ABSTRACT: The enzyme 4-oxalocrotonate tautomerase (4-OT) exploits an N-terminal proline as main catalytic residue to facilitate several promiscuous C–C bond-forming reactions via enzyme-bound enamine intermediates. Here we show that the active site of this enzyme can give rise to further synthetically useful catalytic promiscuity. Specifically, the F50A mutant of 4-OT was found to efficiently promote asymmetric Michael additions of nitromethane to various $\alpha,\beta$-unsaturated aldehydes to give $\gamma$-nitroaldehydes, important precursors to biologically active $\gamma$-aminobutyric acids. High conversions, high enantiocontrol, and good isolated product yields were achieved. The reactions likely proceed via iminium ion intermediates formed between the catalytic Pro-1 residue and the $\alpha,\beta$-unsaturated aldehydes. In addition, a cascade of three 4-OT(F50A)-catalyzed reactions followed by an enzymatic oxidation step enables assembly of $\gamma$-nitrocarboxylic acids from three simple building blocks in one pot. Our results bridge organo- and biocatalysis, and they emphasize the potential of enzyme promiscuity for the preparation of important chiral synthons.

KEYWORDS: biocatalysis, Michael addition, asymmetric synthesis, enzyme catalysis, protein engineering

The $\gamma$-nitroaldehydes are important chiral building blocks for the preparation of biologically active $\gamma$-aminobutyric acids. The asymmetric synthesis of $\gamma$-nitroaldehydes from simple starting materials has become feasible because of outstanding developments within the organocatalysis field, particularly fueled by aminocatalysis.1 This is nicely illustrated by the work of Hayashi and co-workers, who reported that diphenylprolinol silyl ether can promote the asymmetric synthesis of $\gamma$-nitroaldehydes through alternative Michael-type reactions: enamine-mediated addition of aldehydes to nitroalkenes, and nitroalkane addition to $\alpha,\beta$-unsaturated aldehydes activated as iminium ions.

Inspired by these developments in the organocatalysis field, work from our laboratory focused on the development of a biocatalytic procedure for asymmetric synthesis of $\gamma$-nitroaldehydes. We reported that 4-oxaloacetoacete tautomerase (4-OT), which utilizes a unique N-terminal proline as key catalytic residue, can promiscuously catalyze the Michael addition of acetaldehyde (as well as various other aldehydes) to nitroalkenes yielding enantioenriched $\gamma$-nitroaldehydes (Scheme 1A).2 The catalytic mechanism involves the formation of an enzyme species between acetaldehyde and the Pro-1 residue ($pK_a \sim 6.4$).3 Hilvert and co-workers have reported a highly engineered computationally designed artificial aldehyde, RA95.5–8, which can catalyze the asymmetric synthesis of $\gamma$-nitroketones (but not $\gamma$-nitroaldehydes) via acetone addition to nitrostyrenes and nitroalkane addition to conjugated ketones.5 However, a biocatalytic methodology for nitroalkane addition to $\alpha,\beta$-unsaturated aldehydes to yield enantioenriched $\gamma$-nitroaldehydes is an as yet unmet challenge.

Here, we report that the F50A mutant of the 4-OT enzyme can efficiently promote asymmetric Michael additions of nitromethane to $\alpha,\beta$-unsaturated aldehydes, yielding various $\gamma$-nitroaldehydes with high enantiopurity (e.r. up to >99:1) and...
in high isolated yield (61–96%). The catalytic mechanism appears to involve formation of enzyme-bound iminium ion intermediates in a manner reminiscent of organocatalysis (Scheme 1B).

We previously reported that 4-OT catalyzes the aldol condensation of acetaldehyde with benzaldehyde to yield cinnamaldehyde.\(^\text{3,6}\) Considering that the active site of 4-OT can accommodate cinnamaldehyde, this aromatic \(\alpha,\beta\)-unsaturated aldehyde was tested as potential Michael acceptor substrate. Cinnamaldehyde was expected to react with Pro-1, the catalytic amine, to form a covalently bound iminium ion intermediate, which could be attacked by nitromethane (Scheme 1B). This Michael reaction was performed in the presence of wild-type 4-OT in HEPES buffer (pH 7.3), containing 5% (v/v) EtOH, 200 mM of nitromethane (1, Scheme 2), and 3 mM of cinnamaldehyde (2a), and reaction progress was monitored by following the depletion of 2a by UV–vis spectrophotometry. Under these conditions, 50% of substrate 2a was consumed in 24 h, and the corresponding product 3a was obtained in 35% isolated yield (as confirmed by \(^1\)H NMR spectroscopy). Analysis of product 3a by chiral HPLC revealed high enantiocontrol at the site of addition with an e.r. of 96:4. Interestingly, we earlier reported that wild-type 4-OT catalyzes the Michael addition of acetaldehyde to trans-\(\beta\)-nitrostyrene to yield (S)-3a with an e.r. of 95:5.\(^\text{25}\) Hence, 4-OT catalyzes the synthesis of \(\gamma\)-nitroaldehyde 3a via two enantiocomplementary Michael reactions: enamine-mediated addition of acetaldehyde to trans-\(\beta\)-nitrostyrene and nitromethane addition to cinnamaldehyde likely activated as iminium ion.

Encouraged by these initial findings, a systematic mutagenesis approach was applied to enhance this promiscuous Michael addition activity of 4-OT. For this, an earlier constructed collection of 4-OT genes coding for almost all possible single-mutant variants of 4-OT was used.\(^\text{1}\) Improved variants (>2-fold increase in activity) were identified by monitoring the depletion of 2a in a spectrophotometric kinetic assay in multwell plates. Given that several mutations at positions Met-45 and Ala-46 (M45G, M45H, M45S, A46H, and A46S) result in a slight improvement in activity (≈3-fold), three mutations at position Phe-50 (F50I, F50V, and F50A) significantly enhanced the Michael addition activity. Assays with the purified mutant enzymes showed a 6-fold, 8-fold and 15-fold increase in activity for F50I, F50V, and F50A, respectively (Figure S1). Further characterization of the Michael reaction between 1 and 2a catalyzed by the best 4-OT variant (F50A) showed that besides increased activity, this mutant enzyme also has enhanced stereoselectivity, allowing the production of optically pure (R)-3a (e.r. 99:1) in high isolated yield of 92% (Table 1, entry 1; Figures S2–S4). These results underscore the potential of the highly promiscuous 4-OT enzyme for evolutionary optimization. At semipreparative scale, the 4-OT(F50A)-catalyzed Michael addition of 1 (50

\(^a\)All the reactions were performed in buffer [20 mM HEPES/5% (v/v) ethanol] at pH 6.5 with 4-OT F50A (72 \(\mu\)M, except for 2g and 2i for which 36 \(\mu\)M enzyme was used), 1 (25 mM) and 2a–k (3 mM, except for 2g which was used at 2 mM).\(^\text{4}\) Determined by \(^1\)H NMR analysis. \(^\text{5}\)Isolated yield (%). \(^\text{6}\)Determined by chiral HPLC or GC. \(^\text{7}\)The absolute configuration was determined by comparison of chiral HPLC or GC data with those previously reported (see Supporting Information for details). \(^\text{8}\)Apparent kinetic parameters determined with this substrate at a fixed nitromethane concentration of 25 mM: \(k_{\text{cat}} = 0.05 (\pm 0.002) \text{s}^{-1}\); \(K_c = 367 (\pm 37) \mu\text{M}\). \(^\text{9}\)Further purified using flash column chromatography.
mM, 152 mg in 50 mL) to 2a (25 mM, 157 mg in 50 mL) gave product (R)-3a (96% conversion in 11 h) in good isolated yield (204.7 mg, 85% yield) and with a high e.r. of 98:2 (Figures S34, S35).

Notably, the mutation F50A was previously found to improve the aldol condensation activity of 4-OT.6a This mutation makes the active site pocket of 4-OT more accessible to the outside aqueous environment, without changing the pKₐ of Pro-1 too much, and likely enhances the aldol condensation activity of 4-OT by promoting the final hydrolysis step in which product is released from Pro-1, which has been suggested to be rate-limiting.6b Similarly, the F50A mutation may increase the Michael addition activity of 4-OT by making the active site more amenable for hydrolytic cleavage of the covalent enzyme–product intermediate.

Having established that 4-OT(F50A) can efficiently promote the asynchronous Michael addition of 1 to 2a, a set of α,β-unsaturated aldehydes was prepared (see Supporting Information for details) and tested as Michael acceptor substrates. The results demonstrate that the 4-OT(F50A) enzyme has a broad substrate scope, accepting both aromatic and aliphatic Michael acceptor substrates, and catalyzes the addition of 1 to the α,β-unsaturated aldehydes 2b–k to yield the corresponding γ-nitroaldehydes 3b–k with excellent enantiopurity (e.r. up to >99:1) and in good isolated yield (61–96%) (Table 1, Figures S5–S33). Interestingly, the enzymatic Michael reactions with meta- and para-substituted cinnamaldehydes (2c,d and 2f–j) provided the corresponding products as the (R)-configured enantiomers, while those with the ortho-substituted cinnamaldehydes (2b and 2e) yielded the (S)-configured product enantiomers (Table 1, entries 2 and 5). This suggests that positioning substituents on the ortho position of the substrate promoted steric effects, which caused either substrate relocation in the enzyme active site or a stereofacial shielding effect. Notably, the consequence of ortho-substituents on the stereochemical outcome of organo- and biocatalytic reactions with aromatic aldol and Michael acceptor substrates has been observed before.5a,b

We next investigated whether the mechanism of the 4-OT(F50A)-catalyzed Michael reaction proceeds via iminium ion formation between Pro-1 and the α,β-unsaturated aldehyde substrate. A 4-OT(F50A) sample modified by 2a in the presence of NaBH₄ and an unmodified 4-OT(F50A) sample were digested with Glu-C (an endoproteinase from Staphylococcus aureus V8), and the generated peptides were characterized by LC-MS (Figures S43–S45). Comparing the peaks of the modified 4-OT(F50A) sample to those of the nonmodified 4-OT(F50A) sample revealed a modification of the fragment PIAQHILE by a species with a mass of 116 Da. This corresponds to labeling by one cinnamaldehyde molecule. Characterization of the remaining peaks revealed no labeling of other fragments (Figures S44, S45). Within the N-terminal fragment Pro-1 to Glu-9, the most probable positions for alkylation are Pro-1 and His-6. To identify the labeled residue, the modified and unmodified peptides were analyzed by LC-MS/MS (Figure S46). The spectrum of the ion corresponding to the unlabeled PIAQHILE peptide showed the characteristic b5 ion resulting from the peptide fragment PIAQL. MS/MS analysis of the modified PIAQHILE peptide revealed a mass increase of 116 Da for this b5 ion. Therefore, it can be concluded that Pro-1 is the sole site of modification by 2a. This result supports the hypothesis that Pro-1 functions as an amine catalyst in the enzymatic addition reaction, increasing the electrophilicity of the Michael acceptor through Schiff base formation (Scheme 1B). Replacement of Pro-1 with an alanine in wild-type 4-OT led to a 32-fold decrease in activity for the addition of 1 to 2a (Figure S1), providing further support for this mechanism. Work is in progress to determine the structure of 4-OT(F50A) covalently modified by 2a.

We have previously reported that 4-OT(F50A) can catalyze the aldol condensation of acetaldehyde with benzaldehyde to give cinnamaldehyde.3,4 Here we show that the three different activities observed for the 4-OT(F50A) enzyme can be used to prepare γ-nitroaldehydes in a biocatalytic cascade involving sequential aldol addition of acetaldehyde to a suitable aromatic aldehyde, dehydration, and Michael addition of nitromethane. Inclusion of a suitable aldehyde dehydrogenase and cofactor-recycling NADH oxidase in the reaction mixture enabled efficient one-pot synthesis of γ-nitrocarboxylic acids (Scheme 3). Using acetaldehyde (4), benzaldehyde (5a), and nitromethane (1) as starting substrates, product (R)-7a was obtained in 53% isolated yield (65% overall conversion) and with an excellent e.r. of 99:1 (Table 1, Figures S36–S38). Replacing substrate 5a with 5b, yielded product (S)-7b in 80% isolated yield (>99% overall conversion) and with an excellent e.r. of 99:1 (Figures S39–S42). This simple and effective cascade further demonstrates the tremendous potential of combining different enzymes to construct simple synthetic routes for preparation of important chemical products.

In summary, our results indicate that the active site of 4-OT can give rise to synthetically useful promiscuous activities. Like proline-based organocatalysts, 4-OT utilizes a prolyl amine to attack diverse aldehydes forming reactive enamine and iminium ion intermediates. Hence, this natural enzyme with its unique catalytic amino-terminal proline could possibly accelerate many of the bond-forming reactions promoted by organocatalysts. We have therefore initiated studies aimed at exploring the use of organocatalysts in the aldol condensation of acetaldehyde with benzaldehyde to give cinnamaldehyde (Scheme 1B). Replacement of Pro-1 with an alanine in wild-type 4-OT led to a 32-fold decrease in activity for the addition of 1 to 2a (Figure S1), providing further support for this mechanism. Work is in progress to determine the structure of 4-OT(F50A) covalently modified by 2a.

We have previously reported that 4-OT(F50A) can catalyze the aldol condensation of acetaldehyde with benzaldehyde to give cinnamaldehyde.3,4 Here we show that the three different activities observed for the 4-OT(F50A) enzyme can be used to prepare γ-nitroaldehydes in a biocatalytic cascade involving sequential aldol addition of acetaldehyde to a suitable aromatic aldehyde, dehydration, and Michael addition of nitromethane. Inclusion of a suitable aldehyde dehydrogenase and cofactor-recycling NADH oxidase in the reaction mixture enabled efficient one-pot synthesis of γ-nitrocarboxylic acids (Scheme 3). Using acetaldehyde (4), benzaldehyde (5a), and nitromethane (1) as starting substrates, product (R)-7a was obtained in 53% isolated yield (65% overall conversion) and with an excellent e.r. of 99:1 (Table 1, Figures S36–S38). Replacing substrate 5a with 5b, yielded product (S)-7b in 80% isolated yield (>99% overall conversion) and with an excellent e.r. of 99:1 (Figures S39–S42). This simple and effective cascade further demonstrates the tremendous potential of combining different enzymes to construct simple synthetic routes for preparation of important chemical products. efficient biocatalyst for the aldol condensation of acetaldehyde with benzaldehyde to yield cinnamaldehyde, with a >5000-fold enhancement in catalytic efficiency ($k_{\text{cat}}/K_{\text{m}}$) and a $>10^7$-fold change in reaction specificity.\(^6\) It is therefore conceivable that the promiscuous activity of 4-OT(F50A) for the Michael addition of nitromethane to $\alpha\beta$-unsaturated aldehydes can be optimized by directed evolution to generate novel biocatalysts for practical synthesis of chiral precursors for important pharmaceuticals.
