Abstract Vitamin B12 (cobalamin) is the most complex B-type vitamin and is synthetized exclusively in a limited number of prokaryotes. Its biologically active variants contain rare organometallic bonds, which are used by enzymes in a variety of central metabolic pathways such as L-methionine synthesis and ribonucleotide reduction. Although its biosynthesis and role as co-factor are well understood, knowledge about uptake of cobalamin by prokaryotic auxotrophs is scarce. Here, we characterize a cobalamin-specific ECF-type ABC transporter from *Lactobacillus delbrueckii*, ECF-CbrT, and demonstrate that it mediates the specific, ATP-dependent uptake of cobalamin. We solved the crystal structure of ECF-CbrT in an apo conformation to 3.4 Å resolution. Comparison with the ECF transporter for folate (ECF-FolT2) from the same organism, reveals how the identical ECF module adjusts to interact with the different substrate binding proteins FolT2 and CbrT. ECF-CbrT is unrelated to the well-characterized B12 transporter BtuCDF, but their biochemical features indicate functional convergence.

Introduction

Vitamin B12 or cobalamin (Cbl) is regarded as the largest and most complex biological ‘small molecule’. The molecule consists of a corrin ring chelating a cobalt ion using four equatorial coordinating nitrogen atoms (Figure 1, Figure 1—figure supplement 1). At the α-axial position, the cobalt ion is coordinated by the 5,6-dimethylbenzimidazole (DMBI) base that is linked covalently to the corrin ring. Located at the β-axial position is the sixth coordinating moiety (Gruber et al., 2011; Roth et al., 1996). This ligand can vary among cobalamin derivatives and forms a rare organometallic, covalent bond, which offers unique catalytic properties to enzymes that use Cbl as a co-factor. The two most common biological active variants have a methyl or 5′-deoxyadenosyl group at this position, resulting in methyl- and adenosyl-cobalamin (Met-Cbl and Ado-Cbl, respectively). In the industrially produced variant, a cyano-group (CN-Cbl) binds at the β-axial position, and a hydroxy group (OH-Cbl) is present in the degradation product (Gruber et al., 2011).

Enzymes that use Cbl as their co-factor catalyze mostly methyl group transfer reactions, or a variety of different radical-mediated reactions (Giedyk et al., 2015; Gruber et al., 2011). The most prominent example for methyl group transfer is MetH, the Cbl-dependent L-methionine synthase, which uses Met-Cbl to transfer a methyl group onto L-homocysteine to produce L-methionine. The
The ability to synthesize Cbl de novo is restricted to prokaryotic species in only ~20 genera. Two routes for de novo synthesis have been established (aerobic or anaerobic), each requiring approximately 30 different enzymes, which makes de novo synthesis a very energy consuming process, and could explain why roughly two thirds of prokaryotes that require Cbl cannot synthesize the molecule, and hence depend on uptake (Gruber et al., 2011; Roth et al., 1996). For some microbial communities, for instance in the Ross Sea, it has been shown that Cbl production is the limiting factor for biomass production, which generates a demand for Cbl uptake systems among Cbl auxotrophs (Bertrand et al., 2011).

In contrast to the well-characterized chemical properties of Cbl, as well as its biosynthesis and role in many enzymatic reactions, the uptake of the vitamin by bacteria is poorly understood. The only characterized Cbl uptake system is the *Escherichia coli* BtuCDF ATP binding cassette (ABC) transporter, which was first described in 1980 (DeVeaux and Kadner, 1985). Substantial understanding of the system has been obtained through a combination of biochemical and structural studies (Borths et al., 2002; Goudsmits et al., 2017; Korkhov et al., 2012; Korkhov et al., 2014; Locher et al., 2002). The importer uses the periplasmic substrate-binding protein BtuF to capture Cbl or its precursor cobinamide (Cbi) with high affinity (K_d values of ~10 nM and ~40 nM, respectively) (Cadieux et al., 2002; Mireku et al., 2017). Transport is powered by hydrolysis of ATP by the two BtuD subunits located on the cytoplasmic side of the membrane (Borths et al., 2005). The substrate passes through the membrane at the interface between two copies of the transmembrane protein, BtuC (Korkhov et al., 2012; Korkhov et al., 2014). BtuCDF homologs are found widely in prokaryotes, but they are absent from a subset of bacteria that require uptake of vitamin B12 (Rodionov et al., 2009).

An in silico study by Rodionov et al. (2009) predicted that the energy coupling factor (ECF-) type ABC transporter ECF-CbrT might be a Cbl transporter (Rodionov et al., 2009). ECF-transporters are multi-subunit membrane complexes that consist of two ATPases, similar to the ATPases of ABC transporters, and two membrane embedded proteins, not related to any other protein family.

methyl group on Cbl is subsequently restored from methyl-folate (Banerjee and Matthews, 1990; Gruber et al., 2011).
Results

Expression of ECF-CbrT complements an *Escherichia coli* strain lacking its endogenous vitamin B12 transporter

To demonstrate that ECF-CbrT is a vitamin B12 transporter, we constructed an *Escherichia coli* knock-out strain with three genomic deletions: ΔbtuF, ΔmetE, and ΔbtuC::Km<sup>R</sup> (*E. coli* ΔFEC) (Baba et al., 2006; Datsenko and Wanner, 2000; Thomason et al., 2007). A similar strain was previously used by Cadieux et al., 2002 to identify the substrate binding protein BtuF. The knock-out strain lacks the L-methionine synthase MetE (Davis and Mingioli, 1950). *E. coli* possesses two L-methionine synthases, MetE and MetH. MetH uses Cbl as cofactor, whereas MetE is not dependent on the vitamin (Banerjee et al., 1989; Davis and Mingioli, 1950). Thus, deletion of metE makes *E. coli* dependent on Cbl for the synthesis of L-methionine. Because btuF and btuC are also deleted in *E. coli* ΔFEC, endogenous Cbl-uptake mediated by BtuCDF is abolished (Cadieux et al., 2002), and (heterologous) expression of an active Cbl transporter is required to synthesize methionine.

We studied the growth of the deletion strain transformed with an expression plasmid for either BtuCDF (positive control), or an empty plasmid (negative control), or CbrT with or without the ECF module. We grew cells in 96-well plates using minimal medium supplemented with L-methionine or Cbl and monitored the optical density at 600 nm (OD<sub>600</sub>). In the presence of L-methionine, all strains grew readily, with a lag phase of 300–450 min (Figure 2a–d) (Zwiertering et al., 1990). The strains expressing BtuCDF or ECF-CbrT showed similar growth characteristics (lag time of 380 min and 470 min, respectively) in medium containing Cbl instead of L-methionine (Figure 2a and c), respectively, whereas the deletion strain expressing solitary CbrT (without its cognate ECF-module) did not show substantial growth in the absence of L-methionine when supplemented with Cbl (Figure 2d). The results demonstrate that the full ECF-CbrT complex constitutes a new Cbl transporter. ECF-CbrT also supported growth of *E. coli* ΔFEC in the presence of Cbl instead of Cbi, albeit with a longer lag-time (730 min) (Figure 2c), indicating that Cbl is a transported substrate of ECF-CbrT. We hypothesize that the longer lag time is due to the extra time required to express the necessary enzymes for Cbl synthesis from Cbi (Lawrence and Roth, 1995). Our in vitro work shows that ECF-CbrT indeed supports efficient Cbl and Cbi transport (see below).

ECF-CbrT catalyzes ATP-dependent transport of cobalamin and cobaminde

We purified ECF-CbrT, reconstituted the complex in liposomes and assayed for the uptake of radiolabeled Cbl (<sup>57</sup>Co-cyanocobalamin). Uptake of radiolabeled Cbl into proteoliposomes was observed only when the proteoliposomes were loaded with Mg-ATP and not when Mg-ADP was incorporated (Figure 3a). While this experiment shows that transport is strictly ATP-dependent, similar to what was found for other ECF transporters (Swier et al., 2016; ter Beek et al., 2011), the ratio between ATP molecules hydrolyzed and Cbl molecules transported cannot be derived from this data. To
obtain this ratio, simultaneous measurements of Cbl uptake and ATP hydrolysis rates are needed, which is technically difficult. Additionally, the related ECF transporter for folate displays a large extent of futile ATP hydrolysis (not coupled to transport [Swier et al., 2016]), which further complicates the determination of the coupling ratio. Nonetheless, the EcfA and EcfA’ subunits contain all the motifs to form functional ATPases, and therefore we speculate that transport of Cbl is coupled to the hydrolysis of two ATP molecules. Using an Mg-ATP concentration of 5 mM, the apparent $K_M$ for Cbl uptake was $2.1 \pm 0.4$ nM and the $V_{max} = 0.06 \pm 0.01$ nmol $\times$ mg$^{-1}$ $\times$ s$^{-1}$ (Figure 3—figure supplement 1). To test the substrate specificity of the new vitamin B12 transporter, we conducted uptake experiments with a variety of competing compounds that are structurally similar to Cbl (Figure 3b). Addition of a 250-fold excess of unlabeled CN-Cbl inhibited the uptake of the radiolabeled substrate almost completely. Met-Cbl and OH-Cbl inhibited uptake to a similar extent as CN-Cbl, whereas Ado-Cbl was less effective (inhibition to $\sim$25%). Addition of a 250-fold excess of Cbi also decreased the uptake of radiolabeled Cbl to $\sim$25% (Figure 3b). To test whether Cbi is a transported substrate (that competitively inhibits transport of Cbl) or a non-transported compound that can only bind to the transporter, we directly measured uptake of Cbi (Figure 3a). Radiolabeled Cbi is not commercially available and, therefore, we synthesized the compound by treating $^{57}$Co-cyano-cobalamin with perchloric acid (Schneider and Stroinski, 1987). The complete conversion of Cbl into Cbi was confirmed by mass spectrometry. Cbi was transported into liposomes containing ECF-CbrT, and transport required luminal Mg-ATP, confirming that Cbi is a transported substrate (Figure 3a). Finally, we tested whether hemin inhibits Cbl transport (Figure 3b). Hemin and Cbl are structurally related and share the same precursor uroporphyrinogen-III (Roth et al., 1996), but unlike Cbl, hemin consists of a flat porphyrin ring with a chelated iron ion, and has a chloride ion as one of the axial.

Figure 2. ECF-CbrT supports cobalamin-dependent growth of an E.coli deletion strain. (a) The triple knock out strain E. coli ΔFEC expressing the BtuCDF ABC-transporter (positive control) grows in the presence of 50 μg/ml L-methionine or 1 nM CN-Cbl with lag-times of 300 min or 380 min, respectively. (b) E. coli ΔFEC carrying only the empty expression vector (negative control) grows only in the presence of 50 μg/ml L-methionine but not with 1 nM CN-Cbl. The lag-times of the negative controls are 450 min or >1000 min, respectively. (c) E. coli ΔFEC expressing the entire ECF-CbrT transporter supports growth in the presence of either 1 nM Cbl or 1 nM Cbi with a lag-time of 470 min or 730 min, respectively. The lag-time in the presence of 50 μg/ml L-methionine is 410 min. (d) Expression of the solitary S-component CbrT without its cognate ECF-module is not able to support growth of E. coli ΔFEC in the presence of 1 nM CN-Cbl.

DOI: https://doi.org/10.7554/eLife.35828.004
Hemin did not compete with Cbl-uptake (Figure 3b), showing that, although promiscuous among Cbl variants and Cbl-precursors, ECF-CbrT is a dedicated vitamin B12 transporter. We aimed to obtain further biochemical information on the solitary S-component CbrT. We could purify CbrT only in the substrate-bound state (Figure 4a). The protein without substrate was unstable in detergent solution and prone to aggregation. Apparently, substrate binding had a stabilizing effect on CbrT, an observation that has been made more often for membrane proteins (Berntsson et al., 2012; ter Beek et al., 2011).

From the spectral properties of Cbl that was co-purified with CbrT, we conclude that CbrT binds Cbl in a ~1:1 ratio in detergent solution (Figure 4a), which reflects the common substrate to protein stoichiometry for S-components (Berntsson et al., 2012; Erkens et al., 2011; Swier et al., 2016). Because we could not obtain purified apo CbrT, we studied the substrate-binding affinity using E. coli crude membrane vesicles (CMVs) containing overexpressed apo CbrT. Isothermal titration calorimetry (ITC) revealed binding of both CN-Cbl and Cbi with dissociation constants of 9.2 ± 4.5 nM and 36 ± 15 nM, respectively (Figure 4b,c and e). As a negative control, CMVs without CbrT were used to exclude unspecific binding of CN-Cbl or Cbi (Figure 4d). Cbl analogues, OH-Cbl and Met-Cbl, were also probed with ITC and found to bind to CbrT with the similar binding affinities as CN-Cbl (K_d values of 9.6 ± 6.9 nM or 4.5 ± 0.3 nM, respectively, Figure 4—figure supplement 1), supporting the notion that CbrT is promiscuous towards the β-axial ligand of Cbl and corroborating the findings of the competition assay.

Although the use of crude membrane vesicles precluded the determination of the number of binding sites (the concentration of CbrT in the membrane vesicles is unknown), the thermodynamic values (K_d, ΔH and ΔS) derived from the ITC measurements do not depend on this number. Assuming that CbrT has a single substrate binding site (consistent with the spectral properties, Figure 4a), the expression level of CbrT in the membranes could be calculated and we found that CbrT accounted for ~0.9% (w/w) of the protein content in the membrane.
Structure of the vitamin B12-specific ECF transporter in its apo and post substrate-release state

We crystallized the ECF-CbrT complex in detergent (n-Dodecyl-β-D-maltopyranoside, DDM) solution and solved a crystal structure to 3.4 Å resolution using molecular replacement with the structure of the folate transporter, ECF-FolT2, from *L. delbrueckii* as a search model (*Figure 5a*) (Swier et al., 2016). Statistics of data collection and structure refinement are summarized in Supplementary file 1. There are two copies of ECF-CbrT in the asymmetric unit, corresponding to molecules A and B, each of them comprising CbrT, EcfT, EcfA and EcfA'.

The identical ECF modules of the ECF-FolT2 and ECF-CbrT complexes have very similar overall structures, with a few notable conformational differences (*Figure 5b*). In both complexes, the two
Figure 5. Comparison of the structures of ECF-CbrT and ECF-FolT from L. delbrueckii. (a) Cartoon representation of ECF–CbrT from the perspective of the plane of the membrane. Cytoplasmic ATPases, EcfA and EcfA’, are colored in red, EcfT in cyan and CbrT in yellow. (b) Structural differences between the membrane domains of EcfT. The structures of ECF-CbrT (cyan) and ECF-FolT2 (green) from L. delbrueckii were superimposed by structural alignment of the ATPase units. Pro71 of EcfT is represented in sticks. (c) and (d) Surface representation of CbrT (c, yellow) and FolT2 (d, orange)

Figure 5 continued on next page
nucleotide-binding domains (NBDs; EcfA and EcfA’) are in a nucleotide-free state, adopting an open conformation with two incomplete ATP-binding sites. With the NBDs of ECF-FolT2 and ECF-CbrT aligned structurally (rmsd 1.8 Å), the coupling helices of EcfT, which transmit the conformational changes of the NBDs upon ATP-hydrolysis to the membrane domains, also superimpose well between the two complexes (rmsd 1.5 Å). However, the transmembrane-helices of EcfT adopt different conformations (rmsd 4.4 Å). They are offset like rigid bodies, hinging approximately around Pro71 (Figure 5b). Structural flexibility of the membrane domain has been observed before (Swier et al., 2016; Zhang et al., 2014) and is likely necessary to accommodate different S-components, and may facilitate toppling of the S-components during the catalytic cycle (Swier et al., 2016).

The S-components CbrT and FolT2, which interact with the same ECF module in L. delbrueckii, do not share significant sequence similarity (16% identical residues). Accordingly, the structures show pronounced differences (rmsd 3.1 Å), although the overall folds are the same. Particularly, differences in loop 3 and loop 5 cause alterations of the protein surfaces that interact with the membrane domain of EcfT (Figure 5c,d). Therefore, tight association of the different S-components with the same ECF module requires the conformational adaptations in the membrane domain of the interacting EcfT subunits (Figure 5c,d).

CbrT is in a ‘toppled’ orientation in the ECF-CbrT complex with TMs 1, 2, 3 and 4 oriented almost parallel to the membrane plane. Although OH-Cbl was added in excess to the crystallization condition, the substrate was not bound. The apo-state of the toppled S-component was observed before in other ECF-type transporters and likely represents the inward-facing state after substrate release (Swier et al., 2016; Wang et al., 2013; Xu et al., 2013; Zhang et al., 2014). The absence of substrate is in agreement with the proposed transport model, in that the inward oriented apo protein is a low affinity state (Swier et al., 2016). It has been hypothesized that this state precedes ATP hydrolysis, which leads to release of the S-component from the ECF module and reorientation of the S-component in the membrane, which brings the substrate binding site back to the extracellular side (Swier et al., 2016).

We hypothesize that the binding site for Cbl is located in a large cavity observed in the CbrT structure. The location of the cavity matches the position of the substrate-binding sites in structurally characterized S-components in the substrate-bound state (Berntsson et al., 2012; Erkens et al., 2011; Swier et al., 2016). In contrast to ECF-FoIT2 (Swier et al., 2016), and structurally characterized ECF complexes from other organisms (Wang et al., 2013; Xu et al., 2013; Zhang et al., 2014), the binding cavity in ECF-CbrT is largely occluded, and not accessible from the cytosol (Figure 5e,f). The occlusion is caused mainly by the position of loop 3, which obstructs access to the cavity in CbrT. We speculate that occlusion of the empty binding site after cytoplasmic release of the substrate may be required for the subsequent reorientation of the S-component, upon release from the ECF module.

Discussion

Comparative genomics studies have identified a wide range of ECF transporter families along with their putative substrate specificities mediated by their S-components (Rodionov et al., 2009). Based on its genetic organization and the lack of a BtuCDF transporter homolog in the Lactobacillales genomes, CbrT was predicted to be a vitamin B12-specific S-component (Rodionov et al., 2009). In L. delbrueckii, which was shown to be auxotrophic for vitamin B12 (Kusaka and Kitahara, 1962), CbrT occurs within the nrdJ–cbrS–cbrT–pduO gene cluster. This genetic organization strongly implies an involvement of the substrate-binding protein CbrT in Cbl uptake: First, nrdJ is annotated as an adenosylcobalamin-dependent ribonucleotide reductase requiring the vitamin as a co-factor.
Second, PduO is a Cbl adenosyltransferase, which converts Cbl into Ado-Cbl making it accessible for NrdJ. We showed that ECF-CbrT not only transports Cbl, but also mediates uptake of Cbi (Figure 3a). Therefore L. delbrueckii is expected to have the genetic repertoire to synthesize Cbl using Cbi as a precursor. However, we could not find homologs of the enzymes CobS, CobU and CobT, which are known to convert Cbi into cobalamin in E. coli (Lawrence and Roth, 1995). Possibly other proteins might functionally compensate for their absence, which was shown for the thiamine kinase YcfN, which could replace CobU in Salmonella typhimurium (Otte et al., 2007). However, it is also possible that L. delbrueckii CbrT binds Cbi in a futile manner which case Cbi would be transported but not used as a substrate for any enzyme. Finally, predicted CbrT homologs in Lactobacillales display a high degree of sequence identity, ranging from 25% to 60% compared to L. delbrueckii CbrT. Thus, we hypothesize that these CbrT homologs share the same function and represent substrate binding proteins for both Cbl and Cbi.

Our results show that ECF-CbrT is a new vitamin B12 transporter that is able to restore Cbl- and Cbi-dependent growth in E. coli ΔFEC (Figure 2c). Further characterization using uptake experiments with the purified ECF-CbrT complex (Figure 3a) and binding studies on CbrT show that the transporter is promiscuous towards the β-ligand of Cbl and also accepts Cbi as substrate (Figure 3b). A similar behavior has also been observed for BtuCDF (Mireku et al., 2017).

All three naturally occurring Cbl variants, OH-Cbl, Ado-Cbl and Met-Cbl, inhibit uptake of radiolabeled cyano-Cbl (Figure 3b). Whereas almost full inhibition was observed by a 250-fold excess of OH-Cbl, CN-Cbl, and Met-Cbl, Ado-Cbl inhibited only to 25%. This might be due to its bulkier β-ligand and a consequent steric hindrance. Nonetheless, the assay shows that ECF-CbrT is promiscuous toward the β-axial ligand of vitamin B12. Generally, poly-specificity to Cbl (and Cbl-derivatives, see below) and Cbi seems to be an inherent feature of vitamin B12 binding proteins, which is the case for BtuF, human Cbl-carriers, and also CbrT (Fedosov et al., 1995; Mireku et al., 2017). In the human Cbl-carriers that share a similar promiscuity, the β-ligand side of the bound substrate is partially solvent exposed (Furger et al., 2013; Mathews et al., 2007; Wuerges et al., 2007). In CbrT, the broader substrate specificity might be related to flexibility of loops 1 and 3 that are the gates of CbrT and would make contact with the varying β-axial ligands.

In other ECF-transporters, the S-components exhibit remarkable high affinities toward their respective substrates with Kd values in the low nanomolar range (Slotboom, 2014). ITC measurements with CbrT in the absence of the ECF module also show high-affinity binding of CN-Cbl, OH-Cbl, Met-Cbl, and Cbi (Figure 4b,c and e). The slightly lower affinity for Cbi (4-fold) is probably due to the lack of the α-igand (Figure 1—figure supplement 1) that leads to fewer possible protein-substrate interactions.

Strikingly, the affinity binding constants for CN-Cbl and Cbi are in the same range as the respective affinities determined for BtuF (Cbl of 9.1 nM and Cbi of 40 nM) (Mireku et al., 2017), which might imply that Cbl-transporters evolved to acquire the substrates with similar efficiency. Together with our Vmax and Kd (Figure 3—figure supplement 1) determination, we additionally show that the rate limiting step is substrate translocation, which means that the observed affinities are probably optimized for efficient substrate scavenging, followed by a slow translocation step. Human carriers achieve even higher affinities for Cbl (in the sub-picomolar range) (Fedosov et al., 1995), but in these cases, the off rate is practically zero and substrate release requires proteolysis, which is not the mechanism of (ABC-) transporters.

Although it was already known for a long time that a plethora of uncharacterized prokaryotic vitamin B12 uptake systems must exist, only the BtuCDF complex had been extensively characterized. This is somewhat surprising, considering the potential relevance of bacterial vitamin B12 transport for pharmaceutical applications. For instance, given the increase in antibiotic resistance and its serious threat to public health (Alós, 2015), it is imperative to find and characterize novel protein targets for drug design. Several pathogenic bacteria, such as Streptococcus pyogenes and Clostridium tetani, carry a cbrT gene, lack a BtuCDF homolog, and are Cbl-auxotrophs, which makes them strictly dependent on dedicated transporters to scavenge either vitamin B12 or its precursors from the environment. Because humans use endocytosis to take up Cbl (Quadros, 2010), Cbl-specific prokaryotic transporters are potential drug targets for vitamin B12 auxotrophic pathogens.

### Molecular methods

For expression, CbrT (LDB_RS00385) was amplified by means of polymerase chain reaction (PCR) using *L. delbrueckii* subsp. *bulgaricus* genomic DNA as a template. For expression of the entire complex, CbrT was inserted into the second multiple cloning site of p2BAD_ECF ([Swier et al., 2016](https://doi.org/10.7554/eLife.35828)) with XbaI and XhoI restriction sites. For expression of solitary CbrT, the gene was inserted with a C-terminal octa-His-tag into pBAD24 ([Guzman et al., 1995](https://doi.org/10.7554/eLife.35828)) using NcoI and HindIII restriction sites. A single glycine (Gly2) was introduced to be in-frame with the start-codon of the NcoI restriction site, which is not present in the full complex. All primers used are listed in Supplementary file 2 and all sequences were checked for correctness by sequencing.

### Expression and membrane vesicle preparation

ECF–CbrT was expressed as described previously ([Swier et al., 2016](https://doi.org/10.7554/eLife.35828)) with the following adaptations; plain Luria Miller broth (LB) medium was used and the growth temperature was kept constant at 37°C throughout. After 3 hr of expression, the cells were harvested by centrifugation (20 min, 7,446 × g, 4°C) and resuspended in 50 mM KPi, pH 7.5. Cells were either immediately used for membrane vesicles preparation or the resuspended cells were flash frozen in liquid nitrogen and stored at −80°C until use. Membrane vesicles were prepared as previously described ([Swier et al., 2016](https://doi.org/10.7554/eLife.35828)).

### ECF-CbrT purification

Crude membrane vesicles containing ECF-CbrT were solubilized in buffer A (50 mM KPi, pH 7.5, 300 mM NaCl, 10% glycerol, 1% (w/v) n-dodecyl-β-D-maltopyranoside (DDM, Anatrace) for 45 min at 4°C under constant movement. Unsolubilized material was removed by centrifugation (35 min, 287,000 × g, 4°C), the supernatant was loaded on a BioRad PolyPrep column containing 0.5 mL Ni²⁺-sepharose bed volume (GE healthcare), pre-equilibrated with 20 column volumes (CV) buffer B (50 mM KPi, pH 7.5, 300 mM NaCl, 10% glycerol) and allowed to incubate for 1 hr at 4°C under constant movement. Unbound protein was allowed to flow through and the column was washed with 20 CV of buffer C (50 mM KPi, pH 7.5, 300 mM NaCl, 10% glycerol, 50 mM imidazole, 0.05% DDM). ECF–CbrT was eluted with buffer D (50 mM KPi, pH 7.5, 300 mM NaCl, 10% glycerol, 500 mM imidazole, 0.05% (w/v) DDM) in three fractions of 0.4 ml, 0.75 ml and 0.5 ml, respectively. ECF-CbrT eluted mostly in the second elution fraction that was loaded on a Superdex 200 Increase 10/300 gel filtration column (GE Healthcare) that was equilibrated with buffer E (50 mM Hepes pH 8, 150 mM NaCl, 0.05% DDM). For crystallization, ECF-CbrT was purified following the same protocol but buffers A to D contained 1% DDM. Buffers A to D were supplemented with 0.5 mM hydroxyl-cobalamin (OH-Cbl, Sigma Aldrich), and buffer E contained 10 μM OH-Cbl. For all experiments, the peak fractions were collected, combined and either used directly for reconstitution or concentrated in a Viva-spin disposable ultrafiltration device with a molecular weight cut-off of 30 kDa (Sartorius Stedim Biotech SA) to a final concentration of 6 mg*ml⁻¹.
Construction of the E. coli ΔFEC strain

The E. coli strains JW0154 (ΔbtuF::Km\textsuperscript{R}), JW3805(ΔmetE::Km\textsuperscript{R}) and JW1701(ΔbtuC::Km\textsuperscript{R}) from the Keio collection (Baba et al., 2006) were purchased from the Coli Genetic Stock Center, Yale. E. coli JW0154 (ΔbtuF::Km\textsuperscript{R}) was used as the basis for constructing E. coliΔFEC. The kanamycin resistance cassette of JW0154 was removed using the FLP recombinase as described before (Datsenko and Wanner, 2000), resulting in E. coliΔF. The metE::Km\textsuperscript{R} locus from JW3805 was introduced in E. coliΔF using P1-mediated generalized transduction as described (Miller, 1972; Thomason et al., 2007), resulting in E. coliΔFE::Km\textsuperscript{R}. The kanamycin cassette was removed using the FLP recombinase, resulting in E. coliΔFE. The ΔbtuC::Km\textsuperscript{R} locus of JW1701 was introduced in E. coliΔFE using P1-mediated generalized transduction, resulting in E. coliΔFEC. Colony PCRs based on three primer pairs (buF-locus, 5’-atgcctagcctactgtcaggg-3’ and 5’-ctaatctacctgtgaaagcgc-3’; buC-locus, 5’-atgctgaccttgcgccg-3’ and 5’-ctaactcctcgctgttaataaa-3’; metE-locus, 5’-atgacattgatctcggctcagc-3’ and 5’-ttaccccccagcagttc-3’) were used to verify Km\textsuperscript{R}-insertions, the FLP-recombinase-mediated removal of Km\textsuperscript{R}-markers and the absence of any genomic duplications resulting in the presence of any wild-type metE, buC and btuF loci.

Growth assay with E. coli ΔFEC strains

The strains carrying various expression vectors were grown overnight at 37°C on LB-agar plates supplemented with 25 µg ml\textsuperscript{-1} kanamycin and 100 µg ml\textsuperscript{-1} ampicillin. The composition of the M9-based (47.7 mM Na\textsubscript{2}HPO\textsubscript{4}·12H\textsubscript{2}O, 17.2 mM KH\textsubscript{2}PO\textsubscript{4}, 18.7 mM NH\textsubscript{4}Cl, 8.6 mM NaCl) minimal medium was supplemented with 0.4% glycerol, 2 mM MgSO\textsubscript{4}, 0.1 mM CaCl\textsubscript{2}, 100 µg ml\textsuperscript{-1} L-arginine, 25 µg ml\textsuperscript{-1} kanamycin and 100 µg ml\textsuperscript{-1} ampicillin. A single colony was picked and used to inoculate a 3 ml to 6 ml liquid pre-culture supplemented with 0 µg ml\textsuperscript{-1} L-methionine (Sigma-Aldrich). The pre-culture was grown ~ 24 h at 37°C, shaking in tubes with gas-permeable lids (Cellstar). The main cultures were inoculated in a 1:500 inoculation ratio. The main culture had a volume of 200 µl and was supplemented with 0.00001% L-arabinose (Sigma-Aldrich) and either 50 µg ml\textsuperscript{-1} L-methionine, 1 mM dicyano-cobinamide (Sigma Aldrich), or 1 nM cyano-cobalamin (Acros Organics). The medium was added to a sterile 96 well-plate (Cellstar). The 96-well plate was sealed and 5’-ctaatctacctgtgaaagcgc-3’ and 5’-ptaactcctcgctgttaataaa-3’ were used to verify Km\textsuperscript{R}-insertions, the FLP-recombinase-mediated removal of Km\textsuperscript{R}-markers and the absence of any genomic duplications resulting in the presence of any wild-type metE, buC and btuF loci.

Crystallization and structure determination

Initial crystallization conditions for ECF-CbrT were screened at 4°C using commercial sparse-matrix crystallization screens in a sitting-drop setup and a Mosquito robot (TTP Labtech, UK). Initial crystals were found in the B11 condition (0.2 M KCl, 0.1 M Sodium citrate, pH 5.5, 37% (v/v) Pentaerythritol propoxylate (5/4 PO/OH)) of the MemGold1 HT-96 screen (Molecular Dimensions, UK) that diffracted up to 7.5 Å resolution. Using this condition as a starting point and the detergent (HR2-408) Fractonated up to 7.5 Å resolution. Using this condition as a starting point and the detergent (HR2-408) cate. To obtain lag-times the averaged growth curves were fitted with the Gompertz-fit in Origin eight and further analyzed as described (Zwietering et al., 1990).

X-ray diffraction data were collected from cooled (100 K) single crystals at synchrotron beam lines at the Swiss Light Source (SLS) beamline PXI, Switzerland. The crystals of apo ECF-CbrT belong to space group P1 (unit cell parameters: a = 85.47, b = 92.86, c = 105.51, α = 72.568, β = 66.274, γ = 62.893).

To correct for anisotropy, the dataset was treated at the diffraction anisotropy server prior to further processing (Strong et al., 2006). Data were processed with XDS (Kabsch, 2010b) and scaled with Xscale (Kabsch, 2010a). Data collection statistics are summarized in Supplementary file 1. The structure of the ECF-CbrT complex was solved by molecular replacement with PHASER MR (McCoy et al., 2007) using the apo ECF-FolT structure of L. delbrueckii (Swier et al., 2016) (PDB code 5JSZ) as a search model. For model completion, several cycles of model building with COOT (Emsley et al., 2010) and refinement with PHENIX (Adams et al., 2010) were performed. The Ramachandran statistics are 72.32% for favoured regions, 26.64% for allowed regions and 1.05% for
outliers. All structural figures in the main text were prepared with an open-source version of pymol (https://sourceforge.net/projects/pymol/).

**Preparation of radiolabeled cobinamide from radiolabeled cobalamin**

The required amount of cyano-cobalamin (radiolabeled and unlabeled) was mixed in a 1:1 (v/v) ratio with 70% perchloric acid (Sigma-Aldrich) and incubated for ten minutes at 70°C. To quench the reaction and prevent damage to the substrate, the resulting cobinamide substrate was added to buffer G (as described above), which was additionally supplemented with 5 M NaOH to restore the pH back to 7.5.

**Radiolabeled vitamin B12 transport assay**

Purified ECF-CbrT was reconstituted in proteoliposomes as described previously (Geertsma et al., 2008). Proteoliposomes were thawed and loaded with 5 mM MgSO$_4$ or MgCl$_2$ and 5 mM Na$_2$-ATP or Na$_2$-ADP through three freeze-thaw cycles. Loaded proteoliposomes were extruded nine times through a polycarbonate filter with a 400 nm pore-size (Avestin), pelleted by centrifugation (267,008 g, 35 min, 4°C) and resuspended in buffer F (50 mM KPi pH 7.5) to 2 μl*mg$^{-1}$ lipids. The uptake reaction was started by addition of concentrated and loaded proteoliposomes to buffer G (50 mM KPi pH 7.5, varying concentrations of $^{57}$Co-cyanocobalamin (150 to 300 μCi*mg$^{-1}$, in 0.9% benzylalcohol, MP Biomedicals) in a 1:100 ratio. At elsewhere specified time points 200 μl samples were taken transferred into 2 ml ice cold buffer F and filtered over OE67 cellulose acetate filters (GE Healthcare) soaked in Buffer F supplemented with cyanocobalamin (Acros chemicals). The filter was washed with 2 ml ice cold buffer F and transport of radiolabeled substrate was counted in Perkin Elmer Packard Cobra II gamma counter. All uptake assays were performed at 30°C while stirring.

**Substrate-binding assay by isothermal thermal calorimetry (ITC)**

ITC measurements were performed using a NanoITC calorimeter (TA Instruments) at 25°C. Membrane vesicles containing CbrT (200 μl, 10 mg*ml$^{-1}$ in 50 mM KPi, pH 7.5) were added to the NanoITC cell. Ligands were prepared in 50 mM KPi, pH 7.5 and titrated into the cell in 1 μl injections with 140 s between each injection. Membrane vesicles containing the full-complex ECF-CbrT that does not bind CN-Cbl (10 mg*ml$^{-1}$ in 50 mM KPi, pH 7.5) were used as a negative control. Data were analyzed with the Nano Analyze Software.

**Data deposition**

The atomic coordinates and structure factors have been deposited in the Protein Data Bank, www.pdb.org (PDB ID code 6FNP).

**Acknowledgements**

We thank Prof. Dr. AJM Driessen for the use of the setup in the isotope lab and we thank the beamline personnel of PXI at SLS for their technical support. This work was supported by grants from the Netherlands Organisation for Scientific Research (NWO Vici grant 865.11.001 to D-JS and NWO Vidi grant 723.014.002 to AG), the São Paulo Research Foundation (BEPE fellowship 2015/26203-0 to CTP), the European Research Council (ERC starting grant 282083 to D-JS), and the European Molecular Biology Organization (EMBO long-term fellowship ALTF 687–2015 to JAS. and EMBO short-term fellowship ASTF-382–2015 to SR).
