### ABOUT COVER

Editorial board member of *World Journal of Gastroenterology*, Amedeo Amedei, BSc, Professor, Department of Experimental and Clinical Medicine, University of Florence, Firenze 50134, Italy

### AIMS AND SCOPE

*World Journal of Gastroenterology (World J Gastroenterol, WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a peer-reviewed open access journal. The WJG Editorial Board consists of 642 experts in gastroenterology and hepatology from 59 countries.

The primary task of WJG is to rapidly publish high-quality original articles, reviews, and commentaries in the fields of gastroenterology, hepatology, gastrointestinal endoscopy, gastrointestinal surgery, hepatobiliary surgery, gastrointestinal oncology, gastrointestinal radiation oncology, etc. WJG is dedicated to become an influential and prestigious journal in gastroenterology and hepatology, to promote the development of above disciplines, and to improve the diagnostic and therapeutic skill and expertise of clinicians.

### INDEXING/ABSTRACTING

*World Journal of Gastroenterology (WJG) is now indexed in Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®), Journal Citation Reports®, Index Medicus, MEDLINE, PubMed, PubMed Central and Directory of Open Access Journals. The 2018 edition of Journal Citation Report® cites the 2017 impact factor for WJG as 3.300 (5-year impact factor: 3.387), ranking WJG as 35th among 80 journals in gastroenterology and hepatology (quartile in category Q2).

Abstract

AIM
To identify factors other than active disease and anemia that contribute to fatigue in pediatric inflammatory bowel disease (IBD).

METHODS
We performed an electronic search in Medline and EMBASE from their inception to May 2017 using the search term “fatigue” or the related keywords “physical impairment” and “inflammatory bowel disease” with the filter “child” (age 0-18 years). Cross-sectional and case-control studies were included. We restricted our search to studies published in English. We used the PRISMA checklist and flow diagram. Duplicate articles were manually deleted in End Note. To identify further relevant studies, we checked the reference lists of the selected articles.

RESULTS
We identified 149 papers, of which 19 were retrieved for full text review. Eleven studies were subsequently excluded because fatigue was not evaluated as an outcome measure. Eight papers focused on the desired topic and were discussed in the final analysis. A lack of uniformity of outcome measures made the pooling of data impossible. In all but one study, questionnaires were used to evaluate fatigue. In the remaining study, an accelerometer was used to measure daily activities, sleeping time and their relationships with fatigue in a more
quantifiable manner. Adolescents with IBD are significantly more fatigued than healthy controls. In addition to active disease, increased anxiety or depression and disturbed family relationships were frequently reported predictors of fatigue. Quantitative measurement of physical activity in patients with Crohn’s disease showed a reduction in the number of steps per day, and patients with ulcerative colitis had a shorter duration of physical activity during the day.

CONCLUSION
Fatigue in pediatric IBD is related to a combination of biological, functional and behavioral factors, which should all be taken into account when managing fatigue.

Key words: Adolescents; Children; Fatigue; Inflammatory bowel disease; Physical impairment; Sleep

INTRODUCTION
Inflammatory bowel disease (IBD) is a chronic disease of the gastrointestinal tract. The disease is characterized by relapsing periods of inflammation and remission and usually presents with abdominal pain, diarrhea, rectal bleeding and weight loss[1]. The ultimate goal in IBD treatment is to reach clinical remission as quickly as possible. Fatigue and decreased physical fitness may continue to affect a patient’s daily life despite disease remission. Ten percent of patients with IBD are diagnosed before the age of 19 years[2].

Fatigue refers to a subjectively overwhelming sense of tiredness, lack of energy, and feeling of exhaustion that decreases one’s capacity for physical and mental activity[3]. It is a common, independent, and nonspecific symptom identified in numerous chronic health conditions in childhood[4]. In adults with chronic disease, fatigue can be a major source of disablement and is often reported as being among the most severe and distressing symptoms[5]. It affects physical, emotional, cognitive, and social functioning, impacting quality of life. Nevertheless, fatigue has typically been ignored in the assessment of symptom severity or outcome in many diseases in which it is observed[5].

The quantification of fatigue is challenging due to the lack of a consensus framework, vague terminology, and the multidimensional nature of symptoms. Subjective methods, such as self-reported or parent-reported surveys[6-7], are commonly used but can be distorted by response and recall bias. More objective methods, such as polysomnography and performance tests[8-10], are expensive and time-consuming. Furthermore, the prevalence of fatigue varies among healthy pediatric age groups; it is common in infancy, early childhood, and late adolescence and less frequently observed during mid-childhood; it is more common in girls than in boys[9].

We aimed to systematically review the literature to identify factors that contribute to fatigue in children and adolescents with IBD.
MATERIALS AND METHODS

Identification and selection of studies
We searched for studies published in Medline and EMBASE up to May 2017. The search strategy for Medline was as follows: (“fatigue” [MeSH Terms] OR “fatigue” [All Fields]) AND (“inflammatory bowel diseases”[MeSH Terms] OR (“inflammatory” [All Fields] AND “bowel” [All Fields] AND “disease” [All Fields] OR “inflammatory bowel disease” [All Fields]); (“physical examination” [MeSH Terms] OR (“physical” [All Fields] AND “examination”[All Fields]) OR “physical examination” [All Fields] OR “physical” [All Fields] AND impairment [All Fields]) AND (“inflammatory bowel diseases”[MeSH Terms] OR (“inflammatory”[All Fields] AND “bowel”[All Fields] AND “diseases”[All Fields]) OR “inflammatory bowel diseases”[All Fields] OR (“inflammatory”[All Fields] AND “bowel”[All Fields] AND “disease”[All Fields]) OR “inflammatory bowel disease”[All Fields]), with the filter “child” (age 0-18 years). For EMBASE, the search strategy was as follows: (“fatigue”/exp OR fatigue) AND Inflammatory AND (“bowel”/exp OR bowel) AND (“disease”/exp OR disease). We restricted our search to studies published in English. Duplicate articles identified in both Medline and EMBASE were manually deleted in End Note. To identify additional relevant studies, we checked the reference lists of the selected articles.

We selected cross-sectional or case-control studies reporting on fatigue (or its synonyms) in patients under the age of 19 years with IBD. Two reviewers (Van de Vijver E and Van Gils A) independently screened the abstracts of all identified articles to determine their eligibility. Any disagreements regarding the inclusion of articles were solved by discussion until consensus was reached.

Quality assessment and data extraction
Study quality was assessed using the online criteria for case-control and cross-sectional studies[11]. Each item was scored as “yes”, “no”, or “not reported”.

The guidelines of the PRISMA 2009 Statement were adopted.

RESULTS

Study selection
This study includes paper retrieved by electronic searches up to May 2017. In total, 149 papers were identified, of which 19 were retrieved for full-text review. Eleven were subsequently excluded because fatigue was not evaluated as an outcome measure. Eight focused on the desired topic and were discussed in the final analysis (Figure 1).

The selected studies varied considerably with regard to the fatigue assessment method, which made pooling of data impossible (see Table 1).

Six papers reported fatigue or physical activity related to IBD as their primary outcome. The remaining two studies reported quality-of-life as the primary outcome; one used a quality-of-life questionnaire and evaluated the domain “motor functioning” separately, while the other conducted a semi structured interview with questions about the functional impact of the disease. The methodological quality of the studies is summarized in Table 2.

Assessment of fatigue
Seven of eight papers used subjective methods, such as questionnaires, to evaluate fatigue[6,7,12-16]. Most research teams used self-reported surveys [IMPACT-III, semistructured interviews, Youth Self Report (YSR), Sleep Self Report (SSR), RCMAS, KINDL, KIDSCREEN and TACQOL][7,12,13,15,16], while others used a combination of parent proxy-reported and self-reported surveys (PedsQL multidimensional fatigue scale and PedsQL 4.0 generic care scale)[14]. Only one paper used a parent proxy-reported questionnaire [Child Behavior Checklist (CBCL)][16]. Table 3 describes the myriad of fatigue-related diagnostic tests that were used in the included studies.

Scientists from Chicago and Texas performed a cross-sectional study among 70 children with IBD and 157 healthy controls and their parents[6]. They categorized fatigue as general fatigue (e.g., “feeling tired”), sleep/rest fatigue (e.g., “feeling tired when waking up”) or cognitive fatigue (e.g., “attention problem”) based on the PedsQL Multidimensional Fatigue Scale[11]. General fatigue and sleep/rest fatigue were more frequently observed in pediatric IBD patients than in healthy control subjects, even when their disease was in remission. Differences in cognitive fatigue were not observed[6]. A Canadian team from Toronto conducted in-depth interviews among 80 children and adolescents who were purposively selected for their variation
in age and condition and found that children and teenagers with IBD commonly mentioned that “exhaustion” and “malaise” (“having no energy and being tired”) had large impacts on their lives[13]. A Finnish research team evaluated sleep problems and daytime tiredness in 160 adolescents by both a parent proxy-reported survey (CBCL) and a self-reported questionnaire (YSR)[17]. Twenty-five percent of parents reported that their adolescent child had trouble sleeping. This was a significantly greater percentage than was found among the parents of healthy controls. Overall, parents of adolescents with IBD more commonly reported sleeping during the day and night and overtiredness than did parents of healthy controls. The self-reported questionnaire did not confirm the high prevalence of sleep-related problems among IBD patients when compared to healthy subjects (11% vs 16%)[16].

A Swiss research team evaluated 110 adolescents with IBD who were included in the national IBD Cohort Study[7]. They assessed fatigue as physical activity using the KIDSCREEN 27. Physical well-being (e.g., “feeling fit, being physical active, able to run”) was only moderately disturbed in IBD patients compared to healthy controls[7].

A German research group conducted the only study that evaluated fatigue in an objective manner with a wearable device. They assessed physical activity using the SenseWear Pro2 armband (a portable motion sensor) and reported a trend towards a shorter duration of physical activity and significantly prolonged sleep duration in patients with mild IBD compared to controls, but there were no statistically significant differences[8].

Biological factors related to fatigue

Disease activity: All included studies observed a positive correlation between disease activity and fatigue, but the scoring systems used to discriminate active disease from disease remission differed among the papers. The team from Chicago and Texas used the Pediatric Crohn’s Disease Activity Index (PCDAI) and defined disease remission as a score < 10. They reported that children with active Crohn’s disease (CD) had significantly more symptoms of general fatigue (“feeling tired”) and sleep/rest fatigue (“feeling tired when waking up”) than children and teenagers in remission[6]. The Finnish study among 160 children and teenagers used a visual analogue scale (VAS) to measure disease activity. Children with severe IBD (VAS scores above 3) had significantly more trouble falling asleep (41% vs 22%), felt significantly more overtired (80% vs 44%) and had significantly longer sleep duration than adolescents with less severe disease[17].

Family dysfunction is related to an increased frequency of fatigue in adolescents; Maternal positive affect is inversely related to fatigue (not significant); Fatigue is independent of maternal negative affect

Family support: A group from Detroit found a significant association between fatigue and dysfunction in the family. The researchers used the McMaster Family Assessment Device. They also evaluated two additional items created by the authors themselves, which assessed the frequency of IBD-related pain and IBD-related fatigue over the past 3 mo. They found that maternal positive affect, including being attentive, active, and interested, was inversely related to fatigue but the association was not significant. Fathers were not included in the study because they almost never accompanied their children to the clinic, and a considerable proportion of the adolescents did not have fathers living with them.

Psychological variables: In another paper, the Detroit team assessed 56 adolescents with IBD (aged between 11 and 17 years) with the Revised Children’s Manifest Anxiety Scale and found that adolescents with a negative affect (i.e., those who reported anxiety and depression) also experienced more pain and fatigue. The group from Chicago and Texas used the Children’s Depression Inventory and found that adolescents with primarily inactive IBD did not report more depressive symptoms than healthy controls (1.4% vs 1.3%).

DISCUSSION

Eight studies were included in this systematic review. These studies were selected for their focus on fatigue in adolescents with IBD.

Medication: The research team from Chicago and Texas evaluated the association between fatigue and medication and concluded that the use of mesalamine, thiopurine or anti-tumor necrosis factor (TNF) were not predictors of fatigue as measured with the PedsQL Fatigue Scale.

Psychobehavioral factors related to IBD

Family support: A group from Detroit found a significant association between fatigue and dysfunction in the family. The researchers used the McMaster Family Assessment Device. They also evaluated two additional items created by the authors themselves, which assessed the frequency of IBD-related pain and IBD-related fatigue over the past 3 mo. They found that maternal positive affect, including being attentive, active, and interested, was inversely related to fatigue but the association was not significant. Fathers were not included in the study because they almost never accompanied their children to the clinic, and a considerable proportion of the adolescents did not have fathers living with them.

Psychological variables: In another paper, the Detroit team assessed 56 adolescents with IBD (aged between 11 and 17 years) with the Revised Children’s Manifest Anxiety Scale and found that adolescents with a negative affect (i.e., those who reported anxiety and depression) also experienced more pain and fatigue. The group from Chicago and Texas used the Children’s Depression Inventory and found that adolescents with primarily inactive IBD did not report more depressive symptoms than healthy controls (1.4% vs 1.3%).

Functional factors related to IBD

Disease type: The studies that used questionnaires to assess fatigue did not observe differences between CD and ulcerative colitis (UC) patients. The German research group that evaluated physical activity with a wearable device found that patients with CD tended towards taking fewer steps per day, and UC patients had a shorter duration of physical activity compared with healthy controls.

DISCUSSION

Eight studies were included in this systematic review. These studies were selected for their focus on fatigue in adolescents with IBD.

Key findings

This review demonstrates that fatigue, exhaustion, diminished physical activity and trouble sleeping are more common in children and adolescents with IBD than in their healthy peers. Fatigue is likely to be a multifactorial phenomenon and includes biological factors (such as disease activity), psychobehavioral factors (such as anxiety, depression and family support) and functional factors (such as decreased functional capacity). The model depicted in Figure 2 addresses the various etiological factors and the connection with the fatigue-related diagnostic tests mentioned in this paper. The
Anxiety Scale; UC: ulcerative colitis.
Pediatric Quality of Life; PGA: Physician Global Assessment; PUCAI: Pediatric Ulcerative Colitis Activity Index; RCMAS: Revised Children’s Manifest Anxiety Scale; CDI: Children’s Depression Inventory; CD: Crohn’s disease; IBD: Inflammatory bowel disease; PCDAI: Pediatric Crohn’s Disease Activity Index; PedsQL: Pediatric Quality of Life; UC: ulcerative colitis.

model highlights the importance of the multifaceted nature of fatigue, and this fatigue model could act as a guide on which to base treatment interventions.

**Biological factors:** Fatigue is a common finding\(^6\) in children and adolescents with IBD, and several studies have shown a positive relationship between the degree of disease activity and fatigue. Adolescents with active IBD experience more fatigue than their peers in disease remission, who, in turn, experience more fatigue than healthy controls. It is plausible that active disease impairs sleep quality due to nocturnal abdominal pain and diarrhea. Inflammation and immune activation, together with the subsequent activation of glial cells and mitochondrial damage, likely account for the severe levels of intractable fatigue and disability seen in patients with autoimmune diseases\(^6\).

Adolescents in clinical remission are fatigued, but patients in deep remission were not assessed: deep remission could have an impact on less fatigue.

Reduced muscle mass\(^6\) and anemia\(^6\), both of which are frequently observed in patients with IBD, even when their disease is in remission, may also have affect fatigue, but so far, these factors have not been investigated in the adolescent IBD population.

**Psychobehavioral factors:** The papers that sought correlations between psychobehavioral factors and fatigue showed conflicting results. One paper\(^6\) linked anxiety, depression and lack of family support with IBD-related fatigue, while another paper failed to show that depression occurs more often in adolescents with IBD than in their healthy peers\(^6\). Sleep disorders can affect the feeling of being tired,

YSR  Youth Self Report  Adolescent self-reported assessment with the following eight empirically-based syndrome scales: anxious/depressed, withdrawn/depressed and somatic complaints composing the internalizing (i.e., emotional) broad-band scale; rule-breaking behavior and aggressive behavior composing the externalizing (i.e., behavioral) broad-band scale; and these two scales, together with the syndrome scales of social, thought and attention problems, compose the total problems scale.

as shown in 2 of the included papers. Sleep deprivation leads to more anxiety and depression and to an increase in somatic complaints and aggressive behavior[13,16,17]. Sleep itself was not often a research objective; only one study had sleeping problems as an outcome measurement[16], while a German study only reported a trend towards prolonged sleep duration in patients with mild IBD compared to healthy controls[8].

Functional factors: Only one paper focused on functional capacity in relation to fatigue and used a wearable device to plot activity over time; this study did not find a significant difference between patients with IBD and healthy controls[16]. Functional factors:

Comparison with adult-oriented publications
In 2010, a systematic review[3] identified 10 papers about fatigue in patients with IBD and mentioned that the topic deserved more attention, as the prevalence of fatigue approached 50% in patients with IBD in remission and up to 86% in patients with active IBD. Cuzber-Dochan and colleagues published a systematic review in 2013 that included 28 papers on adults, and they concluded that the use of terminology regarding fatigue is inconsistent and that knowledge of the causes, severity and ways of measuring IBD fatigue is incomplete[28]. Three years later, the same research group repeated the literature search and identified a number of psychosocial and physical factors that could potentially be modified through targeted health interventions to improve fatigue in IBD. As in this study, they concluded that fatigue is multifactorial and is associated with active disease, poor sleep quality, anxiety and depression, but the complex interplay between these factors has yet to be deciphered[29].

In studies among adolescents, disease activity and sleep quality are also related to fatigue, but the relationship with anxiety and depression is unclear. Approximately one-quarter of adolescents with IBD have somatic or cognitive symptoms of depression[30], and this is comparable with the prevalence observed in their healthy peers.

Depression among adult patients with IBD, on the other hand, is more common compared to among control subjects[12,21-29].

Previous studies described a poor to low degree of parent-adolescent agreement on psychosocial symptoms[17,30]. Moreover, adolescents and parents report different symptoms. Therefore, to gain a comprehensive picture of the complaints in adolescents with IBD, both the adolescents and their parents need to be questioned[34].

Methodological limitations of the review
The cross-sectional design of most included studies precludes the ability to draw conclusions concerning the causal relations between variables. Prospective observational cohort studies are needed to gain more insight into the direction and mechanism of the identified associations. If prospective cohort studies are conducted in ethnically and socioeconomically diverse groups of children and adolescents, causative factors of fatigue can be identified, and these could potentially lead to more efficacious ways of treating fatigue in adolescents with IBD.

Implications for clinical practice
Future research opportunities: The mechanism underlying fatigue in children and adolescents with IBD remains poorly understood. Fatigue is a subjective sensation and presents with a multitude of symptoms, which makes it difficult to describe, measure and quantify. Past studies have mainly focused on one aspect of fatigue. Future studies should explore fatigue manifestations at several levels simultaneously, including illness-related aspects (such as ongoing inflammation, disease activity, medication use and pain), physical functioning (health-related quality of life, sleep quality and disability), and psychosocial factors.
Conclusion
Fatigue is a common problem in children and teenagers with IBD, and it is significantly more prevalent among young patients with IBD than in the healthy control population. It is multidimensional and caused by both physical and psychosocial factors. The most predictive factor seems to be disease activity. Health care providers need to pay attention to this problem because it is associated with reduced quality of life, increased sleeping problems and increased anxiety. The multifactorial nature of fatigue necessitates multilevel testing.

ARTICLE HIGHLIGHTS

Research background
Children and adolescents with inflammatory bowel disease (IBD) regularly report fatigue as their most severe and distressing symptom. Fatigue is often attributed to active disease and anemia, but also in quiescent IBD, fatigue can trouble daily life.

Research motivation
The ultimate goal in IBD management is not only to reach disease remission, but also to counteract fatigue and decreased physical fitness.

Research objectives
We aimed to systematically review the literature to identify factors that contribute to fatigue in children and adolescents with IBD.

Research methods
We performed an electronic search in Medline and EMBASE from their inception to May 2017 using the search term “fatigue” or the related keyword “physical impairment” and “inflammatory bowel disease” with the filter “child” (age 0-18 years). Cross-sectional and case-control studies were included. We restricted our search to studies published in English. To identify further relevant studies, we checked the reference lists of the selected articles.
Research results
We ultimately identified eight papers that matched the search criteria. A lack of uniformity of outcome measures made the pooling of data impossible. In all but one study, questionnaires were used to evaluate fatigue. In the remaining study, an accelerometer was used to measure daily activities, sleeping time and their relationships with fatigue in a more quantifiable manner. Adolescents with IBD are significantly more fatigued than healthy controls. In addition to active disease, increased anxiety or depression and disturbed family relationships were frequently reported predictors of fatigue. Quantitative measurement of physical activity in patients with Crohn’s disease showed a reduction in the number of steps per day, and patients with ulcerative colitis had a shorter duration of physical activity during the day.

Research conclusions
Fatigue is a common problem in children and teenagers with IBD, and it is significantly more prevalent among young patients with IBD than in the healthy control population. It is multidimensional and caused by both physical and psychosocial factors. The most predictive factor seems to be disease activity. Health care providers need to pay attention to this problem because it is associated with reduced quality of life, increased sleeping problems and increased anxiety.

Research perspectives
The multifactorial nature of fatigue necessitates multilevel testing. Fatigue in pediatric IBD is related to a combination of biological, functional and behavioral factors, which should all be taken into account when managing fatigue.
