systematically identified.

ANAGRELIDE RESPONSE ACCORDING TO THE MOLECULAR PROFILE: SOMETHING TO CONCLUDE ON THE MECHANISM OF ACTION OF THE DRUG IN MYELOPROLIFERATIVE NEOPLASMS (MPN)?
M. Montero1, T. Knight1, M. Dominguez1, E. Camillo1, F. Marquez1, P. Guerreiro1, M. Suito1, A. Blum1, N. Alkadi1, J. González1, J. Falantes1, N. Rodriguez1, M. Martín1, I. Espigado1, J. Pérez-Simón1
1Haematology and haemotherapy Service, Hospital Universitario Virgen del Rocio, Sevilla, Spain

Background: Anagrelide is a useful drug in the control of thrombocytopathy in MPN. Although it is known that in therapeutic levels it primarily influences in the post-mitotic phase of megakaryocytic development interfering with its complete maturation, its mechanism of action is still unknown.

Aims: The progress in the diagnosis of MPN due to the discovery of driver mutations (JAK2, calreticulin and MPL) leads us in the present study to correlate them with the response to anagrelide in a group of patients treated with this drug, investigating the possible interference in the referred biological pathways.

Methods: The medical records of patients treated with anagrelide in our centre between 1993 and 2015 were studied. The median age was 49 years, with 19 patients older than 60 years. 83% were female and 17% were male. The diagnosis was initially carried out based on the WHO criteria 2008 and subsequently reviewed the medical records with the new criteria of 2016. A molecular study on peripheral blood samples was carried out using quantitative allelic-specific PCR techni-
quies for JAK2, qualitative for MPL (L515V mutation) and Sanger sequencing of exon 9 for calreticulin. Type 1 mutation was considered at 52 bp deletion and type 2 at 5 bp insertion. In all patients, the goal of anagrelide therapy was to control thrombocytopathy (platelet count below 600x10^9/L), with dosage within the range of efficacy and safety recommended in the datasheet. The results were analysed with the statistical software SPSS vs 15.0

Results: 80.5% of the patients were diagnosed with ET, 12.5% of PV, 3.5% of myelofibrosis and 3.3% of unclassifiable MPN. 59% of the patients had a V617F JAK2 mutation, with allelic load higher than 20% in 47.5% of the cases. 28.5% presented mutation in calreticulin; of which 50% were type 1 and 50% type 2. Only one patient had a mutation in MPL (2%), the remaining 6% being classified as “triple negative”. The median daily dose of anagrelide received was 1.5mg. 17.5% of the patients required more than 2mg for an adequate control, half of them being positive for mutations in calreticulin and the other 50% of the muta-
tion V617F JAK2 with allelic load higher than 20%. 26% of the patients received daily dose of 1mg, being 70% positive for the mutation V617FJAK2 with allelic load lower than 20%, although there were no statistically significant differences between the groups according to the mutational profile. 16% of patients dis-
tinued treatment due to toxicity, with the most common adverse effects being mild (headache and palpitations).

Summary/Conclusions: Patients requiring higher doses of anagrelide present mutations in calreticulin or JAK2 V617F allelic load higher than 20% and patients with lower allelic load having greater sensitivity to the drug, with no statistically significant differences. It is possible that the first situation is asso-
ciated with a greater pre-mitotic deregulation in the megakaryocyte where the drug does not interfere whereas the second one could be related to anagrelide interference through the JAK2 pathway in post mitotic maturation although larg-
er exploratory studies are required.

THE DELAYED DIAGNOSIS OF PHILADELPHIA-NEGATIVE MYELOPRO-
LIFERATIVE NEOPLASMS (MPN) IS COMMON AND RESULTS IN A HIGH INCIDENCE OF POTENTIALLY PREVENTABLE THROMBOTIC COMPLI-
CATIONS
C. Forsyth1,*, C. Tiley2, B. Wylie2, M. Dean2, T. Armytage2, K. Melville2
1Medicine, Wyong Hospital, Kanwal, 2Haematology, Gosford Hospital, Gosford, Australia

Background: Ph-negative MPNs are a heterogeneous group of stem cell derived, clonal bone marrow disorders characterised by increased production of mature blood cells. Patients with MPNs are at significantly increased risk of thrombotic and haemorrhagic complications which are a major cause of morbidity and mor-
tality. The early diagnosis and treatment of MPN may reduce the incidence of thrombotic complications and the associated morbidity and mortality.

Aims: We performed a study to determine if the delayed-diagnosis of MPN was common and the implications of any such delay.

Methods: The medical records of patients treated at our centre with a new diagnosis of MPN between January 2010 and June 2016 were audited. We determined the duration from first appearance of a full blood count (FBC) abnor-
mality consistent with the diagnosis of MPN until the time of formal diagnosis. The occurrence of any thrombotic or haemorrhagic complications during this time was recorded.

Results: 143 patients were diagnosed with MPN: 35 with polycythemia vera, 79 with essential thrombocythemia, 25 with primary myelofibrosis and 13 with MPN-unclassifiable. Patients with PV had a median time to diagnosis of 156 days (range 0-2650 days) and 26% had potentially preventable events. Patients with ET had median diagnosis delay of 823 days (range 0-8731 days) and 23% had potentially preventable thrombotic events including 2 patients with multiple endovascular events. Patients with PMF had a median diagnosis delay of 196 days (range 0-3684 days) and 12% had potentially preventable thrombotic events. In MPN-
U the median diagnosis delay was 1371 days (range 42-3255) and 31% of patients had potentially preventable adverse events.

Summary/Conclusions: Over 5.5 years we identified 143 patients with a new diagnosis of Ph-negative MPN within our centre. The overall median diagnosis delay was 723 days (0-8731) with delays of more than 12 months in ET, PV and MPN-U, and more than 6 months in PMF. 21% of patients had potentially preventable thrombotic events and 2.8% had potentially preventable haemor-
 rhagic events. Earlier recognition of FBC abnormalities consistent with MPN and earlier referral for specialist haematological management would, with earlier intervention, would be expected to prevent many thrombo-haemor-
 rhagic complications and reduce MPN-associated morbidity and mortality.

LONG-TERM AND LOW-DOSE BUSULFAN IS SAFE AND EFFECTIVE IN ELDERLY PATIENTS WITH ESSENTIAL THROMBOCYTHEMIA
R. Renso1,*, A. Aroldi1, P. Pioltelli1, C. Gambacorti-Passerini1,2,3, E. M. Elli1
1Hematology Division, 2Clinical Research Unit, Hematology, San Gerardo Hos-
pital, 3Department of Medicine and Surgery, University of Milano-Bicocca, Mon-
da, Italy

Background: Therapeutic options for elderly patients (pts) with Essential Thrombocythemia (ET) resistant or intolerant to hydroxyurea (HU) are limited. Busulfan (BU) is a possible second-line treatment, but conventional schedule
Background: Thrombosis is one of the most frequent events in Ph(-) myeloproliferative neoplasms and the reasons for that are still under investigation.

Aims: The aim of this study was to find out if there is difference in frequency and type of thrombosis in JAK2 V617F positive patients according to their diagnosis, age, sex and V617F allele burden.

Methods: One hundred and eighty two JAK2 V617F positive patients diagnosed with polycythemia vera (PV) N=63, essential thrombocythemia (ET) N=83, and primary myelofibrosis (PMF) N=36 were included in the study. Patients in each group were additionally divided according to sex, age at diagnosis and first thrombosis. V617F allele burden was quantified in peripheral blood granulocyte DNA by real time PCR established by Larsen et al. Br J Haematol 2007;136:745.

Results: Among 182 patients observed, 66 (36%) experienced thrombosis, with arterial thrombosis being twice more frequent than venous thrombosis in all 3 studied groups. In ET group there was statistically significant difference in sex distribution (proportion of females=0.71), p<0.001. Statistically significant difference in age at diagnosis was observed between ET and PV/PMF patients without thrombosis (p<0.001); the youngest patients were those in ET group. The age at diagnosis of ET patients with thrombosis (65 years, range 23-92) was statistically different compared to ET patients without thrombosis (50 years, range 21-83), p=0.002. Our study showed that V617F allele burden in patients without thrombosis was statistically significantly different between ET (17,2%, range 4,2-55,2) compared to PV (43%, range 1,7-99,9) and PMF (37,1%, range 1,4-90,7), p<0.001. The same statistically significant difference for V617 allele burden was established in patients with thrombosis between ET patients (19%, range 1,4-84,5) and PV and PMF patients (42,5%, range 8,9-97,2 and 48,8%, range 1,6-99,8, respectively), p<0.001.

Summary/Conclusions: Our results confirm that arterial thrombosis is more frequent than venous thrombosis in JAK2 V617F positive patients. Female sex was prevalent only in ET group. The age at diagnosis in all studied groups was similar except for ET patients without thrombosis. There was no difference in the frequency and type of thrombosis among ET, PV and PMF patients with high heterogeneity in V617F allele burden between all studied groups regardless of the occurrence of thrombosis.

PROTECTION AGAINST DEVELOPMENT OF B CELL LYMPHOMA BY TETRASPANIN CD37
C. de Winde1, S. Veenbergen1, K. Young2, M. van den Brand3, A. van der Schaaf1, S. Elfrink1, H. van Krieken1, C. Figdor1, S. van Deventer1, B. Scheijen1, A. Van Spriel1,∗
1Radboud University Medical Center, Nijmegen, Netherlands, 2MD Anderson Cancer Center, Houston, United States

Background: B cell non-Hodgkin lymphoma, worldwide the most common hematological malignancy, remains a clinical problem. The molecular events leading to B cell lymphoma are only partially defined. CD37 is a member of the tetranspan superfamily that is highly expressed on mature B cells and is required for optimal GC function and long-lived antibody production.

Aims: We investigated the function of tetranspan CD37 in the development of B cell lymphoma.

Methods: A combination of studies was performed in mouse models (CD37/IL-6-deficient mice), and studies of DLBCL patient material using biochemical, immunological, genetic and microscopical approaches.

Results: We provide evidence that deficiency of CD37 induces the development of B cell lymphoma in vivo. Cd37-deficient mice develop germinal center-derived B cell lymphoma in lymph nodes and spleen with higher incidence than Bcl2-transgenic mice. We discovered that CD37 interacts with SOCS3, and when absent drives tumor development through constitutive activation of the IL-6 signaling pathway. The importance of the IL-6 pathway was confirmed by investigating Cd37xIl6 double knock-out strains that were fully protected against lymphoma development. Our unpublished data shows discovery of inactivating CD37 mutations in patients with DLBCL. Importantly, loss of CD37 on neoplastic cells in patients with diffuse large B cell lymphoma (DLBCL) is directly correlated with activation of the IL-6 signaling pathway and with worse progression-free and overall survival.

Figure 1

Summary/Conclusions: Together, this study identifies tetranspan CD37 as a novel tumor suppressor that directly protects against B cell lymphomagenesis, and provides a strong rationale for blocking the IL-6 pathway in patients with CD37-negative B cell malignancies as therapeutic intervention.

E1355
IDENTIFICATION AND CHARACTERIZATION OF THE LYMPHOMA INITIATING CELL (LIC) POPULATION IN AN ALCCL MOUSE MODEL
S. Kreutmar1,∗, C. Klingeberg1, G. Andrieux2, A. Keller1, C. Mielting1, D. Pfeifer1, M. Follo1, H. Busch2, M. Boerries2, J. Duyster13, A.L. Illert13
1Hematology, Oncology and Stem Cell Transplantation, University medical center Freiburg, 2Institute of Molecular Medicine and Cell Research, Freiburg, 3German Cancer Consortium (DKTK) and German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: In 60% of anaplastic large cell lymphoma (ALCL) patients a translocation (t(2;5);p23;q35) is found, which results in NPM-ALK fusion gene expression and constitutive activation of the ALK tyrosine kinase. Immunophenotypic characterization of human ALCLs revealed highly CD30-positive cells of T- or Null-cell-origin.

Aims: However, the origin of the lymphoma initiating cell population as well as NPM-ALK signal transduction in course of the disease remains unclear and needs to be characterized.

Methods: In this regard, we established a retroviral murine bone marrow transplant model resembling human ALCL. Therefore we use an inducible Cre/IoxP system where NPM-ALK expression is restricted to early T-cells. We infected bone marrow of Lck-Cre transgenic mice with our MSCV-Stop-NPM-ALK-ires-Egfp vector and transplanted it into lethally irradiated recipient mice. We observed the formation of CD4 and CD8 double negative T-cell lymphomas. With a latency of 4-5 months, mice developed CD30-positive lymphomas and died from neoplastic T-cell infiltration of lymphatic organs and bone marrow.

Results: Immunophenotypic analysis confirmed T-cell origin of the lymphomas with a heterogeneous combination of all T-cell stages with mainly CD4/CD8- double negative (DN) T-cell subpopulations including all DN T-cell subpopulations as well as hematopoietic stem cells and lymphatic precursors. Staining of the T-cell subpopulations demonstrated high NPM-ALK expression in immature CD4/CD8- double negative T-cells and undifferentiated CD4+CD8+ double positive T-cells with highest expression of proliferation marker Ki67 as well as the activation marker CD25 in the CD4−CD8− T-cells. We selected CD4+CD8− CD4+CD8− double negative lymphoma population further more aberrantly expressing the T-cell receptor alpha/beta chain, which may allow these early T-cells to establish a systemic lymphoma. To further proof this hypothesis and identify the LIC population we performed secondary transplantations with sorted DN T-cells including all DN T-cell subpopulations as well as hematopoietic stem cells and lymphatic precursors. Staining of the T-cell subpopulations demonstrated high NPM-ALK expression in immature CD4/CD8- double negative T-cells and undifferentiated CD4+CD8+ double positive T-cells with highest expression of proliferation marker Ki67 as well as the activation marker CD25. The CD4+CD8− T-cell subset showed the highest expression of NPM-ALK and presented with 100% engraftment, with a more aggressive phenotype as compared to CD4+CD8+ double positive T-cells. Features were compatible with a high-grade lymphomas. IHC analysis confirmed positivity for CD22 staining (Tdt, Bcl6, CD138 and CD4, CD8 negative). Tumors were confirmed to be B220+IgM+, with either Igk-or Ig-lambda-restriction as demonstrated by flow cytometry; and either mono- or bi-tropic population as demonstrated by Southern blotting. Whereas xenografted mice selected from B220+ selected cells obtained from pathological lymph nodes of CD19/Bl/p53- mice and identified 143 SNVs. Non-syonymous somatic mutations were mapped on genes involved in the regulation of focal adhesion, PDGF signaling, p53-downstream pathway, and lipoprotein metabolism. B220+ cells selected from CD19/Bl/p53- derived lymphoma tumors were implanted s.c. into recipient SCID/Bg mice, and presented with 100% engraftment, with a monomophic lymphomoid infiltration of B220+ and IgM+ cells. B220 positive cells were selected from the s.q. tumor and intravenous injected into recipient SCID/Bg (n: 10) and BL/6 mice (n: 10). Engraftment was demonstrated in all three groups where hepatomegaly and splenomegaly were absent and spleen observed. Infiltration of B220+ cells was documented within bone marrow, liver and spleen. Finally, we found that B220+ selected cells from lymph nodes harvested from CD19/Bl/p53- mice were sensitive to ibrutinib.

Summary/Conclusions: Dual inactivation of p53 and BLIMP in B-cells supports the notion that neoplastic DN T-cells incorporate pathways that are present in patients with ABC-DLBCL, thus providing a novel model for studying high-grade B-cell lymphoma driven by BLIMP-1/p53 dual loss-induced C-Myc expression.
ray analyses. Indeed, heatmap analyses revealed wide pattern similarities in the clonal DNA and RNA subpopulation in contrast to the DN1 and DN2 lymphoma cells. Interestingly, DN3 and DN4 cells show different expression profiles of stemness genes resembling early progenitor cell distribution patterns.

Summary/Conclusions: In summary, our results highlight the existence of a lymphoma driving stem-cell-like population originating within the DN3/DN4 lymphoma cell population in a highly relevant NPM-ALK positive CD30-expressing ALCCL mouse model, thereby giving the opportunity to test the eradication of the LIC with established and new therapeutic approaches.

E1356
HSP110 SUSTAINS MYD88-DEPENDENT NFKB SIGNALING IN ACTIVATED B CELL DIFFUSE LARGE B CELL LYMPHOMA
C. Boudesco1, S. Caussé1, A. Hamman2, E. Verhoeyen3, L. Martin1, F. Jardin4, T. Fest5, O. Wolz6, A. Weber6, C. Garrido2, G. Jego1,*
1University of Burgundy, 2INSERM 1231, Dijon, 3INSERM U1111, Lyon, 4INSERM 918, Rouen, 5INSERM 911, Rennes, France, 6University of Tubingen, Tübingen, Germany

Background: Diffuse large B cell lymphoma (DLBCL) is an aggressive lymphoproliferative disorder of B lymphocytes accounting for 30% of adult Non Hodgkin Lymphoma (NHL). Among DLBCL, Activated B Cell – DLBCL (ABC-DLBCL) is the most aggressive form and has a poor prognosis. Heat-shock proteins (HSPs) are molecular chaperons highly expressed in cancer cells and implicated in resistance to radio- and chemotherapy. Therefore, HSPs are envisioned as therapeutic targets in many cancers. Among the different HSPs, HSP110 has been recently identified as a pro-survival factor in germline centric-derived DLBCL (GC-DLBCL), through stabilization of the GC-DLBCL oncogene Bcl-6.

Aims: Here, we have explored if HSP110 could also be involved in the survival of the most aggressive form of DLBCL

Methods: The study was performed with ABC-DLBC patient samples and several cell lines. SHNAs specific for HSP110 was designed and transcribed through a lentiviral vector designed to infect highly efficiently non-permissive B cell lines. The study was performed with ABC-DLBC patient samples and several cell lines. SHNAs specific for HSP110 was introduced through a lentiviral vector designed to infect highly efficiently non-permissive B cell lines. ShRNA specific for HSP110 was introduced through a lentiviral vector designed to infect highly efficiently non-permissive B cell lines. The study was performed with ABC-DLBC patient samples and several cell lines. SHNAs specific for HSP110 was introduced through a lentiviral vector designed to infect highly efficiently non-permissive B cell lines.

Results: We observed a high HSP110 expression in all ABC-DLBC patient samples, compared to normal reactive lymph nodes by using IHC staining of ABC-DLBC patient tumors. Furthermore, shRNA silencing of HSP110 decreases the survival of several ABC-DLBC cell lines, and downregulates the expression of pro-survival factors such as Bcl2 and Bcl-XL. Sirna silencing of HSP110 abrogates NF-kB silencing, which is the major oncogenic pathway in ABC-DLBC cell lines. In accord with these results, over-expression of HSP110 in DLBCL and non-DLCL cell lines increases NF-kB signaling, indicating a tight interplay between HSP110 and the NF-kB pathway. Using immune-precipitation in DLBCL cell lines and DuolinkTM assays, we identified an interaction between HSP110 and Myd88, a critical protein of the NF-kB pathway that bears an activated mutation in many ABC-DLBC patients and that is responsible for lymphoma aggressiveness. Finally, we demonstrated that HSP110 stabilizes the wild type as well as the mutated form of Myd88, therefore facilitating the chronic NF-kB pathway activation in those cells.

Summary/Conclusions: In conclusion, we identified HSP110 as a regulator of NF-kB signaling through Myd88 stabilization in ABC-DLBC. This finding highlights HSP110 as a new potential therapeutic target in DLBCL and potentially in other hematological malignancies driven by mutated Myd88 as Waldenstrom macroglobulinemia.

E1357
STAT3 ACTIVATION MEDIATES CD8+CD16+CD56- T-LGLL NEUTROPENIA THROUGH FAS LIGAND SECRETION
G. G. Di Girolamo1,2, A. Teramo1,2, G. Calabretta1,2, M. Leoncin1,2, C. Vicenzetti1,2, A. Lipo1, A. Cabrelli2, S. Carraro1, V. Trimarco1, M. Facco1,2, F. Piazzì1,2, L. Trenti1,2, G. Semenzato1,2, R. Zambello1,2
1Dept of Medicine, Hematology and Clinical Immunology section, Padua University School of Medicine, 2Venetian Institute of Molecular Medicine, Padua, Italy

Background: T-cell large granular lymphocyte leukemia (T-LGLL) is a rare chronic lymphoproliferative disorder characterized by the clonal expansion of CD3+ Large Granular Lymphocytes (LGL). In addition to the most common CD8+ T-LGLL, CD4+ T-LGLL is likely to be multifactorial, comprising both tumor (i.e. soluble FAS ligand secretion) and cell-mediated mechanisms.

Aims: The aim of this work was to evaluate whether 1) STAT3 mutations might be associated with a distinctive LGL immunophenotype and/or indicative for symptomatic disease and 2) STAT3 activation is directly related to the development of neutropenia.

Methods: A cohort of 101 patients affected by T-LGLL according to WHO criteria were screened for STAT3 mutation by Sanger sequencing and PCR ARMS assay. All the samples were analysed by flow for CD3, CD4, CD8, CD16, CD56 and CD57 antigen. STAT3 tyr 705 levels were studied by Western blot. FAS ligand mRNA levels were analysed by RT-PCR Assays.

Results: By flow we observed that 68 out of 101 patients (67.3%) were characterized by CD3+CD8+/CD4- expression (CD8+ T-LGLL), while the remaining 33 patients (32.7%) were CD3+/CD4+/CD8+/dim/neg (CD4+ T-LGLL). All STAT3 mutated (n=38) and almost all neutropenic (38 out of 39) patients belonged to CD8+ T-LGLL leukemia (n=68), while among CD4+ T-LGLL leukemia (n=33) no STAT3 mutated and only one neutropenic patient (1 out of 33, 3%) was found. Among CD8+ T-LGLL, immunophenotypic signature CD16+/CD56- was also associated to the presence of neutropenia and STAT3 mutation (37 out of 41, 90.2%, c2=49.5, p<0.0001 and 37 of 41, 90.2%, c2=49.5, p<0.0001 respectively). Furthermore, by western blot we showed that high STAT3 tyrosine phosphorylation observed in LGL obtained by CD8+ T-LGLL patients belonging to CD16+/CD56- subgroup was significantly higher as compared with other immunophenotypic groups. Provided this relationship between STAT3 mutation/activation and neutropenia, by RT-PCR we analysed Fas ligand expression, showing higher transcription levels in CD16+/CD56- CD8+ T-LGLL patients as compared to the not neutropenic patients belonging to the other immunophenotypes, both CD8+ T-LGLL and CD4+ T-LGLL (7.66±0.87, 2.45±0.22 and 2.35±0.28 arbitrary units, respectively; p<0.01). To confirm this relationship, in patient’s PMBCs treatment with STAT3 inhibitor Static decreased both STAT3 phosphorylation and Fas ligand transcription as compared to the untreated conditions. In addition, IL-6 and IL-15 stimulation (which are known STAT3 activator) increased Fas ligand transcription levels (1.59- and 2.01-fold after IL-6 and IL-15, respectively) which is prevented by concomitant Static treatment.

Summary/Conclusions: Our results provide evidence that STAT3 mutation and activation is mostly restricted to neutropenic CD8+ T-LGLL patients equipped with the CD16+/CD56- signature. The relationship between STAT3 activation and neutropenia FAS ligand related further supports to approach STAT3 inhibition as therapeutic strategy in symptomatic CD8+CD16+/CD56- T-LGLL patients, obtaining the dual results of inducing apoptosis in leukemic LGL together with inhibition to FAS ligand mediated neutropenia.

Background: Mantle cell lymphoma (MCL) is a highly aggressive subtype of B-cell lymphoma that is characterized by a poor response to current treatment regimens. Most MCLs carry a prototypical translocation, t(11;14), which juxtaposes the CCND1 gene towards the immunoglobulin heavy chain (IGH) locus, resulting in cyclin D1 overexpression. Notably, a subset of MCL patients are cyclin D1 negative but instead overexpress cyclin D2 (encoded by CCND2) as a consequence of recurrent genomic rearrangements involving the CCND2 locus.

Figure 1.
Aims: Here, we aim to recapitulate MCL in a mouse model of hematopoietic-specific overexpression of cyclin D2. Next, we want to use this preclinical mouse model to evaluate novel therapeutic strategies for the treatment of MCL.

Methods: To evaluate if cyclin D2 could act as a bona fide oncogene in the pathogenesis of MCL, we developed a R26-driven Ccnd2 overexpression mouse model. For this, we used a targeting vector that contained a floxed stop cassette followed by the Ccnd2 gene and a EGFP/luciferase reporter, which was subsequently targeted in mESCs using recombinase-mediated cassette exchange (RMCE).

Results: The resulting R26-Ccnd2 mice were crossed to VavCre mice to enable biallelic R26-driven overexpression of Cyclin D2 in the entire hematopoietic system. Interestingly, these mice developed large lymphomas starting from 36 weeks of age (Figure 1A), with tumor cells showing characteristic MCL immunophenotype (CD19+, CD5+, CD23-). Of note, these malignant B-cells were monoclonal small-sized cells with slightly irregular hyperchromatic nuclei and disseminated into other organs such liver, spleen and the gastrointestinal tract. Infiltration of the (B)1) into the bone marrow and the lymphoma cells expressing SOX11 positive, as evaluated by IHC, suggesting that these tumors indeed reflect a murine form of MCL. Noteworthy, the MCL cells from this mouse model also contain a luciferase reporter, allowing accurate in vivo tracing of tumor cells in xenograft experiments. These xenograft experiments can be used as preclinical models, in which bioluminescence is used to assess the tumor burden and to monitor tumor regression upon drug treatment.

Summary/Conclusions: In conclusion, our preliminary data suggest that modeling cyclin D2 in mice, mimicking the elevated cyclin D2 levels of human MCL patients with translocations involving the CCND2 locus, is sufficient to form MCL.

HDAC6 INHIBITION INCREASES CD20 LEVEL BY STIMULATING TRANSLATION OF CD20 mRNA

A. Graczyk-Jarzynka1,*, M. Bobrowicz1, M. Dwojak1, J. Stachura1, E. Berthel2, S. Minvielle2, S. Le Gouill2,10

Background: HDAC6 (histone deacetylase, isoform 6) is a novel promising target in hematological malignancies. HDAC6 is an atypical member of HDAC family that regulates the acetylation status, and thus the functionality of cytosolic proteins, and has been explored therapeutically for its role in the process of protein degradation. HDAC6 mediates the transport of protein aggregates to the autophagic machinery to diminish their cytotoxicity. Thus, the disruption of the aggresome pathway, similarly to proteasome inhibition, results in a massive accumulation of misfolded protein aggregates and apoptotic cell death. As this inhibition more than 30 months after diagnosis. After ASCT, 41 patients (43%) were randomized in the rituximab maintenance arm and 40 (42%) in the observational arm. Overall, 68 recurrently altered regions were observed in 96% of patients. Deletions were more frequent than amplifications, at 9 vs 3 by patient respectively. HR patients were associated with TP53del (44% vs 14%; p=0.04), CDKN2A del (56% vs 22%; p=0.04), Bp1del (44% vs 15%; p=0.05). Interestingly, we identified in 76% of patients a deletion of a minimal common region of 5.3 Mb located on chromosome 7p22 and including CARD11. This lesion was associated with low MIP (80% vs 12%; p<0.001), and other gains such as 21q21, 10q11 and 6p21 which together define a favorable subgroup (24% of the cohort). These anoma- lies were significantly more associated with LR patients (87% vs 60%; p=.02). None of the patients with CARD11 duplication (n=10) had relapsed despite the presence of TP53 in 2 patients or CDKN2A deletion in 3 patients. This translates into a longer PFS (100%vs70%; p=0.02) (fig.).

Figure 1.
Summary/Conclusions: Our study confirms the worse impact of TP53 and CDKN2A deletion on early relapse in MCL. By contrast, the CARD11 duplication
is associated with an absence of relapse and thus defines a new group of very low risk patients. These findings provide important clues for future therapeutic-driven therapies in MCL.

E1361

CLINICOBIOLICAL FEATURES OF B-CELL NEOPLASMS WITH CDK6 TRANSLOCATIONS: FREQUENT ASSOCIATION WITH MARGINAL-ZONE LYMPHOMA, CONTINGENT OF PROLYMPHOCYTIC CELLS AND TP53 ABNORMALITIES. A GFCH STUDY

Background: Translocation involving the CDK6 gene is a rare but recurrent abnormality in B-cell neoplasms. Three different translocations have been described: t(2;7)(p11;q21), which is the most frequent, (t(7;14)(q21;q32) and (t(7;17)(p11;11)), leading to juxtaposition of CDK6 gene with IGK, IGH or IGL locus respectively.

Aims: The Groupe Francophone de Cytogenetique Hematicque (GFCH) collected 35 chronic B-cell disorders with CDK6 translocation in order to document the clinicobiological features of this uncommon aberration.

Methods: Clinical and biological data were gathered at diagnosis when available. A cytogenetical review was performed by 3 experts in 27/35 cases. FISH was used to detect IG or TRAD and CDK6 rearrangements, and recurrent abnormalities frequent in SMZL and CLL (trisomy 3, 12, 18, deletions of ATM, TP53, 13q14 and 7q22/7q36 loci), TP53 (exons 4-9), NOTCH2 (exon 34), and IGHV genes were analyzed by Sanger sequencing. Detection of MYD88 L626P was performed by real-time AS PCR.

Figure 1. Results: Our cohort included 22M and 13F, with a median age of 71 years. The involvement of CDK6 was confirmed in all cases. A (t(2;7) IGK/CDK6 was found in 33/35 patients. One case had a (t(7;14) IGH/CDK6, and one had a (t(7;14)(q21;q11) involving the TRAD locus. There were 23 (66%) marginal-zone lymphoma (MZL), including 22 splenic MZL (SMZL) (including the (t(7;14) TRAD), and 1 bronchus MALT type, 7 (20%) unclassified small B-cell lymphomas (USBCL) and 5 (14%) chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL) with Matutes score 4/5 (including the (t(7;14) IGH). Morphopathological review showed a contingent of prolymphocytes (median: 10% of lymphoid cells) in 17/27(63%) cases, including 14/19 MZL and 3/4 USBCL and 0/4 CLL/SLL. The CDK6 translocation was the sole aberration in 9/35(26%). K was complex in 18/35(51%). The most frequent additional abnormalities were: del17p (TP53) (51%), del13q (41%), del8p (23%), trisomy 18 (22%), trisomy 18p (17%) and trisomy 12 (11%). Deletion of 7q and 11q were rare (one case each). TP53 was mutated in 6/22 patients (27%), including 5 with del1p. Overall, 19/29 (66%) tested cases had a TP53 abnormality (del and/or mutated), which was significantly associated with complex karyotype

(p=0.016) and del13q (p=0.042). MYD88 L626P was detected in 2/22 cases. No NOTCH2 mutation was found, IGHV analysis showed a preferential usage of VH4 (8/23, 35%), while VH1 was rare (3/23, 13%, including one VH1-2). Most carried IGHV with some impact of somatic hypermutation (85%). Median follow-up was 28 months [0-192]. The median survival was not reached, only 4/32 (12.5%) died. A treatment was undertook in 15/32(47%) cases, with a median follow-up at first treatment of 13 months. In our series, the CDK6+ MZL cases differed from classical SMZL by frequent prolymphocytic differentiation (14/19, 74%), very low incidence of 7q deletion (1/23, 4%), high frequency of TP53 abnormality (12/23, 52%), absence of NOTCH2 mutation (0/3, 0%), and a different IGHV repertoire with low frequency of VH1-2 (1/11). The CDK6+ USBCL also had frequently a contingent of prolymphocytes (3/4, 75%), and showed a genetic profile similar to the CDK6+ MZL (see figure).

Summary/Conclusions: These results, obtained on the largest series to date, suggest that CDK6 translocation is associated with indolent small B-cell lymphomas, mostly SMZL, with distinctive features. However, CDK6 translocations were rarely observed in other phenotypes. We describe one case involving the T-cell receptor (TCR) locus, which is a rare event in B neoplasms. Finally, it is intriguing that this abnormality involves almost exclusively the IGK locus, and not the other IGI loci, especially IGH which is usually the most frequently rearranged.

PRIMARY CUTANEOUS DIFFUSE LARGE B-CELL LYMPHOMA, LEG TYPE, EXPRESS SPECTROTYPE B-CELL RECEPTORS WITH UNIQUE NONSYNONYMOMATICALLY MUTATED CONSTANT REGIONS

M.T. Koning1-7, R. Ubelhart1, S. van der Zeeuw3, S. Kielbasa3, H. Jumaa4, M. Vermeer5, W. Willenme6, C. Tensen6, H. Veelken2,3, 8Department of Hematology, Leiden University Medical Center, Leiden, Netherlands, 9Laboratory of Immunology, University Medical Center Ulm, Ulm, Germany, 3Sequence Analysis Support Core, 4Department of Dermatology, Leiden University Medical Center, Leiden, Netherlands

Background: Primary Cutaneous Diffuse Large B-Cell Lymphoma, Leg Type (DLBCL, LT) is a rare and aggressive neoplasm with a primary cutaneous presentation that shares genetic and phenotypic characteristics with DLBCL of activated B-cell subtype (ABC-DLBCL). Although receptor stereotypes have been observed, the role of the B-cell receptor (BCR) in DLBCL, LT is largely undefined. Previous studies on small cohorts suggested that DLBCL, LT expresses IGH with overrepresentation of IGHV3 alleles and high rates of somatic mutations.

Aims: We aimed to elucidate the stereotype of the BCR in DLBCL, LT and to test for autonomous antigen-independent signaling as described for CLL (Dührren-von Minden, Nature 2012) and non-leg-type ABC-DLBCL (Koning, AACR 2016 & ASH 2016).

Methods: 8 cases of DLBCL, LT were subjected to RNAseq. Additional RNAseq data from 6 healthy volunteers (GEUVADIS project), 10 non leg type DLBCL, and 16 follicular lymphomas were obtained from NCBI publicly available datasets and collaborators. VDJ and rearrangements and IGH constant regions were Sanger sequenced for all cases and two granulocyte controls. Lymphoma-dervised, BCR were tested for autonomous signalling activity in the murine TKO pre-B-cell system (Dührren-von Minden, Nature 2012).

Results: RNAseq analysis demonstrated an IGH isotype in all eight and VJ-kappa in seven of the eight cases of BCL, LT cases. IGHV usage was observed in 7/8 cases; 4 cases expressed the IGHV3-7 gene. DLBCL, LT BCR were strongly mutated (range: VDJ 3.1-22.2%; VJ 0.6-13.5%). No intraclonal sequence variation was observed. Non-synonymous single nucleotide variants (SNV) were observed in the constant regions of four cases and in IGKC of one additional case, but not in available granulocyte DNA of two cases with C region mutations or in the other 32 RNAseq libraries. Constant region mutations were highly specific to DLBCL, LT as compared to other BCL (p=0.0018) and follicular lymphoma (p=0.0013). In contrast to ABC-DLBCL, V(D)J BCR of DLBCL, LT on a murine constant region backbone did not induce antigen-independent calcium flux in TKO cells upon induction of functional signaling of the BCR signalling cascade by taxomycin.

Summary/Conclusions: Our data identify a clearly stereotyped receptor in DLBCL, LT. In contrast to CLL and ABC-DLBCL, BCR stereotypy was not associated with autonomous BCR signalling activity using a murine IgM backbone. The pathogenic potential of the novel constant region mutations for BCR activity in DLBCL, LT warrants further functional studies.

LOSS OF NR4A1 ACCELERATES MYC-DRIVEN LYMPHOMAGENESIS ACCOMPANIED BY OVEREXPRESSION OF GENES INVOLVED IN IMMUNOREGULATION

1Fechter1, K. Wenz1, K. Prochazka1, K. Panely1, B. Pursche1, H. Greinix1, C. Kruepniak2, P. Neumeister1, A. Deutsch1
1Department of Hematology/ University Clinic for Internal Medicine, Medical University of Graz, 2Department of Hematopathology, Institute of Pathology, Medical University of Graz, Graz, Austria
Background: NR4A1 (Nur77) belongs together with NR4A2 (Nur1) and NR4A3 (NOR-1) to the Nur77 family of nuclear orphan receptors. As immediate early- or stress response genes their expression is diverse as it is the cellular outcome upon activation. Recently, there has been attributed a pivotal role to NR4A1 and NR4A3 as tumor suppressors in AML in humans and mice. In our comprehensive NR4A4 expression analysis in various lymphoma entities we demonstrated a significant reduction of NR4A1 expression in aggressive lymphomas, which was associated with poor cancer-specific survival. Moreover, ectopic expression of NR4A1 in aggressive lymphoma cells resulted in induction of apoptosis.

Aims: In order to better dissect the role of NR4A1 in lymphoid malignancies, we used a Myc-driven mouse model of lymphomagenesis and crossed the EµMyc mouse with the Nr4a1-/- mouse. Survival and tumor formation were monitored and RQ-PCR was performed on selected tumor specimens, whereby genes, found to be associated with NR4A1 expression in the publicly available gene expression data set of DLBCLs generated by Lenz et al., were taken. Moreover, the driver function of Nr4a1 in lymphomagenesis at the premalignant stage was investigated by using apoptotic assays and by carrying out transplantations of tumor cells into wt recipients.

Methods: Kaplan Meier analysis was performed for survival and tumor formation in EµMyc Nr4a1-/- (n=154), EµMyc Nr4a1 +/-(n=54) and EµMyc Nr4a1 +/- (n=59), respectively. For RQ-PCR selected tumor specimens from wt and EµMyc mice with (n=14) and without (n=17) Nr4a1 loss were used. For investigation of the role of Nr4a1 at the premalignant stage, mice aged 4 weeks (n=4 per genotype) were sacrificed and AnnexinV staining and cleaved-caspase3 assay were performed on cells isolated from the spleen and bone marrow. In vivo growth of Nr4a1-/- EµMyc tumor cells was induced by tumor cells from the premalignant stage (n=8) and EµMyc Nr4a1-/- (n=11) mice injected into the tail vein of wt mice. Kaplan Meier analysis was used for monitoring survival and tumor formation, and FACs analysis for analysis of bone marrow, spleen and tumor, respectively.

Results: EµMyc Nr4a1-/- mice showed decreased survival with a median of 92 days in Nr4a1-/- EµMyc mice with median survival of 123 days (p<0.001) and tumors developed faster with a median of 45 days for EµMyc Nr4a1-/-, vs 107 days for EµMyc Nr4a1 +/+; p<0.001. Both, survival (median=101 days; p=0.037) and tumor formation (median=66 days; p=0.001) gave intermediate values for EµMyc Nr4a1 +/- mice. Furthermore, EµMyc Nr4a1-/- EµMyc tumor cells were significantly more sensitive to apoptosis than the Nr4a1-/- EµMyc tumor cell subpopulation isolated at the premalignant stage, whereas apoptosis was significantly diminished in EµMyc Nr4a1-/- mice. RQ-PCR showed that several genes involved in immunoregulation and Nr4a1 target genes were upregulated in EµMyc Nr4a1-/- compared to EµMyc Nr4a1 +/-. Last, tumor formation upon i.v. injection showed that tumors developed faster than tumors derived from mice without Nr4a1 loss (25 vs 38 days; p=0.009) and lead to a decreased number of inflammatory cells in the tumor.

Summary/Conclusions: Our results clearly demonstrate the influence of Nr4a1 loss on tumor formation and consequently survival in a Myc-driven model of lymphomagenesis. Importantly, Nr4a1 seems to impact cell death early in B cell development, even ahead of malignant transformation. Additionally, Nr4a1 seems to be involved in driving immune responses towards an anti-inflammation, tolerogenic phenotype, thereby facilitating tumor growth and in altering the tumor environment. Collectively, these data underpin the tumor suppressive function of Nr4a1 in aggressive lymphomas.

E1365

MUTATIONAL PROFILING OF HODGKIN- AND REED-STERNBERG CELLS (HRSC) OF CLASSICAL HODGKIN LYMPHOMA (CHL) ENRICHED FROM ARCHIVAL FORMALIN-FIXED AND PARAFFIN-EMBEDDED TISSUE SPECIES

D. Juskevicius1,*, D. Jucker1, T. Dietsche1, V. Perrina1, C. Ruiz1, S. Dimhofer1, A. Tzankov1
1Institute of Pathology, University Hospital Basel, Basel, Switzerland

Background: CHL can be cured in the majority of cases. However, ~10–20% patients die of the lymphoma after relapse or progressive disease. There are unmet needs for understanding the mechanisms that cause CHL relapses, for development of new prognostic/predictive markers and effective targeted therapies. Comprehensive genetic characterization and in vitro cell lines and in vivo murine models have been used to decipher the pathogenesis of CHL. However, genetic information on CHL is still scarce mainly due to difficulties of isolating malignant HRSC, whose overall frequencies in the affected tissues range from 0.1-5%. Formalin-fixed paraffin-embedded (FFPE) tissue archives are the most abundant source of clinically annotated tumor specimens. However, FFPE tissue processing can be limited because of poor DNA quality and difficulty to enrich neoplastic cells. Therefore, new enrichment techniques are necessary to enable large scale comprehensive genetic investigations of CHL.

Aims: Our aims were: 1) to develop a technique for HRSC enrichment from the archival formalin-fixed paraffin embedded tissue; 2) to reliably detect genetic aberrations in the genomes of enriched tumor samples and to use this information for development of new prognostic and predictive markers as well as for better understanding of the genetic background of CHL.

Methods: We have developed a new high-throughput method for marker-based enrichment of archival FFPE tissue-derived HRSC nuclei by fluorescence-assisted cell sorting (FACS). Genomic DNA extracted from sorted nuclei was used for identification of mutations in 68 genes that are frequently mutated in lymphomas by targeted high throughput sequencing (HTS). Chromosomal copy number aberrations were investigated by the Agilent SurePrint 180k microarray.

Results: Enzymatically extracted FFPE tissue-derived cell nuclei retain their antigenicity and can be reliably labelled with monoclonal antibodies against nuclear (MUM1, PAX5) and cytoplasmic/cell surface (CD30) markers. A mean neoplastic cell purity of 70% (range 40-95%) was achieved by sorting HRSC cells according to their double expression of MUM1 and CD30 in 11 CHL cases. Using sorted non-malignant cells as a germline control we detected somatic single nucleotide mutations and indels in all investigated samples. Mutations of STAT6, PIM1, SOCS1, KMT2D occurred in at least 18% (2/11) of cases. Individual cases contained copy number aberrations such as gain of chr2 (CREL locus), focal deletions of chr4, chr7, chr16 and chr19 affecting genes such as JAK3, CDKN2D, MAP2K3 and NOTCH3. Taken together our study demonstrates that high-quality DNA extracted from the enriched cell populations is suitable for wide-scale genetic profiling.

Summary/Conclusions: A novel rare-cell-enrichment technique is suitable for genetic CHL studies and opens the possibility for the wider use of archived
LACK OF STAT1 PREDISPOSES TO A DIFFUSE LARGE B-CELL LYMPHOMA-LIKE DISEASE

S. Trojlt,1,2 C. Schneckenleithner1, A. Hoebel-Kovacic1, G. Heller2, V. Sexl1

1Institute of Pharmacology and Toxicology, Veterinary University of Vienna, 2Department of Medicine I, Medical University of Vienna, Vienna, Austria

Background: The highly conserved JAK–STAT signaling pathway regulates proliferation, differentiation, apoptosis and immune responses. Activating mutations in STAT3 are considered to drive the development of diffuse large B-cell lymphomas (DLBCL). STAT1 is a critical counter player of STAT3. Of note, many STAT1 target genes are frequently altered or mutated in DLBCL patients, such as SOCS-1, B2M, PDL1, CARD11, CIITA and BCL6. We observed that the loss of STAT1 suffices to provoke spontaneous haematopoietic tumors in mice.

Aims: We aimed at investigating the underlying mechanisms of spontaneous hematopoietic tumor formation in STAT1-deficient mice.

Methods: We characterized the spontaneous haematopoietic tumors by FACS and morphological analysis. To identify the cell of origin for the disease, we performed bone marrow transplantation assays. We high-purity FACS-sorted individual cell populations of diseased STAT1-deficient mice and transplanted them into recipient mice. Ex vivo analysis was performed for lineage-specific surface marker expression and identified as B-cells. Malignant B-lymphoid STAT1-deficient cell lines were established and expression levels of typical lymphoid-specific tumor suppressor and promoter genes were assessed by qPCR. In parallel, STAT17-mice were used for RNA-seq analysis to identify the signaling pathways driving disease. RNA-seq data were compared to publicly available RNA-seq data from different haematological malignancies.

Results: STAT1-deficient mice develop a myeloid hyperplasia that manifests with an incidence of 60% and is characterized by the absence of Rigi. Transplantation of bone marrow masked the development of a B-cell malignancy which can be transferred by CD19+ cells. The malignant B-cells arising in STAT17-mice can be maintained in vitro and display alterations in gene expression that are typically found in human DLBCL such as Irf4, Pdrr1 and p53. RNA-seq analysis revealed features shared with human DLBCL: increased reads a locus of Bim, Meto2, Card11 and Cst7 (PDL1) and decreased expression of Socs-1, Cdkn1a, B2m and Pdrr1. Low levels of STAT1 accumulation combined with low levels of p16INK4A correlated with a reduced life expectancy in DLBCL patients.

Summary/Conclusions: Loss of STAT1 in Balb/C mice provokes a myeloid hyperplasia which masks a B-cell malignancy resembling human DLBCL. DLBCL patients with low levels of STAT1 have a poorer prognosis if they lack the tumor suppressor p16INK4A.

MOLECULAR HETEROGENEITY OF MANTLE CELL LYMPHOMA

1Haematology-Pathology Research Laboratory, Department of Haematology, Odense University Hospital, Odense C, 2Department of Haematology, Aarhus University Hospital, Aarhus C, 3Department of Clinical Genetics, 4Department of Pathology, 5Department of Haematology, Odense University Hospital, Odense C, Denmark

Background: Mantle cell lymphoma (MCL) is a B-cell non-Hodgkin lymphoma characterized by t(11;14)(q13;q32) leading to constitutive cyclin D1 overexpression and cell cycle deregulation. The survival is still poor, especially for patients resistant to frontline drugs. Although patients are brought in remission, relapses often occur with disseminated lymphoma, which is more difficult to treat. There is a need for a better understanding of the clonal heterogeneity of this disease and to identify new signaling pathways with genes which could be targeted by novel drugs or be used as biomarkers to predict response to treatment.

Aims: To address the genetic heterogeneity in MCL in paired patient samples at diagnosis and relapse.

Methods: Highly pure malignant B-cell populations were isolated using fluorescence-activated cell sorting from four patients diagnosed with MCL. In addition T-cells were sorted from the same patients as paired non-malignant control samples. RNA was performed on both the malignant B-cell population and paired T-cells (13 samples in total). Mutations were detected in parallel with CLC Biomedical Workbench 2.5 (Qiagen) and MuTect 1.04 (Broad Institute) (coverage ≥ 20, population allele frequency<0.01) and evaluated with the COSMIC (Wellcome Trust Sanger Institute), dbSNP and PubMed databases. Exonon from informed consent was approved by the National Ethical Committee.

Results: Our data highlighted in each patient persistent gene modifications between diagnosis and relapse. We confirmed gene mutations already well-known in B-cell malignancies (e.g. TP53, NOTCH1 and MYD88). Interestingly, aberrations not previously described in the COSMIC database, were observed with high allele frequency both at diagnosis and at relapse. This included genes in B-cell signaling (e.g. transcriptional repressor SPEN associated to NOTCH pathway regulation and blockage of the precursor B-cell differentiation), inflammatory response (e.g. JRG1), genes found in invasive carcinoma (e.g. integrin β4 subunit) and genes involved in T helper type 1 and 2 responses (e.g. IL13, IL4, IL6 and PLAG1). Genes involved in cell cycle progression or involved in immune reactions were not shared by all patients. However, aberrations in the same signaling pathways were identified across individuals. From allele frequency distributions detected with MuTect we could detect discrete clonal or competing subclonal involvement: A patient harbored one major discrete clone at diagnosis while at relapse two clones were identified, whereas in another patient present at diagnosis evolved and progressed. No gene modification was observed to be shared by all four patients. However, aberrations in the same signaling pathways were identified across individuals. From allele frequency distributions detected with MuTect we could detect discrete clonal or competing subclonal involvement: A patient harbored one major discrete clone at diagnosis while at relapse two clones were identified, whereas in another patient present at diagnosis evolved and progressed. From allele frequency distributions detected with MuTect we could detect discrete clonal or competing subclonal involvement: A patient harbored one major discrete clone at diagnosis while at relapse two clones were identified, whereas in another patient present at
imential conditions we found that a number of the captured genes corresponded to experimentally validated targets of miR-155. Crucially, ontogeny analysis of the PAR-CLIP-captured genes demonstrated an enrichment of genes involved in haematopoietic and/or lymphomagenesis pathways.

Summary/Conclusions: To fully understand the role of a particular miRNA in a specific malignancy, it is essential to identify its target genes in a relevant cellular context. Using a haematopoietic malignancy model of high clinical interest we have developed an optimised method for interrogating the miRNA:mRNA interface (targetome) within a cellular system without the need of ectopically expressed Ago2, keeping physiological levels of the core components of the RISC complex unaffected. Moreover, our optimized protocol allowed us to reduce the number of input cells, therefore opening the exciting possibility of interrogating the targetome of patient primary samples.

DARATUMUMAB, A NOVEL HUMAN CD38 MONOCLONAL ANTIBODY FOR THE TREATMENT OF B-CELL NON-HODGKIN LYMPHOMA

Aims: To evaluate the activity of DARA on MCL and FL cells as monotherapy and in combination with current therapies, both in vitro and in vivo.

Methods: 
- **In vitro**
- **In vivo**

Results: 
- DARA showed significant cytotoxic activity in MCL and FL cell lines in both monotherapy and combination settings.
- In vivo, DARA demonstrated significant antitumor activity in preclinical models.

Summary/Conclusions: DARA represents a promising therapeutic option for the treatment of MCL and FL, showing both monotherapy and combination potential.

Background: Adult T-cell leukemia/lymphoma (ATLL) is a mature T-cell neoplasm, linked to the human T-cell lymphotropic virus, HTLV-1. Patients with ATL are often at the risk of opportunistic infections. It might be possible that this immunocompromised state could be induced by the function of ATL cells having similar phenotypes with regulatory T cells (Tregs). However, difficulties of in vitro studies using primary tumor cells have hampered the progress of ATL research, and it is still controversial whether ATL tumor cells have the immunosuppressive characteristics.

Aims: In this study, we analyzed the roles of molecules expressed in ATL cells associated with immunosuppressive functions of Tregs.

Methods: The protocol of this study was approved by the Institutional Review Board of Osaka University Hospital. Peripheral blood mononuclear cells (PBMCs) were collected from 8 asymptomatic HTLV-1 carriers and 20 ATL patients (3 with smoldering type, 5 with chronic type, and 12 with acute type) after getting informed consent. PBMCs from 3 ATL patients were separated into CD4+CD7-CADM1+ ATL cells and adjacent CD4+ CD7+CADM1 normal T cells using Fluorescence-activated Cell Sorter (FACS), and total RNA sequencing experiments were conducted. And we also examined the expression patterns of CD39 and CD73 in vitro and in vivo carriers or each type of ATL patients.

Results: We compared whole transcriptome of ATL cells and normal CD4+ cells. Bioinformative analyses showed that many genes associated with immunosuppressive functions of Tregs were elevated or downregulated in ATL cells. Among these genes we focused on CD39 and CD73, because recently it has been reported that extracellular adenosine, which is catalyzed by CD39, expressed in human Tregs, and CD73, expressed in murine and human Tregs, has strong anti-inflammatory function and plays major role in Treg-mediated immunosuppression. Therefore, we investigated the expression of CD39 and CD73 in ATL cell lines and primary tumor cells. We found that all of 4 ATL cell lines expressed CD39, but not CD73 just as human effector Tregs. In contrast, the expression patterns of CD39 in 20 ATL patients were various (Table) and interestingly, some ATL tumor cells express CD73. Also in asymptomatic carriers, we could detect CD39 and/or CD73 positive on CD7+CADM1+ abnormal fraction of CD4+ cells. CD26, expressed in human naive but not in effector Tregs, was negative in all cell lines and primary cells except for abnormal cells in one smoldering patient. Next, the role of CD39 and/or CD73 in ATL cells was assessed. Extracellular ATP is converted to AMP by CD39. As expected, CD39+ ATL cells converted significantly more ATP than CD39+ ATL cells, which were comparable with normal effector Tregs. Conversely, mass spectrometry analysis of AMP/adenosine concentration indicated the activity of CD73 mediated AMP hydrolysis was very slow; less than 10% of 1mM ATP was converted to adenosine by CD73+ ATL cells, indicating that the aberrant expression of CD73 could not efficiently increase adenosine synthesis.

Summary/Conclusions: In this study, we showed that about two thirds of ATL samples were CD39+CD26+ just as effector Tregs and have comparable level of ATPase activity as Tregs, which are expected to play some immunosuppressive function in ATL patients. Recently it is also reported that in exhausted CD8+ T cells in cancer patients, CD39 is co-expressed with PD-1. CD39 expression in ATL cells may also have some roles in immunosuppression and thus in the escape from anti-tumor immunity.
and proliferation of several B cell malignancies. BTK is a key regulator of this pathway. In a preliminary clinical study, the selective BTK inhibitor STRO-001 showed therapeutic activity in relapsed/refractory DLBCL of the Activated B-cell phenotype (ABC-DLBC) (Walter et al Blood 127 pp411-419, 2016). However, median treatment duration in ABC-DLBC was only 3 months due to progressive disease and development of resistance. Two acquired resistant mutations C481S and R665W have been reported as dominant resistant mechanisms to BTK inhibition in CLL but resistance mechanisms in DLBCL have not been fully elucidated.

**Aims:** To determine resistance mechanisms in the ABC-DLBC TMD8 cell line and determine new rational combinations to take into the clinic with ONO/GS-4059.

**Methods:** The BTK insensitive ABC-DLBC cell line TMD8 was cloned ONO/GS-4059 and Ibritumomab resistant TMD8 cell lines (TMD8RO and TMD8RI) were used for this study. TMD8RO has PLC2y665W whilst TMD8RI lacks both BTK C481S and PLC2y665W. Cell viability and apoptosis after compound treatment were assessed using Cell titer Glo assay and Annexin V/PI staining. Expression of ONO/GS-4059 in intracellular glycosylation status and expression of immunoreceptor were assessed by immunoblot and Flow cytometry. The mutational status of BTK and PLC2y in TMD8 was determined by Sanger sequencing.

**Results:** ONO/GS-4059 induced apoptosis in TMD8 at nanomolar concentrations in >70% of cells. Although ONO/GS-4059 induced rapid reduction in ERK and AKT activation, activation of ERK and AKT rebounded within 24 hours in surviving cells. Interestingly, surface immunoglobulin M (sigM) expression was increased more than three times in these cells leading to subsequent activation of SYK. The specific SYK inhibitor GS-9973 combined with ONO/GS-4059 inhibited the downstream ERK and AKT reactivation and induced synergistic apoptosis in TMD8. On the other hand, SYK hyper-activation as determined by phosphorylation of SYK and its downstream target BLNK was also observed in the two BTK inhibitor resistant cell lines. Additionally, expression of CDS and CD22, which negatively regulate BTK, was decreased in these cells. The combination of ONO/GS-4059 and GS-9973 restored sensitivity to ONO/GS-4059 and induced synergistic apoptosis in both resistance cell lines.

**Summary/Conclusions:** These data show that SYK is highly activated through increased sigM expression and/or downregulated CDS and CD22 following BTK inhibitor treatment. Changes may contribute not only the development but also the maintenance of resistance to BTK inhibitor. The combination of ONO/GS-4059 with SYK inhibitor is therefore a rational strategy for preventing and overcoming BTK inhibitor resistances.

**STRO-001, A NOVEL ANTI-CD74 ANTIBODY DRUG CONJUGATE (ADC) FOR TREATMENT OF B-CELL NON-HODGKIN’S LYMPHOMA (NHL)**

A. Yu1, C. Abrahams1, M. Embry1, X. Li1, V. DeAlmeida1, J. Lee1, S. Matheny1, T. Kline1, A. Yam1, R. Stafford1, T. Hallam1, M. Lusher1, A. Molina1,*

1Sutro Biopharma, South San Francisco, United States

**Background:** CD74 is a type II transmembrane glycoprotein involved in the formation and transport of MHC class II protein. CD74 is readily internalized and highly expressed in many B-cell malignancies with limited expression in normal tissues (Stein R. et al., CCR 2007). STRO-001 is a novel CD74-targeting antibody-drug conjugate (ADC) containing anti-CD74 aglycosylated human IgG1 antibody (SP7219) conjugated to a non-cleavable dibenzocyclooctyne (DBCO)-maysitindoside linker-warhead. Highly efficient site-specific conjugation enabled by Sutro’s cell-free antibody production and click chemistry produced a well-defined homogeneous ADC with a drug-to-antibody ratio (DAR) of 2. Due to its limited cell permeability, the major catabolite released by STRO-001 has 100X lower cell killing activity on CD74 positive and negative cells compared to a reference cytotoxic maytansine. Since conjugation sites were selected based on highest stability both in vitro and in vivo, thereby limiting loss of drug moiety from STRO-001 in circulation, this novel ADC has potential for improved safety and activity.

**Aims:** The aim of this study was to investigate the therapeutic potential of STRO-001 in non-Hodgkin’s lymphoma (NHL) cell lines and xenografts. A dose-escalating exploratory toxicity study was also conducted in cynomolgus monkeys.

**Materials and Methods:** Biotinylated SP7219 was used for immunochemistry (IHC). DBCO-Alexa647-conjugated SP7219 and flow cytometry were used for detection and quantitation of CD74 expression on NHL cell lines and B-cells from normal human donors. STRO-001 was used to determine the EC50 and percent span of killing in NHL cell lines. The anti-tumor activity of STRO-001 in SCID mice bearing human xenografts was measured as tumor inhibition in the xenografts and compared to control xenografts. We also tested the effect of STRO-001 on TMD8 cell lines, which were derived from a human diffuse large B-cell lymphoma (DLBCL), 2 activated B-cell lymphoma (MCL) cell lines with EC50 values ranging from 0.17-13 nM. STRO-001 has only modest effects on naïve B-cells, but exhibits more potent cell killing in activated human B-cells that have upregulated CD74 expression (similar CD74 expression as SU-DHL-6 cell line). CD74 cell surface expression is required for STRO-001 cytotoxic activity but expression level, as measured by antibody-binding capacity, does not correlate with in vitro potency (R2=0.4154). STRO-001 exhibits dose-dependent tumor growth inhibition in rituximab-resistant SU-DHL-6 xenografts starting at 2.5mg/kg weekly x 3 doses. The standard of care combination of bendamustine/ rituximab (BR) + STRO-001 further improves tumor suppression in SU-DHL-6 xenografts compared to vehicle (p<0.001) or BR alone (p=0.02). Studies with a MCL xenograft model, Jeko-1, demonstrate potent anti-tumor activity compared to vehicle (p<0.0001) starting at a single STRO-001 dose of 3mg/kg, with a single 10mg/kg dose resulting in tumor regression for up to 64 days post treatment. STRO-001 treatment 14 days post tumor inoculation was used to evaluate disease progression in the xenografts, as STRO-001 on intracellular glycosylation status and activity in NHL cell lines and anti-tumor activity in NHL xenograft models, including prolonged survival in the disseminated Mino MCL model. STRO-001 depletes B cells in a dose-dependent manner. Clinical studies of this novel ADC for treatment of B-cell malignancies are under development.

**Summary/Conclusions:** STRO-001 demonstrates potent in vitro cytotoxicity in NHL cell lines and anti-tumor activity in NHL xenograft models, including prolonged survival in the disseminated Mino MCL model. STRO-001 depletes B cells in a dose-dependent manner. Clinical studies of this novel ADC for treatment of B-cell malignancies are under development.
formed following the BIOMED-2 design and protocol. All PCR experiments were done in duplicates, and cases were considered PCR+ when both duplicates showed the same clonal pattern, ruling out false positivity (pseudoclonal pattern) often seen in paucicellular samples.

**Results:** We confirm that FCM and PCR are more sensitive than CM. Indeed, every CM+ cases (n = 16) was also FCM+ and/or PCR+, while 13 cases were FCM+PCR+ but CM+. A total of 569 samples showed similar results by FCM and PCR with presence (n=22) or absence (n=247) of lymphomatous cells whereas 25 samples were classified as suspicious by at least one technique. Eleven samples were FCM+ but PCR-. False negative (FN) PCR results can be explained in part by extensive somatic mutation in IG genes, preventing optimization of the PCR and Southern blot sensitivity, whereas the levels of BCL-2 targets less prone to somatic mutations, such as IGL, should therefore be evaluated. Conversely, 21 samples were PCR+ but FCM-. Absence of FCM detection might have resulted from the presence of very large lymphomatous cells outside the scope of analysis. Also, rapid cell death is an issue with FCM (preventing optimal blocking), and a low tumor cell content might systematically require intact cells. Most of the difficulties encountered with both methods are due to occult blood contamination and poor cellularity, leading to low-intensity clonal signals by PCR and inconsistent cluster of events with FCM. In addition discordant results between FCM and PCR might be explained by sampling heterogeneity. Considering these limitations, it seems highly advisable to choose the best suited method for the follow-up according to the results at diagnosis.

**Summary/Conclusions:** Our results suggest that a multimodal investigation using FCM and PCR is necessary for improved detection of leptomeningeal dissemination in B-cell malignancies. It seems premature to make clinical decisions based on a single technology. Both methods, which suffer limitations that need to be acknowledged, are complementary and should be performed at diagnosis. Specific limitations of each of them should be taken in consideration for follow-up studies.

**THE SYK INHIBITOR R406 DRAMATICALLY INCREASES THE SENSITIVITY OF GCB AND ABC DLBCL CELL LINES TO THE B-2 INHIBITOR VENETOCLAX**

B. Sasli1, T. Turkaj1, D. Efremov1

1Molecular Hematology, International Centre for Genetic Engineering & Biotechnology, Trieste, Italy

**Background:** The BCL-2 inhibitor venetoclax demonstrated significant single-agent activity in recent clinical trials of relapsed/refractory chronic lymphocytic leukemia (CLL). However, results in some other B-cell malignancies characterized by BCL-2 overexpression have not been equally impressive. This particularly refers to diffuse large B cell lymphoma (DLBCL), where only 18% of patients responded to treatment with venetoclax in a recent phase I clinical trial (Davies MS et al, J Clin Oncol. 2017).

**Aims:** Investigate whether the SYK inhibitor R406 can increase sensitivity of DLBCL cells in vitro to venetoclax.

**Methods:** The following cell lines were used: Ly1, Ly4, Ly7, Ly18, DHL4, Toledo and BJAB (all GCB DLBCL) and U2932, DHL2, Ly3, Ly10, HBL1 and TMD8 (all ABC DLBCL). The percentage of apoptotic cells was determined by Annexin V/PI staining and flow cytometry analysis. Expression of BCL-2 family members was determined by immunoblotting or qR-PCR analysis.

**Results:** In a recent study, we showed that MCL-1 increases the resistance of anti-IgM stimulated CLL cells to venetoclax, and that SYK inhibitors can effectively overcome this resistance by blocking B cell receptor (BCR)-mediated MCL-1 upregulation (Bojarczuk K et al. Blood. 2016). Since constitutive activation of the BCR pathway has been described in both ABC and GCB DLBCL (Davies RE et al, Nature 2010; Chen L et al, Cancer Cell. 2013), we investigated whether treatment with the SYK inhibitor R406 can sensitize DLBCL cells to venetoclax. Single-agent venetoclax had only modest activity against most DLBCL cell lines at concentrations ranging up to 0.25 μM (Figure 1). Substantial apoptosis induction (>20%) was observed in only 2 GCB (Ly1 and Ly18) and 2 ABC (U2932 and Ly10) cell lines. R406 as single agent had almost no effect on tumor cell viability, with only one cell line showing >20% apoptosis induction (HBL1). However, addition of R406 to venetoclax resulted in a dramatic increase in the percentage of apoptotic cells in six of the investigated cell lines (Ly18, DHL4, U2932, Ly10, HBL1 and TMD8). A synergistic effect was also observed with Ly1 using a lower concentration of venetoclax, whereas no effect or only minimal differences in cell viability were observed in the remaining cell lines (Ly4, Ly7, Toledo, BJAB, DHL2 and Ly3). Among these, only Toledo expressed similar levels of venetoclax sensitivity in the absence of SYK inhibition, whereas in the other cell lines the effect was less pronounced or undetectable. To understand the mechanisms how R406 increases the sensitivity of DLBCL cells to venetoclax, we evaluated changes in the expression of MCL-1 and other antiapoptotic BCL-2 family proteins that have been associated with venetoclax resistance. Five of the seven R406 + venetoclax sensitive cell lines (Ly1, DHL4, U2932, HBL1 and TMD8) showed a 20-45% reduction in MCL-1 levels following 24 hours culture with 2μM R406, whereas no changes were observed in Ly18 and Ly10. However, a substantial reduction in A1 levels was observed in Ly18 and U2932 cells, whereas no substantial changes in A1 and BCL-XL expression were detected in any of the other investigated cell lines. Finally, we also investigated the effects of R406 on expression of HRK, which is a propapoptotic BCL-2 family member that was recently shown to be induced by SYK inhibition in a subset of GCB DLBCLs (Chen L et al, Cancer Cell. 2013). A substantial increase in HRK expression (140-640%) was observed in 5 of the 7 R406 + venetoclax sensitive cell lines (Ly1, Ly18, DHL4, U2932 and TMD8).

**VB EXPRESSION ASSESSMENT AND CLONALITY DETECTION IN T-CELL PROLYMPHOCYTIC LEUKEMIA (T-PLL) BY FLOW CYTOMETRY (FCM) AND NEXT GENERATION SEQUENCING (NGS): A COMPARISON OF BOTH METHODS**

M. Kotová1, 2, M. Nováková2, S. Oberbeck3, P. Mayer3, A. Schrader3, H. Knecht2, M. Herling3, M. Brüggemann2

1contributed equally. 1Medical Department II, Unit for Hematological Diagnostics, University Hospital Schleswig-Holstein, Kiel, 2Dept. of Medicine I, Cologne University, Cologne, Germany

**Background:** VB repertoire analysis can distinguish monoclonal from polyclonal (reactive) T-cell proliferations. The molecular quantification of clonal T-cell receptor (TR) gene rearrangements can also be used to record minimal residual disease (MRD) in T-cell malignancies. TR clonality can either be assessed by FCM employing VB antibody panels covering ~70% of the normal human TR VB repertoire or by molecular techniques like NGS with primers that amplify virtually all possible VB-JB rearrangements. T-PLL is the most common (primary non-Hodgkin) T-cell leukemia. Clonal TR gene rearrangements are detected in virtually all T-PLL by FCM or PCR from peripheral blood (PB) or bone marrow samples.

**Aims:** To compare the results of parallel TRB-based clonality analyses by FCM and NGS in T-PLL.

**Methods:** We investigated diagnostic PB leukocytes of 73 T-PLL patients with median lymphocytes at 66% (range 13-93; harvesting T-cells at 97% (55-100)). FCM of surface (not intracellular) VB expression was assessed by the IOTest Beta Mark kit (Beckman Coulter). Libraries for NGS were prepared using 100ng of DNA via a 2-step PCR and sequenced on the Illumina MiSeq (2x250bp, v2) with a median coverage of 17,908 reads (range 1,125–41,193/sample). In the first PCR TRB rearrangements were amplified using TRB BIOMED-2 V- and J-region primers (van Dongen et al, Leukemia 2003). In the second PCR step, sequencing adaptors and sample-specific barcodes were added. Annotation of TR V, (D)- and J-regions of TRB sequences was done using ARResT/Interrogate (Bystry et al, Bioinformatics 2016).

**Results:** In all samples one or two dominant clonal TRB rearrangements were detected by NGS and represented in median by 83% of reads (range 15-90%). In 36/73 (49%) of these cases, also FCM demonstrated clonality. Interestingly, in 8/36 (22%) of cases the dominant VB by FCM differed from the molecular clonotype. In 5 of these cases the discrepancy was most likely accountable to a non-functional TRB clone detected by NGS corresponding to a bi-allelic TRB rearrangement with the second non-functional allele being preferentially identified by NGS. In 37/73 (51%) of cases no reaction with one of the VB antibodies was seen. In 16 (43%) of these cases this could be attributed to expression of a TRB rearrangement for which the appropriate VB antibody was not present in the FCM panel. In another 12 (33%) of these cases a non-productive TRB rearrangement represented the dominant NGS clonotype. However, in further 9 cases (24%), the functional TRB clonotype (TRBV 5-6, 6-5, 25-1, 18, 20-1, 27) was not detected by FCM due to theoretical coverage. Of note, overall 10/73 T-PLL (14%) lacked surface TRβ chain expression.

**Summary/Conclusions:** T-cell clonality is detected by TRB NGS in all T-PLL, whereas FCM-based VB repertoire analysis identifies a dominant single VB.
domain expression in only 49%. A substantial proportion of such failures is due to clonal deletion, which can be explained by the loss of TR expression and the limited coverage of the Vβ antibody panel. NGS-based clonality analysis can overcome these limitations, because it detects virtually all TR Vβ-JB rearrangements. On the contrary, NGS is more sensitive and therefore enables the detection of minor subclones, which has great appeal for MRD analysis. Nevertheless, flow cytometric Vβ spectratyping is a faster, cheaper, and less laborious alternative. It has the additional advantage of detecting the actual TR Vβ chain expression and of visualizing individual T-cell subsets for quantification of Vβ cell populations.

IRF4 EXPRESSION IS ASSOCIATED WITH RESPONSE OF MANTLE CELL LYMPHOMA TO BRUTON’S TYROSINE KINASE INHIBITORS

H.P. Thompson1,2, D.L. Tucker2, S.A. Rule1,2, C.V. Hutchinson1,2
1Institute of Translational and Stratified Medicine, Plymouth University, Penin-
sula Schools of Medicine and Dentistry, 2Clinical Haematology, Plymouth Hos-
pitals NHS Trust, Derriford Hospital, Plymouth, United Kingdom

Background: Mantle cell lymphoma (MCL) responds poorly to conventional chemotherapy. Inhibitors of Bruton’s tyrosine kinase (BTKi) have unexpectedly shown significant clinical effect; however despite this success, approximately one third of MCL patients have primary resistance to the drug, and patients who initially respond to treatment frequently acquire secondary resistance and aggressive relapse of the disease. Understanding how BTKi-resistance or sensi-
tivity is mediated can identify new targets for therapy or predictive biomarkers of response. Using an in vitro model system we have identified the transcription factor IRF4 as a sensitive indicator for BTKi response in MCL cell lines and pri-
mary cells.

Aims: To identify molecules or pathways responsible for resistance to BTKi inhibitor-drugs in mantle cell lymphoma using cell line models and primary cells.

Methods: Primary cells and validated MCL cell lines (REC-1, G519, JEKO-1, JVM2) were cultured either alone, or together with murine stromal cells (with or without CD40L transfection). The BTKi sensitive REC-1 cell line was contin-
uously treated with BTKi to generate an acquired resistance model. Cultures were treated with BTKi drugs: ibrutinib or acalabrutinib in the presence or absence of B-cel receptor or CD40L stimulation, and their sensitivity or resist-
tance to treatment was determined using flow cytometry to assess proliferation (Ki67), apoptosis (Annexin-V), or phosphorylation of BTK (pY223). Changes affecting downstream proteins were determined by protein expression or phos-
phorylation analysis (immunoblotting) and by mRNA expression (RT PCR).

Following initial experiments the studies focussed on IRF4.

Results: Each MCL cell line showed basal phosphorylation of BTK (Y223) and its downstream effector molecule ERK1/2 (T204/187); in each case phospho-
rylation was prevented by BTKi. Of the cell lines tested however, only REC-1 cells showed growth inhibition by BTKi (ibrutinib and acalabrutinib), demon-
strating both dose-dependent apoptosis (p<0.01) and inhibition of proliferation. Further investigation showed that only the BTKi-sensitive REC-1 cell line down-
regulated IRF4 in response to BTKi; this downregulation was an early and spec-
ific response (mRNA downregulated after 4 hours, and protein expression after 8 hours). Furthermore in REC-1 cells with acquired partial resistance to BTKi, the downregulation of IRF4 was significantly less than in the parental cell line. Finally in vitro co-culture of REC-1 cells with CD40L prevented IRF4 downregulation, demonstrated the requirement of CD40L for IRF4 downregulation.

Experiments with primary MCL cells reinforced these findings: in vitro CD40L induced proliferation, survival, prevented BTKi-induced IRF4 downregulation and protected the cells from BTKi-induced death. These findings were confirmed using ex vivo samples from treated patients (n=7) analysed before and during BTKi treatment. IRF4 was downregulated in 6 samples from patients shown to be clinically responding to BTKi and was not downregulated in 1 refractory case.

Summary/Conclusions: CD40L encountered in the cellular microenvironment supports the proliferation and survival of MCL cells, and protects them from the effects of BTKi inhibition. This study has identified that BTKi induces down-
regulation of IRF4 in sensitive but not resistant MCL cells, and that downreg-
ulation is opposed by CD40L. This suggests that the expression of IRF4 fol-
lowing treatment with BTKi might be a biomarker for BTKi-sensitivity in MCL, and that proteins modulated by IRF4 may play an important role in MCL treatment response.

E1379

LIQUID BIOPSY: DECIPHERING A SIGNATURE OF CIRCULATING MICRORNAS AS NOVEL NON-INVASIVE BIOMARKERS IN DIFFUSE LARGE B-CELL LYMPHOMA

1Department of Pathology, Medical School, University of Crete, 2Department of Haematology, University Hospital of Heraklion, 3Department of Pathology, Medical School, University of Crete, Heraklion, Greece

Background: While MYC-driven non-Hodgkin lymphomas have aggressive clinical behavior and respond poorly to treatment. However, MYC-dependent lymphogenesis is believed to require additional oncogenic alterations, such as deregulation of genes that counteract the proapoptotic functions of MYC. TPL2 is a MAP3 kinase with an obligatory role in inflammatory signal transduction on the MEK/ERK axis but little is known about its involvement in B lymphocyte biology and lymphogenesis.

Aims: The aim of this study is to define the impact of and the mechanism by which TPL2 kinase affects MYC-induced lymphogenesis.

Methods: CD19+ positive B lymphocytes were isolated from peripheral blood of human healthy individuals and mouse B cells from spleens of WT (C57BL/6) and lymphomagenic mice engineered to overexpress c-myc in B cell pro-
genitor cells under the control of the IgH chain enhancer. Mouse pre-B lymphocytes were isolated from bone marrow by flow cytometric cell sorting. Differ-
entiation status of lymphomas was analysed by flow cytometry using B220, IgM and IgD antibodies. The TPL2 RNA and protein expression levels were measured by qPCR and Western blot analysis, respectively. The extent of apop-
tosis was estimated by immunohistochemical evaluation of activated caspase-
3 in paraffin embedded mouse lymphoma tissues and by flow cytometry using Annexin and 7AAD staining of ex vivo cultured lymphoma cells following cytokine deprivation.

Results: TPL2 RNA levels were found dramatically decreased in various human Burkitt lymphoma cell lines as well as in 7 primary Burkitt lymphoma biopsies compared to B lymphocytes of healthy individuals. In line with this finding, both pre-B and B lymphomas derived from Eμ-myc mice express very low levels of TPL2 RNA and protein level, compared to pre-B and splenic B lymphocytes isolated from WT mice. Interestingly, pre-B and B lympho-
phocytes of healthy (premalignant) Eμ-myc mice express TPL2 in comparable levels to their WT counterparts, suggesting that the reduction of TPL2 expres-
sion in lymphomas is an additional oncogenic alteration. In this regard, genetic ablation of TPL2 in Eμ-myc mice (Eμ-myc/tpl2−/−) significantly shortened their survival to 92 days from 140 days of Eμ-myc/tpl2+/+ mice (p<0.005). Eμ-
myc/tpl2−/− mice also displayed a trend to develop more pre-B cell lymphomas compared to Eμ-myc/tpl2+/+ mice. This may be attributed to the decreased TPL2 expression in mouse pre-B lymphocytes, while it is upregulated in mature B lymphocytes. Finally, Eμ-myc/tpl2−/− lymphomas displayed reduced levels of apoptosis.

Figure 1.

Summary/Conclusions: This study reveals a novel pathway during myc-driven lymphogenesis. We show that MYC deregulation imposes selective pressure in favor of clones with decreased expression of TPL2 kinase. This process seems to be advantageous for the malignant clone, since genetic abla-
tion of TPL2 in the Eμ-myc mouse model accelerates MYC-induced lymphoma-
genesis likely by contributing to apoptosis resistance.
mation in several diseases analyzable by liquid biopsies, representing minimally invasive methods for precision diagnostics and prognosis. Blood extracellular microRNAs (miRNAs) are under investigation as novel biomarkers. While tissue miRNAs in DLBCL patients have been extensively studied, only few reports, and limited to a small subset of miRNAs, evaluated the role of circulating/serum miRNA as potential prognostic factors.

Aims: To identify and validate a serum miRNA signature with prognostic value in a cohort of newly diagnosed DLBCL patients.

Methods: This is a on-going prospective non-interventionist study on a cohort of newly diagnosed de novo DLBCL patients uniformly treated with six courses of R-CHOP (Rituximab, Cyclophosphamide, Vincristine, Doxorubicin and Prednisone). Serum samples of patients were collected at diagnosis and after the end of treatment. Treatment response was evaluated by standard Cheson criteria. The expression profile of selected circulating miRNAs described as associated with lymphoid malignancies by us (let-7c-miR-99a/miR-125b cluster) and by previously published studies (miR-22, miR-18a and miR-20a) was evaluated by qRT-PCR in cyclin D1-overexpressing DLBCL cell lines. RNA samples collected at diagnosis of the first 18 patients enrolled into the study.

Results: Our results showed that the expression level of serum miR-22 as well as let-7c-miR-99a/miR-125b cluster was significantly higher at diagnosis, in patients unresponsive to R-CHOP treatment when compared with responsive patients. On the contrary, miR-18 and miR-20 levels appeared to be not significantly associated to treatment response. In addition, a global expression profile of circulating miRNAs was evaluated in serum samples derived from a smaller cohort of patients (n=4) after first-line chemo-immunotherapy. Interestingly, we found a striking difference in miRNA modulation upon treatment between responsive and unresponsive patients. In particular, we found 31 miRNAs significantly modulated after R-CHOP in the group of responsive patients, including miR-22. In contrast, this miRNA subset did not show remarkable expression changes in unresponsive patients. Moreover, we performed a study interrogating The Cancer Genome Atlas (TCGA) database about miRNA expression levels in samples of DLBCL patients. We found that the only available data are relative to the miRNA expression levels in tumor tissue samples of 47 out of 58 DLBCL patients. Kaplan Meier method and log-rank test revealed a signature of 13 miRNAs with potential prognostic value. Among these we found that miR-22, also emerged as modulated in our genome-wide analysis, was linked to risk of disease recurrence.

Summary/Conclusions: These preliminary data suggest that the serum miR-22 as well as miR-99a/let-7c-miR-125b miRNA cluster are of potential interest as non–invasive biomarkers to predict therapeutic response in DLBCL patients. Ongoing experiments in a wider cohort of patients are aimed to confirm these results and unveil potential miRNA signature with predictive value.

E1380
INTRACELLULAR CALCIUM AND METABOLISM HAVE CRITICAL ROLES IN DETERMINING ANTI-CD20 ANTIBODY EFFICACY IN DLBCL

E. Vilventhraaraj 1, 2, G. Riebl 3, A. Braun 1
1Centre for Haematology-Oncology, Barts Cancer Institute, London, United Kingdom

Background: Since the discovery and utilisation of the Type-I anti-CD20 antibody Rituximab, many have tried to enhance the efficacy of anti-CD20 antibodies in order to improve first-line treatment of B cell malignancies, leading to the development of anti-CD20 and anti-CD20-like antibodies. However, the biological role of CD20 and the mechanism of anti-CD20 antibody action remains unclear. However, CD20 has been shown to be involved in the store operated calcium (Ca2+) system. This complex has the ability to facilitate mitochondrial membrane permeabilisation, resulting in reduced mitochondrial function. Basal oxidative phosphorylation (OxPhos), ATP production, and maximal and spare respiratory capacity of cells can be calculated as a measure of mitochondrial function.

Aims: i) Assess and compare intracellular calcium concentration following treatment with anti-CD20 antibodies ii) Evaluate mitochondrial function of cells following treatment with anti-CD20 antibodies iii) Assess whether cytotoxicity of Type-I and Type-II anti-CD20 mAbs can be enhanced by exploiting cellular metabolism

Methods: We established a panel of four DLBCL cell lines (Karpas422, Pfeiffer, OCI-LY7 and SUDHL4). Following a 24-hour treatment with one of four anti-CD20 antibodies (Rituximab) and three Type-II anti-CD20 antibodies (BH2, Obinotuzumab and Tositumomab), intracellular calcium concentration was quantified and visualised using imaging flow cytometry. Next, we used the XF Seahorse Mito Stress Test to reveal bioenergetic profiles of the cell lines following a 24-hour treatment with the same antibodies. We used Metformin (5 mM) as an OxPhos inhibitor and then characterised the bioenergetic profile of our panel of cell lines again, this time to assess how combining each anti-CD20 antibody with an OxPhos inhibitor affected mitochondrial function. Metformin was also used to reduce the mitochondrial membrane potential (MMP) across our panel of cell lines. We confirmed MMP reduction by staining cells with JC-1, a chameleon dye used as an indicator of MMP and analysed samples using flow cytometry. Under the same conditions, we conducted clonogenic survival assays to see whether cytotoxicity of anti-CD20 antibodies could be enhanced by manipulating metabolism.

Results: Intracellular calcium concentration was decreased across our panel of cell lines following a 24-hour treatment with all Type-II anti-CD20 antibodies in our panel. This decrease was not observed following treatment with the Type-I anti-CD20 antibody Rituximab. Treatment with anti-CD20 antibodies resulted in a significant increase in the maximal respiratory capacity of our panel of cell lines; cells were able to produce more ATP in response to oxidative stress. Conversely, pharmacological inhibition of OxPhos impaired mitochondrial function, causing a significant reduction in basal OxPhos and in maximal respiratory capacity. Under this condition, cells were unable to increase ATP production in response to oxidative stress. We also show that treatment combining Metformin with either Type-I or Type-II anti-CD20 antibodies prevents the increase in maximal respiratory capacity observed with anti-CD20 antibody treatment alone. When analysing the clonogenic survival of cell lines, we have found that only the cytotoxicity of Type-II anti-CD20 antibodies is enhanced by simultaneously treating cell lines with Metformin.

Summary/Conclusions: Our data show for the first time that when cells are treated with anti-CD20 antibodies, intracellular calcium is decreased. Intracellular calcium remains unchanged following treatment with Rituximab. Next, we show anti-CD20 antibody treatment causes cells to increase maximal mitochondrial respiratory capacity to compensate for reduced basal mitochondrial function. We show that inhibition of OxPhos decreases the cells from being sensitive to chemical inhibitors of OxPhos and Metformin. When analysing the clonogenic survival of cell lines, we have found that only the cytotoxicity of Type-II anti-CD20 antibodies is enhanced by simultaneously treating cell lines with Metformin.

CYCLIN D1 ONCOGENIC OVEREXPRESSION LEADS TO A GLOBAL TRANSCRIPTIONAL DOWNREGULATION IN MALIGNANT LYMPHOID CELLS

R. Albero 1, A. Enjuanes 2, S. Demajo 3, G. Castellano 3, M. Pinyol 4, N. Garcia 5, C. Capdevila 1, H. Suarez-Cisneros 6, K. Karube 4, S. Bea 1, I. Martin-Subero 1, E. Campo 1, P. Jares 3
1IDIBAPS, Barcelona, Spain, 2Genomics Unit, IDIBAPS, 3Molecular Biology Core, Hospital Clinic, Barcelona, Spain, 4University of the Ryukyus, Okinawa, Japan, 5Hospital Clinic, Barcelona, Spain

Background: Cyclin D1 is an oncogene frequently overexpressed in human cancers. In hematological neoplasms, mantle cell lymphoma and multiple myeloma are clear examples of deregulated cyclin D1 expression. It plays a dual function as cell cycle and transcriptional regulator, although the latter is widely unexplored.

Aims: In this study, we investigate the transcriptional role of cyclin D1 in lymphoid malignancies.

Methods: Chromatin immunoprecipitation (ChIP) followed sequencing was performed in four established MCL cell lines. RNA-Sequentializing (RNA-Seq) and information from histone ChIP-Seq were correlated with genomic intervals displaying cyclin D1 binding. Transcriptional downregulation was studied through cytotmetric RNA total quantification in lymphoblastic cyclin D1-overexpressing models and RNA Pol II ChIP-Seq.

Results: Endogenous cyclin D1 showed widespread binding to active promoters. Its overexpression was responsible for a global transcriptional down-modulation. Cyclin D1, instead of showing specific gene activation, seems to globally decrease cell transcription. Mantle cell lymphoma and multiple myeloma cell lines displayed an inverse relation with cyclin D1 quantity. This transcriptional effect was associated with an increased RNA polymerase II pausing in promoters due to cyclin D1 overexpression.

Summary/Conclusions: This mechanism expands the oncogenic cyclin D1 functions and places the transcriptional machinery as a potential therapeutic target in cyclin D1 overexpressing tumors.

MICROENVIRONMENTAL EXPRESSION OF IMMUNOREGULATORY MOLECULES AND CYTOKINES CLASSESS CLASSICAL MCDONALD LYMPHOMA PROGNOSIS

O. Novosad 1, N. Svergun 2, O. Skakhova 3, O. Gorbach 2, N. Khranovska 2, I. Kryachok 1
1Oncohematology, 2Experimental Oncology, National Cancer Institute, Kiev, Ukraine

Background: Over the past decade, new biologic insights have revealed a key role of tumor microenvironment in the pathogenesis of classical Hodgkin’s lymphoma (cHL). cHL infiltrating cells produce cytokines and growth factors that provide essential stimulatory signals for survival and proliferation of Hodgkin’s and Reed–Stemberg cells. Moreover, clinical behavior of cHL may be directly regulated by the cross-talk between tumor cells and infiltrating immune cells.
Aims: The aim of our study was to estimate the role of microenvironment expression of immunoregulatory molecules (PD-1 ligands, IDO) and cytokines (TGF-β, IL-13) in clinical outcome of cHL.

Methods: 74 patients (median age: 44, range: 17-71 years; males: 22, females: 52) were included in the study. 55.4% of patients were diagnosed with an early stage of HL, while 44.6% - with advanced stages. ABVD or BEACOPP (14/esc) were administered as a 1st-line therapy. 78.3% of patients achieved complete remission (CR/PR), while 8.1% had progression of disease during the therapy. We recorded 14.8% relapses in patients after the 1st line therapy during the follow-up period (median duration – 36 months; range 6–66 months). PD-L1, PD-L2, IDO, TGF-β, IL-13 mRNA expression levels were analyzed in fresh pre-treatment lymph nodes biopsies using qRT-PCR.

Results: Expression of PD-1 ligands was heterogeneous across the samples and did not depend on histological variant or stage of cHL. Only 12.1% of patients (9/74) were PD-L1 negative and all but one of those cases had a CR and a long-term remission. Patients with PD-L1 overexpression tended to have a higher risk of relapse, comparing to those without PD-L1 expression (p=0.1). We did not find any significant association between PD-L2 expression level and clinical outcome of cHL. Expression levels of IDO, TGF-β, IL-13 were evaluated in 38 cHL samples. 18.4% (7/38) patient were IDO positive and 81.6% (31/38) - IDO negative. The presence of IDO expression was associated with a higher risk of relapse in cHL patients (p=0.008). 85.7% (6/7) and 23.3% (7/30) of relapses were observed during the follow-up period in IDO+ and IDO- patients, respectively (p<0.05). The patients with double negative expression of PD-L1 and IDO were noted to have a favourable outcome of cHL. A 5-year event-free survival (EFS) rate was 80% for double negative PD-L1+/IDO-patients vs 20% for double positive PD-L1+/IDO+ patients (p=0.008). IL-13 was expressed at various levels depending on the stage of cHL with the highest expression levels in advanced stages. A trend for a higher risk of relapse was observed for HL patients with increasing level of IL-13, (p=0.23). TGF-β expression was checked in 15 cHL patient samples, with 78% analyzed by flow cytometry in order to assess complement-dependent cytotoxicity (CDC) on HL cells. Multivariate analysis showed that TGFβ expression is a significant increase EFS in cHL patients with HRs of 6.7 [95% (CI) 1.3-2.1, p=0.04].

Summary/Conclusions: Our results clearly indicate that HDAC6 inhibition can be used as an effective strategy to be associated with the therapy with anti-PD-L1 mAbs. This strategy seems to be highly promising in cHL patients, known to express low CD20 levels. Moreover, we performed cytotoxic assays using flow cytometry in order to assess complement-dependent cytotoxicity (CDC) as well as apoptosis. We used HDAC6-specific chemical inhibitors (tubacin, trichostatin A and clinically tested ricolinostat) as well as HDAC6 shRNA assay. We also performed animal studies using SCID mice injected with Burkitt CD20+ lymphoma cell line s.c. and treated with ricolinostat i.p. We used both the pharmacological (i.p. administration of ricolinostat) and genetic (cells stably transduced with HDAC6 shRNA) approach.

Results: The results of our studies demonstrate that HDAC6 inhibition significantly increases CD20 level and sensitizes tumor cells to rituximab- and ofatumumab-induced CDC, as well as to direct cytotoxicity of obinutuzumab. In in vivo settings HDAC6 inhibition potentiated the efficacy of rituximab by significantly reducing tumor size and prolonging the survival of the mice.

Summary/Conclusions: Our results clearly indicate that HDAC6 inhibition sensitizes tumor B-cells to anti-CD20 immunotherapy. Therefore, we propose HDAC6 inhibition with specific inhibitors as an effective strategy to be associated with the therapy with anti-PD-L1 mAbs. This strategy seems to be highly promising in cHL patients, often expressing very low CD20 level and do not benefit from immunotherapy.

Background: Primary gastrointestinal (GI) T-cell lymphoproliferations (T-CL) are heterogeneous entities, which diagnoses are difficult to perform. T-CL include aggressive lymphoma such as enteropathy-associated T-cell lymphoma (EATL) and as indolent mononuclear lymphoproliferations. Refractory coeliac disease type II (RCDII) is one of the indolent clonal T-CL that complicates coeliac disease (CD) and may evolve toward an overt EATL. The differential diagnosis of RCDII from CD and RCDI is difficult and essentially based on negative expression of sCD3 and CD38 and the presence of a clonal TCR rearrangement. Lymphocytes from RCDII are dependent for survival on IL-15, which promotes T lymphocytes towards a cytotoxic NK phenotype.

Aims: We thus studied the expression of NKp46 on a representative panel of GI T-CL to assess its diagnosis and prognosis value.

Methods: Using formalin-fixed paraffin-embedded tissue biopsies, we assessed NKp46 expression by immunohistochemistry (IHC) and investigated its clinical and biologic significance on 177 intestinal, 11 lymph node and 7 other biopsies from 84 CD or RCD patients (RCDI, n=20; RCDII, n=40), 44 GI T-cell lymphoma patients (EATL, n=25; monomorphic epitheliotropic intestinal T-cell lymphoma_MEITL, n=4; indolent T-LPD, n=15), 11 healthy patients and 5 patients with a GI inflammatory environment as controls.

Results: By doing ROC analysis on number of cells expressing NKp46 on GI-TCL we identify that 25 intra-epithelial lymphocyte (IEL) per 100 epithelial cells (EC) clearly separates RCDII from CD and RCDI patients, with a good positive and negative predictive values (100 and 95% respectively). In healthy controls, CD or RCDI patients, NKp46 was only expressed on scattered IEL (median 3%, 0-15). Based on NKp46 expression the overall survival is poor if over 25% of IEL are positive for NKp46 (OS-5years 96.4% vs 72.8%, P=0.0004) (Figure 1A). Among patients with GI T-cell lymphoma, we show that NKp46 was expressed in most of aggressive lymphoma (EATL 80%, n=20/25 and MEITL 100%, n=4/4). On the other hand, NKp46 was not expressed in the indolent T-LPD (n=15). The NKp46 expression was also associated with a poor prognosis in GI T-cell lymphoma patients (OS-5years 50.5% vs 5.4%, P=0.0011) (Figure 1B).

Summary/Conclusions: The NKp46 expression in more than 25 IEL per 100 EC by IHC analysis can easily identify RCDII from CD and RCDI. Furthermore, the NKp46 expression is associated with aggressive forms of GI T-cell lymphoma. Finally, the NKp46 expression was strongly associated with shortened survival. Thus NKp46 provides a new biomarker for both diagnosis and prognosis in GI T-CL.

HIGH EXPRESSION LEVELS OF MIR23A CLUSTER IN DLBCL ANTAGONIZE INDUCTION OF APOPTOSIS

N. Freytag1, C. Pommerenke2, Y. Merkhofer1, J. Anirbas Arranz1, D. Kube3, H. Drexl1, H. Quentmeier2, S. Eberth1, 1Junior Research Group Molecular Cancer Research, 2Department of Human and Animal Cell Lines, Leibniz-Institute DSMZ - German Collection of Microorganisms and Cell Cultures, Braunschweig, 3Haematology and Oncology, University Medical Center Göttingen, Göttingen, Germany

Background: The microRNA cluster MIR23A, which encodes for the mature microRNAs miR-23a, miR-27a and miR-24, was shown to be deregulated in many different malignancies including subtypes of B cell non-Hodgkin lymphoma (B-NHL). Furthermore, high expression of miR-23a was correlated with poor overall survival in diffuse large B-cell lymphoma (DLBCL) patients (Wang et al., Med Oncol. 2014) indicating that miR-23a might act as an onco-miR (tumor promoting microRNA) in this entity. However, both targets and function of the MIR23A cluster in B-NHL remain unknown.

Aims: This study aims to elucidate the role of the MIR23A cluster as a potential onco-miR in DLBCL by identification of the lymphoma-specific targetomes of miR-23a and miR-27a and subsequent analyses of associated functions.

Methods: We identified novel cell line U-2932 K1, which has a low basal expression level of MIR23A cluster, was used for the lentiviral-based generation of clones overexpressing miR-23a, miR-27a, or a scrambled control. Differentially expressed genes (DEG, fold-change >2, p-value <0.05) between samples were determined by miRNA sequencing (RNA-Seq). miR-23a and miR-27a targetomes were identified by immunoprecipitation of AGO2-bound miRNA (AGO2-RIP) followed by RNA-Seq. MicroRNA targets had to be enriched >2-fold with a p-value <0.05. Validations were performed by qPCR and immunoblotting.

Gene set enrichment analyses (GSEA) and GO-term analyses were applied on identified targetomes and DEG to predict microRNA associated functions. Apoptosis was assessed by Annexin-V staining followed by FACS analyses as well as in immunoblots.

Results: Overexpression of miR-23a and miR-27a, respectively, in a DLBCL model cell line resulted in global alterations of gene expression (so-called indirect targets) with a substantial overlap of 104 of DEG affected by both miRNAs. Using AGO2-RIP, 26 novel direct targets of miR-23a, and 20 novel direct targets of miR-27a were identified. GSEA and GO-term analyses of direct and indirect targets indicated that the MIR23A cluster might regulate processes in apoptosis. Moreover, BBC3 which encodes the pro-apoptotic protein PUMA was one of the identified direct targets of miR-23a. As expected, induced apoptosis was reduced in MIR23A overexpressing DLBCL cells failed to induce PUMA on protein-level. Importantly, functional analyses confirmed that miR-23a overexpression reduces and high levels of miR-27a significantly attenuate the ability of DLBCL cells to undergo apoptosis in response to DNA damage.

Summary/Conclusions: We demonstrate that high levels of miR-23a and miR-27a downregulate induction of apoptosis in a lentiviral-based cell line. This might be one possible explanation why DLBCL patients with high miR-23a expression levels have a worse overall survival rate than patients with low levels. Thus, further studies should address the suitability of the MIR23A cluster as biomarker and potential target in DLBCL.
hours and produced 8.7 – 9.3 X 10^3 ng/ml of IgM. PCs isolated from BCWM.1 increased to 130% and produced 2.5 – 2.8 X 10^3 ng/ml of IgM. LPLs from both cells line proliferated in culture (~ 130 – 140% in MWCL-1 and ~170 – 200% in BCWM.1 at 72 hours), gave rise to the more differentiated PCs (7.5 – 9.0% PCs at 72 hours in MWCL-1 and 1.2 – 1.4% PCs in BCWM.1), and secreted smaller amounts of IgM than PCs (3.5 – 5.0 X 10^3 ng/ml in MWCL-1 and 0.3 – 0.7 X 10^3 ng/ml in BCWM.1).

Summary/Conclusions: Our analysis of the 2 WM cell lines provides evidence to support the common hypothesis that malignant PCs arise from the clonal malignant LPL population, and are primarily responsible for IgM secretion in WM.

LMP-1 MEDIATED UPREGULATION OF IL-2Rα PROMOTES LYMPHOMA-GENESIS AND CHEMOTHERAPY RESISTANCE IN NATURAL KILLER-T-CELL LYMPHOMA AND COULD BE A POTENTIAL THERAPY TARGET

1Medical oncology, 2Hematologic Oncology, Sun Yat-sen University Cancer Center, Guangzhou, China

Background: Natural killer/T-cell lymphoma (NKTCL) is an Epstein–Barr virus (EBV)-associated, highly aggressive lymphoma. Treatment outcome remains sub-optimal, especially for advanced-stage or relapsed diseases. Our previous study demonstrated the prognostic value of IL-2Rα in NKTCL, but the role of IL-2Rα in the lymphomagenesis and chemotherapy resistance and its interactions with EBV in NKTLCL remain to be investigated.

Aims: This study investigated the mechanism of IL-2Rα expression in NKTCL, and explored the role of IL-2Rα in lymphomagenesis and chemotherapy resistance as well as the potential role of anti-IL-2Rα treatment in NKTCL.

Methods: Expression of IL-2Rα was measured in NK-92 (LMP-1 weak expression) and SNK-6 (LMP-1 strong expression) cells by western blot, quantitative real-time PCR, enzyme-linked immunosorbent assay, and flow cytometry, respectively. LMP-1-harboring lentiviral vectors were transfected into NK-92 cells to examine the correlation between LMP-1 and IL-2Rα expression. Proteins in the downstream pathways of LMP-1 signaling were measured in NK-92 cells, at both protein and mRNA levels. Expression of IL-2Rα was remark-ably upregulated in NK-92 cells transfected with LMP-1-harboring lentiviral vectors compared with those transfected with negative control vectors. Proteins in the MAPK/NF-κB pathway were upregulated in LMP-1-expressing NK-92 cells compared with the negative control. Selective inhibitors of those proteins induced the MAPK/NF-κB pathway were upregulated in LMP-1-expressing NK-92 cells compared with those transfected with negative control vectors. Proteins in the downstream pathways of LMP-1 signaling were measured in NK-92 cells, at both protein and mRNA levels. Expression of IL-2Rα was remark-ably upregulated in NK-92 cells transfected with LMP-1-harboring lentiviral vectors, and the cell cycle assay displayed a significant decrease in the percentage of cells in the G0/G1 phase (p<0.05) and an increase in the percentage of cells in the S phase (p<0.05), while apoptosis was not affected. Subsequent western blot tests demonstrated that cyclin A, B, D, and CDK1, 4 were involved in the regulation of cell cycle with overexpression of IL-2Rα. The IC50 values to all three chemotherapy drugs were significantly increased after overexpression of IL-2Rα which can be fully reversed by addition of anti-IL-2Rα antibody.

Summary/Conclusions: IL-2Rα expression was upregulated in NKTCL by LMP-1-mediated activation of MAPK/NF-κB pathway. IL-2Rα can promote NKT-CL cell proliferation partially through regulation of cell cycles and induce chemotherapy resistance, which can be reversed by anti-IL-2Rα antibody, indicating the potential role of IL-2Rα as a therapy target in NKTCL.

San Martino-IST, Genoa, 20Hematology Department, Annunziata Hospital of Cosenza, Cosenza, Italy

Background: PD1 binding to its ligand PDL1 inhibits TCR/BCR signaling; impairs activation; and effector functions of T- and B-cells; induces a state of T-cell exhaustion; and ultimately provokes tolerance towards cancers. PD1 is expressed on Hodgkin lymphoma (HL) and B-cell non-HLTTs. The TME may play an essential role in maintaining PD1-induced immune exhaustion. LEN is an oral immunomodulator (IMiD) with direct antineoplastic activity and immune checkpoint activation. This study aimed to evaluate the role of the TME in supporting the PD1 axis; and 3) to determine whether LEN influences PD1 or cognate ligand expression.

Aims: 1) To better characterize the PD1, PD1L and the lesser-known PDL2, phenotype in peripheral neoplastic CD19+ lymphocytes and T-cell subsets in patients with low-grade B-cell lymphoma; 2)to evaluate the role of the TME in supporting the PD1 axis; and 3) to determine whether LEN influences PD1 or cognate ligand expression.

Methods: Samples obtained from patients attending participating Hematology Units were used to determine PD1, PDL1, PDL2 phenotype (%SEM) by Flow-cytometry (FC). Autologous activated T-cells (AAT) were obtained by in vitro co-culture of patient T-cells with anti-CD3/CD28 beads, rIL2 and with PBMCs. Cultures were monitored daily until sizeable clumping was observed and tested for PD1 and ligand expression. In selected experiments LEN(provided by Cel-gene) was added to cell cultures. Results: Twelve cases of lymphoma were evaluated for PD1, PDL1 and PDL2 expression on malignant B- and T-cells by FC. The expression of PD1 and PDL2 was similarly expressed, while PDL1 was almost undetectable on B-cells. Levels of PD1 expression on CD3+ cells were variable across samples, however they were significantly higher than those expressed on malignant B-cells. Significantly higher levels of PD1 expression and very low levels of ligands were detected in both CD4+ and CD8+ cells.CD4+ and CD8+ cells showed consistent formation of B/T-cell clusters. Higher numbers of CD19+CD56+PD1L+ cells were detected than PDL1+ cells compared to baseline cells. PD1 expression also significantly increased in AAT co-culture on B-cells. PD1 expression
on CD3+ cells was unaffected by AAT, although the expression of both ligands remained increased significantly. Closer analysis of T-cell subsets showed that only in CD4+ cells, PD1 expression increased significantly following co-culture experiments. Preliminary data on lymphoma-AAT co-culture experiments (n=3) indicated that LEN (0.5–1µM) did not negatively influence the formation of AAT clusters. After 48 h of co-culture, the expression of CD19+CD5-CD11c+ cells increased in 2/3 cases following LEN treatment while, PD-L2 expression remained unchanged. PD1 expression gradually increased following exposure to LEN compared to untreated cells. CD3+ cells showed a significant increase in PD1 expression by LEN, while the expression of both ligands remained unaffected. Evaluation of activated T-cell subsets showed similar results, with the exception of stronger induction of PD1 and PD1L expression by LEN in CD8+ cells.

**Summary/Conclusions:** Our data provide support for the potential involvement of the PD1-axis in lymphoma patients. Interestingly, LEN further induces the expression of PD1 in CD8+ and CD4+ cells and may contribute to reactivating PD1 signaling under treatment. The PD1 pathway may be potentially targeted to overcome both the intrinsic and LEN-induced exhaustion phenotype.

**IDENTIFICATION AND DIAGNOSTIC APPLICATION OF GENOMIC NPM-ALK FUSION SEQUENCES IN ANAPLASTIC LARGE CELL LYMPHOMAS**

M. Krumbholz1,*, C. Damm-Welk2, W. Woessmann2, M. Metzler1

1Department of Pediatrics, Justus-Liebig-University, Giessen, Germany

**Background:** ALK positive anaplastic large-cell lymphoma (ALCL) account for 10-15% of pediatric Non-Hodgkin lymphomas. Most of these patients carry the chromosomal translocation t(2;5)(p23;q35) resulting in the fusion gene formation. The quantification of NPM-ALK fusion transcripts is a well-established tool for diagnostic purposes and risk stratification during the course of treatment.

**Aims:** Establishment of a multiplex long-range PCR assay identifying patient-specific genomic NPM-ALK fusion sequences for a DNA-based monitoring of minimal residual disease in ALCL patients. Compared to RNA-based methods the quantification of DNA is independent of the gene expression. Additionally, due to the higher stability of DNA, cell-free circulating tumor DNA (cfDNA) should be detectable in the patient’s plasma and may represent a tumor maker for “liquid biopsies” in ALCL patients.

**Methods:** Using a specifically designed multiplex long-range PCR assay, genomic NPM-ALK fusion sequences were identified in 45 ALCL patients. The genomic NPM-ALK breakpoints were analyzed concerning fine structure and breakpoint distribution pattern. Furthermore, the patient-specific genomic NPM-ALK fusion sequences were evaluated for their use as biomarkers in selected cases. For this purpose patient’s blood and plasma samples were quantified using a high sensitive digital droplet PCR assay.

**Results:** In more than 60% of cases the identified breakpoint was localized within repeat regions. The genomic breakpoints within the breakpoint cluster regions of the fusion genes were randomly distributed. Most of the NPM-ALK fusion sequences were characterized by the occurrence of small insertions or deletions indicating the involvement of the non-homologous end-joining (NHEJ) repair system for chromosomal translocation initiation. Using a DNA based quantification assay in a subset of patients, the genomic NPM-ALK fusion gene sequences were detectable in circulating tumor cells in patient’s blood samples as well as in cell-free tumor DNA in plasma samples.

**Summary/Conclusions:** The established multiplex long-range PCR assay is a useful diagnostic tool for the identification of genomic NPM-ALK fusion sequences. This individual tumor maker is independent of gene expression and can be used for therapy response monitoring and relapse detection.

**E1392**

**ARSENIC TRIOXIDE TARGETS BCL6 FOR DEGRADATION AND INHIBITS THE PROLIFERATION OF BCL6-DEPENDENT DIFFUSE LARGE B-CELL LYMPHOMA**

E. Tse1,*, K. Yue1, D. Chau2, Y.-L. Kwong1

1Department of Medicine, 2Medicine, The University of Hong Kong, Hong Kong, Hong Kong

**Background:** B-cell lymphoma 6 (BCL6) is a transcription repressor and is frequently over-expressed in diffuse large B-cell lymphoma (DLBCL). It suppresses the expression of its target genes ATRX, TP53 and CDKN1A, leading to dysregulation of DNA repair and cell proliferation. It has been shown that BCL6 is an oncoprotein involved in the pathogenesis of DLBCL and represents a potential therapeutic target. Arsenic trioxide (ATO) targets various oncogenic proteins, including PML-RARA in acute promyelocytic leukemia (APL), Tax in adult T-cell leukemia/lymphoma (ATL), cyclin D1 in mantle cell lymphoma (MCL), and NPM-ALK in anaplastic large cell lymphoma (ALCL), for degradation through the ubiquitin-proteasome pathway. ATO is now used for the management of APL, ATL and MCL with proven clinical benefit.

**Aims:** To investigate if ATO targets BCL6 and inhibits the proliferation and growth of BCL6-dependent DLBCL.

**Methods:** BCL6-dependency of a panel of DLBCL cell lines (i.e. OCI-Ly1, OCI-Ly7, SU-DHL-6, OCI-Ly18 and Pfeiffer) was determined based on their sensitivity to proliferation inhibitory activity of the BCL6 inhibitor 79-6 (Calbiochem). The effects of ATO and cisplatin as single agent or in combination on cell viability and apoptosis of DLBCL cells were determined using MTT assay and flow cytometric analysis. Expression of BCL6 and its target genes was examined with quantitative RT-PCR and western immunoblotting. The therapeutic efficacy of ATO treatment was also examined in a DLBCL (OCI-Ly7) xenograft mouse model.

**Results:** OCI-Ly1, OCI-Ly7 and SU-DHL-6 were highly sensitive to inhibitory activity of BCL6 inhibitor and were designated as BCL6-dependent. Treatment of DLBCL cells with ATO led to a decrease in BCL6 protein level and an upregulation of downstream targets of BCL6, including PRDM1, CD44 and CD69. The effect of ATO on BCL6 protein were abrogated by treatment with proteasome inhibitor MG132, suggesting that ATO targets BCL6 for degradation through the ubiquitin-proteasome pathway. Interestingly, ATO also inhibited cell proliferation and induced apoptotic cell death of BCL6-dependent DLBCL cell lines, analogous to the effect of BCL6 inhibitor on these cells. In addition, there was a synergistic inhibitory and cytotoxic activity between ATO and cisplatin. Finally, ATO treatment suppressed the growth of DLBCL in a xenograft mouse model.

**Summary/Conclusions:** ATO targets BCL6 for proteosomal degradation and inhibits the proliferation and growth of BCL6-dependent DLBCL.

**PROTEOMIC PHOSPHOSITE ANALYSIS IDENTIFIED CRUCIAL NIPA SERINE RESIDUES FOR NPM-ALK-MEDIATED TRANSFORMATION**

A. Gengenbacher1,*, A. Rudort2, T. Poggio1, C. Rummelt1, S. Kreutmair1, V.I. Dumitri1, J. Duyster1,2, A.L. Illet1,2

1Dept. of Hematology, Oncology and Stem Cell Transplantation, University Medical Center, Freiburg, 2German Cancer Consortium (DKTK), Heidelberg, 3Center for Biological Systems Analysis, University of Freiburg, Freiburg, Germany

**Background:** Anaplastic large-cell lymphoma(ALCL) is an aggressive non-Hodgkin lymphoma that occurs mainly in children and younger adults. Patients typically show an advanced stage disease as well as an aggressive disease pattern with extraordinary manifestations. At the molecular-genetic level, 60% of the patients with systemic ALCL exhibit a translocation t(2;5)(p23;q35), which leads to the expression of the NPM-ALK fusion protein. Under the control of the NPM promoter, ALK activation causes increased and autonomous cell proliferation. Nuclear interaction partner of ALK (NIPA) was first identified as a new interaction partner of the oncogene NPM-ALK in a yeast-2-hybrid screen which defines an E3-SCF ligase and is physiologically involved in cell cycle regulation at the transition from G2 phase to mitosis. It has already been shown in preliminary studies that co-expression of NIPA with the oncogenic tyrosine kinase NPM-ALK results in the constitutive phosphorylation of NIPA (Illet et al., 2012a). Until now, the specific signal transduction pathway, the crucial phosphorylation sites in NIPA, and the biological role of the phosphosites are still unclear. Molecular insights into the activated pathways of the kinases NPM-ALK may help to identify new druggable targets for therapeutic implications.

**Aims:** In the present study, we investigated the molecular mechanisms as well as the functional impact of the NPM-ALK-induced NIPA phosphorylation.

**Methods:** For this purpose, biochemical methods with ALCL cells were used to examine functional effects of constitutive NIPA phosphorylation. Moreover, we performed a “proteomic-phosphosite-analysis” to identify crucial NPM-ALK specific phosphorylation sites in NIPA. Based on these results, phospho-deficient NIPA mutants were generated to investigate the functional effect of this phosphorylation: MTT proliferation- and Softagar-Assays were performed after cell infection of Ba/F3 and primary NIPA-deficient MEL cells with NPM-ALK and the respective phospho-deficient NIPA to reveal transformation and growth ability.

**Results:** It has already been shown, that cell cycle independent NIPA phosphorylation at critical serine residues 354, 359 and 359 leads to dissociation of the inhibitory SCF-NIPA-complex formation. Proteomic-Phosphosite-analyses identified 10 significant upregulated (ratio >2; Log2Fold Change) NIPA phosphorylations upon NPM-ALK expression. Interestingly, 80% of the identified Serine phospho-sites lie within the NPM-ALK binding region of NIPA. This result was further substantiated by generation of a AAΔ310-402 mutant, where NIPA phosphorylation by NPM-ALK was totally abolished. To further prove biological significance of the identified residues, phospho-deficient mutants were established and transformation assays were performed. Here we were able to show drastically impaired cell proliferation of the mutants with silenced serine/threonine residues 338, 344, 370, 381 and 387 upon NPM-ALK expression.

**Summary/Conclusions:** Taken together, we identified five phosphorylation sites in NIPA to be highly upregulated upon NPM-ALK expression. However,
NPM-ALK mediated NIPA-phosphorylation of those sites did neither change the SCF/kit receptor complex formation nor influence the NIPA localization at the nuclear pore complex, but silencing of these NIPA Serine/Threonine residues led to significantly reduced proliferation and altered transformation ability of Ba/F3 and primary MEF cells. Further analyses will shed some light into the mechanisms underlying these findings and evaluate NIPA as a possible new treatment option for ALCI.

APPLICATION OF CELL-OF-ORIGIN SUBTYPES DETERMINED BY DIGITAL GENE EXPRESSION IN HIV-RELATED DIFFUSE LARGE B CELL LYMPHOMAS

J.-M. Moraleda16, J.-M. Sancho1, J.-M. Ribera1, J.-L. Mate2, J.-T. Navarro1

A series of 55 patients with the diagnosis of HIV-related DLBCL infected patients has been scarcely studied.

Methods:

Aims:

In HIV-related lymphomas, COO subtypes were discordantly assigned with Hans and Lymph2Cx assay and COO subtypes showed no impact on outcomes, independently of the method applied.

Summary/Conclusions:

This work was supported by 2014 SGR225 (GRE) from CERCA Programme/Generalitat de Catalunya, and by funds from Josep Carreras International Foundation, “la Caixa” Foundation and Celgene Spain.

E1395

CXCR4 AND CXCL12 ARE IMPLICATED IN BONE MARROW INFILTRATION PROCESS OF AGGRESSIVE B CELL LYMPHOMAS AND THEIR INHIBITION SUPPRESSES LYMPHOMA CELL GROWTH IN VITRO

A. Deutsch1, 2, B. pursche1, B. Ehlal1, M. Zoidl2, K. Fechter1, E. Steinbauer3, M. Sedej4, H. Greinix1, K. Prochazka 1, T. Wrodnigg2, C. Beham-Schmid 3, P. Neuberger1

Background: The chemokine receptor CXCR4 together with its ligand CXCL12 plays a pivotal role in tumorigenesis of solid and haematological neoplasms. Our comprehensive study on the CXCR4 expression in aggressive lymphoma demonstrated that high CXCR4 expression was associated with poor clinical course of aggressive lymphoma patients.

Aims: Therefore, we aimed to comprehensively study the implication of the CXCR4 - CXCL12 axis in bone marrow infiltration process of aggressive lymphoma and to analyse the effects of CXCR4 antagonists on cell growth and migration of aggressive lymphoma cells in vitro.

Methods: To determine whether CXCR4 and CXCL12 expression have any effects on the bone marrow infiltration process of aggressive lymphomas, we performed gene expression analysis on bone marrow biopsies of our diffuse large B-cell lymphoma patient cohort. Therefore, we used 63 bone marrow specimens, whereby 52 bone marrow biopsies were taken at time of diagnosis. Additionally, we generated a novel CXCR4 antagonist -named WK1- by modification of the side chain of AMD070 - a commercially available CXCR4 antagonist. We treated various aggressive lymphoma cell lines (U2932 and RI-1 as ABC-DLBCL and BL2 and Raji as Burkitt lymphoma lines) with CXCR4 antagonist. We treated various aggressive lymphoma cell lines (U2932 and RI-1 as ABC-DLBCL and BL2 and Raji as Burkitt lymphoma lines) with CXCR4 antagonist. We treated various aggressive lymphoma cell lines (U2932 and RI-1 as ABC-DLBCL and BL2 and Raji as Burkitt lymphoma lines) with CXCR4 antagonist. We treated various aggressive lymphoma cell lines (U2932 and RI-1 as ABC-DLBCL and BL2 and Raji as Burkitt lymphoma lines) with CXCR4 antagonist. We treated various aggressive lymphoma cell lines (U2932 and RI-1 as ABC-DLBCL and BL2 and Raji as Burkitt lymphoma lines) with CXCR4 antagonist. We treated various aggressive lymphoma cell lines (U2932 and RI-1 as ABC-DLBCL and BL2 and Raji as Burkitt lymphoma lines) with CXCR4 antagonist. We treated various aggressive lymphoma cell lines (U2932 and RI-1 as ABC-DLBCL and BL2 and Raji as Burkitt lymphoma lines) with CXCR4 antagonist.

Results: The median follow-up of living patients was 8.5 years. IHC studies showed that 48.8% of the cases expressed CD10, 61.5% expressed BCL6, 55.8% expressed MUM1, and according to Hans algorithm 56.6% had a non-GC phenotype. CD30 was expressed in 15.4% of the cases and EBER was found in 21.2%. The expression of MYC was detected in 32.7% of the cases and BCL2 in 44%, and 18% were dual expressers. Rearrangements involving MYC, BCL2 and BCL6 were detected in 26%, 8% and 28%, respectively.

Features associated with shorter OS and PFS were history of AIDS-defining illnesses, HCV-infection and dual MYC and BCL2 expression. For CXCR4 and CXCL12 expression assays were also good prognostic factors for PFS.

Summary/Conclusions:

These data strongly suggest that CXCR4 and its ligand CXCL12 is implicated in the bone marrow infiltration process of diffuse large B-cell lymphomas. Additionally, our in vitro results indicate that treatment of lymphoma cells with CXCR4 antagonists might be a promising new therapeutic intervention to eliminate lymphoma cells.
CLONOTYPE AND MUTATIONAL PATTERN IN TCRγδ LARGE GRANULAR LYMPHOCYTE LEUKAEMIA

A. Teramo1,2, E. Ciabattoni3, G. Terrin3, I. Petrinì3, G. Barillà1, G. Calabretto1,2, C. Vicentetto1,2, M. Leoncini1,2, C. Ercolì1, A. Cabrelle2, S. Galimberti3, R. Grossi3, N. Pisantì4, G. Semenzato1,2, R. Zambello1

1Department of Medicine, Hematology and Clinical Immunology Branch, Padua University School of Medicine, 2Venetian Institute of Molecular Medicine, 3Department of Clinical and Experimental Medicine, Section of Hematology, 4Department of Translational Research and New Technologies in Medicine, Section of Pathology, 5Department of Informatics, University of Pisa, Pisa, Italy

Background: T-cell large granular lymphocyte leukemia (T-LGLL) is a rare heterogeneous T-cell neoplasia whose leukemic cells usually express the αβ T-cell receptor (TCR); only a small subset of cases expresses the γδ TCR denoting the TCРγδ LGLL. Currently, among the different LGL diseases, TCРγδ LGLL remains less studied and several clinical and laboratory data already described in TCRαβ-LGLL have not yet been explored in TCРγδ-LGLL.

Aims: The aims of this work were 1) to characterize TCРγδ-LGLL defining STAT mutational pattern and CDR3 repertoire diversity/clonal composition (clonotype) and 2) to evaluate correlations among LGL phenotype, mutations, TCR rearrangement and clinical presentations.

Methods: In this work 11 patients affected by TCРγδ-LGLL were included. Sanger sequencing was used for mutational analysis on hot-spot regions in the two genes more frequently mutated in LGL disorders, STAT3 and STAT5b. Immunophenotype of LGL clone was defined by flow cytometry analysis. CDR3 repertoire and frequency distribution of TCR gamma gene rearrangements (clonotype) and kind of mutation observed in TCRαβ-LGLL: γδLGL patients with CD16+ TCR αβ LGL and in a group of HIV-infected patients also at one year before diagnosis (N=11) and at complete response (CR) (N=34). EBV expression was studied by in situ hybridization in tumor biopsies. The following clinical and biological parameters were collected from records: age, gender, date of lymphoma diagnosis, ECOG score, extranodal and bulky disease, B symptoms, Ann Arbor stage, serum lactate dehydrogenase and beta2-microglobulin, International Prognostic Index (IPI), HCV and HBV serology, history of opportunistic infection and of AIDS-defining illness, onset of combination antiretroviral therapy, CD4 counts, HIV loads, type and date of response, relapse date, last follow up or death date. McNemar’s test and Wilcoxon test were used to compare quantitative and qualitative variables, respectively. Survival analyses were performed using the Kaplan-Meier method. P-values of less than 0.05 were considered statistically significant.

Results: Our results showed that TCРγδ LGLL had a high incidence of STAT mutations, 9 out of 11 patients carrying STAT3 or STAT5b mutations in a mutually exclusive pattern. At variance from CD8+ TCR αβ LGLL and CD4+ TCR αβ LGLL, TCРγδ LGLL first being more characterized by STAT3 mutations was the latter by STAT5b. TCРγδ LGLL patients were characterized by both the mutations. Thus, TCРγδ LGLL showed features shared by CD8 and CD4 TCRαβ-LGLL. Consistently, TCРγδ LGLL showed the same correlation between immunophenotype and kind of mutation observed in TCRαβ-LGLL: γδLGL patients with CD16+CD56- LGL immunophenotype were characterized by STAT3 mutations (as in CD8+ T-LGLL), while γδLGL patients with CD56+ LGL immunophenotype by STAT5b mutations (as in CD4+ T-LGLL). Moreover, we observed that patients with γδLGLs positive for Vδ2 showed usually indolent course, while Vδ1 was linked to a more symptomatic disease (4 out of 5 symptomatic patients were Vδ1+), whereas no correlation was found between mutational pattern and clinical course. By NGS of TCR gamma gene, we observed that all patients were clonal but two, showing a polyclonal pattern borderline with clonality percentage defined by sequencing kit criteria. Interestingly, these two last patients were the only two patients without STAT mutations. As far as the remaining cases are concerned, among STAT3 mutated patients (n=4), 3 were polyclonal and one biclonal, while STAT5b mutated patients (n=5) were more frequently monoclonal (4/5 monoclonal and 1/5 biclonal). In terms of clonal rearrangements, Vδ3-Jγ1/2, Vδ9-JpD and Vδ8j1/2 were the combination usages most frequently detected. Concerning the clonotype repertoire, CDR3 sequences of the most prominent clonotype present with low frequency in almost all the other γδ patients and two different CDR3 sequences were found shared, each one in two different patients at frequency >10% of the total rearrangements.

Summary/Conclusions: Our data indicate that TCРγδ LGLL can be considered at the intersection of the two types of TCRαβ-LGLL, share with CD4+ T-LGLL mutational features. As already described in TCRαβ-LGLL, also in γδ disease a decreased diversity of TCR repertoire was demonstrated. However, in these γδLGL patients STAT mutations do not correlate with a symptomatic clinical behavior while STAT5b mutations seem to be more frequently linked to monoclonal nature of the LGL lymphoproliferation. Rather, the marker Vδ1 appears to be correlated to symptomatic disease.
LY10 and OCI-LY1) with IRF6 knockdown or overexpression and two human B lymphoblast cell lines were co-cultured with peripheral blood mononuclear cells (PBMCs) in vitro to determine the effect of IRF8 on the generation of Th17 cells. Quantitative real-time PCR and Western blotting were used to investigate the involvement of retinoic acid receptor-related orphan receptor gamma t (ROTY) in the effect of IRF8 on Th17 cell generation. The survival of 67 DLBCL patients diagnosed at the Kaplan–Meier et al. (2012) analysis of the same patient cohort was used to determine if IRF8 correlated with clinical parameters. **Results:** The percentage of Th17 cells was lower in DLBCL tumor tissues than in PBMCs and corresponding adjacent benign tissues. Relative expression of interleukin (IL)-17A was lower, whereas that of interferon (IFN)-γ was higher in tumor tissues than in benign tissues. Co-culture with DLBCL cell lines inhibited the generation of Th17 cells in vitro. IRF8 upregulation was detected in DLBCL tumor tissues, and it was associated with decreased DLBCL patient survival. Investigation of the underlying mechanism suggested that IRF8 upregulation inhibited Th17 cell generation by suppressing the effect of ROTY on CD4+ T cells. **Summary/Conclusions:** Our findings suggest that IRF8 expression in the tumor microenvironment inhibited the generation of Th17 cells through its antagonistic effect on ROTY in the DLBCL tumor microenvironment, suggesting that it could be a prognostic factor for DLBCL.

E1399

**GENOMIC PROFILING OF BCL2 AND MYC DOUBLE EXPRESSOR DIFFUSE LARGE B CELL LYMPHOMA**

V. Dirse1,2,*, J. Drachneris3, U. Mickys3, M. Stoskus1, L. Griskevicius1,2

1Hematology, Oncology and Transfusion Medicine Center, Vilnius University Hospital Santariskiu Klinikos, 2Department of Internal, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, 3National Center of Pathology, Affiliate of Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania

**Background:** Diffuse large B cell lymphoma (DLBCL) is an aggressive disease featuring heterogeneous genetic, phenotypic and clinical characteristics. Recently, a negative prognostic impact of double expression of BCL2 and MYC (double expressor (DE) lymphoma) has been identified in several studies. SNP-array (SNP-A) studies have already led to the identification of novel genomic aberrations in ABC and GCB subtypes of DLBCL whereas similar analysis has not been done in DE and non-DE DLBCL.

**Aims:** To characterize the landscape of genomic aberrations in DE and non-DE DLBCL groups using SNP-A and interphase fluorescence in situ hybridization (FISH).

**Methods:** Immunohistochemical and FISH analysis was performed on tissue microarray of formalin fixed paraffin embedded (FFPE) tumor tissue samples using Bcl2 (124, DakoCytomation) and MYC (Y69, Epitomics) antibodies and FISH MYC (Zytovision), Bcl2 (Abbott/Vysis), Bcl6 (Abbott/Vysis) break-apart probes and MYC FISH (Zytovision) double fusion probe. Infinium HD whole-genome genotyping assay with the HumanCytoSNP SNP-FPPE-12 BeadChip (Illumina Inc., San Diego, CA, USA) was performed for genomic analysis of the aberrations.

**Results:** A cohort of 91 primary DLBCL patients diagnosed between 2004 and 2012 was selected for the study. Immunohistochemical evaluation was informative for Bcl2 in 90% (56 cases) and MYC in 91% of cases (56 cases) were informative for MYC, 56 cases for Bcl2, and 65 cases for Bcl6. 7 cases (11.4%) were positive for MYC translocation, 14 (25%) for Bcl6, and only 3 (4.6%) were positive for Bcl2. No cases of FISH MYC and bcl2 double positive DLBCL were identified. Genomic DNA from FFPE tumor tissue for SNP-A was available in 66 cases (56%). SNP-A results were informative in total 329 genetic aberrations in about 60% of patients (pts) with diffuse large B-cell lymphoma (DLBCL). Pts available in 66 DLBCL cases. SNP-A analysis detected in total 329 genetic aberrations per case (~5 aberr./case) and shared the most common aberrations in 66 cases, respectively. Cases with MYC positive

**Summary/Conclusions:** Our findings suggest that IRF8 expression in the tumor microenvironment inhibited the generation of Th17 cells through its antagonistic effect on ROTY in the DLBCL tumor microenvironment, suggesting that it could be a prognostic factor for DLBCL.

**ARQ 531, A REVERSIBLE BTK INHIBITOR, DEMONSTRATES POTENT ANTI-TUMOR ACTIVITY IN ABC-DLBC AND GCB-DLBC**

S. Eathathri1, Y. Yu1, T. Hall1, B. Schwartz1, J.A. Woychik1, S. Reiff2, G. Abbades2

1Clinical Development, ArQule Inc., Burlington, 2Division of Hematology, The Ohio State University, Columbus, United States

**Background:** B-cell receptor (BCR) signaling has emerged as a critical pathway for B-cell lymphoma development. BTK, a key mediator of BCR signaling, is a major target for ibrutinib. Ibrutinib has demonstrated efficacy in chronic lymphocytic leukemia (CLL), mantle cell lymphoma and Waldenström macroglobulinemia. However, as anticipated by preclinical models, clinical objective response rates of only 37% in ABC and 5% in GCB diffuse large B cell lymphoma (DLBCL) were reported. ARQ 531 is a potent reversible inhibitor of BTK, highly effective in targeting BCR signaling. Kinase profiling indicated that ARQ 531 is differentially selective in DLBCL vs non-DLBCL regimens with inhibition of HCK and BLK kinases. ARQ 531 caused significant growth inhibition (GI50=1 µM) of hematological malignant cell lines and showed greater efficacy than ibrutinib in a CLL mouse model.

**Aims:** We aim to assess biological and anti-tumor effects of ARQ 531 in in vitro and in vivo models of B-cell lymphoma.

**Methods:** Biochemical inhibition and kinase profiling were assessed using recombinant proteins. The ARQ 531 binding kinetics on BTK were determined by Surface Plasmon Resonance assay. Anti-proliferative activity of ARQ 531 was tested in a MTS-based assay against a panel of hematological malignant cell lines. Pathway inhibition assessments, in vivo efficacy and in vivo tumor inhibition were performed in TMD8 (ABC-DLBC) and SUDHL-4 (GCB-DLBC) cell lines and xenografts. ADME and pharmacokinetic properties of ARQ 531 were also evaluated in rats, dogs and monkeys.

**Results:** ARQ 531 potently inhibited BTK (IC50=0.85 nm) and displayed long residence time (65 min). Inhibitor exhibited strong anti-proliferative activity in TMD8 (GI50=0.13 µM) and SUDHL-4 (GI50=0.02 µM) cell lines. Ibrutinib, while potent on TMD8 cells (GI50=0.002 µM), had a GI50 of 1.1 µM in SUDHL-4, a concentration not reached in human blood, consistent with published studies. Pathway analysis in TMD8 and SUDHL-4 cells showed that ARQ 531 potently inhibited both upstream activating signals (Src kinase family) and downstream signaling pathways such as AKT and ERK. Cell cycle analysis indicated that ARQ 531 inhibited cell growth through G1 phase arrest, similar to ibrutinib. In the TMD8 xenograft mouse model, ARQ 531 strongly inhibited BTK signaling, with better efficacy than reported with ibrutinib: tumor growth reduction was 93% after 14 days of dosing, with no re-growth observed for 17 days post dose interruption. In the ibrutinib-resistant SUDHL-4 mouse xenograft model, ARQ 531 potently suppressed tumor growth (>80% inhibition) compared to the control group.

**Summary/Conclusions:** ARQ 531 is a potent reversible inhibitor of BTK. Its disease selectivity can be used to target constitutive BCR signaling in DLBCL primarily resistant to ibrutinib, as demonstrated by the excellent efficacy in both ABC and GCB DLBCL xenograft models. These models support the clinical investigation of ARQ 531 in patients with hematological malignancies, expected to begin in mid-2017.

**ROLE OF GENETIC POLYMORPHISMS ON R-CHOP EFFICACY IN DIFFUSE LARGE B-CELL LYMPHOMA PATIENTS: AN INTERIM ANALYSIS OF A MULTICENTER PROSPECTIVE PHARMACOGENETIC STUDY**

L. Rigacci1,2, G. Perrone2, S. Nobili3, S. Kovalchuk1, B. Puccini1, R. Tassi2, L. D'Addato3, I. Landini2, I. Lanzoni4, G. S. Bennett1, C. Napoli1, E. Cencioni1, A. Fabbrizzi2, L. Iovino5, M. Petrimi5, S. Birtolo6, G. Melosi6, S. Santini6, P. Bernardeschi6, A. Bosi7, E. Mini2

1Haematology, AOU Careggi and University of Florence, 2Medicina Sperimentale e Clinica, 3Scienze della Salute, University of Florence, Florence, 4Haematology, AO Siena, Siena, 5Haematology, AO Pisa, Pisa, 6Oncologia, Ospedale Pescia, Pescia, 7Oncologia, Ospedale Lucca, Lucca, 8Oncologia, Ospedale Prato, Prato, 9Oncologia, Ospedale Empoli, Empoli, Italy

**Background:** Standard chemotherapy represented by the R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone) regimen is successful in about 60% of patients (pts) with diffuse large B-cell lymphoma (DLBCL). Pts who do not benefit from this treatment, due to the development of tumor drug resistance, have a very poor prognosis. Currently, knowledge on reasons of treatment related failures in DLBCL are scanty and predictive biomarker of resistance is not largely unique. Our findings are consistent with this view.

**Aims:** We hypothesized that polymorphisms of genes involved in the pharmacokinetics and pharmacodynamics of drugs included in R-CHOP regimen may play a role in predicting the outcome in DLBCL pts. Thus, we designed a multicentre prospective pharmacogenetic trial aimed at identifying gene polymorphisms potentially predictive of drug efficacy/resistance in DLBCL pts resistant to R-CHOP. We are reporting update data of an interim analysis on the first 80 enrolled pts.

**Methods:** The study includes chemo naive DLBCL pts (Ann Arbor I-IV stages) candidate to an R-CHOP standard treatment. The Ethical Committee of each participating centre approved the pharmacogenetic protocol, and all pts signed a written informed consent. In this interim analysis, the impact of single nucleotide polymorphisms (SNPs) on R-CHOP efficacy was evaluated by objective response (OR) rate, progression-free survival (PFS) and overall sur-
vival (OS). The efficacy of R-CHOP was evaluated according to Cheson criteria by performing standard hematochemical and instrumental (TC and FDG-PET) tests and defining complete remission (CR), partial remission (PR), non response or progressive disease (PD). Genomic DNA was extracted from peripheral blood of 80 pts. SNPs analysis was performed by an Affimmix array. To date, 21 SNPs from 19 candidate genes (ABC21, ABC1, ABC22, ABC02, CYB5A, CYP3A5, FABP5, FGF2, FGFR2A, GSTP1, IGF, MARCKS, IL1H1, NCF4, NOQ1, NOQ2, RAC2, TNF, TOP2A, TP53, TUBB) involved in pharmacokinetics and pharmacodynamics of R-CHOP (www.pharmkg.org) selected and analysed in relation to R-CHOP efficacy. Univariate and multivariate logistic regression analyses were performed to evaluate associations between SNPs and clinical/pathological characteristics or survival parameters (PFS and OS).

Results: Median age was 63 years. There were 37 men and 43 women. 47.5% of pts were in stage I-II, 52.5% of pts in stage III-IV. 27.5% of pts had bulky disease, 43.8% of pts had involvement of extranodal site. 47.5% of pts had pathological LDH value. According to the revised IP, 15% of pts were in the low risk group, 58.7% in the intermediate, and 28.3% in the high risk group. 468 courses of R-CHOP had been administered (mean: 5.85 courses, range: 4-46). 88.7% of pts had CR to R-CHOP whereas the remaining showed PR or SD (7.5%) or PD (3.8%). Multivariate analysis identified FGR2A rs1801274 as a predictor of PFS (p=0.045). Pts with HR or RR genotypes showed shorter PFS than pts with HR genotype (HR: 2.43, 95% CI: 1.02-5.82). No statistically significant correlation was found between SNPs and OS.

Summary/Conclusions: Our preliminary data obtained in a limited number of pts, show an association between a SNP of the low affinity FGR2A gene involved in the activity of rituximab and PFS. Further insights will derive from the completion of this project accrual to reach the planned number of cases at the end of our study.

This work was supported by a grant from the Associazione Giacomo Onlus, Castiglioncello (LI), Italy to E.M. and Cassa di Risparmio di Firenze, Firenze, Italy to S.N.

CDK4/6-INHIBITION BY ABEMACICLIB INDUCES POTENT EARLY G1-ARREST IN MCL CELL LINES AND SHOWS SEQUENCE-SPECIFIC INTERACTIONS WITH CYTARABINE AND IBRUTINIB

L. Fischer1, A. Mayr1, M. Irger1, B. Freysoldt1, Y. Zimmermann1, G. Hutter1, W. Hiddemann1, M. Dreyling1

1Dept. of Medicine III, Univ. Hospital Grosshadern/LMU; Experimental Haematology, 2Department of Lymphoma Chemotherapy, Munich, Germany

Background: Mantle cell lymphoma (MCL) is characterized by t(11;14) resulting in a constitutive cyclin D1 overexpression. The cyclin D1-CDK4/6 complex inactivates Rb through phosphorylation, leading to G1/S-phase transition. Therefore, inhibition of CDK4/6 is an efficient and rational approach to overcome cell cycle dysregulation in MCL.

Aims: We evaluated the efficiency of the novel CDK4/6 inhibitor abemaciclib in various MCL cell lines and in primary MCL cells in combination with cytarabine (AraC) and ibrutinib.

Methods: MCL cell lines (Granta 519, JeKo-1, Mver-1, Mino) and primary MCL cells were exposed to abemaciclib alone and combined with AraC or ibrutinib. In some experiments, cells were pretreated with abemaciclib and exposed to AraC or ibrutinib with or without consecutive wash-out of the CDK4/6 inhibitor. Proliferation and viability were measured by trypan blue staining and Cell Titer Glo assay. Combination Index (CI) to assess synergy or antagonism was calculated using the Fractional Product method by Webb (1963). Flow cytometry was applied for cell-cycle (PI-staining) and apoptosis analysis (Annexin V PE/7AAD-staining). Protein expression and phosphorylation status of various downstream proteins was analyzed by Western Blot analysis.

Results: Abemaciclib inhibited cell proliferation by induction of early G1-arrest. We observed an almost complete and reversible G1-arrest in all sensitive cell lines by FACScan analysis (JeKo-1: G1-phase +51.7%, S/G2-phase -51.7% at 31.25 nM after 24 h; G1-phase +35.4%, S/G2-phase -38.4% after 72 h), whereas cell viability was not reduced. IC50-values of sensitive cell lines (JeKo-1, Mver-1, Mino) were <30 nM after 72 h. Western Blot analysis revealed reduced phosphorylation of Rb on serine 795 without changes in CDK 4 and cyclin D1 expression. Pretreatment with abemaciclib in a concentration of 31.25 nM after 24 h resulted in synchronized S-phase entry in all sensitive cell lines (e.g. Mino: G1-phase -20.4%; S-phase +30.5%). Accordingly, sequential combination of abemaciclib followed by AraC showed strong synergy in Mino cells (CI=0.22 for 31.25 nM abemaciclib / 3.3 µM AraC). In contrast, simultaneous exposure to both agents had a protective effect against AraC treatment in all sensitive cell lines, due to an ongoing G1-arrest (Mino: CI=0.19 for 31.25 nM abemaciclib / 3.3 µM AraC). Sequential administration of abemaciclib and ibrutinib had synergistic or additive effects in sensitive cell lines (CI: JeKo-1=0.24; Mver-1=0.19; Mino=0.03 for 31.25 nM ibrutinib / 2.5 µM Ibrutinib), whereas the simultaneous administration of both showed additive effects at most (CI: JeKo-1=0.1; Mver-1=0.1; Mino=0.09 for 31.25 nM ibrutinib and 2 µM Ibrutinib). In primary MCL cells abemaciclib had no impact on cell death or sensitization since no cell proliferation was observable and cells where resting in G1-phase.

Figure 1.

Methods: The study included 26 patients (15 males and 11 females; age 36-92, median 67) with the diagnosis of AITL established on the basis of WHO 2008 diagnostic criteria. LN, BM and peripheral blood lymphocytes were tested for T-cell clonality according to BIOMED-2 protocol with subsequent fragments analysis on ABI PRISM 3130 (Applied Biosystems). The material was examined at the diagnosis and at various points of patient’s treatment. In 5 patients selection of CD8+ and CD4+ populations of PB lymphocytes was performed with MidiMACS and MiniMACS Separators using CD4+ and CD8+ MicroBeads (Miltenyi Biotec). In 4 patients, traditional TCR-γ/δ chain gene rearrangements from those detected in the bone marrow (BM), peripheral blood (PB) and other tissues, T-cell clonality testing itself may not distinguish between neoplastic or reactive lymphoproliferation in the BM and PB. Therefore, T-cell clonality of CD4+ and CD8+ populations of peripheral blood lymphocytes in patients with AITL had been tested during the course of disease.

Aims: To determine immunological characteristics of persisting in the PB and BM T-cell clones in AITL patients.

Results: In 21 of 26 patients (80.7%) at least one of the clonal products isolated from the BM and/or PB mismatched the clonal products isolated from the LN. In 12 patients (46%) clonal products found in BM and PB were different from those identified for LN. Thus, at the diagnosis 14 of 20 patients (74%) had PB and BM T-cell clones distinct from LN T-cell clones. 14 of 20 patients T-cell clones of PB and BM were tested repeatedly during the course of disease treatment. In 7 of 14 patients (50%) clonal rearrangements persisted for a long time and do not disappear upon reaching the remission of the disease. The observation period averaged 12 months (1 to 44 months). No correlation of T-cell clones persistence and the activity of EBV infection in the PB was found. Selection of CD4+ and CD8+ T-lymphocyte populations was performed for 4 patients in remission with persistent T-cell clones. In all cases,
Clonal products, which were originally identified in the BM and PB were shown to belong to the CD3+ population of cells (Fig.1). In one case, BM and PB derived CD4+ cells also shared a clonal product with LN cells tested at the diagnosis. In this case, CD4+ population selected from PB cells at the diagnosis carried clonal rearrangements, fully consistent with that of LN.

Summary/Conclusions: One may conclude that CD5+ T-cell clones identified in the BM and PB only match those identified in LN and are all found within patients with AITL (76%). These clones can persist for a long time (the period of observation from 1-40 months), may not disappear in remission and probably have reactive nature. Therefore exclusive T-cell clonality in PB and/or BM should not be treated as minimal disease or relapse in AITL.

E1404
CD5 POSITIVE DIFFUSE LARGE B CELL LYMPHOMA SHOWED FREQUENT MYC EXPRESSION AND AGGRESSIVE CLINICAL BEHAVIOR
1Pathology, Seoul National University Hospital, Seoul, 2Pathology, Hallym University Sacred Heart Hospital, Anyang, 3Pathology, Sanggye Paik Hospital, Inje University college of medicine, Seoul, 4Pathology, Ajou University School of Medicine, Suwon, 5Pathology, Soonchunhyang University Hospital, Pucheon, 6Pathology, Seoul St. Mary’s Hospital, Seoul, 7Pathology, Ulsan University Hospital, Ulsan, 8Pathology, Seoul National University Boramae Hospital, Seoul, Korea, Republic Of

Background: Aberrant expression of CD5 distinguishes a unique immunohistological subtype of diffuse large B cell lymphoma (DLBCL). This CD5+ DLBCLs, either de novo lesions or transformed from preceding low grade lymphomas, may only be identified in LN for the majority of patients with AITL. The incidence of CD5+ DLBCL was variably reported from 5-22% of all DLBCLs in western countries and Japan, however, no exact data available in Koreans.

Aims: This study aimed to investigate clinicopathologic features of CD5+ DLBCL in Korea.

Methods: A total of 350 cases of DLBCL were reviewed 4 university hospitals from 2004 to 2012. Review of the histologic features along with immunohistochemical study for BCL2, BCL6, CD5, CD10, CD23, D30, IRF4/MUM1, MYC, Ki-67 and EBV in situ hybridization was performed. Florescent in situ hybridization (FISH) for MYC rearrangement and amplification was also performed. The results were compared with DLBCL-NOS (N=195).

Results: Thirty cases of CD5+ DLBCL were retrieved among 350 cases of DLBCL (8.6%), which showed predominance of female (20/30), elderly (mean age 64), and extranodal presentation (16/30). Richter transformation was suspected in 7 cases and EBV was negative in all. Most cases (22/30) belong to non-GCB subtype by Hans classifier. Rearrangement of MYC was found in 2 cases and amplification was found in one. Compared with DLBCL-NOS, CD5+ cases revealed significantly higher expression of MYC, BCL5, IRF4/MUM1 and Ki-67 (all p<0.05). Double expression of both BCL2 and MYC was found in 9 of 30 cases (30%). Also, CD5+ DLBCL showed more frequent bone marrow involvement, advanced stages and high international prognostic index (all p<0.05). In univariable survival analysis, CD5+ DLBCL revealed significantly shorter progression free survival (median 8.2 months) compared with DLBCL-NOS (median 56.3 months) (p<0.05)

Summary: The present study confirms the aggressive nature of CD5+ DLBCL in Korea. The incidence, clinical presentation, and pathologic features including cell of origin coincide with previous reports from western population or Japanese. However, frequent high expression of MYC without chromosomal structural alteration was a unique finding in our study. Expression of CD5 should be routinely investigated in DLBCL to find this particular aggressive subtype.

E1405
REACTIVE FLORID B-LINEAGE LYMPHOID PROLIFERATIONS IN HIV INFECTION MAY MIMIC LYMPHOMA
T. Wiggill1,*, J. Vaughan1, E. Mayne1
1Pathology, School of Medicine, University of the Witwatersrand, Johannesburg, South Africa

Background: Approximately 7 million people are living with Human Immunodeficiency Virus (HIV) infection in South Africa (SA) (2015), which is associated with an increased risk of lymphoma. Although there is limited local information available, previously published data from the Johannesburg academic complex of hospitals (SA) showed an HIV prevalence of >90% in patients diagnosed with high grade B cell non Hodgkin lymphoma (NHL) who were tested for HIV (n=568), during the period 2007-2009. The diagnosis of lymphoma with comorbid HIV infection is, however, challenging as lymphomas may present with reactive conditions which may mimic lymphoma (such as Tuberculosis (TB)). Within this setting reactive B lineage lymphoid proliferations (RBLP) in the blood and bone marrow may raise a differential diagnosis of lymphoma.

Aims: This study aims to document the clinicopathological features of florid RBLP in the setting of HIV infection in order to provide an approach to differentiating reactive and clonal processes.

Methods: A retrospective database search was performed of the laboratory information system (National Health Laboratory Service) that screened pathologic reports for samples referred to the Departments of Molecular Medicine and Haematology and Anaesthesiology at the Johannesburg Academic Complex during 2007-2011, supplemented with results of immunophenotypic analysis from 2007-2016. Demographic and clinicopathological findings were collected for patients identified with florid RBLP who showed no definite evidence of monoclonality.

Results: During this period, 38 patients were diagnosed with florid RBLP with up to 70–80% of cells in blood or bone marrow comprising reactive B cells (including mature B, plasma blasts and plasma cells). All patients tested were HIV positive, with a median age of 28 years (range 6 months-79 years). There was a bimodal age pattern with a peak in children <1 year of age (34% of patients) and the second peak in the elderly (33%). A majority of these lymphomas is virtually absent in children under a year of age. Common clinical presentations included cytopenias (85%); infection (70%) (commonly Cytomegalovirus (35%), TB (30%) and bacterial septicaemia (22%)); hepatosplenomegaly (42%); and lymphadenopathy (36%). Patients showed increases in serum total protein levels (reflecting hypergammaglobulinaemia), with increased inflammatory markers (C-reactive protein and erythrocyte sedimentation rate) and evidence of increased cell turnover (high uric acid, B2 microglobulin and lactate dehydrogenase levels). Extremely high HIV viral loads (VL) were documented (median 1 612 003 copies/mL, range 12 000 - 10 000 000). In one patient VL was virologically suppressed. This significantly different from lymphoma patients where median VL ranged from 16 000-97 000 dependent on subtype. Median CD4 counts were also higher in this subgroup of patients when compared to patients with lymphoma (see table 1).

Summary/Conclusions: In the setting of HIV, reactive conditions may mimic lymphoma and vigilance is needed in the confirmation of monoclonality. Patients with RBLP presented at a younger age when compared to their counterparts with lymphoma. They had extremely high VL with higher CD4 counts, suggesting this may be a feature of early HIV disease and the possibility of a seroconversion type illness should be considered.

MICROVESSEL DENSITY IN CD30 POSITIVE DIFFUSE LARGE B-CELL LYMPHOMAS
F. Gaudio1,*, G. Ingravallo2, T. Perrone1, P. Sindaci1, V. Carlocci1, S. D’agostino1, M. Di Noi1, F.E. Laddaga1, R. Tamma1, S. Ruggieri1, P. Pedote4, G. Specchia1
1Hematology, 2Pathology, 3Human Anatomy and Histology, 4Radiology, Bari, Italy

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common and one of the most homogeneous lymphomas. Therefore, it is critical to further stratify cases of DLBCL into biologically similar and clinically meaningful subgroups, which will not only guide prognostic assessment and facilitate therapeutic decisions but also stimulate further research to understand the pathobiology and develop novel therapies to the lymphoma. The current reporting of a number of different kinds of tumors have indicated that microvesSEL quantification may be useful in predicting disease outcome.

Aims: The aim of this study was to examine the relationship between microvesSEL density (MVD) as a parameter of tumor angiogenesis, and the immunohistochemical subtypes with lymphoma and unclassifiable lymphomas with intermediate features CL among Koreans.

Methods: We retrospectively identified cases of DLBCL diagnosed between January 2010 and January 2016 at our Institution. The following large B-cell lymphoma subtypes were excluded from this analysis: post-transplant lympho-proliferative disorders with a DLBCL morphology, Primary Mediastinal large B-cell lymphoma and Burkitt’s lymphoma. A total of 30 cases of CD5+ DLBCL were retrieved among 100 cases of DLBCL.

Results: Limited follow-up data was available, with only 8 patients documented to be limited follow-up data was available, with only 8 patients documented to be 22 nd Congress of the European Hematology Association
Microvascular quantification was performed by immunohistochemical staining, using monoclonal antibodies against platelet/endothelial cell adhesion molecule-CD31. A total of 82 cases of de novo DLBCL treated with R-CHOP were included in the training set for further analysis. There were 45 men and 37 women, with a median age of 57 years (range, 16-84); 35 patients (43%) presented with B symptoms, and 49 (60%) had advanced Ann Arbor stages. Most of the patients had a good performance status (Eastern Cooperative Oncology Group score 0-1, 87%), elevated serum lactate dehydrogenase level (61%), and low or low-intermediate International Prognostic Index (IPI) risk (IPI score 0-2, 63%). Involvement of multiple extranodal sites (≥2) was seen in 22% of cases, and bulky disease in 32% of cases.

Results: The median follow-up time was 47 months. Among the 82 cases in the training set, CD30 was positive in 24 cases (29%). No difference in response rate was observed between CD30 positive and CD30 negative patients. Patients with CD30+ DLBCL showed a significantly superior OS and PFS compared with CD30− patients. The 5-year OS was 79% in patients with CD30+ vs 59% in CD30− (P < 0.05); 5-year PFS was 82% in patients with CD30+ vs 63% in CD30− (P < 0.05).

In patients with CD30 positive diffuse large B cell lymphomas we found a smaller number of vessels compared with patients CD30 negative (fig.1, p < 0.05).

In patients with CD30− DLBCL treated with R-CHOP were found a smaller number of vessels compared with patients CD30 positive (fig.1, p < 0.05).

**Figure 1.**

**Summary/Conclusions:** CD30 is expressed in approximately 29% of all DLBCL and defines a novel subgroup of diffuse large B-cell lymphoma with a more favorable prognosis. Microvascular density expression is lower in CD30 positive DLBCL. The advent of brentuximab vedotin and its well-established effectiveness in other types of relapsed lymphomas has introduced the possibility of its application in this subset of patients.

**ANTIGEN SELECTION PROMOTES CLONAL CYTOTOXIC T-CELL RESPONSES: HIGH-THROUGHPUT IMMUNOGENETIC EVIDENCE**

E. Stalika1, C. Galgialidou1, A. Papalexandri1, A. Vardi2, N. Stavroyianni2, I. Batis2, I. Sakellari2, A. Anagnostopoulou2, N. Magliaveras3, I. Chouvarda3, M. Papaiannou4, K. Stamatopoulos1, A. Haidzeidimou1

1Institute of Applied Biosciences, Centre for Research and Technology Hellas, 2Hematology Department and HCT Unit, G. Papanicolaou Hospital, 3Laboratory of Computing and Medical Informatics, 4First Department of Medicine, Medical School, Thessaloniki, Greece

**Background:** Background of T-LGL leukemia: for this case, the donor blood was analyzed as were two blood samples, one at the first documentation of clonal T-LGL expansion (at 6 months post allo-HCT while investigating persistent neutropenia that developed after Rituximab treatment for EBV reactivation) and a second 3 years later; at both timepoints, the patient had 100% donor chimerism and tested negative for Bcr-Abl transcripts. TRBV-TRBD rearrangements were amplified on gDNA and subjected to paired end NGS, covering the CDR3 twice/sequence.

To increase the consistency of results, raw NGS reads were analyzed by a purpose-built bioinformatics algorithm, performing: (i) quality filtering, (ii) merging of filtered in paired reads and (iii) quality filter of stitched sequences. Filtered-in sequences were submitted to IMGT/HighV-QUEST, and metadata was processed by an in-house dedicated bioinformatics pipeline.

**Results:** Only productive TRBV-TRBD rearrangements were included in the analysis. Overall, 1,129,289 filtered-in sequences from 6 samples were evaluated (median 188,095 sequences/sample). Major findings in the familial cases investigated include: (i) pronounced skewing of the TRBV repertoire, representing the presence of more than one immunodominant clonotype; (ii) in the analysis of longitudinal samples from the son, persisting clonotypes albeit with fluctuating frequencies (clonal drift); and, (iii) shared (‘public’) clonotypes between father and son. In the T-LGL leukemia of donor origin, the immunodominant clonotype was detected amongst the polyclonal donor repertoire and subsequently expanded in the recipient, persisting over time and accompanied by a few other considerably expanded, albeit smaller, clonotypes.

Orsola-Malpighi Hospital, University of Bologna, Bologna, 6Department of Molecular Medicine, Hematology, Sapienza University, Rome, 7Division of Hematology, Azienda Ospedaliera SS Antonio e Biagio e Cesare Aringo, Alessandria, Italy

**Background:** In B-cell non-Hodgkin lymphomas, minimal residual disease (MRD) is a highly valuable tool for the direct assessment of the reduction of the disease burden. In 2009, the four laboratories of the Fondazione Italiana Linfomi (FIL) - FIL MRD network - started a collaborative effort to harmonize and standardize their methodologies, performing QC (Quality Control) rounds twice a year for follicular lymphoma (FL) and mantle cell lymphoma (MCL) MRD assessment.

Aims: We evaluated the molecular results of bone marrow (BM) samples analysis performed during the QC rounds, to determine how borderline samples (i.e. those with a low MRD level) challenge the inter-lab reproducibility and data interpretation.

Methods: Between February 2010 and November 2016, in the context of 14 QC rounds, the FIL MRD Network labs received 167 BM samples: 167 were analyzed by both nested polymerase chain reaction (PCR) and real-time quantitative PCR (RQ-PCR). The sensitivity of each molecular analysis was tested during the QC rounds, to determine how borderline samples (i.e. those with a low MRD level) challenge the inter-lab reproducibility and data interpretation.

Results: The sensitivity and the accuracy of each molecular analysis was tested, reaching a uniform sensitivity of 10-5 and a quantitative range for RQ-PCR of at least 10-3. Ninety-three/114 FL BM samples were submitted to sequencing (75/93) being PCR+/RQ-PCR+ or PCR-/RQ-PCR- in all the 4 labs. The remaining 18/93 (19%) were alternatively positive and negative in the inter-lab evaluations, representing samples with very low MRD levels, thus defined as “borderline” (brd): 6/18 were PCR-brd/RQ-brd; 6/18 were PCR-brd/RQ-positve not detectable by RNQ and 6/18 were PCR-RQ-brd; 6/18 were PCR-RQ-PNQ; and 6/18 were PCR-RQ-RQ-negative. Overall, considering the 167
samples analyzed by both methods, 83% (139/167) of these were classified as +/+ or -/− by all the FIL labs. The remaining 28/167 (17%) were the samples that showed discordant results in the inter-lab assessments: while in 17 cases the “borderline status” was defined alternatively by only one method, 11 resulted brd samples by both techniques (11/167, 6.6%) (Fig.). Given that the 167 samples were tested in three replicates across the 4 labs, a total of 12 replicates/sample were analyzed: 31 brd samples were thus identified, 13 of which brd by both approaches. Of 156 evaluations performed on the 13 brd, 69/156 (44%) resulted PCR-positive and 87/156 (56%) PCR-negative, 58/156 (37%) were RQ-PNQ and 98/156 (63%) RQ-negative.

Summary/Conclusions: Despite the high inter-lab reproducibility in the MRD analysis that can be obtained and maintained by the QC round strategy, samples with the lowest MRD levels can still represent a challenge: 17% (28/167) of our series resulted brd, showing discordant results in inter-lab assessments; 39% of them (11/28) remained brd even applying both methods. The results did not change even increasing the number of replicates/sample. Thus, although representing a minority, brd samples are still problematic, especially when a clinically oriented interpretation is required. As the combined use of standard methods does not totally solve this problem, alternative, novel, methods such as digital PCR and NGS need to be tested in this context.

E1409

RHOA GLY17VAL MUTATION AND T-CELL CLONALITY ANALYSIS IN PATIENTS WITH ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA

Y. Sidorova1,2, N. Chernova2, I. Yakutik1, S. Smirnova1, N. Ryzhikova1, E. Nikulina1, M. Alekseenko2, O. Glinshchikova1, M. Sinitsyna3, A. Kovrigina1, E. Zvonkov2, A. Sudarikov1

1Department of Molecular Hematology, 2Department of Lymphoma Chemotherapy, 3Department of Pathology, National Research Center for Hematology, Moscow, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a rare subtype of T-cell lymphoma, characterized by generalized lymphadenopathy, hyperglobulinemia, and autoimmune manifestations. Interpretation of histological and immunohistochemical data can be difficult due to the small number of tumor cells in biopsies, surrounded by abundant polymorphonuclear infiltrate. AITL could often be misdiagnosed as reactive processes and other lymphomas, including Hodgkin’s lymphoma. T cell clonality assessment plays an important role in AITL diagnosis. However, ambiguous clonality results may be obtained. Recently discovered somatic RHOA Gly17Val mutation is present in 53-71% of angioimmunoblastic T-cell lymphomas. We compared the efficacy of T-cell clonality testing and quantitative allele-specific PCR RHOA Gly17Val mutation assay in different tissues for AITL diagnosis.

Aims: To correlate the number of RHOA Gly17Val mutated cells in lymph nodes, blood, bone marrow and skin of AITL patients with corresponding T cell clonality results.

Methods: Lymph nodes (LN), skin biopsies, blood and bone marrow (BM) samples were studied for 40 patients with AITL. The male/female ratio was 25/15, median age was 65 years (36-92). To evaluate T-cell clonality rearranged TCRγ and TCRβ gene rearrangements were PCR-amplified according to BIO-MED-2 standardized protocol and analyzed by capillary electrophoresis on ABI PRISM 3130 (Applied Biosystems). Sensitivity of T-cell clonality assay was limited to 10% of clonal T-cells of the total T-lymphocytes in the sample. Gly17Val mutation was analyzed by quantitative allele-specific (qAS) TaqMan Real-Time PCR assay. The detection level of this method was 1% of mutated cells in the total cell population.

Results: The clonal TCR gene rearrangements in LN were found in 37 of 40 patients (92%). RHOA (Gly17Val) mutation in LN was revealed in 60% (24 of 40) patients. T-cell clonality was detected in 26 of 28 primary samples of BM, but in 12 of 26 patients (46%) clonal TCR rearrangements were not matched in length with rearrangements detectable in LN. Number of cells with RHOA mutation was highest in the LN (in average 26.7% of the total cells), while in the bone marrow RHOA mutation was undetectable (in 7 patients), or detected in 10 patients in a small amount (in average 2% of the total cells). Combined historical investigation, T-cell clonality and RHOA (Gly17Val) testing showed BM lesion in 76% of patients (13 of 17) with at least one of the methods. Blood and bone marrow samples examined simultaneously showed slightly higher numbers of RHOA positive cells in the blood than in the BM in 5 of the 7 RHOA positive patients. Significant percentage of cells with a RHOA mutation (in average 25% of the total cells) was revealed in 5 of 6 skin samples from RHOA positive patients. We have found good correlation (Spearman’s Rho=0,8198, p-level <0,00001) between T-cell clonality (matching with LN clonal peaks) and the number of RHOA positive cells in the AITL tissues (n 51). Skin, blood and bone marrow samples with the T cell clonality peaks that differ from those found in the LN were also negative for the presence of cells with RHOA (Gly17Val) mutation.

Summary/Conclusions: RHOA (Gly17Val) point mutation is detected in LN by allele-specific PCR in 60% of patients with AITL. The percentage of tumor cells in BM is low (averaging less than 2% of the total cells). However, combined molecular and histological data suggest that BM may be involved in most patients. Extent of T cell clonality (matching with LN clonal peaks) correlates with the amount of cells having a RHOA mutation. T-cell clonality in BM, skin, spleen, etc. with rearrangements not matching those identified for the LN should be considered reactive and possibly associated with autoimmune process or antiviral response.
Other Non-malignant hematopoietic disorders

E1410

USEFULNESS OF CHITOSIDROSIDE ACTIVITY, CCL18/PARC, 7-KETO-CHOLESTEROL AND GLUCOSYLPHOSPHINGOSINE CONCENTRATIONS FOR SCREENING OF LYSOSOMAL STORAGE DISORDERS

P. Irur1,2,*, J. Cellobia1,2,3, L. Lopez de Frutos2,3, P. Giraldo1,2
1Centro de Investigación Biomédica en Red en Enfermedades Raras (CIBER-ER), 2Unidad Investigación Traslacional. Hospital Universitario Miguel Servet, Instituto de Investigación Sanitaria Aragon (IIS Aragon), 3Departamento de Bioquimica, Biología Molecular y Celular, Universidad de Zaragoza, Fundación Española para el Estudio y Terapéutica de la Enfermedad de Gaucher y Otras Lisosomales (FEETEG), Zaragoza, Spain

Background: Gaucher (GD), Niemann-Pick Type A/B (NPA/B), Niemann-Pick Type C (NP-C) and Gaucher-like acid lipase deficiency (LALD) are lysosomal storage diseases (LSDs) difficult to diagnose due to the great heterogeneity of signs and symptoms, including haematological disorders, sometimes common to several pathologies, and the consequent alteration of biomarkers.

Aims: To assess the diagnostic utility of Chitosidroside activity (ChT), CCL18/PARC, 7-ketocholesterol (7KC) and glucosylphosphingosine (Lyso-Gb1) concentrations in previously mentioned LSDs.

Methods: ChT activity, CCL18/PARC and 7KC concentrations were measured in 146 plasma samples from subjects with suspected LSD (32 GD, 7 NPA/B, 90 NP-C and 17 LALD) received in our laboratory. In addition, a new biomarker, the Lyso-Gb1 concentration, was evaluated in 83/146 of previous mentioned subjects, 19 of them with confirmed LSD diagnosis. ChT was evaluated using a fluorogenic substrate, CCL18/PARC concentration by ELISA and 7KC and Lyso-Gb1 by liquid chromatography followed by tandem mass spectrometry.

Results: A total of 9/32 (28%) samples with suspected GD showed high ChT activity, 32/90 (35.5%) with NPA/B, 3/17 (17.6%) with LALD and in the rest the ChT activity was normal. Among the 19/90 (21%) with suspected NP-C and 2 carriers of NP-C only 3/43 (7%) with suspected NPA/B and altered biomarkers were confirmed. Among the 23/90 (26%) with suspected NP-C and some elevated biomarker four were diagnosed of NP-C, and two carriers showed some biomarker higher than cutoff. Of the 8/17 (47%) referred to LALD suspicion with some elevated biomarker six were affected. All GD confirmed patients show high levels of Lyso-Gb1 whereas none of the other cases showed elevation for mentioned biomarker.

Summary/Conclusions: The screening of three biomarkers: ChT activity, CCL18/PARC and 7-ketocholesterol (the latter not applicable in GD) is a powerful tool to identify patients at high risk of suffering from LSDs which should undergo confirmatory diagnostic tests. In this line we would have reduced the number of cases needing confirmatory diagnostic test from 146 to 43 (29%) and 19/43 (44%) were positive for LSDs. Lyso-Gb1 concentration can allow the unambiguous identification of all the GD patients but is not useful for the other LSDs.

E1411

THE VALUE OF SOLUBLE IL-2R ALPHA SUBUNIT MEASUREMENT IN CSF OF CHILDREN WITH HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS (HLH): PRELIMINARY OBSERVATIONS

Y. El Chazli1,*, J. Cebolla1,2,3, L. Lopez de Frutos2,3, P. Giraldo1,2
1Centro de Investigación Biomédica en Red en Enfermedades Raras (CIBER-ER), 2Unidad Investigación Traslacional. Hospital Universitario Miguel Servet, Instituto de Investigación Sanitaria Aragon (IIS Aragon), 3Departamento de Bioquimica, Biología Molecular y Celular, Universidad de Zaragoza, Fundación Española para el Estudio y Terapéutica de la Enfermedad de Gaucher y Otras Lisosomales (FEETEG), Zaragoza, Spain

Background: Hemophagocytic lymphohistiocytosis (HLH) is a life-threatening clinical syndrome due to a severe hyperinflammatory response. HLH is typically divided into a primary, genetic form and a secondary, acquired form. It is characterized by a very wide spectrum of clinical findings. Central nervous system affection “CSN disease” has been frequently described at presentation of HLH, during course of disease, or as isolated CNS-HLH that could precede other systemic clinical manifestations by months to years.

Aims: To study the value of soluble IL-2 receptor alpha subunit (sIL-2Rα) as a marker of CNS affection in children with HLH.

Methods: In this descriptive, observational study done at Alexandria University Children’s Hospital, we analyzed the clinical data of a group of patients diagnosed as HLH. After informed consent was obtained, data was collected from patients who have undergone clinical examination, brain MRI, routine CSF analysis for evaluation of CNS-HLH, and sIL2Rα measurement in the CSF (Quantikine Human CD25/IL-2Rα Immunoassay, R&D Systems). Patients were considered as “CNS-HLH positive” when they had either neurological manifestations, abnormal findings on MRI or routine CSF analysis (elevated proteins &/or pleocytosis), and as “CNS-HLH negative” when they did not show any of these findings.

Results: We analyzed the data of 9 HLH patients; 4 females and 5 males. Their age ranged from 2 months to 13 years with a median of 5 months. Six patients had genetic diseases predisposing to HLH [Griscelli syndrome type II (GSI) & Chediak-Higashi syndrome (CHS)], and 3 other patients were diagnosed according to HLH-2004 diagnostic criteria and presumed to be of familial form (FHL). Out of the 9 patients, only 5 patients (55.6%) showed clinically evident neurological manifestations; 5 patients (55.6%) had elevated CSF proteins &/or pleocytosis, and 4 patients (44.4%) had an abnormal brain MRI. Overall 7 out of the 9 patients (77.8%) with “CNS-HLH positive” versus only 2 (22.2%) “CNS-HLH negative” according to classical criteria. Interestingly, the geometric mean of CSF sIL2Rα in CNS-HLH positive group was lower than in CNS-HLH negative group (734 vs 1952 pg/ml, p = 0.094). Moreover, CSF protein level and cell counts did not statistically correlate with CSF sIL2Rα level. Several patients showed interesting observations. Among the patients with suspected FHL (6/7 HLH-2004 diagnostic criteria fulfilled, NK cell activity not tested), the one with the highest observed CSF sIL2Rα level (17329 pg/ml), a 2 months old infant, was “CNS-HLH negative”, but had severe bilateral papillodema (discovered during workup for suspected autoimmune disorder). The second patient, an 11 months old “CNS-HLH positive” patient (with history of a year of “CNS-HLH” findings and psychomotor regression, he had severe papilledema associated with high CSF sIL2Rα (3700 pg/ml)). The third patient, an 11 months old “CNS-HLH negative” infant also had a relatively elevated CSF sIL2Rα of 220 pg/ml. On the other hand, 2 twin sisters evaluated at the age of 3 months for HLH secondary to CHS (positive family history, grey hair) had high CSF sIL2Rα (600 & 800 pg/ml).

Summary/Conclusions: We hypothesize that routine CSF sIL2Rα level assay could enhance earlier & better detection of CNS-HLH in children especially in high risk genetic forms like Griscelli syndrome, that sIL2Rα is locally produced in the CSF secondary to cellular infiltration of CNS-HLH, that sIL2Rα can allow the unambiguous identification of all the GD patients but is not useful for the other LSDs.
E1413

COMPARISON OF TREATMENT AND OUTCOMES BETWEEN ACQUIRED PRIMARY AND SECONDARY THROMBOTIC THROMBOCYTOPENIC PURPURA

S.H. Wai1,2,*, H.J. Ng2, T.C. Wen2, J. Quek2, H.T. Mya2
1Monash University, Melbourne, Australia, 2Singapore General Hospital, Singapore, Singapore

Background: Thrombotic thrombocytopenic purpura (TTP) is a rare disease that is fatal if untreated. While the main treatment modality is plasmapheresis, immunosuppressants also play a crucial role in the treatment of TTP.

Aims: Our aim is to compare the clinical characteristics, treatment and outcomes of patients with acquired primary TTP to those with secondary TTP (i.e. autoimmune and malignancy/hematopoietic stem cell transplant (HSCT) related).

Methods: We reviewed all patients with TTP who received plasmapheresis at our institution from 1st Jan 2008 to 31st Jan 2017. Clinical and laboratory characteristics, treatment, response to treatment and complications were recorded.

Complete remission (CR) was defined as platelet count normalisation, partial remission (PR) as platelet count doubling and ≥30% increase, and the rest as unresponsive/mortality (UM).

Results: Of 41 cases of TTP, 24% (n=10) was primary, 44% (n=18) was secondary to autoimmune diseases, 27% (n=11) was secondary to malignancy or HSCT, 5% (n=2) was related to DRESS syndrome and acute pancreatitis. The median age was 47 (18-66) years and it was predominately female (81%). About two-thirds of the cases presented with neurological symptoms (66%), renal dysfunction (56%) and fever (59%). Only 12 patients (29%) had TTP related to malignancy. Proportionate to incidence of secondary TTP, 85% required immunosuppressive therapy and rituximab. Although the final remission rates and range were: Hb 10.5±3.38 g/dl (4–14.5 g/dl), WBC 6,233±3,593/mm3 (2,800–62,000/mm3), LDH 372±302 U/L (226±1,162 U/L), bilirubin 1.8±1.78 mg/dl (0.3-8.8 mg/dl), DAT was positive for IgG - IgG/C3d in 13 patients (92.9%) and for IgG/IgA in one patient (7.1%). As to immunology, CD3+CD4+/CD8+ ratio and/or anti-TG in 3 (21.4%) patients. In 10 (71.4%) cases simultaneous, whereas in 4 cases (28.6%) sequential cytopenia presence were reported. All patients presented with thrombocytopenia, all with positive DAT - but only 8 (57.1%) with Hb<11g/dl-, 7 (50%) with leucopenia and 6 (42.8%) with neutropenia. Severe presentation was reported at disease onset in 10 (71.4%) patients. All patients received IVIG (1-6 g/kg) and high dose methyl-prednisolone (30mg/kg/h) – one or more times depending on clinical course. Prednisolone was administered in 10 (71.4%), cyclosporine in 8 (57.1%) and vincristine in 1 patient. Mean follow-up was 5.4 years (18 months - 13 years), during which 5 (35.7%) patients presented with one or more complications related to treatment: Cushing syndrome, osteoporosis, hypothyroidism, renal dysfunction and/or peripheral neuropathy. No severe infection or death was reported during the 15 year period. Disease relapses (1-3) were reported in 8/14 (57.1%) patients. With regards to outcome, 8/14 (57.1%) remained in LCR, 1 (7%) in SCR, 1 (7.1%) in PR, 3/14 (21.4%) in active disease, whereas 1 patient was lost to follow-up.

Summary/Conclusions: The rare entity of Evans syndrome in childhood seems to be associated with various immune manifestations and to carry complications related to treatment. Long term studies are needed to guide optimal management, which still remains challenging.

E1415

LOW DOSE RITUXIMAB IS A USEFUL ADDITION TO CORTICOSTEROIDS FOR NEWLY DIAGNOSED PATIENTS WITH WARM AUTOIMMUNE HEMOLYTIC ANEMIA

A. Gomez-De Leon1,*, P. Colunga Pedraza1, P. Santana-Hernandez1, G. Sotomayor-Duque1, L.D.C. Tarin-Arzaga1, J.C. Jaime-Perez1, C.H. Gutierrez-Avendaño1, O.G. Cantu-Ruiz1, D. Gomez-Ramirez1
1Hematology, Hospital Universitario Dr Jose Eleuterio Gonzalez Universidade Autonoma de Nuevo Leon, Monterrey, Mexico

Background: Warm autoimmune hemolytic anemia (wAIHA) is an infrequent autoimmune disorder with a high response rate to corticosteroids, albeit relapses are common. Low-dose rituximab has been used successfully in autoimmune cytopenias in an effort to increase response duration, while reducing adverse effects and costs associated with a traditional rituximab dose and prolonged prednisone exposure.

Aims: To evaluate the safety and efficacy of low-dose rituximab combined with corticosteroid treatment in newly diagnosed patients with wAIHA.

Methods: We performed a single-center, prospective, single-arm, open-label study in adult patients with newly diagnosed “primary” or idiopathic wAIHA from 2013-2016 using high-dose dexamethasone (40mg IV days 1-4) followed by IVIG (1-6g/kg) and PO PO 1mg/kg once daily. 100mg total dose, days +1, +8, +15, +22. CR was defined as an increase in hemoglobin (Hb) ≥2 g/dL, PR was defined as Hb ≥10 g/dL or an increase of ≥2 g/dL. Response was evaluated at day +28, months +6 and +12. Informed consent was obtained from all participants.

Results: Eight patients were included. Mean age was 32 years (range 18-42), 6 were female. Median Hb at diagnosis was 5.8 g/dL (range 4.8–6.2 g/dL). All patients had response at day +28 (50% CR rate); median time to response was 12 days (range 3-17). During follow-up 7/8 achieved CR (median time to CR: 30 days, range 15-103), all of which were sustained at 6 months. Median follow-up was 24 months (range 8-40). One patient remained steroid-dependent and relapsed after 12 months, achieving a stable PR after re-treatment with low-dose rituximab. Furthermore, two patients had new-onset immune thrombocytopenia (IT; Fisher-Evans’ syndrome), without hemolysis 6.5 and 8 months.
after diagnosis. Two patients were diagnosed with systemic lupus erythematosus during follow-up, they remained in CR. Twelve-month CR rate was 80% (5 evaluable patients). One patient experienced grade 3 neutropenia two months after the last rituximab infusion that resolved without complications. Estimated relapse-free survival was 80% at 2 years (60% if IT is considered). No patient had a splenectomy performed.

Summary/Conclusions: This small study reports favorable outcomes for patients with newly diagnosed wAIHA treated with low-dose rituximab, and adds 8 patients with similar responses to the 7 cases previously published by the Italian group in 2012 and 2016. These results may be comparable to standard doses of rituximab, with a lower cost, and deserves further inquiry. The emergence of additional autoimmune phenomena (SLE, Evan’s syndrome) is unpredictable and can be an obstacle for appropriate data analysis in prospective AIHA studies.

NEW EPO-RECEPTOR MUTATION IN A 17 YEAR OLD WOMAN WITH ERYTHROCYTOSIS
B. Robredo1,2, L. Lo Riso1, B. Lopez1, L. Florensa2, L. Arenillas2, B. Belosillo2, C. Ballestre3, A. Perez1, A. Sampol1, M.A. Duran1,2
1Hematology, Hospital Universitario Son Espases, Palma de Mallorca, Spain, 2Laboratorio Citología Hematológica, Servicio de Patología, Gretnsh. Escuela de Citología Hematólogica Soledad Woessner., Hospital del Mar, Barcelona, Spain

Background: Erythrocytosis is defined when red cell, hematocrit (Hct) and hemoglobin (Hb), are elevated above normal limits. Causes of erythrocytosis can be primary and secondary. Secondary causes are divided into congenital and acquired. There is a group of patients with idiopathic erythrocytosis. Aim: We present a case report of a novel EPO-Receptor mutation.
Methods: We present a case report of a 17-year-old woman with erythrocytosis. In the control blood test she had hemoglobin of 18.6g/dl and hematocrit of 62%. There was a history of consanguineous marriage in 26 of the families (74%). Twenty one of the cases were boys and fourteen were girls. The age at presentation for patients was two week-three years (mean 6.2 months). There was a history of consanguineous marriage in 26 of the families (74%). Fever, anemia, and hypertiglyceridemia were present in all HLH cases. Hepatomegaly was detected in 74%. Splenomegaly was more frequent in patients (85.7%). Hypofibrinogenemia was detected in all patients. All patients had neutropenia and thrombocytopenia. Hypoperfettinemia was present in 94% of patients. Only nine patients found to have hemophagocytosis in the cytological evaluation of the CSF(25.7%). Mutation analysis were performed in 18 patients and of these, 10 had PRF1, 5 had UNC13D, and 3 had STX11 gene mutation. All patients were treated with HLH-2004 protocol. Of the 22 children who were placed in first remission. HSCT was performed in 9 patients (%25.7). The overall mortality rate was 57% (20 cases) in our series. Twenty children died opportunist infection (n=10) or of disease progression (n=10).

Results: The test revealed a new EPO-receptor mutation (c.1275_1290dup), which had never been described before.

E1418

FAMILIAL HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN CHILDREN
Z. Salcioglu1,2, G. Aydogan1, F. Akcil1, C. Bayram1, A. Ayıcıkçı1, G. Ozdemir1,2
1Pediatric Hematology and Oncology Clinic, İstanbul Kanuni Sultan Suleyman Education and Research Hospital, İstanbul, Turkey

Background: Familial hemophagocytic lymphohistiocytosis (FHL) is an autosomal recessive disorder characterized with uncontrolled activation of T-helper lymphocytes and macrophages and over-release of inflammatory cytokines. The only curative treatment is hematopoetic stem cell transplantation (HSCT). Aim: This study evaluates the clinical and laboratory data of children with FHL. Thirty five FEL cases followed and treated at our clinic between 2005 and 2017 were retrospectively evaluated in our study.
Methods: Information of patients were retrieved from patient files and from the records contained in the electronic information processing environment created after 2005. All patients were treated with HLH-2004 protocol. HSCT was performed in nine patients.
Results: Twenty one of the cases were boys and fourteen were girls. The age at presentation for patients was two week-three years (mean 6.2 months). There was a history of consanguineous marriage in 26 of the families (74%). Fever, anemia, and hypertriglyceridemia were present in all HLH cases. Hepatomegaly was detected in 74%. Splenomegaly was more frequent in patients (85.7%). Hypofibrinogenemia was detected in all patients. All patients had neutropenia and thrombocytopenia. Hypoperfettinemia was present in 94% of patients. Only nine patients found to have hemophagocytosis in the cytological evaluation of the CSF(25.7%). Mutation analysis were performed in 18 patients and of these, 10 had PRF1, 5 had UNC13D, and 3 had STX11 gene mutation. All patients were treated with HLH-2004 protocol. Of the 22 children who were placed in first remission. HSCT was performed in 9 patients (%25.7). The overall mortality rate was 57% (20 cases) in our series. Twenty children died opportunist infection (n=10) or of disease progression (n=10).

Figure 1.
ABNORMAL MONOCYTE POPULATIONS IN THE PERIPHERAL BLOOD OF PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA

Methods:

Aims: Monocyte subpopulations display a prominent role in innate immunity but also mediate pro-inflammatory responses and T-cell activation. The monocyte subsets in CIN patients were studied in CIN. The aim of the present study was to evaluate the monocyte subsets, namely the classical CD14++/CD16- intermediate CD14+/CD16+ and non-classical CD14++/CD16+ cells as well as the monocytes CD14+/CD15/DR54/lowCD33/+CD11b+ fraction of the myeloid derived suppressor cells (MDSC), in CIN patients.

Methods: We have studied 25 patients fulfilling the well-defined diagnostic criteria for CIN and 10 age and sex-matched healthy individuals. Three-colour flow cytometry was used to assess the peripheral blood monocytes subsets in the gate of CD14 positive cells and five-colour flow cytometry for the evaluation of the myeloid derived suppressor cells in the gate of cells with intermediate/ high FSC/SSC properties.

Results: The mean number of neutrophils and monocytes in CIN patients was 1176±549/µl and 142±130/µl, respectively (range 200-1800/µl and 700-200/µl, respectively). The proportion of classical CD14++/CD16- cells was significantly decreased in CIN patients (79.60±7.60%) compared to the healthy individuals (87.90%±3.70%) (P<0.0009). In contrast, a significant increase was observed in the proportion of CD16 positive cells in CIN patients (16.81%±6.75%) compared to controls (7.97%±3.16%) (P=0.0001). This increase was due to the higher proportion of the intermediate CD14+/CD16+ but not the non-classical CD14++/CD16+ monocyte subsets in CIN patients (12.74%±5.28% and 4.05%±2.51%, respectively) compared to controls (7.05%±2.47% and 2.73%±1.39%, respectively) (P=0.0014 and P=0.1383, respectively). Furthermore, the proportion of CD14+/CD15/DR54/lowCD33/+CD11b+ MDSCs was significantly increased in the patients (6.18%±3.92%) compared to the healthy controls (0.34%±0.52%) (P<0.0412).

Summary/Conclusions: CIN patients displayed increased proportion of circulating intermediate CD14+/CD16- monocytes that may have a role in the aberrant inflammatory responses commonly seen in these patients. The increased proportion of the CD14+/CD15/DR54/lowCD33/+CD11b+ MDSC in CIN may simply reflect a compensatory reaction aiming to suppress the T-cell activation. Isolation of the above cell populations and transcriptome studies are currently in progress in our laboratory.

References

Background: Autoimmune hemolytic anemia (AIHA) is not commonly seen in childhood, and is extremely rare in infancy. Absence of guidelines renders management of the disease difficult in children – and even more so in infants.

Aims: Aim of the report is to present a number of cases of infantile AIHA, refractory to conventional treatments, demonstrating response in administration of rituximab.

Methods: The report concerns four infants (3 baby girls and one baby boy) who presented with AIHA. Data regarding demographics, personal and family medical history, immunologic assessments, previous treatments and response to rituximab were studied.

Results: Age at diagnosis of AIHA was 4-6 months. In 3 cases (cases number 1, 2 and 3) personal and family history, as well as laboratory screening at diagnosis, did not reveal presence of any other hematologic, autoimmune or immunologic condition. In case number 4 AIHA followed the diagnosis of giant cell hepatitis. Hospitalization before rituximab administration ranged between 1 and 3 months and multiple transfusions, administrations of intravenous immunoglobulin (maximum dose 6g/kg), repeated doses of intravenous methyl-prednisolone (30mg/kg) followed by oral prednizolone (max 5mg/kg), all failing to achieve sustained response. Rituximab was administered at 370mg/m² in 4 weekly infusions. In 3 infants 5 monthly infusions followed. Stabilization of hemoglobin and improvement of hemolysis parameters were observed after the 3rd-4th weekly infusion in all infants. In 3 patients (no 1,2,3) CD19+ and CD20+ B cell assessment before and after rituximab administration was performed. Complete elimination (<1%) was observed in all patients after the 1st-2nd infusion. Despite B cells returning to normal 11 months after treatment, infant no 1 remained in clinical remission during follow-up (22 months post treatment). Infant no 2 remained in clinical remission for the 16 month post treatment follow-up, despite B cell normalization. Infant no 3 relapsed following B cell normalization, 11 months after rituximab administration. Infant no 4 did not undergo B cell measurements and relapsed one year after completing rituximab therapy. The 2 patients that relapsed were re-treated with 4 rituximab infusions: patient no 3 remained well for the 18 month follow-up, whereas patient no 4 remained well for 10 years – again relapsing and receiving her 3rd rituximab treatment with good response for the remaining 7 month follow-up. None of the patients presented with adverse reactions during the infusions or with relevant infections as a result of immunosuppression. However, infant no 1 developed asymptomatic progressive IgG hypogammaglobulinemia 11 months after initial exposure to rituximab, eventually requiring IVIG administration.

Summary/Conclusions: Rituximab administration in refractory AIHA seems to be efficacious and safe in infants. However, close follow-up is warranted in order to ensure absence of long term complications, including the risk of post treatment hypogammaglobulinemia, when the drug is administered at such young ages.

E1424

EARLY LESSONS FROM WHOLE-EXOME SEQUENCING IN THE CLINICAL DIAGNOSIS AND MANAGEMENT OF RARE INHERITED ANEMIAS

1Molecular Haematology Unit, 2BRC Molecular Diagnostic Centre, Oxford University Hospitals NHS Trust, 3Comprehensive Biomedical Research Centre, Weatherall Institute of Molecular Medicine, University of Oxford, 4Molecular Haematology Unit, Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom

Background: Targeted re-sequencing has recently been adopted for the rapid diagnosis of anaemia patients whose disease is likely to have a genetic basis, however, currently results remain inconclusive in 30-60% of cases. Whole-genome sequencing (WGS), provides more uniform coverage than amplification-based panels and is allied to an unbiased approach offering the opportunity to explore both coding and non-coding regions. It is also possible to use WGS data to detect copy number variation with high resolution and sensitivity. Therefore WGS has the potential to offer an accurate molecular diagnosis in a proportion of unsolved anaemia cases and may therefore be a superior initial approach. Furthermore, WGS is likely to lead to the identification of novel genes involved in pathogenic and normal erythropoiesis.

Aims: In the last 12 years we have undertaken WGS in a set of patients in whom targeted re-sequencing had not been able to identify a molecular cause for the inherited anaemia, in an attempt to increase the diagnostic yield of the molecular analyses of such patients and provide novel candidate genes as causative of anaemia.

Methods: We performed WGS of 20 individuals (2 singletons and 6 trios) at 30x coverage where the parents have a rare anaemia of suspected genetic origin. Proband were pre-screened with a targeted panel containing ~50 candidate genes, none of which had harboured likely causative variants. Analysis of WGS data involved Stumpy for read alignment, Platybus for variant calling and Ingenuity Variant Analysis (Qiagen) for variant annotation and filtering, followed by manual verification and classification.

Results: Known causative variants in a gene absent from the targeted panel were detected in two patients (25%), whereas candidate variants in novel genes not previously associated with anaemia were identified across the other six cases. Familial segregation and functional studies are underway to provide further evidence of causality for these novel variants, of which 60% are in genes with previous evidence of a role in erythropoiesis and 40% in genes with no known role in erythropoietic development.

Summary/Conclusions: These results illustrate the overlap in phenotypic abnormalities existing among these conditions and the importance of providing an accurate molecular diagnosis to enable correct diagnostic and clinical management of anaemia patients. We also demonstrate the benefit of using WGS over targeted resequencing given the difficulty of designing comprehensive gene panels and keeping them up-to-date as new candidate genes are identified.
ADAMTS13 <5% or TMA without baseline cause). 2. HUS (TMA with ADAMTS13 >5% and high creatinine level, and positive C. E. coli Shiga-Toxin or HUS related mutation). 3. sTMA (other TMA with a definite triggering cause). Clinical and laboratory parameters were analyzed in each group (TTP/HUS/sTMA) (ADAMTS13 ≤5% or >5%) by a univariate analysis using chi-square for categorical variables and ANOVA test for continuous variables. Kaplan-Meier and multivariate Cox proportional hazards regression was used for survival and relapse.

Table 1.

Results: Patient distribution was: TTP 13, HUS 8, sTMA 23. ADAMTS13 was determined in 28 patients (low 8, high 20). Clinical and laboratory parameters of each group and univariate analysis are summarised in table 1. All patients received 1mg/kg/day steroids on admission and started plasma exchange. Patients in the TTP group showed increased levels of LDH, schistocytes, bilirubin and a low platelet count which was associated with bleeding. They also required a higher number of plasma exchanges to recover. Five patients relapsed, 4 with low ADAMTS13 level. 4 patients were splenectomized and received immunomodulators. One patient received only plasma exchanges when relapsed. One patient died immediately after diagnosis before receiving plasma exchange. HUS group patients had higher creatinine level which was associated with oliguria and dialysis requirement. Neurological symptoms were more frequent as well. Two patients progressed to renal failure and one was transplanted. Two other patients received eculizumab and 1 relapsed when treatment was interrupted during pregnancy. sTMA patients showed more cardiac events and fever. Main triggering causes were: 6 malignant hypertension, 5 systemic lupus erythematosus, 4 neoplasia, 3 pancreatitis, 2 pregnancy, 1 tuberculosis, 1 glomerulonephritis, 1 dermatomyositis. Six patients died (4 cancer related). In the multivariate analysis, high LDH level was significantly associated with relapse (p=0.012) while the number of schistocytes showed a trend to statistical significance (p=0.063).

Summary/Conclusions: ADAMTS13 determination is a useful tool in TMA differential diagnosis. A high LDH level, and also probably the number of schistocytes, could be valuable to predict relapse in TMA patients.

E1427

CHILDREN WITH CHRONIC–REFRACTORY AUTOIMMUNE CYTOPENIAS: A SINGLE CENTER EXPERIENCE

T.H. Karapinar1, Y.E. Dungun1, Y. Oyrmak1, N. Güleş2, Y.Y. Ay1, F. Geneli2, S. Gözmen1, E. Serdaroğlu3, S. Aydin Köker1, E. Töret1, C. Vergin1

1Pediatric Hematology and Oncology, 2Pediatric immunology, 3Pediatric nephrology, Dr. Behçet Uz Children Training and Research Hospital, İzmir, Turkey

Background: Autoimmune cytopenias are a group of heterogeneous disorders characterized by immune-mediated destruction of one or more hematopoetic lineage cells. They can be idiopathic or occur as a manifestation of other underlying disorders, such as autoimmune diseases, immunodeficiency, autoimmune lymphoproliferative syndrome, tumors, medications or infections.

Aims: The aim of this study was to evaluate the clinical course and significance of autoimmune cytopenias due to immunodeficiency or autoimmune diseases in children followed up at our hospital.

Methods: A total of 337 files of information belong to patients with chronic or refractory autoimmunity were evaluated retrospectively at our hematology department between February 1997 and September 2015. Ultimately, patients with immune deficiency or autoimmune diseases (23 patients) were included in this study. Data were analyzed using SPSS 15.0. The results are presented as the mean, SD, median, absolute number, or percentile.

Results: Two–three of the patients with chronic autoimmune cytopenias (6.8%) had an immune deficiency or an autoimmune disease. The median age of diagnosis was 3.1 years (between 6 months–16 years) and the ratio of male/female was 1.3. The median duration of following was 2.6 years (between 4 months and 18.5 years). A total of 13 patients (56.5%) had single- lineage cytopenias and 10 (46.5%) had multi-lineage cytopenias. Shows last diagnosis of the patients. In 10 of the patients, first cytopenias were more than the primary diseases were diagnosed after median 2 months (between 0 and 77 months). Only one patient firstly had diagnosed as CVID, cytopenia has developed after years. All of the patients were treated with corticosteroids or intravenous immune globulin (IVIG) as first-line treatment. Ten patients needed second or further-line immunosuppressive therapies including rituximab, mycophenolate, azathioprine, cyclosporine A, aza thioprine, and danazol. A total of 8 patients (34.7%) recovered from autoimmune cytopenias after the treatment of primer disease. That diseases were diagnosed as systemic lupus erythematosus in 4 patients, hypogammaglobulinemias in 3 patients, and celiac disease in 1 patient. Cytopenias have been in 14 of the patients. One patient had been diagnosed as CVID died.

Summary/Conclusions: Cytopenia may be the first finding of an immunodeficiency or autoimmune disease and primary disease may be diagnosed in the clinical course. Early diagnosis is important because of beginning to the early treatment of underlying disease.
Flow Cytometric Analysis of Tissue Samples in 42 Adult Patients with Malignancy-Associated Hemophagocytic Lymphohistiocytosis

M. Klimkowska1, C. Arlind1, K. Kosior1, M. Machaczka2,3
1Department of Clinical Pathology and Cytology, 2Hematology Center, Karolinska University Hospital, Stockholm, Sweden, 3Medical Faculty, University of Rzeszow, Rzeszow, Poland

Background: Hemophagocytic lymphohistiocytosis (HLH) is a rare, potentially fatal hyperinflammatory syndrome, which in its most common, secondary form, can be induced by infection, malignancy or autoimmune disease. Diagnosis of HLH is made when at least five of eight clinical and laboratory HLH-2004 criteria are met. However, diagnostic criteria were established based on studies from pediatric patients, and it is debated if they can be applied to adults. Assessment of these criteria can be subjective (microscopic identification of hemophagocytes), time-consuming or not easily available (e.g. molecular analyses, functional tests of NK-cells).

Aims: The aim of the study was to evaluate phenotypic findings from flow cytometric (FC) analyses of bone marrow (BM) and other tissue samples from patients with hematological malignancies (HM) who developed HLH. The study was intended to investigate potential utility of a rapid phenotypic screening in diagnostics of suspected HLH.

Methods: Flow cytometric files for 42 patients with HM were retrieved from archive of the Department of Clinical Pathology and Cytology, Karolinska University Hospital. The patients were diagnosed and treated for HM-HLH at the Hematology Center of the same hospital, between 2009 and 2016. Tissue samples (bone marrow, peripheral blood, lymph nodes) were analyzed according to standard procedures, using monoclonal antibodies (BD, DAKO, Beckman Coulter, BioLegend). Cells were acquired using 4-color Canto A or 8-color Canto II cytometers (BD), and analyzed with BD FACSDIVA software. Neoplastic clones of myeloid or lymphoid character were excluded from reanalysis for the purpose of this study. Bone marrow samples were obtained from 31 patients shortly before and from 24 patients following HLH-diagnosis; in 13 patients paired BM samples were available.

Results: Patient characteristics are presented in table 1. Bone marrow B-cell lymphopoenia was observed in 67% patients before and 74% after HLH diagnosis. Decreased amounts of NK-cells were noted in 48% persons at both time points. T-cell lymphopenia below 200 cell/mm³ was noted in 60% patients with myeloid malignancy but in only 25% cases of lymphoid malignancy, whereas in established HLH the respective figures were 27% and 46%. CD4/CD8 ratio was skewed-to-normal in both myeloid and lymphoid tumors before HLH diagnosis was diagnosed. In cases of confirmed hyperinflammation, patients with myeloid tumors showed dominance of CD4+ cells but no such difference was noted in lymphoid disease. Loss of lineage specific markers of non-neoplastic T-cells was a constant feature in lymphoid malignancy, whereas aberrant expression of lymphatic markers (CD2, CD7, CD56) on myeloid cells was uniform in patients with myeloid tumors. Monocytosis was more often observed in myeloid as compared to lymphoid tumors at HLH onset (40% vs 31%), although it was of non-neoplastic character. However, monocytopenia was also noted in cases of established HLH, in 10% of myeloid malignancies and 15% of lymphatic malignancy cases.

Table 1

Summary/Conclusions: In the presented cohort, quantitative shifts could be observed in BM samples around the time of HLH onset. However, different patterns were observed between patients affected by lymphoid or myeloid malignancies, which may reflect disease-specific impact on BM microenvironment. Further study will be carried out to confirm findings in a large, possibly prospectively collected patient group. Control group of patients with respective malignancies but without HLH will be included.

Platelets disorders

Bleeding in Primary Immune Thrombocytopenia: Who Are Most at Risk?

U. Doobere1,1, S. Hodges1, R. Nandigam1, A. Newland1, D. Provan1
1Haematology, Barts and The London School of Medicine and Dentistry, London, United Kingdom

Background: Primary Immune Thrombocytopenia is a rare disorder in which patients are at risk of bleeding due to autoimmune-mediated platelet destruction. The purpose of this study was to identify any factors that can potentially influence the risk of bleeding.

Methods: Data from the United Kingdom Immune Thrombocytopenia Registry were analysed for this study. The registry obtained its data from about 70 centers around the UK. Descriptive and logistic regression statistical techniques were used for this study.

Results: This analysis was based on 2365 (57.8% females) participants who are part of the Registry. The median age at diagnosis was 50 years (IQR 32, 66) and 77% of these patients were of European ethnicity. The commonest comorbid conditions was hypertension (23%). Median platelet count was 19 (IQR: 5, 53). Eighty percent had a platelet count below 30x10⁹/L around ITP diagnosis. The most common bleeding events were skin-related (46.5%) and to the oral cavity (14.4%). About 70% of the cohort experienced at least one bleeding event at some point after diagnosis. After ITP diagnosis the most common bleeds were again skin-related (34.3%) and oral cavity bleeding (14.8%). Epistaxis had risen from 11.6% before diagnosis to 17.7%. Bleeding at other sites did drop. However, the prevalence of intracranial haemorrhage rose from 0.9% pre-diagnosis to 1.2% after diagnosis. Prednisolone (79%) and IVg (43%) were the most used drugs followed by rituximab (26%) among those who were treated. Romiplostim (15%) and Eflotrombopag (9%) are used too but not anymore than mycophenolate (18%) and azathioprine (22%). Seventeen percent of the cohort had a splenectomy at some point. Age but not gender or ethnicity were found to be associated with having a bleeding event around the diagnosis of ITP. Patients aged more than 60 years old were less likely to experience a bleed than older adults (>70 years), who were most at risk. Platelet counts, expectedly, was associated with bleeding with those presenting with a platelet of <30x10⁹/L were at higher risk. No comorbid illness or cotherapies were found to be associated with bleeding events.

Summary/Conclusions: The frequency of bleeding decreased for most sites but for some others a slight increase has been observed since ITP diagnosis. It is possible that bleeding events may have been recorded more accurately or observed more closely and over a longer period of time since diagnosis. However, control of bleeding was an issue after the diagnosis of ITP. Future analysis stratifying its findings by time periods would be beneficial in describing if bleeding events were better controlled over the last few years, especially after the introduction of new therapeutic agents and the publication of the internal consensus report on the diagnosis and management of primary ITP.

A multicentre, single arm open label study evaluating the efficacy and safety of eltrombopag in patients with severe persistent immune thrombocytopenic purpuria (ITP) within six months of diagnosis

H. Tran1,2, R. Bird1, S. Chunilal3, T. Brighten1, J. Reynolds6, S. He7, C. Mazis1, R. Hall1, P. Shuttlesworth1, A. Grigg7
1Clinical Haematology, The Alfred Hospital, 2Clinical Haematology, Monash University, Melbourne, 3Clinical Haematology, Princess Alexandra Hospital, Brisbane, 4Clinical Haematology, Monash Health, Melbourne, 5Clinical Haematology, Prince of Wales Hospital, Sydney, 6Clinical Epidemiology and Preventative Medicine, Monash University, 7Clinical Haematology, Austin Hospital, Melbourne, Australia

Background: Patients with acute ITP who fail or are dependent on steroids or intravenous immunoglobulin (IVg) are often committed to splenectomy or prolonged immunosuppression. Splenectomy is potentially curative but not without operative risk with many patients reluctant to undergo surgery, while the response to immunomodulation is often suboptimal with significant side effects. Although effective, to date, there is no published studies evaluating the benefit of eltrombopag among steroid dependent or resistant, non-splenectomised ITP patients diagnosed within 6 months.

Aims: To evaluate the efficacy and safety of eltrombopag in patients with severe “acute” and persistent ITP within 6 months of diagnosis.

Methods: A multicentre, single arm open label study involving 39 patients with refractory ITP with platelet counts of <30x10⁹/L, despite a daily dose of prednisolone of 1mg/kg for at least 2 weeks from diagnosis OR (b) requiring prednisolone ≥10mg daily and/or recurrent doses of IVg to maintain a platelet of ≥30x10⁹/L within 6 months of diagnosis. Prior splenectomy was not a requisite.
Patients with platelets <10x10^9/L will commence on eltrombopag 75mg daily while those with a count 10x10^9/L will commence on 50mg daily. A reduced dose is used for subjects of East Asian heritage. The dose of eltrombopag can be progressively increased by 25mg increment every 2 weeks to maximum of 150mg daily (patients of East Asian heritage should have a maximum eltrombopag dose of 100mg daily) if the platelet count remains ≤30x10^9/L or there is clinically significant bleeding every 2 weeks. The steroid can be progressively weaned to zero over the subsequent 6 weeks if clinically appropriate. The primary endpoint was overall response rate (ORR) at week 12, defined as the proportion of patients achieving complete response (CR; platelet >100x10^9/L), partial response (PR; platelet >50x10^9/L) or minor response (MR; platelet ≥30x10^9/L) with ≥50% reduction in the dose intensity of concomitant ITP therapy compared with screening. The protocol specified a 1-sided 5% level binomial test of the null hypothesis that ORR at week 12 ≤30% and reporting of a 90% two-sided confidence interval (CI).

**Results:**
Of the 39 patients enrolled, 46% were women, median (Q1, Q3) age was 54 (40, 64) years, and median (Q1, Q3) platelet count was 113 (55, 293)x10^9/L. Of the 29 patients with ITP diagnosed ≥6 months, 18 (62%) had a history of antiplatelet therapy (90% CI: 51-77%); CR, PR, MR rates were 41%, 15% and 8% respectively. Two patients had serious adverse events (SAEs) with two episodes of venous thromboembolism (one deep vein thrombosis at platelet 97x10^9/L; one pulmonary embolism at platelet 240x10^9/L). Prior treatments included steroids (95%), IVIG (58%), and immunosuppression (28%). 35 patients (90%) completed 12 weeks of treatment, 4 (10%) discontinued eltrombopag prior to week 12 [3 required new ITP therapy; 1 patient withdrew]. The median (Q1, Q3) dose eltrombopag at week 12 was 50 (50, 100)mg daily. The median (Q1, Q3) dose of steroid at week 12, zero (0, 5)mg daily. At week 12, the ORR was 64% (p<0.001; 90% CI: 51-77%); CR, PR, MR rates were 41%, 15% and 8% respectively and the median (Q1, Q3) platelet count among responders was 168 (98, 252)x10^9/L. At day 42, PR and MR rates were 40% (90% CI 40-67%); CR, PR, MR rates were 28%, 21% and 5% respectively. Two patients had serious adverse events (SAEs) with two episodes of venous thromboembolism (one deep vein thrombosis at platelet 97x10^9/L; one pulmonary embolism at platelet 240x10^9/L).

There were no other adverse events or deaths.

**Summary/Conclusions:**
The majority of patients with ITP diagnosed for ≤6 months had a favourable overall response rate to eltrombopag and the drug was generally well tolerated. Longer-term follow up data (beyond 6 mos) will be presented at the meeting.

**Background:**
MicroRNAs (miRNAs) are small noncoding RNAs involved in regulation of gene expression. Dysregulated expression of miRNAs has been associated with several autoimmune diseases. ITP is an autoimmune disease characterized by isolated thrombocytopenia and increased risk of bleeding. The development of autoantibodies against platelets and megakaryocytes results in increased platelet destruction and insufficient platelet production leading to pathophysiology of ITP. Platelets contain high levels of miRNAs and a substantial fraction of circulating miRNAs originates from platelets. Circulating miRNAs are stable and relatively easy to measure and considered as potential disease biomarkers. The role of miRNAs in the pathogenesis of ITP has not been well explored.

**Aims:** Determine the expression profile of circulating miRNAs in ITP patients in order to identify miRNAs that can be used as disease biomarkers and to explore the potential biological pathways that might be involved in the pathogenesis of ITP.

**Methods:** Exiqon Serum/plasma Focus microRNA PCR panel was used to determine the expression profile of 179 miRNAs in plasma acquired from 8 ITP patients with low platelet count and who failed to respond to various treatments for ITP, and from 8 age- and sex-matched controls. In addition, next generation sequencing (NGS) for miRNAs was performed in 2 pooled plasma samples (pool 1 from 4 ITP patients, and pool 2 from 4 matched controls), on the Illumina NextSeq 5500 system. Statistical analyses were performed with the GenEx software and SPSS. Pathway analysis was performed using DIANA-miPath v3.0 to explore the probable pathways involved in the pathogenesis of ITP.

**Results:**
Comparing the expression profiling from the PCR panel between ITP patients and matched controls, 81 circulating miRNAs were differentially expressed (p<0.05), of those 17 miRNAs had a high statistical significance (q<0.001). Four miRNAs were up-regulated and 13 miRNAs were down-regulated in ITP compared to controls. Interestingly, 15 of the 17 differentially expressed miRNAs from PCR panel were also differentially expressed in NGS. Using the 17 differentially expressed miRNAs in the miRPath analysis, we uncovered some immune system related pathways, including MYD88-independent toll-like receptor signaling pathway and TRIF-dependent toll-like receptor signaling pathway, as enriched pathways in target genes of miRNAs differentially expressed between ITP patients and controls.

**Summary/Conclusions:** We identified a large number of miRNAs that were differentially expressed in ITP patients compared to controls that might be associated with the pathogenesis of ITP. Pathways analysis uncovered some possible biological pathways that might be involved in the pathogenesis of ITP. Further validation of these miRNAs in a larger patient cohort and preferably in comparison to patients with other causes of thrombocytopenia such as aplastic anemia could explore the role of these miRNAs in the pathogenesis of ITP. Future studies of these miRNAs in relation to initiation of treatment with defined clinical outcomes as treatment response/ remission after initiation of treatment will clarify their potential as biomarkers for treatment response.
NORDIC COUNTRY PATIENT REGISTRY FOR IMMUNE THROMBOCYTOPENIA (NCPRTIP): A COHORT OF PATIENTS WITH CHRONIC IMMUNE THROMBOCYTOPENIA IN DENMARK, SWEDEN, AND NORWAY

Background: Immune thrombocytopenia (ITP) is a rare disease characterized by isolated platelet counts and an increased tendency to bleed. As yet, there have been no large, multi-country, population-based cohorts established to describe its long-term clinical course and investigate the effectiveness and safety of related therapies.

Aims: To describe the establishment of the NCPRTIP and the characteristics of patients enrolled.

Methods: Encompassing Denmark, Norway, and Sweden, the NCPRTIP started as a population-based post-authority safety study to assess the long-term safety of romiplostim in treating ITP. It includes patients with prevalent chronic ITP (cITP – ITP lasting >6 months) as of 04/01/2009 in 9 of 10 ITP diagnosed from 04/01/2009-12/31/2014, confirmed through medical record review. Since the start of the registry, guidelines have changed to define cITP as ITP lasting >12 months. For consistency, incident cases of ITP for a duration of >6 months will continue to be accrued through 2019. Through linkage of data from the Danish national health registers and medical record review, the registry has rich clinical information for all enrolled ITP patients, as well as comorbidities (including scores according to the Charlson Comorbidity Index [CCI] – a validated tool developed to predict 1-year mortality), treatments, lab values (e.g., platelet counts), and complete follow-up for several clinical outcomes of interest (e.g., clinically significant bleeding, the need for rescue therapies, and thromboembolic/thrombotic events). Additionally, available bone marrow samples are restained and reexamined for reticulin and collagen content to assess Thiele’s myelofibrosis (MF) grading.

Results: The NCPRTIP includes 3,749 patients with confirmed cITP (35% Danish, 51% Swedish, and 14% Norwegian), with a female preponderance (58%) and median age of 56 years at cITP diagnosis. Forty-one percent of the cohort was prevalent at study inclusion; 59% represent incident cITP patients. Median follow-up time thus far is 4.3 years. At study enrollment, 24% had a platelet count <50×10^9/L. 16% were splenectomized, and 41% had at least one previous ITP therapy (mainly oral glucocorticoid steroids). The majority (68%) of the cohort had no underlying conditions included in the CCI at study enrollment, but 8% had a CCI score of 3 or higher, indicating severe comorbidity. Of note, based on hospital diagnoses of specific comorbidities recorded within 5 years before study entry, 11% of the cohort had hypertension (9%), diabetes, and 18% had a history of hypertension. Currently, 718 bone marrow samples from 566 patients have been retrieved.

Summary/Conclusions: The NCPRTIP provides an example of how, within the Nordic countries’ uniform health care systems, registries can be established to study the clinical course of rare diseases such as ITP and the safety of drugs used to treat these patients.

EPIEMIOLOGY OF PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) IN ADULTS IN RUSSIAN FEDERATION (RESULTS OF REGISTRY OF NATIONAL HEMATOLOGIC ASSOCIATION)

Background: Immune thrombocytopenia (ITP) is a rare disease characterized by isolated platelet counts and an increased tendency to bleed. As yet, there have been no large, multi-country, population-based cohorts established to describe its long-term clinical course and investigate the effectiveness and safety of related therapies.

Aims: To describe the establishment of the NCPRTIP and the characteristics of patients enrolled.

Methods: Encompassing Denmark, Norway, and Sweden, the NCPRTIP started as a population-based post-authority safety study to assess the long-term safety of romiplostim in treating ITP. It includes patients with prevalent chronic ITP (cITP – ITP lasting >6 months) as of 04/01/2009 in 9 of 10 ITP diagnosed from 04/01/2009-12/31/2014, confirmed through medical record review. Since the start of the registry, guidelines have changed to define cITP as ITP lasting >12 months. For consistency, incident cases of ITP for a duration of >6 months will continue to be accrued through 2019. Through linkage of data from the Danish national health registers and medical record review, the registry has rich clinical information for all enrolled ITP patients, as well as comorbidities (including scores according to the Charlson Comorbidity Index [CCI] – a validated tool developed to predict 1-year mortality), treatments, lab values (e.g., platelet counts), and complete follow-up for several clinical outcomes of interest (e.g., clinically significant bleeding, the need for rescue therapies, and thromboembolic/thrombotic events). Additionally, available bone marrow samples are restained and reexamined for reticulin and collagen content to assess Thiele’s myelofibrosis (MF) grading.

Results: The NCPRTIP includes 3,749 patients with confirmed cITP (35% Danish, 51% Swedish, and 14% Norwegian), with a female preponderance (58%) and median age of 56 years at cITP diagnosis. Forty-one percent of the cohort was prevalent at study inclusion; 59% represent incident cITP patients. Median follow-up time thus far is 4.3 years. At study enrollment, 24% had a platelet count <50×10^9/L. 16% were splenectomized, and 41% had at least one previous ITP therapy (mainly oral glucocorticoid steroids). Summary/Conclusions: The NCPRTIP provides an example of how, within the Nordic countries’ uniform health care systems, registries can be established to study the clinical course of rare diseases such as ITP and the safety of drugs used to treat these patients.

ELTROMBOPAG (EPAG) FOR THE TREATMENT OF PATIENTS AGED ≥65 YEARS WITH CHRONIC IMMUNE THROMBOCYTOPENIA (CITP): SAFETY AND EFFICACY RESULTS FROM THE EXTEND STUDY

Background: ITP is an acquired autoimmune disorder characterized by isolated platelet reduction, which is considered chronic when persisting for ≥12 months. Evidence suggests that age may influence both the hematologic manifestations of ITP and also response and adverse events (AEs) associated with some therapies. Changes in drug metabolism can contribute to increased AE rates in patients (pts) ≥65 yrs compared with younger adults. The oral thrombopoietin-receptor agonist, EPAG, is approved for the treatment of newly diagnosed and some therapies. Changes in drug metabolism can contribute to increased AE rates in patients (pts) ≥65 yrs compared with younger adults. The oral thrombopoietin-receptor agonist, EPAG, is approved for the treatment of newly diagnosed and persistent (eg corticosteroids, immunoglobulins) CITP pts, but limited data are available in pts ≥65 yrs old. The EXTEND study was a global, open-label, extension study that evaluated long-term efficacy, safety and tolerability of EPAG in adults with cITP who had participated in prior EPAG studies. Aims: To describe the efficacy, durability of response, and safety of EPAG use in pts with cITP aged ≥65 yrs.

Methods: All pts on EXTEND started EPAG at 50mg/day, titrated to 25–75mg/day or less often as required, based on individual platelet count responses: to achieve counts in the range ≥50–200×10^9/L. Maintenance dosing continued to maximize platelet count response and optimize ITP dosing. Pts could remain on EPAG either for 2 yrs in countries where the NCIP persist for ≥12 months. Evidence suggests that age may influence both the hematologic manifestations of ITP and also response and adverse events (AEs) associated with some therapies. Changes in drug metabolism can contribute to increased AE rates in patients (pts) ≥65 yrs compared with younger adults. while not receiving rescue treatment, was 78 (range, 0–350) weeks. Incidence of bleeding symptoms (WHO grades 1–4) decreased from BL (86%) to 1 y (15%). AEs were reported in 47 (94%) pts, most frequently nasopharyngitis (n=13, 26%), constipation (n=12, 24%), fatigue (n=12, 24%), diarrea, arthralgia, urinary tract infection, cataract and cough (all n=11, 22%). Serious AEs occurred in 24 (48%) pts, most frequently >5% cataracts (n=7, 14%), pneumonia (n=6, 12%), and urinary tract infection (n=3, 6%). The most frequent AEs with suspected relationship to study drug were cataracts (n=8, 16%), headache, fatigue, and increased ALT, AST and bilirubin (all n=3, 6%).

### CHILDHOOD IMMUNE THROMBOCYTOPENIA: A NATIONWIDE COHORT STUDY ON CONDITION MANAGEMENT AND OUTCOMES

N. Aladjidi1, C. Nordon2,*, G. Leverger 1, T. Leblanc 3, L. Grimaldi-Bensouda2
1CHU Bordeaux, Bordeaux, 2LASER, 3CHU Robert Debré, Paris, France

**Background:** Little is known about the management of pediatric ITP in real life, that is, routine clinical practice. Moreover, the predictive value of these factors upon disease outcome was explored individually and therefore the confounding effect of associated exposures remains unknown.

**Aims:** With this nationwide prospective cohort study, our objectives were to explore (1) the factors associated with treatment initiation (vs. watchful waiting) in children with primary immune thrombocytopenia (ITP) followed in routine clinical practice and (2) the predictors of chronicity at 12 months.

**Methods:** Between 2008 and 2013, 23 centers throughout France consecutively included 257 children aged 6 months to 18 years and diagnosed with primary ITP over a 5-year period. Data on ITP clinical features along with medical management were collected at baseline and 12 months. Multivariate logistic regressions were used to determine (1) and (2) as defined above, providing odds ratio (OR) with 95% confidence intervals (95% CI).

**Results:** 137 (53%) children were males, median age 4.6 years, median platelet count was 7×109/L, and 214 (81%) patients initiated medication. Factors independently associated with treatment initiation included platelet counts <10×109/L (p<0.0001) and mucocutaneous bleeding symptoms at baseline (p<0.001). At 12 months, data were available in 211 (82%) children, of whom 100 (74%) had recovered. Predictors of chronicity included female gender (OR=2.2; 95% CI=1.0–4.8), age ≥10 years (OR=2.6; 95% CI=1.1–6.0) and platelet counts ≥10×109/L (OR=3.2; 95% CI=1.5–6.9).

**Summary/Conclusions:** In routine clinical practice, the decision to apply a watchful-waiting strategy seems to be driven by platelet counts even in the presence of bleeding symptoms, resulting in treatment being initiated in more than 80% of the children surveyed. Overall, younger children with ITP showed good prognosis, with lower platelet counts and, to a lesser extent, male gender predicting more favorable outcomes.

## E1440

### SIROLIMUS FOR THE TREATMENT OF CHILDREN WITH IMMUNE THROMBOCYTOPENIA AND EVANS SYNDROME: A SINGLE CENTRE EXPERIENCE

M. Miano1,*, A. Rotulo1, E. Palmisani1, A. Grossi2, F. Pierri1, M. Calvillo1, C. Micalizzi2, P. Terranova1, E. Capelli1, T. Lanza1, M.T. Giaino1, I. Ceccherini1, C. Dufour1, F. Fioredda1
1Haematology Unit, 2Molecular Genetic Unit, IRCCS Istituto Giannina Gaslini, Genova, Italy

**Background:** The treatment of chronic relapsing immune thrombocytopenia purpura (ITP) is not well established due to the lack of evidence-based data, and is particularly challenging in children who are more at risk of severe side-effects secondary to prolonged steroid therapies. Sirolimus has been shown to be effective in patients with ITP secondary to ALPS1 and in very few patients with primary disease or secondary to ALPS-like syndromes.2

**Aims:** The aim of this study is to evaluate the outcome and toxicity of patients with ITP either primary or secondary to ALPS-like syndromes, with or without involvement of other cell lineages.

**Methods:** We retrospectively evaluated charts of patients followed in our Unit for ITP primary or secondary to ALPS-like syndromes. Patients with ALPS were excluded. ALPS-like was defined as the presence of at least one absolute or primary additional criterion for ALPS. Complete response (CR) and partial response (PR) were defined as a platelet count >100×109/L and >30×109/L and at least 2 fold increase of the baseline count, respectively.

**Results:** 23 children aged 0-12 yrs (median 6) with primary ITP (7) or secondary to ALPS-like disorder (16), were treated with Sirolimus. Seven patients (30%) with ALPS-like also had an Evans syndrome (ES), due to the association of leukopenia (1), or to the presence of trilinear cytopenia (6). Four patients with ALPS-like were found to have mutations on PI3KCD, CTLA4, TACI, and CARD 11 gene. All patients, but one treated in first-line, received Sirolimus. Seven patients were treated as second (4), third (14) or fourth (4) line treatment, respectively. Prevalent side effects were limited in 67 (86%) cases. Children with mono-linear ITP achieved a response in 11/16 (74%) and at least 2 fold increase of the baseline count, respectively.

**Summary/Conclusions:** To the best of our knowledge this is the largest cohort of patients with ITP or ES other than ALPS -treated with Sirolimus, that showed to be safe and effective in most cases, including patients who previously failed
MMF treatment. Therefore, it can be considered as an alternative therapeutic option in the setting of ITP non only for patients with an underlying diagnosis of ALPS but also for the ones with primitive disease or with an ALPS-like disorder.

References

RESULTS
The mean age of patients and control was 29.5±2.8 yrs; 13.86 yrs and 27.90± 8.89 yrs respectively. Male/Female ratio in patients and control was 1:2. Under additive model, the heterozygous genotype (AG) of the FcγRIIA 131 H/R (A>G) polymorphism shows the significant association with ITP, (Odds Ratio 2.41 (95% CI, Lower - 1.19 Upper 4.90 P-value 0.0149) whereas the homozygous mutant genotype (GG) had no significant association with ITP (Odds Ratio 2.47 (95% CI, Lower - 0.63 Upper 9.72 with P-value 0.2976). Under dominant model, the Odds Ratio was 2.42 (95% CI, Lower - 0.34 Upper 9.94) with the significant P-value 0.0167. Mutant allele (G) frequency was 37.85% in patients and 25.71% in controls (Odds ratio 1.76 1.05-2.93 with the p-value 0.0297).

Summary/Conclusions: The study shows the association of heterozygous genotype (AG) of FcγRIIA 131 H/R (A>G) with ITP. The dominant model also shows significant association with ITP. We conclude that mutant allele (G) in FcγRIIA 131 H/R (A>G) gene polymorphism may have impact on susceptibility to ITP.

ASSESSMENT OF ROMIPLOSTIM SELF-ADMINISTRATION BY PATIENTS WITH IMMUNE THROMBOCYTOPENIC PURPURA AND CAREGIVERS FOLLOWING RECEIPT OF HOME ADMINISTRATION TRAINING (HAT) MATERIALS:A PROSPECTIVE SECTIONAL STUDY
M. Schippetiza, G. Kaina, L. Taylor, S. Wetten, J. Bennett, G. Kreuzbauer, A. Boshiere, A. Seesaghour
1Department of Haematology, Haga Teaching Hospital, The Hague, Netherlands, 2AHEPA University Hospital, Thessaloniki, Greece, 3Royal London Hospital, London, 4Aemgen Limited, London (Uxbridge), United Kingdom, 5Aemgen (Europe), Zug, Switzerland, 6Aemgen Limited, Cambridge, United Kingdom

Background: A HAT pack was designed as an additional risk minimization tool to support healthcare providers (HCPs) in selecting patients and training of patients/caregivers to mitigate medication error risk when self-administering romiplostim subcutaneously, a thromboepoetin- receptor agonist which is approved in the European Union (EU) to treat chronic immune thrombocytopenic purpura (ITP) refractory to other treatments.

Aims: To estimate the proportion of adult patients and caregivers who administer romiplostim after HAT pack training.

Methods: This non-interventional, cross-sectional study enrolled 40 patients/caregivers and was conducted at 12 centres in Austria, Belgium, France, Germany, Greece, The Netherlands, Spain, and The United Kingdom, from 7 July 2014 to 20 November 2015. HCPs directly observed adults (≥18 years of age) with chronic ITP or caregivers new to administering romiplostim in the act of product administration at the first standard-of-care (SoC) 4-week visit after HAT pack training. Correct administration of romiplostim (primary endpoint) was defined as dose accuracy within 10% margin of error between prescribed and administered romiplostim doses, and correct romiplostim reconstitution and successful injection, and no HCP intervention during administration to correct patient/caregiver error. All analyses were descriptive and no formal hypothesis was tested.

Results: At the first SoC visit, 4 weeks (range: 2-8 weeks) after HAT pack training, 35 patients/caregivers (87.5%) administered romiplostim correctly. The dose accuracy was within 10% margin of error for all patients. HCP intervention was required in 5 instances: 1 patient did not ensure all romiplostim was dissolved, 1 patient and 1 caregiver needed verbal encouragement, 1 patient needed nursing intervention to read the correct dose from the vial due to poor eyesight, and 1 caregiver needed guidance with syringe and vial connection. Further follow-up data was available for only 2 of these 5 patients/caregivers; they both administered romiplostim correctly at a voluntary subsequent visit.

Summary/Conclusions: Given that this study was conducted on a convenience instead of random sample of patients, generalizability of the results may be limited. Direct observation can be susceptible to observation bias and to the Hawthorne effect with the patients/caregivers acting differently when observed. Nonetheless, the success of most patients and caregivers in correctly administering romiplostim after HAT pack training suggests that self-administration of romiplostim is a feasible option for suitable romiplostim-treated ITP patients.

E1442
FCγIIA 131 H/R (A>G) RECEPTOR GENE POLYMORPHISM IN PATIENTS OF PRIMARY IMMUNE THROMBOCYTOPENIA (ITP)
A. Tripathi1, D. Yadav1, A. Kumar2
1Clinical Hematology, 2K.G. Medical University Lucknow India, Lucknow, India

Background: Primary Immune Thrombocytopenia (ITP) is an autoimmune hematologic disorder characterized by isolated thrombocytopenia (<100,000/mm3) in the absence of other causes or disorders that may be associated with thrombocytopenia. The predominant mechanism is enhanced peripheral destruction of autoantibody coated platelets through binding of Fc portion of antibody with the Fcγ receptors on cells of reticuloendothelial system mainly monocytes/macrophages.

Aims: This study was aimed to investigate the association of polymorphisms in FCγIIA 131 H/R (A>G) with Primary Immune thrombocytopenia (ITP).

Methods: Genotyping for the FCγIIA 131 H/R (A>G) was performed using polymerase chain reaction and restriction fragment length polymorphism (PCR-RFLP) in 70 ITP patients and 70 healthy controls.

Figure 1.

Results: A total of 45 pts (M: 21) were eligible for analysis; median age at treatment was 60 yrs (range 18-87) and median time between diagnosis and treatment start was 3 days (range 0-4686). Pts received a median of 5,15 courses (range 3-6); 27/45 completed 6 courses: 21/45 received the full dose of 40mg/day (=960mg total dose) while 6/45 received the reduced dose of 20mg/day (=480mg total dose). Median total Dxm dose was 80mg in ITP along with 1st Dxm course were required in 11/45 pts. In between courses, no bleeding complications were observed and no emergency therapies were required. Short-term response was achieved in 39/45 (87%); complete response (CR) in 28/45 (62%), response (R) in 7/45 (16%); 4/45 (9%) pts were classified as steroid-dependent ITP and excluded from subsequent analysis. Long-term response off therapy, lasting for a median time of 28 mos (range 5-80) without relapses was observed in 25/35 responding pts (71.5%); CR in 18/25, R in 7/25 at last follow-up) with a RFS of 51% at 50 mos (Fig. 1). Median pvl count at last
follow-up was 102±10.9 days (range 54-336). Disease duration of less than 3 mos prior to therapy start was associated with better outcome (log rank p=0.049, Fig.2) with a median RFS not reached; median RFS for pts treated after 3 mos of diagnosis was 31 mos [OR: 3.8 (CI 95% 0.9-16.3), p=0.067]. No significant association between gender (p=0.67), age at treatment (more or less than 60 yrs) (p=0.85), DTX total dose (more or less than 480mg) (p=0.35) was found. Summary/Conclusions: Pulsed HD-DXM is a well tolerated and highly effective first line treatment for ITP in every day clinical practice. The role of a reduced-dose schedule needs to be explored in a larger cohort of pts. Treatment of newly diagnosed ITP pts - i.e. within 3 mos of diagnosis (Rodeghiero Blood 2007) - seems to lead to longer RFS.

E1444
EFFECT OF OSELTAMIVIR TREATMENT ON PLATELET COUNTS
N. Revilla1, I. Heras2, M.E. de la Morena-Barrio3, P. Iniesta2, J.B. Nieto2, J. Corral4, V. Vicente3, M.L. Lozano4
1Servicio de Hematología y Oncología Médica, 2Hospital Universitario Morales Meseguer, Centro Regional de Hemodinamación, Universidad de Murcia, IMIB-Arraxaca, 3Hospital Universitario Morales Meseguer, Centro Regional de Hemodinamación, Universidad de Murcia, IMIB-Arraxaca. Grupo de Investigación CB15/00055 del CIBERER, ISCIII, Murcia, Spain

Background: As platelets lose sialic acid during aging and circulation, they are cleared by the hepatic Ashwell-Morell receptor (AMR) (1). A recent study suggests that inhibition of sialidase by oseltamivir, a commonly administered anti-influenza medication that inhibits viral sialidase, could associate with an increase in platelet counts (2).

Aims: The aim of this study was to analyze the effect of oseltamivir treatment in platelet counts.

Methods: We performed a retrospective single-center study. From November 2009 until March 2015, a total of 168 patients from our Hematology Unit were prescribed oseltamivir due to clinical suspicion of influenza. A total of 120 patients were excluded because they had received myelotoxic chemotherapy within 30 days (n=82) or platelet count was not available before treatment (n=38). The direct immunofluorescent antigen test was carried out with nasopharyngeal aspirate specimens. Those specimens that were negative by the antigen detection assay underwent RT-PCR testing for influenza virus types A and B. Platelet count was available before and after treatment (median of 5 days) in 48 patients and in 44 patients also when the infection was cleared (median of 30 days).

Results: Patients were divided into those with proven influenza (n=34) and without influenza (n=14). Median age was 58.0 and 59.5 years; respectively. Treatment consisted of 75mg oseltamivir bid for 5 days, with the exception of 3 patients in the proven influenza group receiving 150mg bid for 10 days (allo-genic stem cell and transplant recipients). We observed a significant increase in the mean platelet count after treatment with oseltamivir (170±95 x10⁹/L vs 192±103 x10⁹/L, p=0.04). As in the previous study (2), this effect was independent of whether influenza was diagnosed (Table 1). In addition, we did not discern significant fluctuation in platelet counts when treatment was immediately interrupted after a 30-day time lapse (184±100 x10⁹/L vs 182±91 x10⁹/L).

Table 1.

Summary/Conclusions: Our study confirms the effect of oseltamivir on increasing platelet counts regardless of influenza infection. Although an increase in platelet counts related to the viral syndrome healing is not ruled out, the lack of long-term fluctuations after the end of treatment may indicate a late inhibition that contributes to reduction in platelet clearance via the hepatic receptor.

CLINICAL UTILITY OF CARDIAC MRI IN IMMUNE MEDIATED THROMBOCYTOPENIC PURPURA
F. Alwan1, D. Mahdi1, S. Mc Guckin1, J. P. Westwood2, M. Thomas1, J. Moon2, M. Scully1
1Haematology Department, University College London Hospital, 2Cardiac Imaging Department, Barts Heart Centre, London, United Kingdom

Background: Immune Mediated Thrombotic Thrombocytopenic Purpura (TTP) is a life threatening thrombomicroangiopathy caused by acquired antibody mediated inhibition of ADAMTS13. Cardiac complications are a common cause of death in patients with TTP. Using a recently developed test for ADAMTS13, we showed that 58% of patients had a reduced level of ADAMTS13 in TTP. There is scant evidence on the best investigations for patients suspected of being at risk of cardiac complications with no evidence on the clinical utility of cardiac magnetic resonance imaging (MRI) in acute TTP episodes.

Aims: A retrospective review evaluating the value of cardiac MRI scanning in TTP. Medical records of patients under treatment for cardiologic symptoms between November 2008 and November 2014 whilst being treated for an acute episode of immune mediated TTP. All patients had troponin-I measurement on admission and a transthoracic echocardiogram within 72 hours of presentation. All patients were treated for their TTP episode with plasmapheresis, steroids and Rituximab. Two cardiologists reported each MRI scan and only agreed, unequivocal findings were considered.

Results: The median age of patients was 49 (range 13-75), 71% of whom were women. Two patients had a diagnosis of hypercholesterolemia prior to TTP diagnosis but otherwise there was no previous cardiac history. 71% of patients had a raised troponin-I at presentation (normal <14ng/ml). Two patients developed bradycardia and one atrial fibrillation during their acute admission. One patient had symptoms of heart failure. Three patients had transient ST depression suggestive of ischemia on EKG monitoring and a further four had non-specific T-wave inversion. There were no incidences of cardiogenic shock or atrial fibrillation. 88% of patients had at least one abnormal finding in their transthoracic echocardiogram. LGE seen in combination with regional wall motion abnormalities (RWMA) suggests irreversible myocardial dysfunction. No patient was found to have RWMA on transthoracic echocardiogram but this was seen in five patients on cardiac MRI imaging, all of whom also had LGE. The mean troponin-I level was increased in those with an abnormal cardiac MRI (normal MRI 100ng/ml, abnormal MRI 165ng/ml, p=0.9), nor was there a significant difference in median age (49 vs 49), symptom duration (abnormal MRI 7 days, normal 5 days, p=0.39) or presenting anti-ADAMTS13 antibody level (abnormal MRI 41%, normal MRI 40%, p=0.66).

Summary/Conclusions: Cardiac MRI scanning in TTP is a sensitive tool for detecting ischemic cardiac changes that would otherwise be missed by transthoracic echocardiogram. Mid-Apical late gadolinium enhancement appears to be a characteristic finding in TTP. These findings help increase the understanding of the pathophysiology behind the TTP disease process.

E1446
THE FREQUENCY AND CLINICAL SIGNIFICANCE OF MEFV GENE MUTATIONS IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA
I. Kaygusuz Atagunduz1,*, C. Keklikkiran2, T. Toptas1, O. Kara1, A. Sezgin1, F. Gecgel1, T. Ozgunus1, T. Firatli Tugular1
1Hematology- Internal Medicine, Marmara University Hospital, Istanbul, Turkey

Background: Immune thrombocytopenia (ITP) is an immune-mediated acquired disease characterized by transient or persistent decrease of the platelet counts. MFEV gene mutations are responsible for Familial Mediterranean Fever (FMF) a hereditary autoinflammatory disease characterized by recurrent febrile inflammatory attacks of serosal and synovial membranes. MFEV gene’s protein product, pyrin or marenostrin, play an essential role in recurrent febrile inflammatory attacks of serosal and synovial membranes. Mutations in the MEFV gene cause an increase in Th17 numbers. Th17 cells may have a key role in neutrophil activation and autoimmune diseases. Recently, mutations in the MEFV gene were found in a subset of ITP patients.

Aims: We aimed to reveal the frequency and clinical significance of MEFV mutations in a population presenting with ITP.

Methods: We studied the prevalence of exon 2 and 10 mutations (E148Q in exon 2, M694V, M694I, M680I, V726A, A744S and R761H in exon 10) in 81 adult ITP patients and 186 healthy controls. Patients were classified in two subgroups according to the presence of mutations. Demographic and clinical features were compared between groups to assess possible impacts of these mutations on clinical severity.

Results: Female to male ratio was 61/20=3.05 in the study group and 98/88=1.1 in the control group. The median age was 50 (21-79) in the ITP
Summary/Conclusions: Our findings indicate that PD-1 gene polymorphisms contribute to the susceptibility of cITP, and PD-1 low producer genotype affects the severity of cITP. In addition, CTLA-4 high producer genotypes suggest the good clinical features and a little requirement of treatment in patients with cITP.

E1448
IS THE SPLENECTOMY OUTCOME PREDICTABLE IN PATIENTS WITH ITP?
M. Mitrovic1,2, S. Matic3, J. Bodrozic1, M. Smiljanic1, J. Jelicic1, D. Antic1,2, M. Todorovic - Tiranic2, D. Tomin1,2, I. Elezovic1,2, N. Suzavic1,2
1Clinic of Hematology, CCS, 2Faculty of Medicine, University of Belgrade, 3Clinic for Digestive Surgery, 4Center for Nuclear Medicine CCS, Belgrade, Serbia

Background: Splenectomy may lead to a good response in 60-80% of adults with corticosteroid refractory immune thrombocytopenia (ITP). However, in the era of new drugs the proper selection of patients for splenectomy is essential for optimizing treatment outcomes. Accordingly, it is important to identify pre- or post-operative parameters that are able to predict the response to splenectomy.

Aims: To identify the pre- and post-operative parameters predictive of successful splenectomy in ITP.

Methods: We retrospectively analyzed 130 ITP patients (median age 43 years, range 19-74; 84/39 female/male; median time from diagnosis to splenectomy 19 months, range 2-132; median number of pre-splenectomy therapies 2, range 0-10; median platelet count before splenectomy 23.6%; p=0.043, 0.003 and 0.018, respectively). On the other hand, CTLA-4 -1577 AA genotypes was significantly associated with higher minimum platelet count than AG & GG genotype (22.5 vs 14.0 ×109/L, p=0.048).

PD-1 AND CTLA-4 POLYMORPHISMS AFFECT THE SUSCEPTIBILITY AND CLINICAL FEATURES OF CHRONIC IMMUNE THROMBOCYTOPENIA
R. Ino1,*, T. Kasamatsu1, Y. Kitamura1, K. Honma1, T. Nagashima1, N. Takahashi2, G. Hasegawa3, H. Maruhashi4, T. Tsujimura3, Y. Hasegawa3, T. Nagashima1,*, K. Uemura1, K. Yamauchi5, T. Watanabe1, T. Hara1
1Department of Laboratory Medicine, 2Department of Internal Medicine, 3Department of Hematology and 4Department of Microbiology, Gunma University Graduate School of Medical Sciences, 5General Medicine, Gunma University, Gunma, Japan

Background: The programmed death-1 (PD-1) and cytotoxic T lymphocyte-associated antigen-4 (CTLA-4) play a central role in immune checkpoint pathways. The PD-1 negatively regulates self-reactive T and B cells in peripheral immune tolerance. The CTLA-4 antagonizes the binding of CD28 to its ligands including CD80 and CD86, and inhibits T cell activation. Previous studies have shown the lower expression of serum soluble PD-1 and CTLA-4 mRNA in patients with chronic immune thrombocytopenia (cITP) than healthy individuals. Single nucleotide polymorphisms (SNPs) of PD-1 and CTLA-4 have been reported to be associated with susceptibility of some autoimmune diseases; however, the possible association between these immune checkpoint SNPs and cITP risk remain controversial and obscure.

Aims: In order to explore the role of PD-1 and CTLA-4 in the pathogenesis of cITP, we investigated the impact of PD-1 and CTLA-4 SNPs on the susceptibility and clinical features of adult cITP.

Methods: We extracted the genomic DNA from 141 cITP patients and 223 healthy controls, and determined, 3 PD-1 SNPs (-606G/A, -7290G/C, 2A15V) and 4 CTLA-4 SNPs (-1722T/C, -1577G/A, +49A/G, +6230G/A) by using the polymerase chain reaction -restriction fragment length polymorphism (PCR-RFLP) method. The severity of bleeding tendency and thrombocytopenia was assessed according to the previously described criteria by Han JJ. The risk criteria, ”corticosteroid dependence”, severe CTP, and refractory cTP were used to define the criteria for the response of cITP to corticosteroid therapy.

Results: The minimum platelet count of all clinical course ranged from 0 to 98×109/L with a median count of 13×109/L. Eighty-six patients (61.0%) had bleeding tendency and 24 patients (17.0%) had severe thrombocytopenia (<10×109/L). Eighty-six patients (61.0%) received the treatment with corticosteroids, and 11 patients (8.2%) were corticosteroid-dependent. Twenty-four patients (17.0%) were responsive to healthy controls, the higher frequency of PD-1 -7290 TT genotype (low producer) was observed in cITP patients (12.8% vs 4.5%, p=0.004). There were no significant differences in CTLA-4 SNPs between cITP patients and healthy controls. In cITP patients, PD-1 -7290 TT genotypes (low producer) was significantly associated with high frequency of treated patients, treated patients with corticosteroid, and corticosteroid-dependent patients compared with CC & CT genotype (high producer) (94.4% vs 71.5%, 94.4% vs 57.7% and 52.9% vs 23.8%; p=0.043, 0.003 and 0.018, respectively). On the other hand, CTLA-4 +49 AA genotype (high producer) was significantly associated with low bleeding tendency and thrombocytopenia (AG & GG genotype (low producer) (27.3% vs 63.8%, p=0.017). CTLA-4 -1577 AA genotypes (high producer) was significantly associated with low bleeding tendency and steroid treatment than AG & GG genotype (low producer) (26.4% vs 65.6%, p=0.010). CTLA-4 -6230 AA genotypes (high producer) was significantly associated with higher minimum platelet count than AG & GG genotype (22.5 vs 14.0 ×109/L, p=0.048).

FINAL RESULTS FROM AN OBSERVATIONAL STUDY (PLATEAU) OF ADULT PATIENTS TREATED WITH ROMIPOSTIM FOR PRIMARY IMMUNE THROMBOCYTOPENIA (ITP) IN ROUTINE CLINICAL PRACTICE IN GERMANY
M. Reiser1, M. Welslau2, K. Josten3, H. Dietzfelbinger4, A. Kuhn5
1PIOH Koeln, Koeln, 2Gemeinschaftspraxis Dr. Klausmann, Dr. Welslau, Aschaffenburg, 3Hämato logie und Onkologie, Helios Kliniken Praxis, Wies baden, 4Haematologisch-onkologische Schwerpunktprazis, Herrsching, 5Amen GbmH, München, Germany

Background: In the European Union, the thrombopoietin-receptor agonist romipos tin (Nplate®) is recommended since January 2016 for treatment of ITP in patients who are refractory to other treatments (e.g. corticoids, immunoglobulins).

Aims: The aim of this study was to assess the use of romipos tin in clinical practice in Germany.

Methods: This multicentre, prospective and retrospective observational study of patients with chronic immune thrombocytopenia (romipos tin) enrolled ITP patients >18 years who received at least one dose of romipos tin in routine clinical practice, with an observation period of 2 years following romipos tin initiation. Endpoints included patient demographics, romipos tin use, platelet counts, adverse
drug reactions (ADRs), and other clinically relevant parameters. We report results from a full data analysis.

Results: A total of 59 patients were enrolled (49.4% male; 54% aged 65 years or above) from 38 sites; 22 of them were excluded due to protocol violations (e.g., incomplete documentation, inclusion criteria not met). Of the 137 remaining patients (the full analysis set, FAS), 102 completed the 2-year observation periods from randomization to 15.5 months. Data were collected from 102 patients (61%). The median platelet count rose sharply from (29.0 × 10^9/L) to two weeks of treatment (62.5 × 10^9/L). From week 3 to 6 months, the safety platelet data maintained a range between 50 and 101 × 10^9/L and 145.5 × 10^9/L. Since the start of the romiplostim therapy, 59 patients out of 137 (43.1%) received concomitant therapies, mostly corticosteroids (49 patients [35.8%]). The overall number of ADRs was 112 in the FAS, affecting 57 patients (27.0%). The most frequent ADRs were gastrointestinal (10.2%) and psychiatric (11.7%) ADRs, followed by constitutional symptoms (10.9%). Adverse drug reactions pertaining to blood/bone marrow affected 2.9% of patients (vascular/thrombotic events, bone marrow fibrosis), whereas bleeding as an ADR was seen in 0.7% of patients. The exposure-adjusted rate of bleeding events (grade 3 or 4) per 100 patient-years in the FAS was 7.2 before treatment vs 4.0 after starting the treatment. The rate of ITP-related hospitalization per 100 patient-years decreased from 23.3 before the start of therapy to 15.5 since the start of the therapy.

Summary/Conclusions: This study of routine clinical practice in Germany showed that treatment with romiplostim in ITP patients resulted in a rapid increase in platelet counts to levels maintained between 50 and 100 x 10^9/L over time, regardless of the splenectomy status of the patients; most of them were non-splenectomized. The product was well tolerated and achieved a decrease in the rate of ITP-related hospitalization.

E1450
THE CLINICAL UTILITY OF NEUropsychology Testing in IMMUNE MEDIATED THROMBOTIC THROMBOCYTOPENIC PURPURA

F. Alwan1,*, S. Tayabali1, D. Mahdi1, M. Thomas1, J.P. Westwood1, L. Cipolotti2, M. Scully1
1Haematology Department, University College London Hospital, 2Neuropsychology Department, National Hospital for Neurology and Neurosurgery, London, United Kingdom

Background: It is well recognized that neurological manifestations are common in thrombotic Thrombocytopenic Purpura (TTP) however research into the neuropsychological impact of the disease is lacking despite evidence suggesting patients who experience critical illnesses are at high risk for long-term cognitive impairment.

Aims: To review the clinical utility of neuropsychology testing in thrombotic thrombocytopenic purpura.

Methods: Between 2010 and 2015, all patients within a single tertiary haematology center with a confirmed diagnosis of TTP were reviewed as outpatients for neuropsychological assessment. The Wechsler Adult Intelligence Scale III (WAIS-III) IQ test was used to assess factors including verbal IQ and performance IQs.

Results: 18 patients were included. 89% were female with a median age of 51 (16-67 years). 56% were Caucasian, 33% Afro-Caribbean and 11% of South Asian ethnic origin. 33% had experienced TIA or stroke-like symptoms during the acute phase. Only 29% had no neurological symptoms during their initial presentation. The most common symptom leading to neuropsychology review was problems with concentration, experienced by 89% of patients. 44% had problems with memory, 39% felt depressed and 33% had anxiety issues. The median time from acute TTP episode to neuropsychology review was 29 months (range 3-90 months). 50% had signs of sub-acute infarction on imaging and two patients scans showed both mature infarcts and microhaemorrhages. The median scores for both verbal and performance IQs were reduced compared to normal (100, range 90-110). The median verbal IQ was 87 (range: 65-122) and the median performance IQ was 93 (range: 80-100). Taking all aspects of the WAIS-III into consideration, one patient had a normal assessment. 50% (n=9) were found to have mild cognitive impairment, 33% (n=6) mild-moderate impairment and 11% (n=2) significant impairment. The two cases with significant impairment had a widespread pattern of dysfunction whilst in the other cases the most common deficits were sub-cortical/cognitive.

Summary/Conclusions: Persisting psychological symptoms after an acute TTP episode are highly suggestive of underlying cognitive impairment as a result of cerebral sub-acute infarction or microhaemorrhages.

E1451
FIVE NEW CASES OF HERMANSKY-PUDLAK SYNDROME: IDENTIFICATION OF NOVEL GENETIC VARIANTS IN HPS4 AND HPS3 ASSOCIATED TO RELEVANT CLINICAL COMPLICATIONS

J. Bastida1,*, J. Gonzalez-Porras1, M. Lizano2, R. Benito3, K. Janusz3, N. Bermejo3, M. Karkukla3, M. Trapero1, M. del Rey1, Y. Yuce1, J. Hernandez-Sanchez3, V. Palma-Barquero2, V. Vicent3, J. Hernandez-Rivas1, J. Rivera1
1Department of Haematology, Hospital Universitario de Salamanca-IBSAL, Salamanca, 2Department of Haematology and Oncology, Hospital Universitario Morales Meseguer, Centro Regional de Hemostasia y Trombosis, Murcia, 3Department of Haematology, IBSAL, IBMCC, Universidad de Salamanca-CSIC, Salamanca, 4Department of Haematology, Hospital San Pedro de Alcántara, Caceres, Spain, 5Department of Medical Genetic, Sakarya University Training and Research Hospital, Sakarya, Turkey, 6Department of Haematology, Hospital Universitario Puerta de Hierro, Majadahonda, Spain

Background: Hermansky-Pudlak syndrome (HPS) is an inherited platelet disorder characterized by bleeding diathesis, oculo cutaneous albinism and some-times serious clinical complications. Heterogeneous clinical symptoms and a large number of possible genetic culprits (9 HPS genes, >110 exons) complicate unequivocal HPS diagnosis.

Aims: To assess the clinical and platelet phenotype in five patients with HPS suspicion and to identify their genetic defects (through high throughput sequencing).

Methods: We studied 5 patients from 3 families (2 Spanish, 1 Turkish) presenting with oculocutaneous albinism. Clinical records were reviewed and bleeding scored using ISTH-BAT. Platelet phenotyping (only Spanish patients) included: platelet aggregation, GP2 expression and granule secretion. 14C-serotonin uptake and whole mount electron microscopy. Patients DNAs were analyzed using HTS using a 71 gene panel.

Results: Clinical and laboratory findings in these patients are shown in Table 1. The Spanish patients (P1,P2,P5) showed impaired platelet aggregation to mild agonists and reduced platelet dense granules. In family 1 (F1), HTS identified a heterozygous, potentially harmful, c.2054delC(p.Pro685Leu fs*17) variant in HPS4, one sister (P1) had Cron’s disease and severe gastrointestinal (GI) bleeding. This variant had been reported in a 46yr Asian patient with pulmonary fibrosis (Bachi EB. Am J Med Genet 2004). A novel missense homozygous HPS4 variant, c.272T>C(p.Leu91Pro), was found in two Turkish siblings (F2). One had severe GI bleeding requiring colostomy (P4) and the other developed pulmonary fibrosis. Patient 5, suffering from mild GI bleeding, bears a heterozygous novel variant in HPS3 (c.2464C>T,p.Arg822X) and, most likely, an additional unrevealed mutation.

Summary/Conclusions: HTS facilitates genetic confirmation of HPS diagnosis, and may help investigating phenotype-genotype relationships in HPS. The novel p.Leu91Pro variant in HPS4 associates with severe clinical phenotype. Funding: JMB: Gerencia Regional de Salud [GRS 1370/A/16]; JR: ISCIII & Feder (PI14/01956), Ciberer CB15/00055, Sociedad Española de Trombosis y Hemostasia.

E1452
CHARACTERIZATION OF PLATELET ACTIVATION MARKERS IN EARLY ONSET PREECLAMPSIA

D. Angelov1,2,*, K. Egan1,2, F. Ni Ainle1,2,3,4,5
1UCD Conway SPHERE Research Group, 2School of Medicine, University College Dublin, 3Department of Haematology, Rotunda Hospital, 4Department of Haematology, Mater Misericordiae University Hospital, 5School of Molecular and Biomedical Sciences, University College Dublin, Dublin, Ireland

Background: Preeclampsia is a serious pregnancy complication with potentially life-threatening consequences for both mother and baby, diagnosed when new onset hypertension and proteinuria develops after 20 weeks gestation. Early onset preeclampsia (EOP; onset <34 gestational weeks), is associated with higher maternal and fetal risks than late onset preeclampsia. At the extreme end of the severity spectrum, HELLP syndrome is characterised by...
hemolysis, elevated liver enzymes, and low platelets. Previous studies have demonstrated enhanced platelet activation in pregnant women with pre-eclampsia, using cell surface markers and platelet microparticles. Although severe pre-eclampsia is associated with increased inflammatory markers in vitro, levels of platelet activation do not necessarily correlate with severity of disease.

Aims: To assess the presence, and degree, of platelet activation in a cohort of patients with early onset pre-eclampsia (EOP) and compare it with healthy controls.

Methods: Plasma samples from 191 healthy controls and 64 patients with EOP were collected. Platelet activation was assessed using ELISA and flow cytometry. Platelet microparticles were measured by flow cytometry. Platelet activation biomarker levels were adjusted by platelet count and expressed as %/10^8 platelets/ml. All data was analysed using GraphPad Prism 7. Parameters were reported as means±SEM.

Results: Plasma samples from 19 individual patients were included. Patients with HELLP syndrome demonstrated significantly greater numbers of CD42a+ microparticles when corrected for platelet count compared with those without HELLP syndrome (598x10^3±203x10^3 versus 297x10^3±37x10^3, p=0.04). Similarly, patients with HELLP syndrome demonstrated increased levels of sGPVI than those without HELLP; corrected for platelet count (2.57±0.9667 versus 1.22±0.124 ng/ml, p=0.0334). There was no difference in NAP-2 or PF4 levels between those with HELLP and those without HELLP, nor between severe and moderate pre-eclampsia patients. Severe pre-eclampsia patients in this cohort had a D-dimer level of 3.7±10:742 µg/ml compared with non-severe patients 1.85±0.350 µg/ml (t=2.403, p=0.0337). The correlation between sGPVI levels and D-dimer levels (Spearmann Rank correlation coefficient, r=-0.532, p=0.04).

Discussion: Our data suggests that platelet activation is associated with HELLP syndrome. The increased levels of platelet microparticles and sGPVI in patients with HELLP syndrome suggests a role for low-dose aspirin therapy as prevention for pre-eclampsia, and there is Grade 2B evidence for its use in those at risk of severe pre-eclampsia. The evidence of enhanced platelet activation in our study provides rationale for the efficacy of aspirin in this setting, and the potential for novel antiplatelet agents to be studied for the same indication.

E1453 PRIMARY ITP IN ADULTS TREATED WITH ELTROMBOPAG: A RETROSPECTIVE STUDY USING DATA FROM THE UNITED KINGDOM ADULT IMMUNE THROMBOCYTOPENIA REGISTRY.

D. Provan1,*, U. Doobare2, A. Newland1, J. Fleming3
1Haematology, Barts and The London School of Medicine and Dentistry, London, UK
2Haematology, Novartis, Camberley, Surrey, United Kingdom
3ADULT IMMUNE THROMBOCYTOPENIA REGISTRY

Background: Primary ITP is an autoimmune disorder associated with a reduced peripheral blood platelet count. Although many patients are relatively asymptomatic, many suffer with bruising, mucosal bleeding and quality of life issues. First-line therapy has remained unchanged for decades and until recently, second-line therapy has been unsatisfactory, using empirical treatments. The recently approved thrombopoietin receptor agonists eltrombopag and romiplostim have transformed patient care and these agents are licensed second-line therapies in adults.

Aims: To describe the adult patients receiving eltrombopag using data from the UK Adult ITP Registry. In particular we were interested in understanding the mean dose used, number of prior therapies, median length of treatment with eltrombopag, median counts at baseline before treatment and at six months following treatment, and sustained response in patients who have received eltrombopag.

Methods: The UK Adult ITP Registry involved more than 70 UK collaborating centres, coordinated by The Royal London Hospital. In this study we analysed data from all patients receiving eltrombopag and analysed these using various statistical techniques.

Results: The total number of patients evaluated was 129. The median age at diagnosis was 49.4 years (26.9-66.4). There were 74 males (57.4%) and 55 females (42.6%). 29 patients (22.4%) had undergone prior splenectomy. The median age at eltrombopag initiation was 59.5 years (37.0-70.7 years). The median time from ITP diagnosis to eltrombopag initiation was 1.6 years (0.7-2.3 years). The majority of patients started eltrombopag between 2013 and 2016 (93%).

Summary/Conclusions: This is the first UK registry-based study of adult ITP patients treated with eltrombopag. Although limited in size, these data suggest several important points: the majority of patients were older, and the median time from ITP diagnosis to eltrombopag initiation was 1.6 years. As clinicians become more familiar with its use, a greater proportion of patients are likely to receive eltrombopag as a second line therapy.
PREVALENCE AND RISK FACTORS FOR THROMBOSIS IN ADULT ITP PATIENTS

C. Morel1, A. Tichelli2, A. Wieland-Greguar-Sander3, A. Angelillo-Scherrer3, A. Rovó3,∗

1Faculty of Medicine, University of Bern, Bern, 2University Hospital of Basel, Basel, 3University Hospital of Bern, Bern, Switzerland

Background: Immune thrombocytopenia (ITP) is characterized by severe thrombocytopenia due to autoantibody- and cell-mediated peripheral platelet destruction and attenuated thrombopoiesis. Despite a higher risk for bleeding, thromboembolic events (TEE) have been observed.

Aims: We aimed to investigate the prevalence and type of TEE and the potential risk factors in adult ITP patients.

Methods: Retrospective cohort study, including all ITP patients followed in our clinic between 01/1990 and 05/2016. Information on gender, age, date of ITP diagnosis, platelets count, type and clinical form of ITP, type of ITP treatments and its response, severe bleeding and follow up time were collected. Furthermore we evaluated date of first appearance, number and type of thromboembolic events, cardiovascular risk factors, date and cause of death. We assessed and compared risk factors of ITP patients with and without TEE in univariate and multivariate analysis.

Results: Medical files of 480 patients registered as ITP were reviewed; 42 patients were excluded from the analysis (not fulfilling the ITP criteria according to Rodeghiero et al. Blood 2009). In total 438 patients were retained for analysis, 10% out of them (44 patients) presented ≥1 TEE after ITP diagnosis. Within these patients, in total 54 TEE occurred: 34 venous (61%), 19 arterial (34%) and 3 arterial and venous (5%) thromboembolic events. The most frequent venous TEE were pulmonary embolism, deep vein thrombosis, and superficial vein thrombosis; arterial TEE were cerebrovascular insults, myocardial infarction and peripheral artery thrombosis. At time of TEE, 43% of patients were on treatment with corticosteroids, 14% with thrombopoietin receptor agonists (TPO-ra) and 18% were off-treatment. In the univariate analysis, older age at diagnosis (<50 years, P=0.015), longer interval since ITP diagnosis (P=0.009), ≥2 treatments (RR, 2.539; 95%CI, 1.305-4.941; P=0.006), persistent or chronic ITP (RR, 3.830; 95% CI, 1.111-13.196; P=0.033), and smoking (RR, 2.622; P=0.041) revealed to be significant. The multivariate analysis model (P=0.0002), TPO-ra at time of thrombosis (P=0.027), non-response to first-line treatment (P=0.010), smoking (P=0.011), arterial hypertension (P=0.005), and obesity (P=0.041) revealed to be significant. The multivariate analysis model showed that older age at diagnosis (RR, 2.272; 95% CI, 1.167-4.426; P=0.016), ≥2 treatments (RR, 2.539; 95%CI, 1.305-4.941; P=0.006), persistent or chronic ITP (RR, 3.830; 95% CI, 1.111-13.196; P=0.033), and smoking (RR, 2.622; 95% CI, 1.250-5.499; P=0.011) were independent risk factors for TEE. When the variable "number of treatments" (<2 versus ≥2) was excluded from the multivariate model, having a splenectomy increased the risk for TEE. The cumulative incidence of TEE at year 1, 5, 10, 15 and 20 years since diagnosis of ITP was 6.2% (95% CI, 4.1-9.3), 11.9% (95% CI, 8.3-17.0), 15.8% (95% CI, 11.1-22.4), 24.2% (95% CI, 16.9-34.7) and 32.8% (95% CI, 22.8-47.3) respectively (Figure). Death occurred in 7/44 (16%) patients with TEE, and in 12/394 (3%) patients without TEE (P=0.0001). Most frequent causes of death were infection (32%) and bleeding (21%).

Summary/Conclusions: Adult ITP patients are at risk for thromboembolic events. Patients older than 50 years, having a persistent/chronic form of the disease, requiring two or more lines to treat the ITP, previous splenectomy, and smokers were more likely to develop TEE. The knowledge about the risk of thromboembolic events in adult ITP patients could have an impact on management attitude for patients at risk.

OSELTAMIVIR FOR THE TREATMENT OF ITP PATIENTS NOT RESPONDING TO CONVENTIONAL TREATMENT: BIOLOGICAL CHARACTERIZATION AND CLINICAL RESPONSES

N. Revilla1,∗, M. Campos2, F. Velasco3, A. Mirano4, J. Fuentes5, J. Rivera6, I. Martínez-Martínez2, M.E. de la Morena-Barrio6, J. Corral6, V. Vicente6, M.L. Lozano6

Grupo de Investigación CB15/00055 del CIBERER, ISCIII, Murcia, Spain

Background: Oseltamivir phosphate, a drug that conventionally serves as an antiviral sialidase inhibitor classically prescribed for the treatment of patients with influenza, has shown to induce an increase in platelet counts in 2 patients with primary immune thrombocytopenia (ITP) (1,2). A previous study has suggested a mechanism of Fcγ receptors (FcγR)-independent platelet clearance with primary immune thrombocytopenia (ITP) (1.2). A previous study has suggested a mechanism of Fcγ receptors (FcγR)-independent platelet clearance with influenza, has shown to induce an increase in platelet counts in 2 patients with primary immune thrombocytopenia (ITP) (1,2). A previous study has suggested a mechanism of Fcγ receptors (FcγR)-independent platelet clearance with influenza, has shown to induce an increase in platelet counts in 2 patients with primary immune thrombocytopenia (ITP) (1,2). A previous study has suggested a mechanism of Fcγ receptors (FcγR)-independent platelet clearance with influenza, has shown to induce an increase in platelet counts in 2 patients with primary immune thrombocytopenia (ITP) (1,2).

Aims: To analyze the biological features and clinical responses following oseltamivir treatment in patients that are non-responders to conventional treatments.

Table 1.

Methods: We performed a prospective study in 4 ITP patients who exhibited no response to standard therapies (steroid, IVIG and/or splenectomy) and showing relevant platelet desialylation levels. Patients were given off-label oseltamivir at the referring physician’s discretion. Desialylation of GP platelet surface was examined via flow cytometry (FC) analysis, with fluorescein-conjugated Ricinus Communis Agglutinin I (RCA-1), which binds galactose residues only if the terminal sialic acid has been removed. FC data are expressed as fold change compared to control samples. Additionally, patients’ sera were incubated with normal human platelets to analyze the ability to induce desialylation of normal platelets. Analysis of plasma proteins was performed by Western blot (FXI, FXII) and HPLC (transferrin). Platelet autoantibody specificity was detected by a solid-phase modified antigen capture ELISA test (MACE).

Results: Patients’ characteristics are summarized in Table 1. Two patients achieved complete platelet response (>100x10^9/L) after oseltamivir treatment. The oral dose was 75mg twice daily, for a variable duration (5 days in one case and 4 months in the other showing response criteria since the third week of from start) combined with low doses of other treatments (azathioprine or romiplostim). A sustained platelet response was observed after 4 weeks of the sial-

BORTEZOMIB THERAPY IS ASSOCIATED WITH SIGNIFICANT RESOURCE IMPLICATIONS FOR BOTH PATIENTS AND PROVIDERS: RESULTS OF A TIME-IN-MOTION STUDY
M. Tatarczuch1, K. Ramasamy1, A. Peniket1, M. Sultanova1, G. Vallance1, F. Panitsas1
1Haematology, Oxford University Hospitals NHS Trust, Oxford, United Kingdom

Background: Bortezomib is a proteasome-inhibitor, which has improved outcomes in multiple myeloma (MM). Its use is approved within the UK NHS. Bortezomib is frequently administered as a subcutaneous injection in a hospital day treatment unit. Whilst the administration of a subcutaneous injection is brief, the process for the patient travelling to hospital, assessment and waiting for the delivery of the injection can take considerable time. From a patient perspective, significant amount of time spent without economic activity and travel costs add up during the course of therapy. From the health-care provider the process of safely administering bortezomib has significant resource implications beyond those of drug procurement.

Aims: We set up a time-in-motion study to evaluate the costs to health care provider and patients during bortezomib therapy to estimate the ‘real-world’ cost of delivering bortezomib therapy.

Methods: Retrospective data collection was undertaken, using electronic prescribing records for patients treated between July 2014 -August 2016. Travel distance and time was estimated using Google maps and costed using HMRC mileage (an approved costing of mileage used for taxation purposes). The NHS schedule of service costs was used to estimate the cost of bortezomib administration. Cost of delivery of Bortezomib for healthcare providers is a sum of these individual costs.

Results: We identified 127 patients who incurred a total of 2,134 visits whilst receiving Bortezomib therapy at the Churchill Hospital in Oxford during this 2 year period. Median age was 70 years-old (yo) (39-95); Male 74 patients (58%) 53 patients (42%). We restricted the analysis to 110 patients who started and completed therapy during the study period. Median number of patient visits was 16 (range 11-52). The median travel distance (return journey) for each patient was 33 miles (53 km) (range: 1.2-224 mi; 1.9-360 km). Median travel time was 90 min (range: 8-300 min). The range travel cost per patient was £8.35-£13.20. Twenty-seven patients (21%) required use of specialist hospital transport services, which resulted in 295 transport-episodes (14%) in total. In order to assess the time spent in the day therapy unit, a subgroup of 589 patient-episodes were analysed to assess time from arrival to administration of Bortezomib: the median time from patient registration to bortezomib administration was 63min (range: 5-433min). Pharmacy cost for preparation of Bortezomib was £50 per dose. The cost of delivery of bortezomib (not including cost of drug) was £1,160 per cycle, which equated to a total median cost of £4,640 per patient (range: £290-£15,080). Drug procurement costs for Bortezomib is estimated at an additional £12,261 per course of therapy (BNF 2016). Delivery costs therefore added an additional 38% to the procurement costs.

Summary/Conclusions: We provide the first time-in-motion data on myeloma patients treated with Bortezomib. The ‘real-world’ cost of delivering therapy is 37% higher than the drug-costs alone. In addition the impact on patients is substantial: over a two year period 127 patients required 2,134 visits with a median time in the day unit of 63 minutes and a median travel time of 90 minutes per visit. Our data highlights the burden of both time and economic costs to patients during therapy. Novel oral proteasome inhibitors offer the potential to reduce this resource impact in the future. This data could be used by health care providers and reimbursing agents for economic modeling of the potential benefits of oral proteasome inhibitors.

Background: In France, azacitidine (AZA) is indicated for the treatment of adult patients affected by Myelodysplastic Syndrome with intermediate-2 or high risk according to the International Prognostic Scoring System (IPSS), Chronic Myelomonocytic Leukemia (CMLL) with 10-29% medullary blasts and Acute Myeloblastic Leukemia (AML) with 20-30% blasts. It’s also a drug treatment of adult AML patients over 65 years with >30% of medullary blasts. Azacitidine is an antimitotic agent, administrated once a day for 7 days of each 28-day cycle. It is used mainly for patients who could not tolerate effective, treatment cycles require frequent hospital visits which could decrease patient comfort and increase medical personnel workload. Limousin is a region with the oldest population of France and with a very low population density. There is one university hospital and two local state-run hospitals each with a hematology department. In 2009, HEMATO for the Limousin hematology network, set up a protocol called ESCADHEM (externalization and securitization of injectable chemotherapy at home for malignant hematological diseases) that facilitates chemotherapy administration via local hospital at Home (HaH) establishments, which is an alternative to conventional hospitalization in France (www.frenchad.fr). This study aimed to minimize the frequent hospital visit of the patients that these treatments require. This organization includes the three previously mentioned hospitals, four HaH structures, and three central pharmacies with an integrated preparation unit for cancer treatments. From 2009 to 2015, a total of 11,367 infusions were administrated at home for 464 pts. In 2016, we demonstrated the feasibility of ESCADHEM and the medico-economic interest of such care with infusions were administrated at home for 169 pts with AML/MDS received AZA therapy. From 2009 to 2015, 169 patients were treated with AZA by a combination of oral and subcutaneous AZA, is in process and results will be presented at the EHA meeting.

Aims: Our work aimed to demonstrate that HaH administration of AZA is feasible and well preferred by patients compared to hospital administration.

Methods: Chemotherapy at home obeys to strict rules. The first chemotherapy cycle (C1) and the first infusion (D1) of subsequent cycles were administrated at the outpatient care unit. The following injections were administrated at the patient’s home and carried out by HaH, according to a predefined procedures (Fig 1) to comply with safety rules essential to the protection of the professional, the patient, the entourage and the environment. Subcutaneous AZA injections were administrated at 101 (60%) pts with AML/MDS patients and 81 (50%) pts with AML. Patients received a median number of 5 cycles (1-41) and 26 injections of AZA (1-244) at home. The total duration of HaH management lasted from less than 1 day to more than 3.4 years with a mean of 6.3 months. During the period of HaH administration of AZA, 101 (60%) pts had to return to the hospital unit for a non programmed rehospitalization: 90% of the time the patient needed a transfusion, 4% because of infection and 6% for other reasons.

Results: From 2009 to 2015, a total of 6369 subcutaneous injections of AZA were administrated at home for 169 pts with AML/MDS received AZA therapy. Among all pts, 110 were males and 59 females with a median age of 75 years (range 41-92) there are 88 (52%) MDS patients and 81 (48%) pts with AML. Patients received a median number of 5 cycles (1-41) and 26 injections of AZA (1-244) at home. The total duration of HaH management lasted from less than 1 day to more than 3.4 years with a mean of 6.3 months. During the period of HaH administration of AZA, 101 (60%) pts had to return to the hospital unit for a non programmed rehospitalization: 90% of the time the patient needed a transfusion, 4% because of infection and 6% for other reasons.

Summary/Conclusions:Administration of oral analgesia and anxiolysis is a safe and feasible option to be used in outpatient setting: sedo-analgesia is very effective in reducing pain during the biopsy and diminishes the anticipatory anxiety related to a painful procedure. Patients should have the possibility to choose between local anesthesia alone or sedo-analgesia plus local anesthesia. The results of the satisfaction survey, focused on pts treated with subcutaneous AZA, is in process and results will be presented at the EHA meeting.

Table 1.

Background: Bone marrow aspiration and biopsy (BMAB) is a painful procedure, and the commonly adopted local infiltration anesthesia (LIA) with lidocaine is unable to relieve the pain during the most uncomfortable phases, or the anticipatory anxiety related to pain recalling thereafter. As there are no formal guidelines for adding a sedoanalgesic premedication before beginning the BMAB, many combinations have been adopted by several authors.

Methods: Patients were randomly assigned into two arms for receiving either sedoanalgesic placebo plus LIA (standard group, 48.6%) or oral fentanyl citrate 200 mcg plus oral midazolam 5mg in addition to LIA (combo-group, 51.4%) during BMAB. Pre-procedural anxiety and procedural pain were assessed according to the Numered Rating Scale (NRS: 0-10), dividing the time of the procedure into five intervals (T0, T1, T2a, T2b, and T3) and evaluating discomfort grade during each moment of procedure in both groups. Cognitive function was measured before and 30 minutes after the procedure. Possible side effects were recorded, as well as the adequacy of tissue samples harvested. A telephone interview was performed 24 hours later: A total number of one-hundred-sixteen (n=116, Table 1) were enrolled in the study. Nine (n=9) patients did not meet inclusion criteria and were excluded. Fifty-two (n=52) patients were randomized and assigned to standard group and fifty-five (n=55) to combo group.

Results: At T2b (corresponding to the biopsy time and time after the biopsy, respectively) there was a significantly lower (p < 0.05) perception of pain in the patients who received sedo-analgesia (combo-group) compared to those who did not (standard group). Moreover, 100% of the patients in combo group who had previously undergone this procedure without premedication, reported that they would prefer sedoanalgesia for the subsequent procedures, thus showing the effectiveness of this combination also in relieving anticipatory anxiety. Finally, the histological specimen was found to be high in quality, as defined by standards.

Table 1.
Aims: To assess cost-effectiveness of ATGAM (horse antithymocyte globulin) in comparison to rabbit antithymocyte globulin (r-ATG) in the treatment of moderate to severe aplastic anaemia (sAA) patients in Sweden.

Methods: A semi-Markov state-transition cohort model was developed to estimate long-term (up to five years) clinical and economic outcomes for patients with AA receiving either ATGAM or r-ATG as first-line IST treatment. The follow-up key assumptions were included in the model: responders who relapse are assumed to be re-treated with no expected change in survival. Patients that do not respond to first-line treatment move onto a second-line treatment comprised of either IST, IST + eltrombopag or hematopoietic stem cell transplantation (HSCT). Although response rates are lower, those who respond to second-line treatment are assumed to have the same outcomes as those who respond to first-line. Patients who continue to not respond receive standard supportive care with a significant decrease in expected survival. Efficacy data for ATGAM and r-ATG were obtained from published literature. Adverse events were not included due to lack of evidence of any difference between the two comparators. Medication, administration, and disease management costs were obtained from published literature, publicly available sources and clinical expert opinion. As resource utilization for disease management changes over time and differs considerably between responders and non-responders, three distinct phases have been included in the model: short-term (first 6 months post-IST administration), medium-term (6-12 months) and long-term (greater than 1 year), for patients in either of the response categories.

Results: Response to treatment was calculated to be seen in 67% of ATGAM patients’ vs 35% in r-ATG (accounting for mortality). Over 5 years, the model estimated that patients gained 4.15 life-years (3.28 quality-adjusted) on ATGAM vs 3.52 (2.56) on r-ATG. Short-term disease management costs were estimated to be SEK 800,144 (€96,816) in responders vs SEK 1,264,016 (€139,041) in non-responders. Medium and long-term costs also followed the same pattern. Overall costs (drug plus disease management), were significantly lower for patients receiving ATGAM vs r-ATG; making ATGAM cost-saving by being both more effective and less costly than r-ATG. When considering treatment costs only (including cyclosporine and HSCT), the model estimated a cost of SEK 107,097/life-year gained (approx. €11,781) and SEK 135,655/quality-adjusted life-year (approx. €14,922), showing ATGAM is highly cost-effective. The analysis showed that when treatment and disease management costs are considered, ATGAM dominates r-ATG as the gain in QALYs and LYs are achieved at a lower cost. Therefore making ATGAM cost-saving with greater health benefits in comparison to r-ATG.

Summary/Conclusions: Due to improved treatment response, survival, and quality of life outcomes, the model shows that ATGAM is at least more cost-effective, if not cost-saving, in comparison to r-ATG for the treatment of patients with aplastic anaemia.
E1463
ASSESSING REAL-WORLD TREATMENT PATTERNS, OUTCOMES AND RESOURCE USE IN PATIENTS WITH NEWLY DIAGNOSED MULTIPLE MYELOMA (MM) POST AUTOLOGOUS STEM CELL TRANSPLANT ACROSS EUROPE

J. Ashcroft1, G. Taylor-Stokes2, S. Dhanasiri3, D. Judge4,5
1Mid-Yorkshire Hospitals NHS, Wakefield, 2Adelphi Real World, Bollington, United Kingdom, 3Celgene International, Boudry, Switzerland

Background: Autologous stem cell transplant (ASCT) is the standard of care for first line (1L) treatment (tx) for patients (pts) with MM deemed of suitable fitness to safely undergo the procedure. More recently introduced tx options have significantly increased the life expectancy of pts with MM and continue to provide further promise for the future in this devastating disease. The increasing therapeutic armamentary across the MM pathway allows for varied tx patterns providing both potential differences in outcomes and healthcare resource use (HCRU).

Aims: The aim of the analysis was to determine current management of pts in the post ASCT setting, assess outcomes of pts and HCRU.

Methods: A retrospective chart review was conducted in France, Germany, Italy, Spain and the UK. Data collection took place in Q1 2017. Physicians provided data on consecutive pts with MM who had undergone an ASCT as part of 1L tx on or after 1st January 2014, to specifically examine the HCRU post 1L tx. Data collected pertained to pt characteristics, tx patterns, duration of tx and outcomes (including time to progression (TTP) and best response achieved (IMWG updated criteria), HCRU in terms of hospitalizations, additional supportive drugs prescribed and healthcare professional (HCP) visits. Pt records included in this interim analysis were completed by Feb 17th 2017, with data collection continuing in all countries.

Results: 214 record forms have been reviewed to date. Pts’ mean age at diagnosis was 59 (±7.8 SD) years; 43% female and 57% male. Mean duration from diagnosis to receiving an ASCT was 9.6 months (±13.3 SD). Of the pts included in the study, 62%, 28% and 8% had received 1st, 2nd and 3rd line tx respectively. In the 1L setting, 72% of pts did not receive any drug therapy post 1L tx, 21% received consolidation and 8% maintenance therapy. Of the pts who did not receive maintenance therapy, 42% and 34% went onto receive 2L and 3L drug therapy respectively; whereas, only 24% of pts who received maintenance therapy went onto 2L and none onto 3L. The most frequently prescribed regimens at 1L maintenance were Lenalidomide (82%), Bortezomib (12%) and Thalidomide (11%). 22.2% of pts not receiving maintenance and 33.0 months (±8.1 SD) for pts receiving maintenance. Overall 43% of pts achieved a sCR and CR, 51% achieved a VGPR and PR. The period during which pts did not receive any drug therapy post 2L tx was 22.2 months (±11.1 SD) for pts not receiving maintenance and 33.0 months (±8.1 SD) for pts receiving maintenance. Overall 43% of pts achieved a sCR and CR, 51% achieved a VGPR and PR. The period during which pts did not receive any drug therapy post 2L tx was 22.2 months (±11.1 SD) for pts not receiving maintenance and 33.0 months (±8.1 SD) for pts receiving maintenance. Overall 43% of pts achieved a sCR and CR, 51% achieved a VGPR and PR.

Summary/Conclusions: The sample is reflective of the pt demographics data reported in Raab et al. 2016. Furthermore, the TTP for pts not receiving any active ongoing tx post ASCT in this real-world study is comparable to findings in the literature. Although no data exists on HCRU post ASCT. This study demonstrates that there is ongoing HCRU impact even if pts are not receiving any active ongoing tx post first ASCT. Prolonging the remission period post ASCT may therefore spread the marginal cost of HCRU whilst simultaneously enhancing a pt’s quality of life by deferring future tx lines.

E1465
THE COST-EFFECTIVENESS OF PEGASPARAGASE FOR FIRST-LINE TREATMENT OF ACUTE LYMPHOBLASTIC LEUKAEMIA: A COST-UTILITY ANALYSIS

S. Basu1, P. Lin2, C. Rowntree3,4, V. Saha2,5
1Shire, London, United Kingdom, 2Shire, Cambridge, United States, 3University Hospital of Wales, Cardiff, 4University of Manchester, Manchester, United Kingdom

Background: Asparaginase is a key component in the multi-agent chemotherapeutic regimen for the treatment of children, adolescents, and adults with acute lymphoblastic leukaemia (ALL). Compared to native asparaginase (native ASP), pegaspargase (PEG-ASP) has a longer half-life, can be given less frequently, and is less immunogenic, which leads to fewer hypersensitivity reactions. In the UK, patients with newly diagnosed ALL are treated with PEG-ASP followed by Erwinia-derived asparaginase (ERW-ASP) in cases of hypersensitivity, based on the UKALL protocols. Although native ASP is no longer used as the first choice of asparaginase therapy, it was the standard of care before PEG-ASP was available. A cost-utility analysis (CUA) was conducted to evaluate overall cost-effectiveness of PEG-ASP in comparison to native ASP when utilized as part of antineoplastic combination therapy for treating newly diagnosed ALL in children, young people, and adults.

Aims: To evaluate the cost-effectiveness of a treatment strategy including PEG-ASP in a multi-agent in patients with newly diagnosed ALL compared to regimens that include native ASP.

Methods: In line with accepted National Institute for Clinical Excellence (NICE) methodology, a combined decision tree and health state transition Markov model was developed to compare treatment sequences starting with PEG-ASP versus native ASP, followed by ERW-ASP in case of hypersensitivity. Although ERW-ASP is not used first-line in the United Kingdom, alternative switching scenarios could be clinically possible, and therefore all scenarios were modelled. Paediatric, young adult (≤25 years), and adult (26-65 years) patients were modelled separately using the UKALL 2003 and UKALL14 protocols, respectively. Further splits were made between high-, intermediate-, and standard-risk patients in the paediatric model, between patients aged ≤40 vs >41 years and patients eligible vs ineligible for transplant in the adult model. Key model parameters (survival, risk of hypersensitivity) were based on published data and clinical expert input. In the base-case analysis, overall survival and event-free survival were assumed to be equivalent for PEG-ASP, native ASP, and ERW-ASP. With 1,000 U/m2 dosing (per UKALL protocols) used for treatment with PEG-ASP, the 2,000 U/m2 dosing (per Seppi protocol) of PEG-ASP was examined, as well as variations in comparative survival and hypersensitivity rates. Incremental cost-effectiveness ratios (ICER; defined as incremental costs/quality-adjusted life years (QALYs) gained) were produced.

Table 1.

<table>
<thead>
<tr>
<th>Technologies</th>
<th>Total Cost (€)</th>
<th>Incremental ICER (€)</th>
</tr>
</thead>
<tbody>
<tr>
<td>PEG-ASP &gt; ERW-ASP</td>
<td>€7,871</td>
<td></td>
</tr>
<tr>
<td>ERW-ASP &gt; PEG-ASP</td>
<td>€5,324</td>
<td></td>
</tr>
</tbody>
</table>

* Dominates indicates more cost and less benefit compared to the alternative strategy
Results: The base-case scenario demonstrated that PEG-ASP followed by ERW-ASP dominated (i.e., was both less costly and more effective than) native ASP followed by ERW-ASP in adults, children, and the whole (combined) population (Table). Scenario analyses highlighted the robustness of the cost-effectiveness results. Differences in total QALYs between PEG-ASP and native ASP were driven primarily by the difference in hypersensitivity rates.

Summary/Conclusions: This analysis demonstrates that PEG-ASP, as part of multi-drug chemotherapy, is a cost-effective treatment option compared to native ASP for treating ALL in children, young people and adults with newly diagnosed ALL.

E1466 IMPACT OF VENETOCLAX ON THE QUALITY OF LIFE OF PATIENTS WITH RELAPSED/REFRACTORY CHRONIC LYMPHOCYTIC LEUKEMIA: RESULTS OF A PHASE 2, OPEN-LABEL STUDY OF VENETOCLAX (ABT-199/ GDC-0198) MONOTHERAPY

W. Wierda1, K. Saiit, L. Noe2, R. Kamalakar2, J. Gdovin2, M. Verdugo2, S. Kim2, R. Humerekhouse2, S. Stigenbauer3
1The University of Texas MD Anderson Cancer Center, Houston, 2AbbVie Inc, North Chicago, United States, 3Department of Internal Medicine III, Ulm University, ULM, Germany

Background: Chronic lymphocytic leukemia (CLL) is associated with reduced health-related quality of life (HRQoL), with progressive severe fatigue being a particularly relevant burden. Disease-related symptoms, toxic effects of therapy, and the awareness of living with an incurable disease can have a profound impact on HRQoL. Venetoclax (VEN) is an oral BCL-2 inhibitor that has demonstrated deep and durable responses in relapsed/refractory (R/R) CLL patients.

Aims: To assess whether Venetoclax has a sustained impact on health related quality of life among patients with relapsed/refractory CLL based on a second interim analysis (first interim results through week 24) of patients treated with VEN monotherapy.

Methods: Patients ≥18 years of age with R/R CLL received VEN monotherapy until disease progression, unacceptable side effects, or discontinuation for any other reason. Patient-reported HRQoL measures included the EORTC QLQ-C30 and EORTC QLQ-CLL16, which were assessed at Baseline (BL), at 4 weeks and every 12 weeks thereafter. Mean change in the HRQoL measures from BL to each assessment are reported. Clinical relevance was based on minimum important difference (MID) of values from BL at different assessment points. The lower bound of 5–10 point changes, considered a “little” change for MID acceptance for both measures.

Results: Clinically meaningful improvements from BL were observed early and were sustained through week 96 in VEN treated patients in the EORTC-QLC-C30 global health status and the role, social, and emotional functioning scales. Improvements in VEN treated patients in EORTC-QLC-CLL16 based on a second interim analysis (first interim results through week 24) of patients treated with VEN monotherapy.

Table 1. Table 1.}

Summary/Conclusions: These updated interim results suggest that patients receiving VEN monotherapy experienced early and sustained clinically relevant improvement in several key aspects of functioning and HRQoL for up to 96 weeks in a very symptomatic and difficult to treat patient population. These results are important to consider when making treatment decisions in the R/R settings.

E1467 WHICH HEMATOLOGICAL CONDITIONS CAN THIRD YEAR MEDICAL STUDENTS RECOGNISE INTERPRETING FULL BLOOD COUNT RESULTS?

S. Lovato1,2, J. Arnold1,2

Aims: To prospectively examine the association between health-related quality of life and healthcare utilization among patients with AL amyloidosis.

Background: AL amyloidosis is a rare, complex disease associated with significant organ dysfunction, disability, and death. AL amyloidosis patients interact with the healthcare system in a myriad of ways; however, few studies have quantified healthcare utilization (HCU) in this condition.

Methods: A multiple choice test “best of four” containing ten clinical cases including full blood count results was given to the students. According to the Team Based Learning “TBL” model the students completed the test first individually, “i-RAT” and then after discussing the results in small groups “t-RAT”. The topics and the percentage of correct answers are shown in Table 1.

Results: Twenty four students participated. In the i-RAT none of the scenarios were correctly interpreted by 100% of the students, the scenarios interpreted correctly by at least 70% of the students were only two: B12/folate deficiency and iron deficiency; less than 30% of the students could identify CML, NHL and Multiple myeloma; the remaining topics: thalassemic trait, MDS AML, CLL and Multiple myeloma the number of correct answers was the same for i-RAT and t-RAT.

Summary/Conclusions: This group of medical students found it difficult to correctly diagnose some of the haematological conditions presented, even though they had studied all the conditions before, however the use of a “Team Based Learning” approach where students could discuss the cases in small groups did improve their results. Interestingly for two conditions, for CML and Multiple myeloma the number of correct answers was the same for i-RAT and t-RAT, possibly the students who responded correctly during the i-RAT were each in a different group during the t-RAT and worked as peer-to-peer teachers for the other students. The i-RAT results for AML were actually worse than for the i-RAT, probably the students who replied correctly in the i-RAT were concentrated in fewer groups. To the author’s knowledge this is the first study on the effect of applying the Team Based Learning method to haematology teaching. This study showed that TBL could be a useful teaching tool to improve teaching of haematological conditions in medical schools, however the size of the sample was small and the results should be validated with a bigger study.

E1468 LONGITUDINAL ASSOCIATIONS BETWEEN HEALTH-RELATED QUALITY OF LIFE AND HEALTHCARE UTILIZATION IN ALamyloidosis

M. Baylis1, T.P. Quock2, S.D. Guthrie2, M.K. White1, K.L. McCausland1, 1Optum, Lincoln, 2Prothena Biosciences Inc, South San Francisco, United States

Background: Light chain (AL) amyloidosis is a rare, complex disease associated with significant organ dysfunction, disability, and death. AL amyloidosis patients interact with the healthcare system in a myriad of ways; however, few studies have quantified healthcare utilization (HCU) in this condition.

Aims: To prospectively examine the association between health-related quality of life and healthcare utilization among patients with AL amyloidosis.

Summary/Conclusions: This group of medical students found it difficult to correctly diagnose some of the haematological conditions presented, even though they had studied all the conditions before, however the use of a “Team Based Learning” approach where students could discuss the cases in small groups did improve their results. E1467 WHICH HEMATOLOGICAL CONDITIONS CAN THIRD YEAR MEDICAL STUDENTS RECOGNISE INTERPRETING FULL BLOOD COUNT RESULTS?

S. Lovato1,2, J. Arnold1,2

Aims: To prospectively examine the association between health-related quality of life and healthcare utilization among patients with AL amyloidosis.

Background: AL amyloidosis is a rare, complex disease associated with significant organ dysfunction, disability, and death. AL amyloidosis patients interact with the healthcare system in a myriad of ways; however, few studies have quantified healthcare utilization (HCU) in this condition.

Aims: To prospectively examine the association between health-related quality of life and healthcare utilization among patients with AL amyloidosis.

Summary/Conclusions: This group of medical students found it difficult to correctly diagnose some of the haematological conditions presented, even though they had studied all the conditions before, however the use of a “Team Based Learning” approach where students could discuss the cases in small groups did improve their results. Interestingly for two conditions, for CML and Multiple myeloma the number of correct answers was the same for i-RAT and t-RAT, possibly the students who responded correctly during the i-RAT were each in a different group during the t-RAT and worked as peer-to-peer teachers for the other students. The i-RAT results for AML were actually worse than for the i-RAT, probably the students who replied correctly in the i-RAT were concentrated in fewer groups. To the author’s knowledge this is the first study on the effect of applying the Team Based Learning method to haematology teaching. This study showed that TBL could be a useful teaching tool to improve teaching of haematological conditions in medical schools, however the size of the sample was small and the results should be validated with a bigger study.
Methods: A non-interventional, longitudinal online study was conducted among patients with AL amyloidosis who were recruited with assistance from patient advocacy groups. Initial (n=341) and six-month follow-up (n=226) surveys assessed demographics, disease and treatment characteristics, and health-related quality of life (HRQoL), measured by the SF-36v2® Health Survey physical and mental component summary scores (PCS and MCS). HCU (e.g., outpatient visits, hospitalization, treatment to myeloma care room) was measured during the six-month follow-up. Prevalence of HCU and its bivariate associations with patient characteristics were evaluated. Multivariable logistic regression models were used to test for associations between HRQoL and having an ER visit or hospitalization in the past six months.

Results: Overall, visits with specialists and other healthcare providers during the previous six months were nearly ubiquitous (92.0% and 94.6%, respectively). Collectively, 56.0% of patients reported having ≥1 ER visit or hospitalization. ER visits and hospitalizations were not associated with the numbers or types of organs affected by the disease or the duration of disease. There were significant associations between PCS and ER visits (p<0.05) and between both PCS and MCS and hospitalizations (p<0.05 for all) based on multivariable analyses.

Summary/Conclusions: There is a lack of real-world evidence regarding HCU among AL amyloidosis. This research identified longitudinal associations between HRQoL and HCU, indicating there is potential for using HRQoL surveys as screening tools to predict future HCU for AL amyloidosis patients. The development of prediction models for HCU in AL amyloidosis should consider incorporating HRQoL, as well as disease staging and treatment type.

SAFETY, FEASIBILITY AND EFFECTIVENESS OF ELECTRICAL MUSCLE STIMULATION IN HOSPITALIZED PATIENTS UNDERGOING AUTOLOGOUS OR ALLOGENIC STEM CELL TRANSPLANTATION AND INTENSIVE CHEMOTHERAPY

D. Kadzi-Muiltynda1, A. Klostermann1, M. Bewarder1, J. Bittenbring1, M. Pfreundschuh1
1Innere Medizin I, Universitätsklinikum des Saarlandes, Homburg, Germany

Background: Autologous and allogeneic stem cell transplantation (HSCT) or intensive chemotherapy are the only treatment option for many patients with haematological malignancies. Even after complete remission many patients are physically and psychologically impaired because of intensive treatment and weeks of immobilisation. Electrical muscle stimulation (EMS) is a verified training tool to prevent muscle decline in seniors and helps improving physical performance, functioning, and quality of life, indicated by favourable test results in the EMS group. To our knowledge, the study aimed to answer the following questions: What treatment attributes to myeloma patients and the maximum acceptable risk they are willing to accept? What risk-benefit trade-offs characterise patients’ decision-making around the value of new myeloma medicines. For example, to establish what treatments do myeloma patients value? What is the relative importance of different benefits and risks of treatment. The purpose of this study was to assess myeloma patients' preferences for treatment.

Aims: The study aimed to answer the following questions: What treatment attributes do myeloma patients value? What is the relative importance of different benefits and risks of treatment. The purpose of this study was to assess myeloma patients' preferences for treatment.

Methods: Participants were 475 Myeloma patients in the UK. Data were collected using discrete choice experiments (DCEs) through an online survey. The DCEs presented patients with a traditional treatment choice experiment (e.g., treatment A vs treatment B), focusing on the clinical benefits of treatments and the associated risks. The attributes and levels of the attributes were selected based on previous research, literature review and expert opinion. The DCE data were modelled using a Latent Class Model (LCM), and the effect of demographic characteristics were also examined.
